QUANTCONNECT DOCUMENTATION

Learn to use QuantConnect and Explore Features

WRITING ALGORITHMS

Learn tools you need to build algorithmic trading strategies

Build on a mature, flexible, feature-complete API managing billions of dollars capital, and used by 5,000+ investors every month.

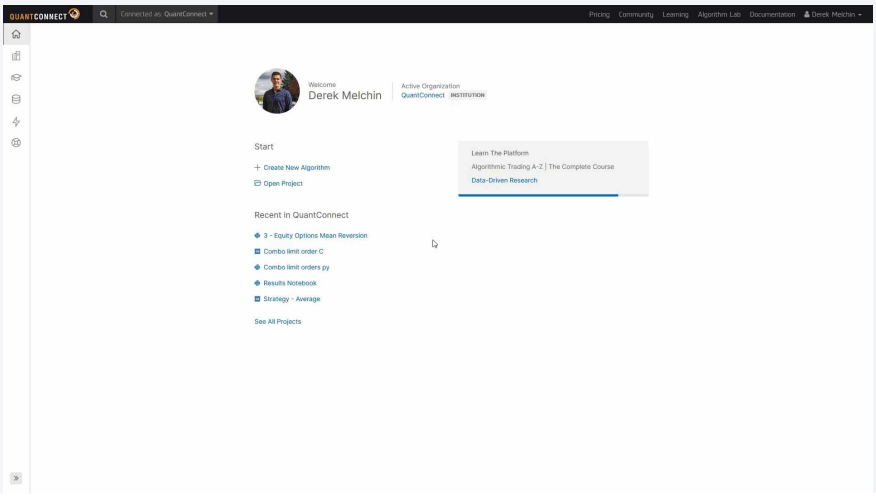
Key Concepts

Key Concepts

Getting Started

GET STARTED WITH WRITING ALGORITHMS

Guide through creating a project, running your first backtest, and live algo trading.



Follow these steps to create, backtest, and paper trade a new algorithm:

1. Create a new project.

The process to creating a new project depends on if you use the Cloud Platform , Local Platform , or CLI .

2. Backtest the default algorithm.

The process to backtest the algorithm depends on if you use the Cloud Platform , Local Platform , or CLI .

3. Deploy the algorithm to live paper trading.

The process to deploy the algorithm live depends on if you use the Cloud Platform , Local Platform , or CLI .

Key Concepts

Algorithm Engine

Introduction

LEAN Engine is an open-source algorithmic trading engine built for easy strategy research, backtesting, and live trading. We integrate with common data providers and brokerages, so you can quickly deploy algorithmic trading strategies. The core of the LEAN Engine is written in C#, but it operates seamlessly on Linux, Mac and Windows operating systems. To use it, you can write algorithms in Python 3.11 or C#. QuantConnect maintains the LEAN project and uses it to drive the web-based algorithmic trading platform on the website.

Since LEAN is open-source, you aren't locked-in to the QuantConnect platform. You can run LEAN with your own infrastructure, data, and brokerage connections. If you use QuantConnect, our team of engineers manage the infrastructure, you can run the latest version of LEAN with all of its brokerage connections, and you can utilize the datasets in the Dataset Market .

Your Algorithm and LEAN

To create a trading algorithm with LEAN, define a subclass of the `QCAlgorithm` class. LEAN loads your algorithm into the engine during the building and compilation process. LEAN runs an algorithm manager that synchronizes the data your algorithm requests, injects the data into your algorithm so you can place trades, processes your orders, and then updates your algorithm state.

The LEAN engine manages your portfolio and data feeds, so you focus on your algorithm strategy and execution. We automatically provide basic portfolio management and reality modeling underneath the hood. The `QCAlgorithm` class provides some key helper properties for you to use, including the Security Manager, Portfolio Manager, Transactions Manager, Notification Manager, and Scheduling Manager. The class also has hundreds of helper methods to make the API easy to use.

The Securities property is a dictionary of `Security` objects. Each asset (Equity, Forex pair, etc) in your algorithm has a `Security` object. All the models for a security live on these objects. For example, `self.Securities["IBM"].FeeModel` and `self.Securities["IBM"].Price` return the fee model and price of IBM, respectively.

The Portfolio is a dictionary of `SecurityHolding` objects. These classes track the profits, losses, fees, and quantity of individual portfolio holdings. For example, `self.portfolio["IBM"].last_trade_profit` returns the profit of your last IBM trade.

Other helpers like Transactions , Schedule , Notify , and Universe have their own helper methods.

```py
class QCAlgorithm:
    securities   # Array of Security objects.
    portfolio    # Array of SecurityHolding objects
    transactions # Transactions helper
    schedule     # Scheduling helper
    notify       # Email, SMS helper
    universe     # Universe helper

    # Set up Requested Data, Cash, Time Period.
    def initialize(self) -> None:

    # Other Event Handlers
    def on_data(self, slice: Slice) -> None:
    def on_end_of_day(self, symbol: Symbol) -> None:
    def on_end_of_algorithm(self) -> None:

    # Indicator Helpers
    def sma(self, symbol: Symbol, period: int) -> SimpleMovingAverage:
```

Only define one algorithm class per project. To trade multiple strategies in a single algorithm, implement an Algorithm Framework design with multiple Alpha models . To be notified when you can define more than one algorithm class per project, subscribe to GitHub Issue #6968 .

Threads in LEAN

LEAN is multi-threaded and attempts to consume as much CPU as possible to perform given work as quickly as possible. The analysis engine loads data parallel and synchronizes it to generate the requested security information.

The client algorithm is plugged into LEAN, and has its events triggered synchronously in backtesting. The primary bottle neck to LEAN execution is

executing client code.

In live trading, most events are synchronous as in backtesting, however order events are triggered immediately from the brokerage thread (asynchronously) to ensure the lowest latency. For example; a strategy using hourly data, with a limit order could fill between data bars. This fill event is triggered when it occurs in live trading.

We recommend using thread safe collections when possible, or locks around collections to ensure they are thread-safe.

Batch vs Stream Analysis

Backtesting platforms come in two general varieties, batch processing and event streaming. Batch processing backtesting is much simpler. It loads all data into an array and passes it to your algorithm for analysis. Because your algorithm has access to future data points, it is easy to introduce look-ahead bias . Most home-grown analysis tools are batch systems.

QuantConnect/LEAN is a streaming analysis system. In live trading, your algorithm receives data points one after another over time. QuantConnect models this in backtesting, streaming data to your algorithm in fast-forward mode. Because of this, you can't access price data beyond the Time Frontier . Although streaming analysis is slightly trickier to understand, it allows your algorithm to seamlessly work in backtests and live trading with no code changes.

Event Flow

When you deploy an algorithm, LEAN first calls the initialize method. In live mode, the engine loads your holdings and open orders from your brokerage account to add data subscriptions and populate the `securities` , `portfolio` , and `transactions` objects. LEAN receives the data from the subscriptions, synchronizes the data to create a timeslice , and then performs the following steps. Your algorithm can spend up to 10 minutes on each timeslice unless you call the train method.

1. If it's a backtest, check if there are Scheduled Events in the past that didn't fire because there was no data between the previous slice and the current slice. LEAN automatically creates a Scheduled Event to call the `on_end_of_day` method at the end of each day.

   In live mode, Scheduled Events occur in a separate thread from the algorithm manager, so they run at the correct time.

2. Update the algorithm time.
3. Update the `current_slice` .
4. Pass the `SymbolChangedEvents` to the `on_symbol_changed_events` method.
5. Cancel all open orders for securities that changed their ticker .
6. Add a `Security` object to the `securities` collection for each new security in the universe.
7. Update the `Security` objects with the latest data.
8. Update the `Cash` objects in the CashBook with the latest data.
9. Process fill models for non-market orders.
10. Submit market on open orders to liquidate Equity Option contracts if the underlying Equity has a split warning .
11. Process margin calls .
12. If it's time to settle unsettled cash , perform settlement.
13. Call the on_securities_changed method with the latest security changes.
14. Apply dividends to the portfolio.
15. For securities that have a split warning, update their portfolio holdings and adjust their open orders to account for the split.
16. Update consolidators with the latest data.
17. Pass the `Dividends` to the `on_dividends` method.
18. Pass the `Splits` to the `on_splits` method.
19. Pass the `Delistings` to the `on_delistings` method.
20. Pass the `Slice` to the `on_data` method.
21. Perform universe selection .
22. Pass the `Slice` to the `update` method of each Alpha model .
23. Pass the `Insight` objects from the Alpha model to the Portfolio Construction model .
24. Pass the `PortfolioTarget` objects from the Portfolio Construction model to each Risk Management model .
25. Pass the risk-adjusted `PortfolioTarget` objects from the Risk Management models to the Execution model .

When your algorithm stops executing, LEAN calls the `on_end_of_algorithm` method .

Python Support

The LEAN engine is written in C#, but you can create algorithms in C# or Python. If you program in Python, LEAN uses Python.Net to bridge between the C# engine and your algorithm. It can be slow to move from Python to C#. If you access C# objects in your Python algorithm, it's fastest to only access them once and save a reference if you need to access them again.

```py
# Store the security holding in a variable for better readability and performance.
security_holding = self.portfolio[self._symbol]
avg_price = security_holding.average_price
quantity = security_holding.quantity

# Avoid indexing the portfolio object multiple times for each attribute.
avg_price = self.portfolio[self._symbol].average_price
quantity = self.portfolio[self._symbol].quantity
```

Key Concepts

Multi-Asset Modeling

Introduction

We designed LEAN as a multi-asset platform with out-of-the-box support for multiple securities, so you can model complex portfolios like hedge funds.

Asset Portfolio

The portfolio manages the individual securities it contains. It tracks the cost of holding each security. It aggregates the performance of the individual securities in the portfolio to produce statistics like net profit and drawdown . The portfolio also holds information about each currency in its cashbook.

Cashbooks

We designed LEAN to be a multi-currency platform. LEAN can trade Forex, Cryptocurrencies, and other assets that are quoted in other currencies. A benefit of supporting multiple currencies is that as we add new asset classes from new countries, LEAN is already prepared to transact in those assets by using their quote currency. For instance, we added the India Equity market, which quotes assets in the INR currency.

The portfolio manages your currencies in its cashbook, which models the cash as a ledger of transactions. When you buy assets, LEAN uses the currencies in your cashbook to purchase the asset and pay the transaction fees. For more information about the cashbook, see Cashbook .

Buying Power

We model the margin requirements of each asset and reflect that in the buying power available to the algorithm. We source Futures margins from CME SPAN margins. Equity margin is 2x for standard margin accounts and 4x intraday for Pattern Day Trading accounts. For more information about buying power modeling, see Buying Power .

Examples

The following examples demonstrate some common practices for multi-asset modeling.

Example 1: BTC Spot-Crypto Future Arbitration

This algorithm demonstrates an arbitration between Spot and Crypto Future BTCUSDT using a BTC cash account. If one's price is above 0.5% of another's, we sell the relatively overpriced one and buy the counter side. To ensure the cash position is sufficient to open the buy position, we order the buy side after the sell side is filled and the cash is replenished.

```py
class MultiAssetModelingAlgorithm(QCAlgorithm):

    _threshold = 0.005

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Seed the last price to set the initial price of the BTCUSDT holdings.
        self.settings.seed_initial_prices = True

        # Simulate a cash Bybit account.
        self.set_brokerage_model(BrokerageName.BYBIT, AccountType.CASH)
        self.set_account_currency("USDT", 0)
        spot_balance = 2  # BTC
        self.set_cash('BTC', spot_balance)

        # Request BTCUSD spot and future data to trade their price discrepancies.
        self._spot = self.add_crypto("BTCUSDT", market=Market.BYBIT)
        self._future = self.add_crypto_future("BTCUSDT", market=Market.BYBIT)

        # Simulate the portfolio is holding BTC cash initially via BTCUSDT position.
        # Note that the performance will also be affected by the BTC performance in the default account currency.
        self._spot.holdings.set_holdings(average_price=self._spot.price, quantity=spot_balance)
        self._trade_quantity = spot_balance/2

    def on_data(self, slice: Slice) -> None:
        # Wait for the Slice to contain QuoteBar objects for both assets.
        if not(self._spot.symbol in slice.quote_bars and self._future.symbol in slice.quote_bars):
            return
        # If the spot price is higher than the future price more than the threshold,
        # Do arbitration by selling the spot BTC and buying the future.
        if self._spot.price >= self._future.price * (1 + self._threshold) and not self._future.holdings.is_long:
            self.sell(self._spot.symbol, self._trade_quantity)
        # If the future price is higher than the spot price more than the threshold,
        # Do arbitration by buying the spot BTC and selling the future.
        if self._future.price >= self._spot.price * (1 + self._threshold) and self._future.holdings.is_long:
            self.sell(self._future.symbol, self._trade_quantity)

    def on_order_event(self, order_event: OrderEvent) -> None:
        # Order the buy-side of the arb only when the BTC is sold and USDT is obtained.
        if not(order_event.quantity < 0 and order_event.status == OrderStatus.FILLED):
            return
        security = self._future if order_event.symbol == self._spot.symbol else self._spot
        # Calculate the initial margin needed, we need to sell the same amount of BTC to obtain sufficient USDT for trade.
        margin = security.buying_power_model.get_initial_margin_requirement(
            InitialMarginParameters(security, self._trade_quantity)
        ).value
        # Check if USDT cash is sufficient to open the position.
        if self.portfolio.cash_book["USDT"].amount >= margin:
            self.buy(security.symbol, self._trade_quantity)
```

Example 2: BTC Spot-Future Arbitration

This algorithm implements a similar logic to the above example of an arbitration algorithm between spot BTCUSD and Future BTC using a cash account. If one's price is above 0.5% of another's, we sell the relatively overpriced one and buy the counter side. Note that we need to calculate the future value of the Future fairly compared to the spot BTC. Also, we need to rollover any Futures contracts.

Key Concepts

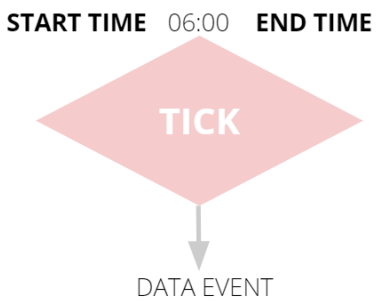
Time Modeling

Time Modeling

Periods

Introduction

Data comes in two different "shapes" according to the time period it covers: point values or period values. In QuantConnect, ticks are point values, and bars are a period values. These data formats have different properties, which control when LEAN emits them into your algorithm.



Start and End Time

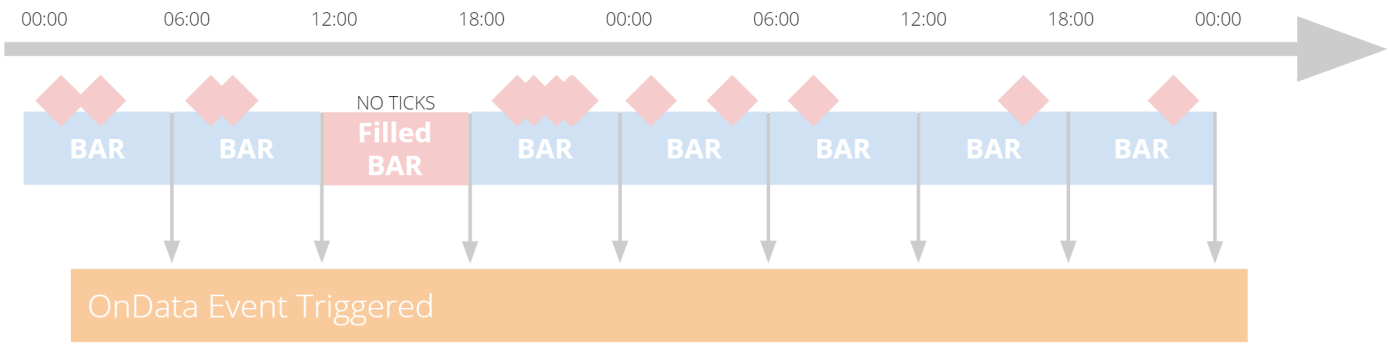
Bars have a start and end time that represent the time period of which the bar aggregates data. LEAN passes the bar to your algorithm at the end time so that you don't receive the bar before it was actually available. Free online data providers commonly timestamp their bars to the start time of the bar and include the bar close price, making your research prone to look ahead bias.

Carefully consider the end-time of data to avoid one-off errors when you import the data into QC or compare indicator values across different platforms. Generally, bar timestamps can be represented as follows: `bar.end_time = bar.time + bar.period`.

Period Values

Bars aggregate data across a period of time into a single object. We make this easy for you by pre-aggregating billions of raw trade-ticks into `TradeBar` objects and quote-ticks into `QuoteBar` objects.

We don't know the close of an intraday bar until the start of the next bar, which can sometimes be confusing. For daily bars, the bar will include all the ticks from market open to market close, but LEAN will emit it to your algorithm at market close. As a result, if you analyze the Friday data and then place an order, LEAN sends the order to your brokerage on Friday after the market close.



When there are no ticks during a period, LEAN emits the previous bar. This is the default behavior for bar data and it's referred to as "filling the data forward". You can enable and disable this setting when you create the security subscription .

We provide bar data in second, minute, hour, and daily bar formats. To create other periods of bars, see Consolidating Data .

Daily Periods

LEAN emits daily bars at market close or midnight, depending on your `daily_precise_end_time` setting . To be notified when a security has finished trading for the day, add an `on_end_of_day` method to your algorithm. LEAN calls this method for each security every day.

```
# Perform end-of-day logic for a given symbol.
def on_end_of_day(self, symbol: Symbol) -> None:
    pass
```

Point Values

Point values have no period because they occur at a singular point in time. Examples of point data includes ticks, open interest, and news releases. Tick data represents a single trade or quote in the market. It's a discrete event with no period, so the `time` and `end_time` properties are the same. LEAN emits ticks as soon as they arrive and doesn't fill them forward.

Examples

The following examples demonstrate some common practices for period time modeling.

Example 1: Tick Signals & Daily Bars

This example shows using a tick/pointwise signal from the Smart Insider Intention dataset while trading Starbuck's stock with daily bars. To liquidate the position after two trading days, you can count the number of `TradeBar` objects you get in the `on_data` method.

PY

```
class PeriodTimeModelingAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add an Equity asset. We will enter with a market on open order
        # and hold for 2 full days, so daily resolution is sufficient.
        self._equity = self.add_equity("SBUX", Resolution.DAILY)
        # Add insider trade intention as the sentiment trading signal.
        self._smart_insider_intention = self.add_data(
            SmartInsiderIntention, self._equity.symbol
        )
        # Add a member to track the number of days until the position
        # should be liquidated.
        self._hold_days = 0

    def on_data(self, slice: Slice):
        # Buy Starbuck's stock whenever we receive a buyback intention
        # or transaction notification due to volatility.
        if self._smart_insider_intention.symbol in slice:
            self.set_holdings(self._equity.symbol, 1)
            # Hold the position for 2 days to fully digest the insider
            # intention sentiment.
            self._hold_days = 2
        # Count down the holding day per each daily trade bar received.
        if self._equity.holdings.invested and self._equity.symbol in slice.bars:
            self._hold_days -= 1
            # Liquidate the position if 2 days were fully counted.
            if self._hold_days <= 0:
                self.liquidate(self._equity.symbol)
```

Time Modeling

Timeslices

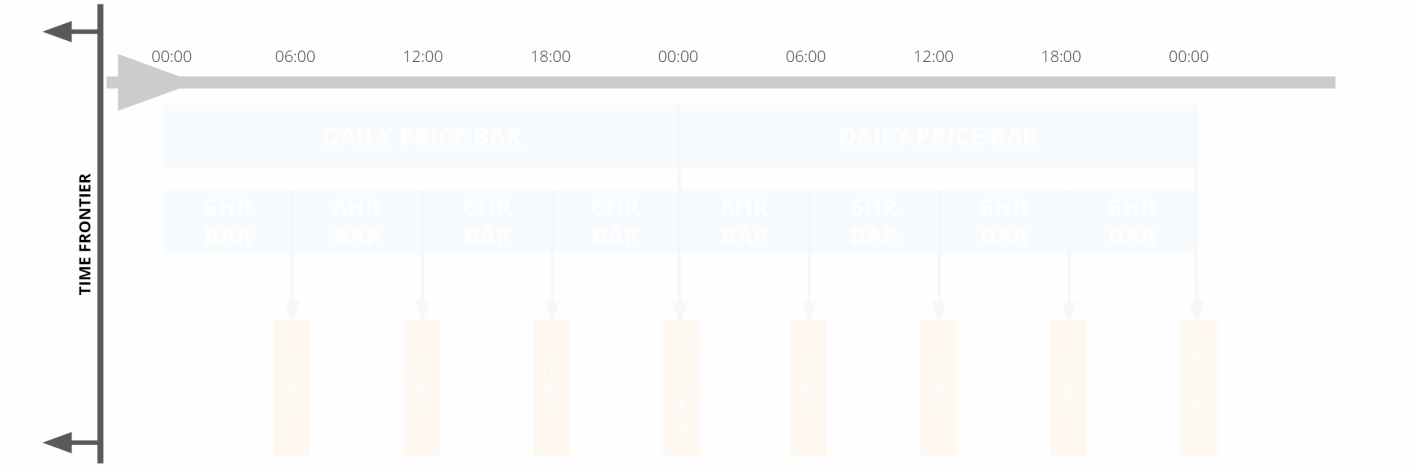
Introduction

The core technology behind QuantConnect algorithmic trading is an event-based, streaming analysis system called LEAN . LEAN attempts to model the stream of time as accurately as possible, presenting data ("events") to your algorithms in the order it arrives, as you would experience in reality.

All QuantConnect algorithms have this time-stream baked in as the primary event handler, `on_data` . The `Slice` object this method receives represents all of the data at a moment of time, a time-slice . No matter what data you request, you receive it in the order created according to simulated algorithm time. By only letting your algorithm see the present and past moments, we can prevent the most common quantitative-analysis error, look-ahead bias .

Time Frontier

If you request data for multiple securities and multiple resolutions, it can create a situation where one of your data subscriptions is ready to emit, but another subscription with a longer period is still be constructing its bar. Furthermore, if you request multiple datasets that have different time zones, your algorithm will receive the daily bars of each dataset at market close for the respective asset. To coordinate the data in these situations, we use the `end_time` of each data point to signal when LEAN should transmit it to your algorithm.



Once your algorithm reaches the `end_time` of a data point, LEAN sends the data to your `on_data` method. For intraday bars, this is the beginning of the next period. For daily bars, it's market close or midnight, depending on your `daily_precise_end_time` setting . To avoid look-ahead bias, you can only access data from before this Time Frontier. The `time` property of your algorithm is always equal to the Time Frontier.

Properties

`Slice` objects have the following properties:

Get Time Slices

To get the current `Slice` object, define an `on_data` method or use the `current_slice` property of your algorithm. The `Slice` contains all the data for a given moment in time. The and properties are `Symbol` /string indexed dictionaries. The property is a list of ticks for that moment of time, indexed by the `Symbol` . To check which data formats are available for each asset class, see the Data Formats page in the Asset Classes chapter.

The `Slice` object gives you the following ways to access your data:

- Indexing the `Slice` , which returns a dynamic object of your type.

```
# Get the current dynamic object for the specified symbol by indexing the Slice object.
def on_data(self, slice: Slice) -> None:
    data = slice[self._symbol]
```

With minute and second resolution data, the dynamic type is `TradeBar` for Equities and `QuoteBar` for other asset classes.

- Indexing the static properties, which returns the type you specify.

```
# Get the current trade and quote bars for a specific symbol from the data slice.
def on_data(self, slice: Slice) -> None:
    trade_bar = slice.bars[self._symbol]
    quote_bar = slice.quote_bars[self._symbol]
```

Check if the `Slice` contains the data you're looking for before you index it. If there is little trading, or you are in the same time loop as when you added the security, it may not have any data. Even if you enabled fill-forward for a security subscription, you should check if the data exists in the dictionary before you try to index it. To check if the `Slice` contains for a security, call the `contains_key` method. Note: if the `Slice` object doesn't contain any market data but it contains auxiliary data, the `slice.contains_key(symbol)` method can return true while `slice[symbol]` returns `None` .

```
# Check if the slice contains data for the symbol and retrieve it if it's available.
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self._symbol) and slice[self._symbol]:
        data = slice[self._symbol]
```

Examples

The following examples demonstrate some common practices for timeslices time modeling.

Example 1: 6-Hour Consolidated Bars

```
class TimeslicesTimeModelingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Request AAPL data to trade it. We need a resolution denser than 6-hour for the consolidator.
        self.aapl = self.add_equity("AAPL", Resolution.Hour).symbol

        # Create a 6-hour consolidator for smoothing the noise.
        self.consolidator = TradeBarConsolidator(timedelta(hours=6))
        # Subscribe the consolidator to update with the security's data automatically.
        self.subscription_manager.add_consolidator(self.aapl, self.consolidator)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self.aapl)
        if bar and self.consolidator.working_bar is not None:
            # Trade on a rising trend, suggested by the current close is above the past hour open
            # and the past hour open is above the 6-hour bar open.
            if self.consolidator.working_bar.open < bar.open < bar.close:
                self.set_holdings(self.aapl, 1)
            # Trade on a down trend, suggested by the current close is below the past hour open
            # and the past hour open is below the 6-hour bar open.
            elif self.consolidator.working_bar.open > bar.open > bar.close:
                self.set_holdings(self.aapl, -1)
            # Otherwise, do not hold a position if there is no deterministic trend.
            else:
                self.liquidate()
```

Time Modeling

Time Zones

Introduction

LEAN is an international trading engine, so it can operate across time zones. The exchange, your algorithm, and the data in your algorithm can all have different time zones.

Exchange Time Zone

Exchanges are located in different areas, so they can have different time zones. LEAN tracks the time zone of each exchange so that you receive the correct data at the right point in time in your algorithm. If you have multiple exchanges in your algorithm from different time zones, LEAN synchronizes them to your algorithm time. Furthermore, if you set up time period consolidators , LEAN consolidates the data based on the data time zone.

To get the time zone of the exchange that a `Security` trades on, use its `exchange.hours.time_zone` property.

```
# Get the time zone of the exchange for a specific asset.
time_zone = self.securities[self._symbol].exchange.hours.time_zone
```

Algorithm Time Zone

LEAN supports international trading across multiple time zones and markets, so it needs a reference time zone for the algorithm to set the `time` . The default time zone is Eastern Time (ET), which is UTC-4 in summer and UTC-5 in winter. To set a different time zone, call the `set_time_zone` method. This method accepts either a string following the IANA Time Zone database convention or a NodaTime .DateTimeZone object. If you pass a string, the method converts it to a `NodaTime.DateTimeZone` object. The `TimeZones` class provides the following helper attributes to create `NodaTime.DateTimeZone` objects:

```
self.set_time_zone("Europe/London")
self.set_time_zone(TimeZones.CHICAGO)
```

To get the time zone of your algorithm, use the `time_zone` property.

```
# The algorithm timezone property can assist with multi-asset trading.
time_zone = self.time_zone
```

To get the algorithm time in Coordinated Universal Time (UTC), use the `utc_time` property.

```
# Access the current UTC time to coordinate multi-timezone events or improve logging.
utc_time = self.utc_time
```

The `time` and `utc_time` objects have no time zone. LEAN maintains their state to be consistent.

Data Time Zone

Datasets can have different time zones because the time zone is up to the data provider, where they are located, and where they collect the data. LEAN converts their time zones to their exchange time zone and synchronizes them to your algorithm time.

To get the time zone of a dataset, view the listing page in the Dataset Market or call the `GetDataTimeZone` method.

```
# Get the time zone of an asset.
time_zone = self.market_hours_database.get_data_time_zone(Market.USA, self._symbol, SecurityType.EQUITY)
```

Examples

The following examples demonstrate some common practices for time zone modeling.

Example 1: Futures Time Zone

The following algorithm changes its time zone to be the same as the EMini SP500 Futures exchange, i.e., Chicago time zone. It is comparable in validating data across different sources and has a more convenient time notification without further conversion.

```py
class TimeZoneModelingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Request ES future data for trading.
        self._future = self.add_future("ES", Resolution.Minute,
            extended_market_hours=True,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            contract_depth_offset=0)

        # Set the time zone to be the same as the Future (Chicago).
        # It will make the time in the backtest more comparable and easily analyzed with any other data sources.
        # Performance of the backtest will only be altered by this change if the trading logic depends on the Time property.
        self.set_time_zone(self._future.exchange.time_zone)

        self.ticket = None

    def on_data(self, slice: Slice) -> None:
        if not self.portfolio.invested and not self.ticket:
            contract = self.securities[self._future.mapped]
            # Set a limit price that repsects the brokerage's precision requirements.
            limit_price = self._adjust_limit_price(contract, contract.price * 0.995)
            self.ticket = self.limit_order(contract.symbol, 1, limit_price)

        # Cancel unfilled orders if they are not filled within 2 minutes to avoid stale fills.
        # Note that the Time property in the order ticket is in UTC timezone.
        if self.ticket.status != OrderStatus.Filled and self.ticket.time + timedelta(minutes=2) < self.utc_time:
            # You can change to a different time zone and compare the log differences.
            self.ticket.cancel(f"{self.time} :: utc: {self.utc_time} :: Order canceled due to placed over 2 minutes")

            self.ticket = None

    def _adjust_limit_price(self, security, price, round_up=True):
        pip = security.price_variation_model.get_minimum_price_variation(
            GetMinimumPriceVariationParameters(security, price)
        )
        return (int(price / pip) + int(round_up)) * pip
```

Key Concepts

Security Identifiers

Introduction

We implemented `Symbol` objects in the LEAN open-source project as a way to identify or "finger-print" tradable assets so that no further database look-up is required. All QuantConnect and LEAN Algorithm API methods use `Symbol` objects to identify assets.

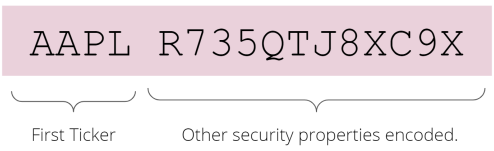
Encoding Symbols

`SecurityIdentifier` objects have several public properties to uniquely identify each asset. The following table describes these properties:

Property	Data Type	Description
`market`	`str`	The market in which the asset trades
`security_type`	`SecurityType`	The asset class
`option_style`	`OptionStyle`	American or European Option style
`option_right`	`OptionRight`	Call or put Option type
`strike_price`	`float`	The Option contract strike price
`date`	`datetime`	Earliest listing date for Equities; expiry for Futures and Options; December 30, 1899 for continuous Futures contracts and Indices.
`has_underlying`	`bool`	A flag to represent if its a derivative asset with another underlying asset

We encode the preceding properties to create `Symbol` objects. We do our best to hide the details of this process from your algorithm, but you'll occasionally see it come through as an encoded hash like `AAPL R735QTJ8XC9X`. The first half of the encoded string represents the first ticker AAPL was listed under. The other letters at the end of the string represent the serialized form of the preceding `SecurityIdentifier` properties. You may also see an encoded has like `AAPL XL7X5I241SO6|AAPL R735QTJ8XC9X` for a derivative contract. In this case, the part before the `|` is contract hash and the part after the `|` is the underlying hash. This serialization approach lets LEAN assign a short, unique string to octillions of different security objects.

Apple Inc. (same name since listed).



Google Class-C Shares (renamed to GOOG).

LEAN assumes the ticker you pass to the add_equity method is the current ticker of the Equity asset. To access this ticker, use the `value` property of the `Symbol` object.

```
# Add equity for "GOOG" and print symbol id value, symbol value and encoded symbol id.
self._symbol = self.add_equity("GOOG").symbol
self.debug(self._symbol.id.value) # Prints "GOOCV"
self.debug(self._symbol.value)    # Prints "GOOG"
self.debug(str(self._symbol.id))  # Prints "GOOCV VP83T1ZUHROL"
```

If you create the security subscription with a universe selection function, the `value` property of the `Symbol` object is the point-in-time ticker.

Decoding Symbols

When a `SecurityIdentifier` is serialized to a string, it looks something like `SPY R735QTJ8XC9X`. This two-part string is a base64 encoded set of data. Encoding all of the properties into a short format allows dense communication without requiring a third-party list or look-up. Most of the time, you will not need to work with these encoded strings. However, to deserialize the string into a `Symbol` object, call the `symbol` method.

```
# Extract the market, security type, and value from the symbol with ID "GOOCV VP83T1ZUHROL".
symbol = self.symbol("GOOCV VP83T1ZUHROL")
symbol.id.market      # => "USA"
symbol.security_type  # => SecurityType.EQUITY
symbol.value          # => "GOOCV"
```

Tickers

Tickers are a string shortcode representation for an asset. Some examples of popular tickers include "AAPL" for Apple Corporation and "IBM" for International Business Machines Corporation. These tickers often change when the company rebrands or they undergo a merger or reverse merger.

The ticker of an asset is not the same as the `Symbol`. `Symbol` objects are permanent and track the underlying entity. When a company rebrands or changes its name, the `Symbol` object remains constant, giving algorithms a way to reliably track assets over time.

Tickers are also often reused by different brokerages. For example Coinbase, a leading US Crypto Brokerage lists the "BTCUSD" ticker for trading. Its competitor, Bitfinex, also lists "BTCUSD". You can trade both tickers with LEAN. `Symbol` objects allow LEAN to identify which market you reference in your algorithms.

To create a `Symbol` object for a point-in-time ticker, call the `generate_equity` method to create the security identifier and then call the `Symbol` constructor. For example, Heliogen, Inc. changed their ticker from ATHN to HLGN on December 31, 2021. To convert the ATHN ticker to the Equity `Symbol`, type:

```
# Generate an Equity security identifier for a ticker and then create a symbol with it.
ticker = "ATHN"
security_id = SecurityIdentifier.generate_equity(ticker, Market.USA, mapping_resolve_date=datetime(2021, 12, 1))
symbol = Symbol(security_id, ticker)
```

In the preceding code snippet, the `mapping_resolve_date` must be a date when the point-in-time ticker was trading.

Symbol Cache

To make using the API easier, we have built the Symbol Cache technology, which accepts strings and tries to guess which `Symbol` object you might mean. With the Symbol Cache, many methods can accept a string such as "IBM" instead of a complete `Symbol` object. We highly recommend you don't rely on this technology and instead save explicit references to your securities when you need them.

```
# Example 1: Relying On Symbol Cache:
self.add_equity("IBM")          # Add by IBM string ticker, save reference to Symbol Cache.
self.market_order("IBM", 100)   # Determine refering to IBM Equity from Symbol Cache.
self.history("AAPL", 14)        # Makes a guess referring to AAPL Equity.

# Example 2: Correctly Using Symbols:
self.ibm = self.add_equity("IBM").symbol   # Add IBM Equity string ticker, save Symbol.
self.market_order(self.ibm, 100)           # Use IBM Symbol in future API calls.

self.aapl = Symbol.create("AAPL", SecurityType.EQUITY, Market.USA)
self.history(self.aapl, 14)
```

Markets

The `market` property distinguishes between tickers that have the same string value but represent different underlying assets. A prime example of this is the various market makers who have different prices for EURUSD. We store this data separately and as they have different fill prices, we treat the execution venues as different markets.

The following table shows the available markets for each security type:

Security Type	Market(s)
`SecurityType.EQUITY`	`Market.USA`
`SecurityType.OPTION`	`Market.USA`

`SecurityType.CRYPTO`	`Market.BINANCE`
	`Market.BINANCE_US`
	`Market.BITFINEX`
	`Market.BYBIT`
	`Market.COINBASE`
	`Market.KRAKEN`

`SecurityType.CRYPTO_FUTURE`	`Market.BINANCE`
	`Market.BYBIT`
	`Market.DYDX`

`SecurityType.FOREX`	`Market.OANDA`

`SecurityType.FUTURE`	`Market.CBOT`
	`Market.CFE`
	`Market.CME`
	`Market.COMEX`
	`Market.EUREX`
	`Market.HKFE`
	`Market.ICE`
	`Market.INDIA`
	`Market.NYMEX`
	`Market.NYSELIFFE`
	`Market.SGX`

`SecurityType.FUTURE_OPTION`	`Market.CBOT`
	`Market.COMEX`
	`Market.NYSELIFFE`

`SecurityType.INDEX`	`Market.EUREX`
	`Market.HKFE`
	`Market.OSE`
	`Market.USA`

`SecurityType.INDEX_OPTION`	`Market.USA`
`SecurityType.CFD`	`Market.INTERACTIVE_BROKERS` `Market.OANDA`

Industry Standard Identifiers

You can convert industry-standard security identifiers like CUSIP, FIGI, ISIN, and SEDOL to `Symbol` objects and you can convert `Symbol` objects to industry-standard security identifiers.

CUSIP

To convert a Committee on Uniform Securities Identification Procedures (CUSIP) number to a `Symbol` or a `Symbol` to a CUSIP number, call the `cusip` method.

```py
# Get the CUSIP for the symbol and vice versa.
symbol = self.cusip("03783310") # AAPL Symbol
cusip = self.cusip(symbol) # AAPL CUSIP (03783310)
```

FIGI

To convert a Financial Instrument Global Identifier (FIGI) to a `Symbol` or a `Symbol` to a FIGI, call the `composite_figi` method.

```
# Get the FIGI for the symbol and vice versa.
symbol = self.composite_figi("BBG000B9XRY4") # AAPL Symbol
figi = self.composite_figi(symbol) # AAPL FIGI (BBG000B9XRY4)
```

ISIN

To convert an International Securities Identification Number (ISIN) to a `Symbol` or a `Symbol` to an ISIN, call the `isin` method.

```
# Get the ISIN for the symbol and vice versa.
symbol = self.isin("US0378331005") # AAPL Symbol
isin = self.isin(symbol) # AAPL ISIN (US0378331005)
```

SEDOL

To convert a Stock Exchange Daily Official List (SEDOL) number to a `Symbol` or a `Symbol` to a SEDOL number, call the `sedol` method.

```
# Get the SEDOL for the symbol and vice versa
symbol = self.sedol("2046251") # AAPL Symbol
sedol = self.sedol(symbol) # AAPL SEDOL (2046251)
```

Examples

The following examples demonstrate some common practices for using the security identifier.

Example 1: Future Contract Expiry

The following example demonstrates the use of the security identifier of a Future contract to access its expiry date for contract selection and schedule a singular non-repeating event to rollover using `future.symbol.id.date` .

```
class SecurityIdentifierExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Seed the price data in order to allow the mapped contract to fill despite sparse data.
        self.settings.seed_initial_prices = True
        self._last_scheduled_event = None

    def on_warmup_finished(self) -> None:
        # Since we do not subscribe to any data source, we can use the on_warmup_finished event handler instead of OnData for the initial
position.
        es = Symbol.create(Futures.Indices.SP_500_E_MINI, SecurityType.FUTURE, Market.CME)
        self.open_future_position(es, self.time + timedelta(30), 1)

    def open_future_position(self, symbol: Symbol, min_expiry: DateTime, quantity: float) -> None:
        # Select the next mapped future contract with the nearest expiry,
        # which should be further than the current contract.
        selected = selected = [c.symbol for c in self.futures_chain(symbol) if c.expiry > min_expiry][0]
        # Subscribe to its data to trade it.
        self._future = self.add_future_contract(selected, extended_market_hours=True)

        # Buy back the corresponding number of contracts as the previous mapped contract.
        self.market_order(self._future.symbol, quantity)

        # Schedule the next rollover to be 1 week before the expiry to avoid excessive volatility.
        # It will only be triggered once 7 days before the expiry and discarded afterward.
        if self._last_scheduled_event:
            self.schedule.remove(self._last_scheduled_event)
        self.schedule.on(
            self.date_rules.on([self._future.symbol.id.date - timedelta(7)]),
            self.time_rules.at(9, 30),
            self.roll_over
        )

    def roll_over(self) -> None:
        # Save the current number of contracts to roll over to the next mapped contract.
        quantity = self._future.holdings.quantity
        # Liquidate the to-be-expired contract to roll over the position.
        self.liquidate(self._future.symbol)

        self.open_future_position(self._future.symbol.canonical, self._future.symbol.id.date, quantity)
```

Key Concepts

Event Handlers

Introduction

Event handlers are called during an algorithm execution to pass information to your strategy. Most of the events are not needed for simple strategies, but can be helpful for debugging issues in more complex algorithms.

Data Events

```py
# Get data for a specific symbol to analyze its price movements or trading signals.
def on_data(self, slice: Slice) -> None:
    my_data = slice.get(self._symbol)

# Get split information to adjust holdings and calculations for the symbol.
def on_splits(self, splits: Splits) -> None:
    split = splits.get(self._symbol)

# Capture dividend events to account for income or adjust the strategy based on the dividend payout.
def on_dividends(self, dividends: Dividends) -> None:
    dividend = dividends.get(self._symbol)

# Track events when a security changes its ticker, allowing the algorithm to adapt to these changes.
def on_symbol_changed_events(self, symbol_changed_events: SymbolChangedEvents) -> None:
    symbol_changed_event = symbol_changed_events.get(self._symbol)

# Handle delisting events to manage the position or adjust the strategy when the symbol is delisted.
def on_delistings(self, delistings: Delistings) -> None:
    delisting = delistings.get(self._symbol)
```

The `on_data` method is the primary event handler for receiving financial data events to your algorithm. It is triggered sequentially at the point in time the data is available; in backtesting and live. For daily data, this means the event is processed at market close. In this method, all data for a given moment of time is grouped in a single event, including custom data types. This data is passed with the Slice object.

When fill-forward is enabled for your asset, the OnData event handler will be called regularly even if there was no new data. This is the default behavior.

In backtesting, if your algorithm takes a long time to process a slice, the following slice objects queue up and the next event triggers when your algorithm finishes processing the current slice. In live trading, if your algorithm takes longer to process the current slice than the time period that the slice spans, the next event triggers when your algorithm finishes processing the current slice, but the slice of the following event is the most recent slice. For example, say your algorithm consumes second resolution Crypto data but it takes your algorithm 3.5 seconds to process each slice. In backtesting, you'll get every slice. In live trading, if you deploy at 12:00:00 AM Coordinated Universal Time (UTC), you'll get the first slice at 12:00:01 AM UTC (spanning 12:00:00 AM UTC to 12:00:01 AM UTC) and you'll get the second slice at 12:00:04.5 AM UTC (roughly spanning 12:00:03 AM UTC to 12:00:04 AM UTC).

The `on_splits` , `on_dividends` , `on_symbol_changed_events` , and `on_delistings` event handlers provide data for their respective types in an isolated way. However, all of the data for these corporate actions is also available in the `Slice` in `on_data` .

To perform intensive computation before the market opens, use a Scheduled Event or the train method.

For more information on the `Slice` object and OnData event, see Handling Data .

Securities Changed Event

```
# Log the universe changes.
def on_securities_changed(self, changes: SecurityChanges) -> None:
    for security in changes.added_securities:
        self.debug(f"{self.time}: Added {security.symbol}")

    for security in changes.removed_securities:
        self.debug(f"{self.time}: Removed {security.symbol}")

        if security.invested:
            self.liquidate(security.symbol, "Removed from Universe")
```

The `on_securities_changed` event notifies the algorithm when assets are added or removed from the universe. This can be due to changes in the Universe constituents , delisting , contract expiration, or an explicit call to the remove_security method.

The event is triggered immediately when the asset is removed from the universe; however the data feed for the asset may remain active if the algorithm has open orders.

For more information, see how to use Security Changed Events .

Order Events

```
# Track filled orders and get the details of each fill.
def on_order_event(self, order_event: OrderEvent) -> None:
    order = self.transactions.get_order_by_id(order_event.order_id)
    if order_event.status == OrderStatus.FILLED:
        self.debug(f"{self.time}: {order.type}: {order_event}")

# Track Option assignment events to handle assigned Equity holdings.
def on_assignment_order_event(self, assignment_event: OrderEvent) -> None:
    self.log(str(assignment_event))
```

The `on_order_event` method notifies the algorithm of new orders, and changes in the order status such as fill events and cancelations. For options assignment events there is a dedicated event handler `on_assignment_order_event` .

In backtesting order events are triggered synchronously after the main data events. In live trading, order events are asynchronously as they occur. To avoid infinite loops, we recommend not to place orders in the OnOrderEvent.

For more information, see how to use Order Events .

Brokerage Events

```
# Track brokerage messages.
def on_brokerage_message(self, message: BrokerageMessageEvent) -> None:
    if message.type == BrokerageMessageType.RECONNECT:
        self.log(f"{self.time}: {message.type}: Message: {message.message}")

# Track brokerage disconnections and respond to connectivity interruptions.
def on_brokerage_disconnect(self) -> None:
    self.log(f"Brokerage disconnection detected at {self.time}")

 # Track brokerage reconnections to resume trading operations.
def on_brokerage_reconnect(self) -> None:
    self.log(f"Brokerage reconnected at {self.time}")
```

The `on_brokerage_disconnect` and `on_brokerage_reconnect` event handlers pass information to the algorithm about the brokerage connection status. This can be helpful for considering when to place a trade when a brokerage API is unreliable or under maintenance. The `on_brokerage_message` event handler provides information from the brokerages, including the disconnect and reconnect messages. Message content varies with each brokerage.

Brokerage events are triggered asynchronously in live trading, and are not created in backtesting.

Margin Call Events

```
# Track when remaining margin is low.
def on_margin_call_warning(self) -> None:
    self.log("Margin call warning, 5% margin remaining")

# Review and adjust liquidation orders in response to a margin call.
def on_margin_call(self, requests): -> List[SubmitOrderRequest]:
    # Modify order requests to choose what to liquidate.
    return requests
```

The `on_margin_call_warning` and `on_margin_call` event handlers provide information and control over how to reduce algorithm leverage when performance is poor.

The `on_margin_call_warning` method is called when there is less than 5% margin remaining to give you an opportunity to reduce leverage before an official margin call is performed by the brokerage. The `on_margin_call` event handler is passed a list of `SubmitOrderRequest` objects which will be executed on exiting the method.

Margin events are called before the data events are processed.

The following demonstration processes suggested orders and modifies the qualities to liquidate more than necessary and prevent a second margin call. For more information, see how to handle Margin Calls .

Warmup Finished Event

```
# This event handler runs when the algorithm is done warming up.
def on_warmup_finished(self) -> None:
    pass # Done warming up.
```

The `on_warmup_finished` event handler runs once initialization and warm up is complete.

Command Events

```
# An event handler for receiving external commands.
def on_command(self, data):
    self.log(f'Got command at {self.time} with data: {data}')
    return True
```

The `on_command` event handler runs when you send external commands to your algorithm.

End Of Algorithm Events

```
# The final step after algorithm execution.
def on_end_of_algorithm(self) -> None:
    self.debug("Algorithm done")
```

The `on_end_of_algorithm` event handler is when the algorithm has finished executing as its final step. This event handler is helpful for performing final analysis, or saving algorithm state.

Event Flow

When you deploy an algorithm, LEAN first calls the initialize method. In live mode, the engine loads your holdings and open orders from your brokerage account to add data subscriptions and populate the `securities` , `portfolio` , and `transactions` objects. LEAN receives the data from the subscriptions, synchronizes the data to create a timeslice , and then performs the following steps. Your algorithm can spend up to 10 minutes on each timeslice unless you call the train method.

1. If it's a backtest, check if there are Scheduled Events in the past that didn't fire because there was no data between the previous slice and the current slice. LEAN automatically creates a Scheduled Event to call the `on_end_of_day` method at the end of each day.

   In live mode, Scheduled Events occur in a separate thread from the algorithm manager, so they run at the correct time.

2. Update the algorithm time.
3. Update the `current_slice` .

4. Pass the `SymbolChangedEvents` to the `on_symbol_changed_events` method.
5. Cancel all open orders for securities that changed their ticker .
6. Add a `Security` object to the `securities` collection for each new security in the universe.
7. Update the `Security` objects with the latest data.
8. Update the `Cash` objects in the CashBook with the latest data.
9. Process fill models for non-market orders.
10. Submit market on open orders to liquidate Equity Option contracts if the underlying Equity has a split warning .
11. Process margin calls .
12. If it's time to settle unsettled cash , perform settlement.
13. Call the on_securities_changed method with the latest security changes.
14. Apply dividends to the portfolio.
15. For securities that have a split warning, update their portfolio holdings and adjust their open orders to account for the split.
16. Update consolidators with the latest data.
17. Pass the `Dividends` to the `on_dividends` method.
18. Pass the `Splits` to the `on_splits` method.
19. Pass the `Delistings` to the `on_delistings` method.
20. Pass the `Slice` to the `on_data` method.
21. Perform universe selection .
22. Pass the `Slice` to the `update` method of each Alpha model .
23. Pass the `Insight` objects from the Alpha model to the Portfolio Construction model .
24. Pass the `PortfolioTarget` objects from the Portfolio Construction model to each Risk Management model .
25. Pass the risk-adjusted `PortfolioTarget` objects from the Risk Management models to the Execution model .

When your algorithm stops executing, LEAN calls the `on_end_of_algorithm` method .

Key Concepts

Python and LEAN

Introduction

The LEAN open-source package powers the core functionality of QuantConnect. Strategies plugin to LEAN to request data, and process trades. LEAN is written in C# and accessed in python with a defined API. Most of these interactions are using native python types, with a few key exceptions. To comfortably use LEAN you should learn to recognize error messages when you hit a non-native API, and how to convert back to a native type.

Enumerable Types

When LEAN returns an enumerable, the object should be converted to a `list()` to be easily read by python classes. Popular API methods which return an enumerable are shown below:

Historical Data

QuantConnect also provides methods to request historical data that return a pandas dataframe, or an enumerable. If loading a large amount of data using an enumerable streams the results reducing RAM usage.

The enumerable types might look like the `MemoizingEnumerable` that is a raw C# type accessible in python.

```
qb = QuantBook()
start = datetime(2023, 2, 1)
end = datetime(2023, 2, 4)
ibm = qb.AddEquity('IBM', Resolution.Minute)
bars = qb.History[TradeBar](ibm.Symbol, start, end, Resolution.Minute)
bars
```

✓ 0.3s Python

```
<QuantConnect.Util.MemoizingEnumerable[TradeBar] object at 0x7fd5313209c0>
```

You can directly enumerate this object with standard python `for` loops, or to convert it to a native type, wrap the object in the `list()` :

```
# Loop over enumerable
import numpy as np
close = []
for bar in bars:
    close.append( bar.Close )
print( np.mean(close) )

# Manipulate as a list
barList =  list(bars)
len(barList)
```

✓ 0.8s Python

```
135.29654786324787

1170
```

Underlying Plugin Architecture

Your strategy code implements the QCAlgorithm class, which can communicate with the LEAN Engine. These method calls are done at the same speed as cython, directly invoking calls at the C layer of python. Your algorithm is imported as syntax checked, interpreted python.

Key Concepts

Duck Typing

Introduction

Duck typing is popular type system in Python. The language documentation defines duck typing as follows:

> A programming style which does not look at an object's type to determine if it has the right interface; instead, the method or attribute is simply called or used ("If it looks like a duck and quacks like a duck, it must be a duck.") By emphasizing interfaces rather than specific types, well-designed code improves its flexibility by allowing polymorphic substitution.
>
> Duck-typing avoids tests using `type()` or `isinstance()` . (Note, however, that duck-typing can be complemented with abstract base classes .) Instead, it typically employs `hasattr()` tests or EAFP programming.

You can use duck-typing to add attributes to all non-primitive types in Python

```py
# Duck-typing enables you to add attributes to non-primitive types in Python.
class Duck:
    pass

duck = Duck()
duck.quacks = "Quack!"
print(duck.quacks)
```

Custom Security Properties

You can add attributes to the `Security` object. For example, you can add an exponential moving average .

```py
# Add an EMA indicator to the SPY Equity object.
equity = self.add_equity("SPY")
equity.ema = self.ema(equity.symbol, 10, Resolution.DAILY)
```

This feature is helpful because you can get the `Security` object from the `securities` object.

```py
# Get the SPY Equity object from the securities object to get the EMA indicator.
ema = self.securities["SPY"].ema.current.value
```

Other Types

You can add properties to all types. However, these properties live in the Python space, so you can't access them without a reference. The following example demonstrates that you can add an exponential moving average to the `symbol` attribute of a `Security` object.

```py
# Add an EMA to the SPY security.
equity = self.add_equity("SPY")
self._symbol = equity.symbol
self._symbol.ema = self.ema(self._symbol, 10)
ema = self._symbol.ema.current.value

ema = self.securities["SPY"].symbol.ema.current.value
```

Examples

The following examples demonstrate some common practices for duck typing.

Example 1: Store EMA Indicator

The following example implements a trend-following strategy using the EMA indicator for the top 20 liquid equities. It uses duck typing to store the

EMA indicator in each Security object , so the indicator is discarded together with the `Security` when it is removed from the universe.

```py
class DuckTypingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Weekly renewal on the universe to allow time to capitalize on the trend.
        self.universe_settings.schedule.on(self.date_rules.week_start())
        # Trade on the top 20 liquid equities since they have higher volume and hence price movements.
        self._universe = self.add_universe(self.universe.top(20))

    def on_data(self, slice: Slice) -> None:
        for kvp in self._universe.members:
            symbol, security = kvp.key, kvp.value

            # Trade on updated price data.
            bar = slice.bars.get(symbol)
            if bar:
                ema = security.ema.current.value
                # Switch to long if the current price is above EMA, suggesting an uptrend.
                if bar.close > ema and not self.portfolio[symbol].is_long:
                    self.set_holdings(symbol, 0.025)
                elif bar.close < ema and not self.portfolio[symbol].is_short:
                    self.set_holdings(symbol, -0.025)

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for removed in changes.removed_securities:
            # Liquidate if it is not in the top 50 liquidity stocks anymore.
            self.liquidate(removed.symbol)
            # Release resources that update automatic indicators
            self.deregister_indicator(removed.ema)

        for added in changes.added_securities:
            # Use duck typing to create an EMA indicator for trend trading.
            # Discarded together when the security is removed from the universe, you won't need to handle it.
            added.ema = self.ema(added.symbol, 60, Resolution.DAILY)
            # Warm up the EMA indicator to ensure its readiness for immediate usage.
            self.warm_up_indicator(added.symbol, added.ema, Resolution.DAILY)
```

Key Concepts

Research Guide

Introduction

We aim to teach and inspire our community to create high-performing algorithmic trading strategies. We measure our success by the profits community members create through their live trading. As such, we try to build the best quantitative research techniques possible into the product to encourage a robust research process.

Hypothesis-Driven Research

We recommend you develop an algorithmic trading strategy based on a central hypothesis. You should develop an algorithm hypothesis at the start of your research and spend the remaining time exploring how to test your theory. If you find yourself deviating from your core theory or introducing code that isn't based around that hypothesis, you should stop and go back to thesis development.

Wang et al. (2014) illustrate the danger of creating your hypothesis based on test results. In their research, they examined the earnings yield factor in the technology sector over time. During 1998-1999, before the tech bubble burst, the factor was unprofitable. If you saw the results and then decided to bet against the factor during 2000-2002, you would have lost a lot of money because the factor performed extremely well during that time.

Hypothesis development is somewhat of an art and requires creativity and great observation skills. It is one of the most powerful skills a quant can learn. We recommend that an algorithm hypothesis follow the pattern of cause and effect. Your aim should be to express your strategy in the following sentence:

> *A change in {cause} leads to an {effect}.*

To search for inspiration, consider causes from your own experience, intuition, or the media. Generally, causes of financial market movements fall into the following categories:

- Human psychology
- Real-world events/fundamentals
- Invisible financial actions

Consider the following examples:

Cause	***leads to***	**Effect**
Share class stocks are the same company, so any price divergence is irrational...		A perfect pairs trade. Since they are the same company, the price will revert.
New stock addition to the S&P500 Index causes fund managers to buy up stock...		An increase in the price of the new asset in the universe from buying pressure.
Increase in sunshine-hours increases the production of oranges...		An increase in the supply of oranges, decreasing the price of Orange Juice Futures.
Allegations of fraud by the CEO causes investor faith in the stock to fall...		A collapse of stock prices for the company as people panic.
FDA approval of a new drug opens up new markets for the pharmaceutical company...		A jump in stock prices for the company.
Increasing federal interest rates restrict lending from banks, raising interest rates...		Restricted REIT leverage and lower REIT ETF returns.

There are millions of potential alpha strategies to explore, each of them a candidate for an algorithm. Once you have chosen a strategy, we recommend exploring it for no more than 8-32 hours, depending on your coding ability.

Data Mining Driven Research

An alternative view is to follow any statistical anomaly without explaining it. In this case, you can use statistical techniques to identify the

discontinuities and eliminate them when their edge is gone. Apparently, Renaissance Technologies has data mining models like this.

Overfitting

Overfitting occurs when you fine-tune the parameters of an algorithm to fit the detail and noise of backtesting data to the extent that it negatively impacts the performance of the algorithm on new data. The problem is that the parameters don't necessarily apply to new data and thus negatively impact the algorithm's ability to generalize and trade well in all market conditions. The following table shows ways that overfitting can manifest itself:

Data Practice	Description
Data Dredging	Performing many statistical tests on data and only paying attention to those that come back with significant results.
Hyper-Tuning Parameters	Manually changing algorithm parameters to produce better results without altering the test data.
Overfit Regression Models	Regression, machine learning, or other statistical models with too many variables will likely introduce overfitting to an algorithm.
Stale Testing Data	Not changing the backtesting data set when testing the algorithm. Any improvements might not be able to be generalized to different datasets.

An algorithm that is dynamic and generalizes to new data is more valuable to funds and individual investors. It is more likely to survive across different market conditions and apply to new asset classes and markets.

If you have a collection of factors, you can backtest over a period of time to find the best-performing factors for the time period. If you then narrow the collection of factors to just the best-performing ones and backtest over the same period, the backtest will show great results. However, if you take the same best-performing factors and backtest them on an out-of-sample dataset, the performance will almost always underperform the in-sample period. To avoid issues with overfitting, follow these guidelines:

- Use walk-forward optimization to train your models on historical data and test them on future data.
- Test your strategy with live paper trading.
- Test your model on different asset classes and markets.

Look-ahead Bias

Look-ahead bias occurs when you use information from the future to inform decisions in the present. An example of look-ahead bias is using financial statement data to make trading decisions at the end of the reporting period instead of when the financial statement data was released. Another example is using updated financial statement data before the updated figures were actually available. Wang et al. (2014) show that using the date of when the period ends instead of when the data is actually available can increase the performance of the earnings yield factor by 60%.

Another culprit of look-ahead bias is adjusted price data. Splits and reverse splits can improve liquidity or attract certain investors, causing the performance of the stock to be different than without the split or reverse split. Wang et al (2014) build a portfolio using the 25 lowest priced stocks in the S&P index based on adjusted and non-adjusted prices. The portfolio based on adjusted prices greatly outperformed the one with raw prices in terms of return and Sharpe ratio . In this case, if you were to analyze the low price factor with adjusted prices, it would lead you to believe the factor is very informative, but it would not perform well out-of-sample with raw data.

Look-ahead bias can also occur if you set the universe to assets that have performed well during the backtest period or initialize indicators with values that have performed well during the backtest period. To avoid issues with look-ahead bias, trade a dynamic universe of assets and use point-in-time data. If point-in-time data is not available for the dataset you use, apply a reporting lag. Since the backtesting environment is event-driven and you can't pass the time frontier, it naturally helps to reduce the risk of look-ahead bias.

Survivorship Bias

Survivorship bias occurs when you test a strategy using only the securities that have survived to the end of the testing period and omit securities that have been delisted. If you use the current constituents of an index and backtest over the past, you'll most likely outperform the index because many of the underperformers have dropped out of the index over time and outperformers have been added to the index. In this case, the current constituent universe would consist of only outperformers. This technique is a form of look-ahead bias because if you were trading the strategy in real-time throughout the backtest period, you would not know the current index constituents until today.

If you analyze a dataset that has survivorship bias, you can discover results that are opposite of the true results. For example, Wang et al. (2014) analyze the low volatility factor using two universes. The first universe was the current S&P 500 constituents and the second universe was the point-

in-time constituents. When they used the point-in-time constituents, the low volatility quintile outperformed the high volatility quintile. However, when they used the current constituents, the high volatility quintile significantly outperformed the low volatility quintile.

To avoid issues with survivorship bias, trade a dynamic universe of assets and use the datasets in the Dataset Market . We thoroughly vet the datasets we add to the market to ensure they're free of survivorship bias.

Outliers

Outliers in a dataset can have large impacts on how models train. In some cases, you may leave outliers in a dataset because they can contain useful information. In other cases, you may want to transform the data to handle the outlier data points. There are several common methods to handle outliers.

Winsorization Method

The winsorization method removes outliers at the x% of the extremes. For example, if you winsorize at 1%, it removes the 1% of data points with the lowest value and the 1% of data points with the highest value. This threshold percentage is subjective, so it can result in overfitting.

IQR Method

The interquartile range method removes data points that fall outside of the interval $[Q_1 - k(Q_3 - Q_1),\ Q_3 + k(Q_3 - Q_1)]$ for some constant $k \geq 0$. This method can exclude up to 25% of observations on each side of the extremes. The interquartile range method doesn't work if the data is skewed or non-normal. Therefore, the disadvantage to this method is you need to review the factor distribution properties. If you need to, you can normalize the data with z-scores.

$$Z = \frac{x - \mu}{\sigma}$$

Factor Ranking Method

The factor ranking method ranks the data values instead of taking their raw values. With this method, you don't need to remove any outlier data points. This method transforms the data into a uniform distribution. After converting the data to a uniform distribution, Wang et al. (2014) perform an inverse normal transformation to make the factor values normally distributed. Wang et al. found this ranking technique outperforms the z-score transformation, suggesting that the distance between factor scores doesn't add useful information.

Short Availability

To open a short position, you need to borrow shares from an investor or brokerage that owns them. Wang et al. (2014) show that some factors have a larger edge for long positions and some have a larger edge for short positions. Their research found that the factors that perform better on the short side usually target more securities that are on hard-to-borrow lists than factors that perform better on the long side. Their research also shows that a large part of the returns from these short-biased factors come from securities that are on hard-to-borrow lists. Therefore, if you don't account for short availability, your backtest results can be unrealistic and not reproducible in live trading.

To avoid issues with short availability, add a shortable provider to your algorithm. The shortable provider only lets you open a short trade if there are actually shares available to borrow. By default, LEAN doesn't simulate the cost of borrowing shorts in backtests, but you can enable them by setting a margin interest model.

Examples

The following examples demonstrate some common practices for applying research.

Example 1: Hypothesis-Driven Research

The following example hypothesized that 2 different classes of Google stocks are cointegrated with each other, and we can capitalize spread reversal from occasional, irrational price divergence. To prove it, we make use of the augmented Dickey-Fuller test to verify the cointegration relationship.

```py
from sklearn.linear_model import LinearRegression
from statsmodels.tsa.stattools import adfuller

class HypothesisDrivenResearchAlgorithm(QCAlgorithm):
    # The threshold that the spread/residual of the cointegrated series triggers a trade.
    threshold = 0
    # Store the coefficient and intercept of the cointegrated series for calculating the spread of a new data point.
    coefficients = [0, 0]
    # Store the price series of each symbol for cointegration calculation.
    windows = {}
```

```
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Subscribe to 2 classes of Google stocks to trade their price divergence.
        self.goog1 = self.add_equity("GOOGL", Resolution.MINUTE).symbol        # Class A
        self.goog2 = self.add_equity("GOOG", Resolution.MINUTE).symbol         # Class C

        for symbol in [self.goog1, self.goog2]:
            self.windows[symbol] = RollingWindow(252)

            # Add a consolidator to aggregate a daily bar to update the window's daily price series.
            consolidator = TradeBarConsolidator(timedelta(1))
            consolidator.data_consolidated += lambda _, bar: self.windows[bar.symbol].add(bar.close)
            # Subscribe to the consolidator to update automatically.
            self.subscription_manager.add_consolidator(symbol, consolidator)

            # Warm up the rolling window's daily price series with historical data.
            history = self.history[TradeBar](symbol, 253, Resolution.DAILY)
            for bar in history:
                consolidator.update(bar)

        # Adjust the cointegration factor between the 2 classes' monthly price series.
        self.schedule.on(
            self.date_rules.month_start(),
            self.time_rules.at(0, 1),
            self.calculate_cointegration
        )

        self.calculate_cointegration()

    def on_data(self, slice: Slice) -> None:
        bar1 = slice.quote_bars.get(self.goog1)
        bar2 = slice.quote_bars.get(self.goog2)
        if bar1 and bar2:
            # Calculate the current cointegrated series spread.
            residual = self.coefficients[0] * bar2.close + self.coefficients[1] - bar1.close

            # If the residual is lower than the negative threshold, it means class A's price is much higher than it should be compared to
class C.
            # We sell class A and buy class C to bet on their price convergence.
            if residual < -self.threshold and not self.portfolio[self.goog1].is_short:
                self.set_holdings(self.goog1, -0.5)
                self.set_holdings(self.goog2, 0.5 * self.coefficients[0])
            # If the residual is higher than the threshold, it means class A price is much lower than what it should be compared to class
C.
            # We buy class A and sell class C to bet on their price convergence.
            elif residual > self.threshold and not self.portfolio[self.goog1].is_long:
                self.set_holdings(self.goog1, 0.5)
                self.set_holdings(self.goog2, -0.5 * self.coefficients[0])
            # Close positions of the price are converged.
            elif (self.portfolio[self.goog1].is_short and residual > 0) or (self.portfolio[self.goog1].is_long and residual < 0):
                self.liquidate()

    def calculate_cointegration(self) -> None:
        # Lag direction is unimportant; it is just a sign flip in the linear regression, so we don't need to flip the window order.
        y = np.array(list(self.windows[self.goog1])).reshape(-1, 1)
        x = np.array(list(self.windows[self.goog2])).reshape(-1, 1)

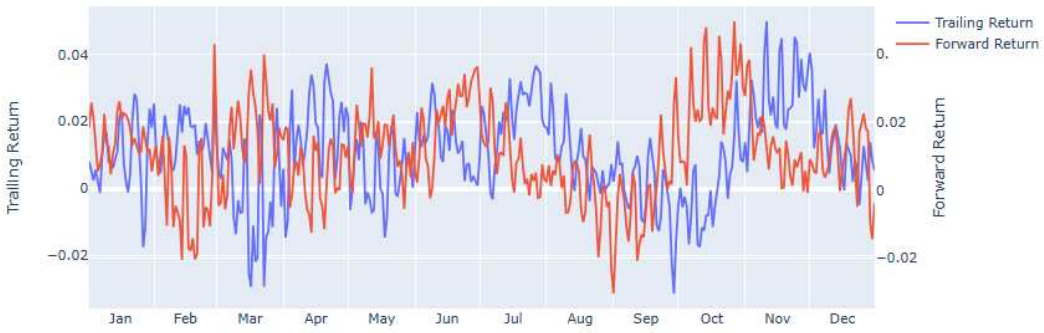
        # Perform Linear Regression on both price series to investigate their relationship.
        lr = LinearRegression().fit(x, y)
        slope = lr.coef_[0]
        intercept = lr.intercept_

        # Calculate the residuals series to check if it is stationary, meaning if the 2 price series move together.
        residuals = y - (intercept + slope * x)

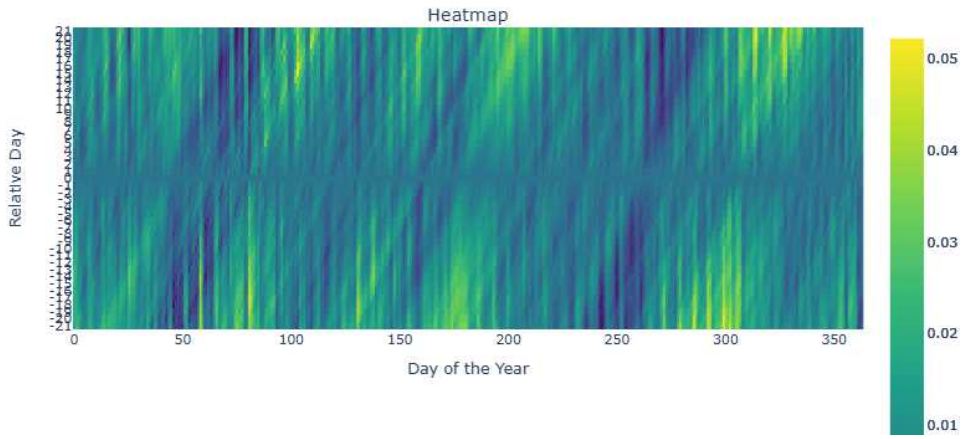
        # Check if the residuals are stationary using the augmented Dickey-Fuller test.
        # Reject the null hypothesis of a unit root is present if test statistic <= -3.45 (approximate α=0.05 for n=250)
        # Which means no unit root for difference series and the residuals are stationary.
        adf_reject = adfuller(residuals)[0] <= -3.45
        if adf_reject:
            # If cointegrated, update the positional sizing ratio and the spread threshold of the trade trigger.
            self.coefficients = [slope, intercept]
            self.threshold = 2 * np.std(residuals)
        else:
            # If not cointegrated, liquidate and set the size to zeros for no positions.
            self.liquidate()
            self.coefficients = [0, 0]
            self.threshold = 100000000          # An arbitrarily large number that the class A price will never reach.
```

Example 2: Data-Driven Research

By exploring the return pattern of SPY in 2020, we use that information to invest in 2021. Since the macroeconomic environment is similar (low interest rate), we assume the market seasonality would follow through. We can observe from the figures below that an around 50-day cycle, like a sine function, exists, and the next cycle starts around Jan 2021. Hence, we switch long and short every 25 days in 2021.



Return Analysis



PY

```
class DataDrivenResearchAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Request SPY data to trade it.
        self.spy = self.add_equity("SPY", Resolution.MINUTE).symbol
        # Add a warm-up period so SPY has a price before the first trade.
        self.set_warm_up(timedelta(7))

    def on_warmup_finished(self) -> None:
        # According to the data, the first cycle is downgoing.
        self.set_holdings(self.spy, -1)
        # Schedule a switch 25 days later.
        self.last_scheduled_event = self.schedule.on(
            self.date_rules.On(self.time + timedelta(25)),
            self.time_rules.at(9, 30),
            self.switch
        )

    def switch(self) -> None:
        # Switch long/short after the cycle change.
        if self.portfolio[self.spy].is_long:
            self.set_holdings(self.spy, -1)
        else:
            self.set_holdings(self.spy, 1)

        # Schedule the next switch 25 days later.
        self.schedule.remove(self.last_scheduled_event)
        self.last_scheduled_event = self.schedule.on(
            self.date_rules.On(self.time + timedelta(25)),
            self.time_rules.at(9, 30),
            self.switch
        )
```

Key Concepts

Behavioral Finance

Introduction

Behavioral finance studies how cognitive biases and emotional responses cause investors to make irrational decisions. These systematic errors create persistent market inefficiencies that algorithmic trading strategies can exploit. Understanding the behavioral "why" behind a strategy helps you design better hypotheses, avoid overfitting to noise, and recognize when an edge might disappear.

Traditional finance assumes that market participants act rationally and that prices reflect all available information. In practice, investors consistently deviate from rationality in predictable ways. They follow the crowd, anchor to irrelevant reference points, overreact to recent news, and avoid realizing losses. These patterns repeat across markets and time periods because they stem from deep-seated cognitive tendencies.

Algorithmic trading is well suited to exploit behavioral biases because algorithms execute rules without emotion. However, the algo trader who designs the rules is still susceptible to the same biases. Knowing which biases drive your strategy and which biases threaten your decision-making process makes you a more effective quant.

This section covers four strategy families and the biases behind them:

- Momentum - Assets that have performed well recently tend to continue performing well. Exploits herd mentality, anchoring bias, and confirmation bias.
- Mean Reversion - Assets that deviate from historical averages tend to revert. Exploits overreaction, the disposition effect, and availability bias.
- Value Factor - Undervalued assets tend to appreciate as the market corrects its pessimism. Exploits loss aversion, recency bias, and status quo bias.
- Quality Factor - High-quality companies tend to outperform because investors chase exciting stories instead. Exploits narrative fallacy, overconfidence, and the endowment effect.

The section also includes a reference page covering the 12 most dangerous investment biases and example algorithms for each strategy type.

Momentum

Momentum strategies buy assets that have performed well recently and sell assets that have performed poorly. The core observation is that recent winners tend to keep winning and recent losers tend to keep losing over intermediate time horizons (3 to 12 months). This effect has been documented across equities, bonds, commodities, and currencies.

Behavioral biases that create momentum

Several cognitive biases cause momentum to persist in financial markets. **Herd mentality** amplifies trends as investors follow the crowd into rising assets. **Anchoring bias** causes slow adjustment to new information, creating gradual price drifts that momentum captures. **Confirmation bias** reinforces trends as investors seek information that supports their existing positions and dismiss contradictory signals.

Algorithmic approach

A typical cross-sectional momentum algorithm follows these steps:

- Define a universe of assets (for example, US equities with sufficient liquidity).
- Rank each asset by its trailing return over a lookback period (commonly 12 months with a 1-month skip to avoid short-term reversal).
- Go long the top decile of performers. Optionally, go short the bottom decile.
- Rebalance the portfolio monthly or at a fixed interval.

The 1-month skip at the end of the lookback period is important because very short-term returns (1 month or less) tend to reverse rather than continue. This short-term reversal is a separate effect driven by liquidity and microstructure, not the behavioral biases that drive intermediate-term momentum.

Biases that threaten momentum traders

While momentum strategies exploit behavioral biases in others, the algo trader designing and managing the strategy is susceptible to several biases:

- **Herd mentality** - Piling into popular momentum strategies when they are already crowded increases exposure to momentum crashes.
- **Anchoring** - Anchoring to a recent period of strong momentum returns can cause you to over-allocate to the strategy.
- **Overconfidence** - Holding momentum positions too long because you believe the trend will continue beyond what the evidence supports.

Mean Reversion

Mean reversion strategies bet that assets which have deviated significantly from their historical average will revert back. When a price moves far above or below its mean, the strategy takes a contrarian position and profits when the price returns to normal levels. Mean reversion operates on shorter time horizons than momentum, typically days to weeks.

Behavioral biases that create reversion opportunities

Several cognitive biases cause prices to overshoot and then revert. **Recency bias** causes investors to overweight recent events and extrapolate short-term trends, creating overreactions that correct over time. The **disposition effect** drives investors to sell winners too early and hold losers too long, creating predictable reversion patterns. **Availability bias** causes dramatic events to receive outsized attention, producing temporary mispricings that fade as investors process the actual impact.

Algorithmic approach

A typical mean reversion algorithm follows these steps:

- Select one or more assets and compute a measure of deviation from the mean. Common measures include z-scores, Bollinger Bands, and RSI.
- When the deviation exceeds a threshold (for example, price drops below the lower Bollinger Band), enter a contrarian position.
- Exit the position when the price reverts to the mean or crosses a take-profit level.
- Use stop-losses to protect against cases where the deviation reflects a genuine regime change rather than a temporary overreaction.

Pairs trading is a common mean reversion variant. You identify two correlated assets, monitor the spread between them, and trade the convergence when the spread widens beyond its historical norm.

Biases that threaten mean reversion traders

Mean reversion traders face their own behavioral pitfalls:

- **Recency bias** - Extrapolating a recent deviation as the "new normal" instead of recognizing it as a temporary overreaction. This can cause you to exit too early or avoid entering at all.
- **Overconfidence** - Believing a deviation will revert when it actually reflects a fundamental shift. Not every drop is a buying opportunity; sometimes the new price is the correct price.

Value Factor

Value strategies buy assets that appear undervalued relative to their fundamentals and sell assets that appear overvalued. The value premium is one of the most studied anomalies in finance: stocks with low price-to-earnings ratios, low price-to-book ratios, or high dividend yields have historically outperformed their expensive peers over long horizons.

Behavioral biases that create value opportunities

Several cognitive biases cause the market to misprice value stocks. **Loss aversion** causes investors to dump declining stocks to avoid further pain, pushing prices below intrinsic value. **Recency bias** leads investors to overweight recent poor performance and project it into the future, treating temporarily struggling companies as permanently impaired. **Status quo bias** makes investors reluctant to buy unfamiliar or out-of-favor stocks, leaving undervalued stocks cheap for longer.

Algorithmic approach

A typical value algorithm follows these steps:

- Define a universe of equities with sufficient liquidity and market capitalization.
- Screen for value using fundamental data: low P/E ratio, low price-to-book ratio, high dividend yield, or a composite of multiple value factors.
- Rank the universe by the value metric and select the most undervalued stocks.
- Construct an equal-weight or value-weight portfolio of the selected stocks.
- Rebalance quarterly to allow time for the value thesis to play out while keeping the portfolio current.

Value strategies require patience because undervalued stocks can remain cheap for extended periods. The quarterly rebalance frequency reflects this longer time horizon compared to momentum or mean reversion strategies.

Biases that threaten value traders

Value investors face specific behavioral challenges:

- **Loss aversion** - Value stocks often continue to decline after you buy them. The same bias that creates the opportunity also makes it difficult to hold positions through drawdowns.
- **Narrative fallacy** - Requiring a compelling "story" for why a cheap stock will recover. Sometimes the quantitative signal is sufficient, and waiting for a narrative can cause you to miss the opportunity.

Quality Factor

Quality factor strategies invest in companies with strong fundamentals: high profitability, stable earnings, low financial leverage, and consistent growth. These "boring but profitable" companies tend to outperform over time, despite receiving less attention than high-growth or turnaround stories.

Behavioral biases that create the quality premium

Several cognitive biases cause investors to undervalue quality stocks. The **narrative fallacy** draws investors toward stocks with exciting stories while steady, predictable businesses get ignored. **Overconfidence bias** leads investors to take concentrated bets on speculative stocks while overlooking quality companies with proven track records. The **endowment effect** makes investors reluctant to sell overvalued glamour stocks and rotate into higher-quality alternatives.

Algorithmic approach

A typical quality factor algorithm follows these steps:

- Define a universe of equities with sufficient liquidity and market capitalization.
- Screen for quality using fundamental metrics: high return on equity (ROE), low debt-to-equity ratio, stable or growing earnings, and strong gross margins.
- Rank the universe by a composite quality score that combines multiple metrics.
- Construct a portfolio of the highest-ranked quality stocks.
- Rebalance quarterly as new fundamental data becomes available.

Quality strategies pair well with value strategies because they address a common criticism of pure value investing: buying cheap stocks that are cheap for good reason (value traps). Adding a quality filter helps you avoid deteriorating businesses and focus on undervalued companies with strong fundamentals.

Biases that threaten quality traders

Quality factor investors face their own behavioral challenges:

- **Narrative fallacy** - Even algo traders can be tempted to override quality signals in favor of an exciting growth story. Trust the quantitative metrics over qualitative narratives.
- **Overconfidence** - Believing that a high-risk, high-reward bet will pay off better than a diversified portfolio of quality companies. The quality premium is modest but consistent, and chasing larger returns often destroys value.

Dangerous Investment Biases

The following 12 cognitive biases are among the most dangerous for investors. Each bias creates exploitable market inefficiencies, but each can also undermine your own trading decisions. For every bias, consider two questions: how can your algorithm exploit this bias in others, and how can you prevent this bias from affecting your algorithm design?

1. Anchoring bias

Anchoring is the tendency to over-rely on the first piece of information you encounter. Investors anchor to purchase prices, 52-week highs, analyst price targets, or round numbers. This causes them to adjust too slowly when new information changes an asset's fair value.

Susceptible strategies: Momentum (slow adjustment creates the trends that momentum exploits), Value Factor (anchoring to past prices instead of current intrinsic value).

Algorithmic antidote: Use relative metrics (percentile ranks, z-scores) instead of absolute price levels. Recompute signals from scratch at each rebalance rather than adjusting from previous values.

2. Availability bias

Availability bias is the tendency to overweight information that is easy to recall, usually because it is recent, dramatic, or emotionally charged. A vivid market crash receives more mental weight than a slow, steady recovery. This causes investors to overreact to dramatic events and create temporary mispricings.

Susceptible strategies: Mean Reversion (dramatic events cause temporary mispricings that revert as emotions fade).

Algorithmic antidote: Base decisions on systematic data analysis rather than salient events. Weight all data points equally unless you have a quantitative reason to do otherwise.

3. Confirmation bias

Confirmation bias is the tendency to seek information that supports your existing beliefs and ignore information that contradicts them. An investor who is bullish on a stock will focus on positive news and dismiss negative signals. This selective processing reinforces trends and delays corrections.

Susceptible strategies: Momentum (reinforces the belief that trends will continue), All types (ignoring disconfirming signals in backtests).

Algorithmic antidote: Validate strategies with out-of-sample data and stress tests. Actively look for conditions where your strategy fails. If you can't find scenarios where it loses money, your testing process likely has confirmation bias built into it.

4. Disposition effect

The disposition effect is the tendency to sell winning investments and hold losing ones. Investors want to realize gains (which feels good) and avoid realizing losses (which feels bad). This creates predictable patterns: winning stocks face selling pressure and losing stocks face holding pressure, both of which eventually correct.

Susceptible strategies: Mean Reversion (disposition-driven selling and holding creates reversion patterns), Momentum (undermines trend following by encouraging premature profit-taking).

Algorithmic antidote: Remove your entry price from the decision process entirely. Use trailing stops or signal-based exits rather than profit targets tied to your cost basis.

5. Endowment effect

The endowment effect is the tendency to value something more simply because you own it. Investors demand a higher price to sell a stock they own than they would pay to buy the same stock. This creates inertia in portfolios and causes investors to hold overvalued positions longer than they should.

Susceptible strategies: Quality Factor (overvaluing flashy holdings over fundamentally strong alternatives), Value Factor (refusing to sell a holding that has become overvalued).

Algorithmic antidote: Rebalance on a fixed schedule using objective ranking criteria. An algorithm that ranks the entire universe at each rebalance does not "remember" what it owns and is immune to the endowment effect.

6. Herd mentality

Herd mentality is the tendency to follow the crowd rather than think independently. When investors see others buying, they buy. When they see others selling, they sell. This collective behavior amplifies price movements beyond what fundamentals justify and creates the trends that momentum strategies exploit.

Susceptible strategies: Momentum (crowd behavior amplifies trends that the strategy rides).

Algorithmic antidote: Monitor crowding metrics and position concentration. Reduce exposure when too many market participants are on the same side of a trade. Momentum crashes often occur when a crowded trade reverses suddenly.

7. Loss aversion

Losses feel approximately twice as painful as equivalent gains feel pleasurable. This asymmetry causes investors to hold losing positions too long (hoping to break even) and sell winning positions too early (locking in gains). Loss aversion creates undervaluation in declining stocks and suppresses returns in rising stocks.

Susceptible strategies: Value Factor (difficulty holding underperformers through drawdowns), Momentum (cutting winners short instead of letting

them run).

Algorithmic antidote: Define exit rules based on quantitative signals, not profit or loss relative to your entry price. Your algorithm should not know or care about its purchase price when making sell decisions.

8. Narrative fallacy

The narrative fallacy is the tendency to create compelling stories to explain random events. Investors prefer stocks with an exciting narrative (a disruptive technology, a charismatic founder) over stocks with strong but boring fundamentals. This preference channels capital toward glamour stocks and away from quality and value stocks.

Susceptible strategies: Quality Factor (investors prefer exciting stories over fundamentals), Value Factor (requiring a "story" to justify buying an undervalued stock instead of trusting the data).

Algorithmic antidote: Let quantitative signals drive decisions. If your algorithm requires a human-readable narrative to justify every trade, you are introducing narrative bias into a systematic process.

9. Overconfidence bias

Overconfidence is the tendency to overestimate your knowledge, ability, or the precision of your predictions. Overconfident investors trade too frequently, take concentrated positions, and underestimate risk. In algo trading, overconfidence manifests as overfitting to historical data and deploying strategies with insufficient out-of-sample validation.

Susceptible strategies: All types (overtrading, over-concentration, and insufficient diversification).

Algorithmic antidote: Use conservative position sizing. Require a strategy to pass multiple independent tests before deploying capital. Track your prediction accuracy honestly and adjust your confidence accordingly.

10. Recency bias

Recency bias is the tendency to overweight recent events when making decisions. Investors extrapolate recent trends, assuming that what happened last quarter will continue next quarter. This causes overreaction to short-term news and creates mispricings that revert over time.

Susceptible strategies: Mean Reversion (overreaction creates the mean-reversion opportunities), Value Factor (recent poor performance causes investors to undervalue fundamentally sound companies).

Algorithmic antidote: Use longer lookback periods that incorporate multiple market regimes. Evaluate strategy performance across full market cycles, not just recent periods.

11. Status quo bias

Status quo bias is the preference for the current state of affairs. Changing your portfolio feels risky, even when the evidence supports a change. Investors stick with familiar holdings and avoid unfamiliar opportunities, which delays the correction of mispricings.

Susceptible strategies: Value Factor (reluctance to buy out-of-favor or unfamiliar stocks).

Algorithmic antidote: Automate rebalancing so that portfolio changes happen systematically. An algorithm that executes a defined rebalancing rule does not experience the discomfort of change.

12. Sunk cost fallacy

The sunk cost fallacy is the tendency to continue investing in something because of the resources already committed, even when continuing is irrational. Investors double down on losing positions because they have "already invested so much" rather than evaluating the position on its current merits.

Susceptible strategies: Value Factor (averaging down on a stock when the original value thesis is broken).

Algorithmic antidote: Evaluate every position at every rebalance as if you were building the portfolio from scratch. The question is not "should I hold this?" but "would I buy this today at this price?"

Examples

The following examples demonstrate algorithmic strategies that exploit behavioral biases. Each example targets a different strategy family and the biases that create its edge.

Example 1: Cross-Sectional Momentum Strategy

The following algorithm exploits herd mentality and anchoring bias by going long equities with the strongest trailing 12-month returns (skipping the most recent month to avoid short-term reversal). It rebalances monthly using a fundamental universe to identify the top momentum stocks.

```py
class MomentumBiasAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Use a universe of liquid US equities.
        self.universe_settings.resolution = Resolution.DAILY
        self.add_universe(self.fundamental_selection)

        # Rebalance on the first trading day of each month.
        self.schedule.on(
            self.date_rules.month_start(),
            self.time_rules.after_market_open("SPY", 30),
            self.rebalance
        )

        self.selected = []

    def fundamental_selection(self, fundamental: list[Fundamental]) -> list[Symbol]:
        # Filter for liquid equities with prices above $5.
        filtered = [x for x in fundamental if x.has_fundamental_data and x.price > 5 and x.dollar_volume > 10000000]
        sorted_by_volume = sorted(filtered, key=lambda x: x.dollar_volume, reverse=True)[:500]
        return [x.symbol for x in sorted_by_volume]

    def rebalance(self) -> None:
        # Calculate trailing 12-month return with a 1-month skip for each security.
        momentum = {}

        for symbol, security in self.active_securities.items():
            # Request 13 months of history: 12-month return skipping the most recent month.
            history = self.history[TradeBar](symbol, 280, Resolution.DAILY)
            history_list = list(history)
            if len(history_list) < 252:
                continue

            # Skip the most recent 21 trading days (~1 month) to avoid short-term reversal.
            end_price = history_list[-22].close
            start_price = history_list[0].close
            if start_price == 0:
                continue

            momentum[symbol] = float(end_price / start_price - 1)

        if not momentum:
            return

        # Select the top 10% of momentum stocks.
        top_count = max(1, len(momentum) // 10)
        sorted_momentum = sorted(momentum.items(), key=lambda x: x[1], reverse=True)[:top_count]
        self.selected = [x[0] for x in sorted_momentum]

        # Equal-weight the portfolio across the selected stocks.
        weight = 1.0 / len(self.selected)
        for symbol in self.selected:
            self.set_holdings(symbol, weight)

        # Liquidate positions no longer in the selection.
        for holding in self.portfolio.values():
            if holding.invested and holding.symbol not in self.selected:
                self.liquidate(holding.symbol)
```

Example 2: Bollinger Band Mean Reversion Strategy

The following algorithm exploits overreaction and the disposition effect. It uses Bollinger Bands on SPY to identify overbought and oversold conditions. When the price drops below the lower band, the algorithm enters a long position betting on reversion to the mean. It exits when the price returns to the middle band.

```
class MeanReversionBiasAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Subscribe to SPY daily data.
        self.spy = self.add_equity("SPY", Resolution.DAILY).symbol

        # Create a 20-day Bollinger Band with 2 standard deviations.
        self.bollinger = self.bb(self.spy, 20, 2, MovingAverageType.SIMPLE, Resolution.DAILY)

        # Warm up the indicator with historical data.
        self.set_warm_up(20, Resolution.DAILY)

    def on_data(self, slice: Slice) -> None:
        if self.is_warming_up or not self.bollinger.is_ready:
            return
        if self.spy not in slice.bars:
            return

        price = slice.bars[self.spy].close

        if not self.portfolio[self.spy].invested:
            # Enter long when price drops below the lower Bollinger Band (oversold / overreaction).
            if price < self.bollinger.lower_band.current.value:
                self.set_holdings(self.spy, 1, tag=f"Enter long at {price:.2f} (lower band:
{self.bollinger.lower_band.current.value:.2f})")
        elif self.portfolio[self.spy].is_long:
            # Exit when price reverts to the middle band (mean).
            if price >= self.bollinger.middle_band.current.value:
                self.liquidate(self.spy, tag=f"Exit at {price:.2f} (middle band: {self.bollinger.middle_band.current.value:.2f})")
```

Example 3: Fundamental Value Strategy

The following algorithm exploits loss aversion and recency bias by screening for undervalued equities using the price-to-earnings ratio. Investors dump stocks with recent poor performance, pushing prices below intrinsic value. The algorithm identifies these opportunities using fundamental data and rebalances quarterly.

```py
class ValueBiasAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Use a fundamental universe for value screening.
        self.universe_settings.resolution = Resolution.DAILY
        self.add_universe(self.fundamental_selection)

        self.selected = []
        self.last_rebalance_month = -1

    def fundamental_selection(self, fundamental: list[Fundamental]) -> list[Symbol]:
        # Only rebalance quarterly (January, April, July, October).
        if self.time.month not in [1, 4, 7, 10]:
            return Universe.UNCHANGED
        if self.time.month == self.last_rebalance_month:
            return Universe.UNCHANGED
        self.last_rebalance_month = self.time.month

        # Screen for value: liquid stocks with positive earnings and low P/E ratios.
        with_earnings = [x for x in fundamental
                         if x.has_fundamental_data and x.price > 5 and x.dollar_volume > 5000000
                         and 0 < x.valuation_ratios.pe_ratio < 50
                         and x.market_cap > 1e9]

        if not with_earnings:
            return []

        # Select the 20 stocks with the lowest P/E ratio (most undervalued).
        sorted_by_pe = sorted(with_earnings, key=lambda x: x.valuation_ratios.pe_ratio)[:20]
        self.selected = [x.symbol for x in sorted_by_pe]
        return self.selected

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        # Liquidate stocks removed from the universe.
        for security in changes.removed_securities:
            if security.invested:
                self.liquidate(security.symbol)

        # Equal-weight the portfolio across selected value stocks.
        if self.selected:
            weight = 1.0 / len(self.selected)
            for symbol in self.selected:
                self.set_holdings(symbol, weight)
```

Example 4: Quality Factor Strategy

The following algorithm exploits narrative fallacy and overconfidence by screening for high-quality companies that the market overlooks in favor of more exciting stories. It uses return on equity and debt-to-equity ratio as quality metrics, constructs an equal-weight portfolio, and rebalances quarterly.

PY

```
class QualityBiasAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Use a fundamental universe for quality screening.
        self.universe_settings.resolution = Resolution.DAILY
        self.add_universe(self.fundamental_selection)

        self.selected = []
        self.last_rebalance_month = -1

    def fundamental_selection(self, fundamental: list[Fundamental]) -> list[Symbol]:
        # Only rebalance quarterly (January, April, July, October).
        if self.time.month not in [1, 4, 7, 10]:
            return Universe.UNCHANGED
        if self.time.month == self.last_rebalance_month:
            return Universe.UNCHANGED
        self.last_rebalance_month = self.time.month

        # Screen for quality: liquid stocks with high ROE and low debt-to-equity.
        quality = [x for x in fundamental
                   if x.has_fundamental_data and x.price > 5 and x.dollar_volume > 5000000
                   and x.operation_ratios.roe.value > 0
                   and 0 <= x.operation_ratios.total_debt_equity_ratio.value < 1.5
                   and x.market_cap > 1e9]

        if not quality:
            return []

        # Rank by ROE descending (higher ROE = higher quality).
        sorted_by_roe = sorted(quality, key=lambda x: x.operation_ratios.roe.value, reverse=True)[:20]
        self.selected = [x.symbol for x in sorted_by_roe]
        return self.selected

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        # Liquidate stocks removed from the universe.
        for security in changes.removed_securities:
            if security.invested:
                self.liquidate(security.symbol)

        # Equal-weight the portfolio across selected quality stocks.
        if self.selected:
            weight = 1.0 / len(self.selected)
            for symbol in self.selected:
                self.set_holdings(symbol, weight)
```

Key Concepts

Globals and Statics

Introduction

It is often convenient to access the QCAlgorithm API in classes outside of the QCAlgorithm class. To achieve this, pass an instance reference or access a global static variable. Whenever possible, we recommend using an instance reference to keep your global namespace clean.

API Access by Algorithm Instance

You can access the QCAlgorithm API by passing the `self` object into a constructor of your target class. The class constructor receives it as a variable you can use to initialize your algorithm. The following algorithm demonstrates this process:

```py
class CustomPartialFillModelAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Request SPY data for trading.
        equity = self.add_equity("SPY", Resolution.HOUR)
        self._spy = equity.symbol
        self._holdings = equity.holdings

        # Set the fill model with the algorithm instance.
        equity.set_fill_model(CustomPartialFillModel(self))

    def on_data(self, data: Slice) -> None:
        # To get all SPY open orders, use the transaction manager.
        open_orders = self.transactions.get_open_orders(self._spy)
        if len(open_orders) != 0: return

        # Hold SPY during 10th-20th in each month.
        if self.time.day > 10 and self._holdings.quantity <= 0:
            self.market_order(self._spy, 105, True)
        elif self.time.day > 20 and self._holdings.quantity >= 0:
            self.market_order(self._spy, -100, True)

class CustomPartialFillModel(FillModel):
    def __init__(self, algorithm: QCAlgorithm) -> None:
        self._algorithm = algorithm
        self._absolute_remaining_by_order_id = {}

    def market_fill(self, asset: Security, order: MarketOrder) -> OrderEvent:
        absolute_remaining = self._absolute_remaining_by_order_id.get(order.id, order.absolute_quantity)
        fill = super().market_fill(asset, order)

        # Allow at most 10 shares to be filled at once.
        fill.fill_quantity = np.sign(order.quantity) * 10

        # If the remaining shares are less than or equal to 10, the order will be fully filled.
        if (min(abs(fill.fill_quantity), absolute_remaining) == absolute_remaining):
            fill.fill_quantity = np.sign(order.quantity) * absolute_remaining
            fill.status = OrderStatus.FILLED
            self._absolute_remaining_by_order_id.pop(order.id, None)
        # Otherwise, the order is only partially filled out, and we need to update the remaining quantity.
        else:
            fill.status = OrderStatus.PARTIALLY_FILLED
            self._absolute_remaining_by_order_id[order.id] = absolute_remaining - abs(fill.fill_quantity)
            price = fill.fill_price
            # Use the instance of the algorithm to log the information
            self._algorithm.debug(f"{self._algorithm.time} - Partial Fill - Remaining {self._absolute_remaining_by_order_id[order.id]}
Price - {price}")

        return fill
```

API Access by Global Static Variable

Occasionally, passing the QCAlgorithm object to your class constructor is impossible, so you need to use global static variables to access the API for debugging and initialization purposes. The most common case is custom data implementations , where the LEAN Engine is creating the objects, and you're unable to specify a custom constructor.

To create a global static variable, assign the reference to the global variable in the algorithm's `initialize` method. This assignment sets the active instance of the variable to the global static. Then, in your custom class, you can access the QCAlgorithm API through the global. The following

algorithm demonstrates this process:

```py
class MyAlgorithmInstance(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Instantiate a custom type as a global variable in the QCAlgorithm instance.
        # Assign self to Static Cape Variable.
        Cape.algorithm = self
        # Request data for trading or signal.
        self._symbol = self.add_data(Cape, "CAPE")

    def on_data(self, data: Slice) -> None:
        cape = data.get(self._symbol)
        if not cape:
            return
        self.plot("CAPE", "Value", cape.value)

class Cape(PythonData):
    def get_source(self, config: SubscriptionDataConfig, date:datetime, isLiveMode: bool) -> SubscriptionDataSource:
        Cape.algorithm.debug("Test Static: GetSource")
        return SubscriptionDataSource("https://raw.githubusercontent.com/QuantConnect/Documentation/master/Resources/datasets/custom-
data/CAPE.csv", SubscriptionTransportMedium.REMOTE_FILE)

    def reader(self, config: SubscriptionDataConfig, line: str, date:datetime, isLiveMode: bool) -> BaseData:
        index = Cape()
        index.symbol = config.symbol
        data = [x.strip() for x in line.split(',')]
        if len(data) < 12 or line.startswith('Date'):
            return index

        try:
            # Construct the custom data type with input data entry.
            index.value = float(data[12])
            index.time = datetime.strptime(data[0], "%Y.%m")
        except ValueError:
            Cape.algorithm.debug("Test Static 2: ValueError")
        return index
```

Key Concepts

Libraries

Introduction

Libraries (or packages) are third-party software that you can use in your projects. You can use many of the available open-source libraries to complement the classes and methods that you create. Libraries reduce your development time because it's faster to use a pre-built, open-source library than to write the functionality. Libraries can be used in backtesting, research, and live trading. The environments support various libraries for machine learning, plotting, and data processing. As members often request new libraries, we frequently add new libraries to the underlying docker image that runs the Lean engine.

This feature is primarily for Python algorithms as not all Python libraries are compatible with each other. We've bundled together different sets of libraries into distinct environments. To use the libraries of an environment, set the environment in your project and add the relevant `import` statement of a library at the top of your file.

Supported Libraries

The following libraries are supported in each environment :

Add New Libraries

To request a new library, contact us . We will add the library to the queue for review and deployment. Since the libraries run on our servers, we need to ensure they are secure and won't cause harm. The process of adding new libraries takes 2-4 weeks to complete. View the list of libraries currently under review on the Issues list of the Lean GitHub repository .

Project Libraries

Project libraries are QuantConnect projects you can merge into your project to avoid duplicating code files. If you have tools that you use across several projects, create a library.

The process to create a library depends on if you use the Cloud Platform , Local Platform , or CLI .

Key Concepts

Debugging Tools

Introduction

When your algorithm throws errors or doesn't operate how you expect, use debugging tools to diagnose and resolve the issue. The tools to debug LEAN algorithms include a built-in debugger, logs, charts, and the Object Store.

Debugger

The debugger is a built-in tool to help you debug coding errors while backtesting. The debugger enables you to slow down the code execution, step through the program line-by-line, and inspect the variables to understand the internal state of the program. The learn how to start and operate the backtest debugger in your development environment, see the Debugging page in the Cloud Platform , Local Platform , or CLI documentation.

Logs

Algorithms can record string messages ('log statements') to a file for analysis after a backtest is complete, or as a live algorithm is running. These records can assist in debugging logical flow errors in the project code or recording key decision moments. Backtests can process millions of data points. If you place a log statement in the wrong place, it can generate gigabytes of logs, which can be difficult to sift through. When you add to the log file, ensure they are readable.

```py
# Logging records messages to a file so you can debug errors and record key decisions.
self.log(f"Signal triggered. Placing limit order: {limit}")
```

Debug statements are the same as log statements, but `debug` method statements are orange in the Cloud Terminal to provide more emphasis. Debug statements are streamed to the Cloud Terminal while the backtest is running. This can be helpful for real-time updates or monitoring in live-trading.

```py
# Debugging streams messages to the Cloud Terminal for real-time analysis.
self.debug("Exposure to the {sector_name} sector is above 50%!")
```

For more information about log statements, see Logging .

Charts

Plotting values over time can help you understand its range, identify outliers in data, and see times when your algorithm generates unusual values. Before you create a plot, develop a theory about what you expect to see before you view it to gain a deeper understanding of your algorithm. For example, a plot of an asset's price standard deviations should be between -4 and +4, with any outliers happening during extreme market conditions like the COVID pandemic in March 2020. LEAN provides a powerful charting API. You can create time series plots with just a single line of code.

```py
# Create time series plots to understand the asset range and identify outliers.
self.plot("Deviations", "aapl", asset_deviation)
```

For more information about creating charts, see Charting .

Object Store

The Object Store is a key-value data store for low-latency information storage and retrieval. During a backtest, you can build large objects you'd like to analyze and write them for later analysis. This workflow can be helpful when the objects are large and plotting is impossible or when you want to perform analysis across many backtests.

```py
# The Object Store provides a key-value data store optimized for fast access and retrieval of information.
self.object_store.save("key", value)
```

For more information about the Object Store, see Object Store . For a specific example of saving indicator values during a backtest into the Object

Store and then plotting them in the Research Environment, see Example for Plotting .

Performance Chart

QuantConnect provides a series of metrics to help you analyze the computational performance of your algorithms. To enable the Performance Chart , set the `self.settings.performance_sample_period` attribute to the desired sampling period:

```
self.settings.performance_sample_period = timedelta(7)
```

Python Profilers from the Python Standard Library enable you to find the functions and methods in your algorithm that consume most of the runtime. To analyze your algorithm's efficiency with the Python Profilers, follow these steps:

1. Open the project in the Cloud Platform , Local Platform , or a local IDE if you use the CLI.
2. At the top of the main.py file, import the classes you need and enable the `Profile` .

   ```
   from cProfile import Profile
   from pstats import Stats
   from io import StringIO

   # Create the profile and start collecting profiling data.
   profile = Profile()
   profile.enable()
   ```

3. Define or extend the on_end_of_algorithm method to `disable` the `Profile` and save information on the most time-consuming functions to the Object Store .

   ```
   class FunctionTimeConsumptionAlgorithm(QCAlgorithm):
       def initialize(self):
           pass

       def on_end_of_algorithm(self):
           # Stop collecting profiling data
           profile.disable()
           stream = StringIO()
           # Save the top 20 time-consuming functions to a file in the Object Store.
           Stats(profile, stream=stream).sort_stats('cumulative').print_stats(20)
           # Save the profiling data to the Object Store using the algorithm ID.
           self.object_store.save(f"{self.algorithm_id}_profile", stream.getvalue())
   ```

4. Open the Research Environment and create a `QuantBook` .

   ```
   qb = QuantBook()
   ```

5. Get the backtest Id and read the profiling data from the Object Store.

   The process to get the backtest Id depends on if you use the Cloud Platform , Local Platform , or CLI .

   ```
   backtest_id = "8b16cec0c44f75188d82f9eadb310e17"
   profile_output = qb.object_store.read(f"{backtest_id}_profile")
   print(profile_output)
   ```

Memory Metrics

The static `OS` class in the `QuantConnect` namespace exposes memory and CPU metrics that you can read from your algorithm to monitor resource usage during backtests and live trading.

The following table lists the static members of the `OS` class that report memory and CPU usage:

Member	Data Type	Description
`APPLICATION_MEMORY_USED`	`int`	Private memory allocated to the current process, including managed and unmanaged memory, in megabytes.
`TOTAL_PHYSICAL_MEMORY_USED`	`int`	Managed-runtime RAM usage (sampled with `gc.get_total_memory`), in megabytes. LEAN's memory monitor samples this value.
`CPU_USAGE`	`float`	Total CPU usage as a percentage, sampled on a background thread.
`get_server_statistics()`	`Dictionary[str, str]`	Snapshot dictionary with `CPU Usage`, `Used RAM`, `Total RAM`, `Hostname`, and `LEAN Version` entries.

The following examples show how to read these metrics from an algorithm:

```py
# Log the current memory usage of the algorithm process.
self.log(f"Total physical memory used: {OS.TOTAL_PHYSICAL_MEMORY_USED} MB")
self.log(f"Application memory used: {OS.APPLICATION_MEMORY_USED} MB")

# Log the current CPU usage as a percentage.
self.log(f"CPU usage: {OS.CPU_USAGE}%")

# Log a full snapshot of the server statistics.
for kvp in OS.get_server_statistics():
    self.log(f"{kvp.key}: {kvp.value}")
```

LEAN monitors the process's RAM usage during backtests and live trading so it can stop the algorithm gracefully when it approaches the node's memory limit, instead of letting the runtime crash. To avoid killing an algorithm over a short-lived spike, LEAN does not act on the raw reading — it smooths the sampled value first and checks the smoothed value against the limit.

LEAN samples `OS.TOTAL_PHYSICAL_MEMORY_USED` once per minute and feeds each sample into an exponential moving average. The engine sets `emaPeriod = 60`, which gives you roughly a 1-hour rolling window.

```py
# Update the smoothed memory reading each minute.
sample = OS.TOTAL_PHYSICAL_MEMORY_USED
memory_used = int((ema_period - 1) / ema_period * memory_used + (1 / ema_period) * sample)
```

If the smoothed value exceeds the node's memory limit, LEAN terminates the algorithm with the runtime message `Execution Security Error: Memory Usage Maxed Out - {memoryCap}MB max, with last sample of {lastSample}MB.`, where `{memoryCap}` is the node's configured limit and `{lastSample}` is the most recent reading.

JIT Compilation

To increase the speed of some methods, you can use decorators like `@jit` or `@lru_cache`. The `@jit` decorator from Numba is for Just-In-Time (JIT) compilation. It compiles Python code to machine code at runtime to increase the speed of loops and mathematical operations. However, Numba can't compile all Python code. It performs best with NumPy arrays. If you add the `@jit` decorator to your methods, it can make the debugging process more challenging since the code is compiled to machine code. The following code snippet shows an example of using the `@jit` decorator:

```py
import numpy as np
from numba import jit
import time

# Without JIT
def slow_function(arr):
    result = 0
    for i in range(len(arr)):
        result += np.sin(arr[i]) * np.cos(arr[i])
    return result

# With JIT
@jit(nopython=True)
def fast_function(arr):
    result = 0
    for i in range(len(arr)):
        result += np.sin(arr[i]) * np.cos(arr[i])
    return result

# Example usage
arr = np.random.rand(1000000)

# Test without JIT.
start = time.time()
slow_function(arr)
print(f"Slow function took: {time.time() - start} seconds")

# Test with JIT.
start = time.time()
fast_function(arr)  # This will compile first, then run.
print(f"Fast function took: {time.time() - start} seconds")
```

Slow function took: 1.1557221412658691 seconds

Fast function took: 0.32973551750183105 seconds

The `@lru_cache` decorator from the `functools` module is for Least Recently Used (LRU) caching. It caches the result of a function based on its arguments, so that the function body doesn't have to repeatedly execute when you call the function multiple times with the same inputs. The `maxsize` argument of the decorator defines the number of results to cache. For example, `@lru_cache(maxsize=512)` means that it should cache a maximum of 512 results. If you add the `@lru_cache` decorator to your methods, make sure your function is completely dependent on the arguments (not any global state variables) or else the caching process may lead to incorrect results. The following code snippet shows an example of using the `@lru_cache` decorator:

```py
from functools import lru_cache
import time

# Without caching
def fibonacci(n):
    if n < 2:
        return n
    return fibonacci(n-1) + fibonacci(n-2)

# With caching
@lru_cache(maxsize=512)
def fibonacci_cached(n):
    if n < 2:
        return n
    return fibonacci_cached(n-1) + fibonacci_cached(n-2)

n = 30

# Test without caching.
start = time.time()
for _ in range(n):
    fibonacci(n)
print(f"Fibonacci without cache took: {time.time() - start} seconds")

# Test with caching.
start = time.time()
for _ in range(n):
    fibonacci_cached(n)
print(f"Fibonacci with cache took: {time.time() - start} seconds")
```

Fibonacci without cache took: 4.387492418289185 seconds

Fibonacci with cache took: 9.322166442871094e-05 seconds

Key Concepts

Glossary

alpha

The excess return of an algorithm relative to its benchmark after adjusting for risk. Alpha measures the value added by the algorithm's strategy beyond what could be explained by exposure to market movements.

It is calculated as

$$\alpha = R_p - \left[R_f + \beta\left(R_b - R_f\right)\right]$$

where R_p is the portfolio return, R_f is the risk-free rate, β is the portfolio's beta, and R_b is the benchmark return. A positive alpha indicates the algorithm outperformed its risk-adjusted benchmark.

annual standard deviation

A statistical measure that describes the dispersion of annual returns relative to the mean annual return. It is the square root of the annual variance. Assuming independent and identically distributed daily returns, it is calculated as

$$\sigma_{\text{annual}} = \sigma_{\text{daily}} \times \sqrt{252}$$

where σ_{daily} is the standard deviation of daily returns and 252 is the typical number of trading days in a year.

annual variance

A statistical measure that describes the dispersion of annual returns relative to the mean annual return. Assuming independent and identically distributed daily returns, it is calculated as

$$\sigma^2_{\text{annual}} = \sigma^2_{\text{daily}} \times 252$$

where σ^2_{daily} is the variance of daily returns and 252 is the typical number of trading days in a year.

average loss

The average rate of return for unprofitable trades.

It is calculated as

$$\bar{L} = \frac{1}{n_L}\sum_{i=1}^{n_L} R_i$$

where n_L is the number of unprofitable trades and R_i is the return of each unprofitable trade.

average win

The average rate of return for profitable trades.

It is calculated as

$$\bar{W} = \frac{1}{n_W}\sum_{i=1}^{n_W} R_i$$

where n_W is the number of profitable trades and R_i is the return of each profitable trade.

beta

The scale and direction of an algorithm's returns relative to movements in the underlying benchmark.

It is calculated as

$$\beta = \frac{\text{Cov}(R_p, R_b)}{\text{Var}(R_b)}$$

where R_p is the portfolio return and R_b is the benchmark return. A beta of 1 indicates the algorithm moves in lockstep with the benchmark, a beta greater than 1 indicates amplified movements, and a negative beta indicates inverse movements.

capacity

The maximum amount of money an algorithm can trade before its performance degrades from market impact. Capacity is determined by the liquidity of the assets the algorithm trades and the size of positions it takes.

compounding annual return

The annual percentage return that would be required to grow a portfolio from its starting value to its ending value.

It is calculated as

$$\text{CAGR} = \left(\frac{e}{s}\right)^{\frac{1}{y}} - 1$$

where s is starting equity, e is ending equity, and y is the number of years in the backtest period.

day trade

Buying and selling the same asset within one trading day. In the US Equity market, the Financial Industry Regulatory Authority (FINRA) monitors day trading activity and enforces the pattern day trader rule.

drawdown

The largest peak to trough decline in an algorithm's equity curve.

It is calculated as

$$1 - \frac{v_{\text{min}}^{t \geq s}}{v_{\text{max}}^{s}}$$

where v_{max}^{s} is the maximum equity value up to time s and $v_{\text{min}}^{t \geq s}$ is the minimum equity value at time t where $t \geq s$.

equity

The total portfolio value if all of the holdings were sold at current market rates. Equity equals the sum of cash and the market value of all open positions.

expectancy

The expected return per trade.

It is calculated as

$$E = (W_r \times \bar{W}) + (L_r \times \bar{L})$$

where W_r is the win rate, $\bar{W}$ is the average win, L_r is the loss rate, and $\bar{L}$ is the average loss. A positive expectancy indicates the algorithm is expected to be profitable over time.

holdings

The absolute sum of the items in the portfolio. Holdings represent the total market value of all positions, regardless of whether they are long or short.

implied volatility

The volatility of an Option's underlying asset that, when input into an Options pricing model, returns a theoretical value equal to the current market price of the Option.

An initial estimate can be calculated as

$$\sigma \approx \frac{P}{S}\sqrt{\frac{2\pi}{T}}$$

where P is the Option price, S is the underlying asset price, and T is the time to expiration in years. For more information, see Brenner and Subrahmanyam (1988) .

information ratio

The amount of excess return relative to the benchmark per unit of tracking error.

It is calculated as

$$IR = \frac{R_p - R_b}{\sigma_{R_p - R_b}}$$

where R_p is the portfolio return, R_b is the benchmark return, and $\sigma_{R_p - R_b}$ is the tracking error (the standard deviation of the difference between the portfolio and benchmark returns). A higher information ratio indicates more consistent outperformance.

intrinsic value

(Call Option) The price of an asset minus the strike price if the price is above the strike price, otherwise zero.

It is calculated as

$IV_{\text{call}} = \max$

(Put Option) The strike price minus the price of an asset if the price is below the strike price, otherwise zero.

It is calculated as

```
IV_{\text{put}} = \max(K - S,\, 0)
```

where `S` is the current price of the underlying asset and `K` is the strike price of the Option contract.

look ahead bias

The practice of making decisions using information that would not be available until some time in the future. Look-ahead bias invalidates backtest results because the algorithm uses data it would not have access to in live trading.

loss rate

The proportion of trades that were not profitable.

It is calculated as

```
L_r = \frac{n_L}{N}
```

where `n_L` is the number of unprofitable trades and `N` is the total number of trades. The loss rate equals `1 - W_r`, where `W_r` is the win rate.

lowest capacity asset

The asset an algorithm traded that has the lowest capacity. This asset acts as the bottleneck that limits the total capital the algorithm can deploy without degrading performance.

net profit

(Percent) The rate of return across the entire trading period.

It is calculated as

```
\text{Net Profit (\%)} = \frac{e - s}{s} \times 100
```

(Dollar-value) The dollar-value return across the entire trading period.

It is calculated as

```
\text{Net Profit (\$)} = e - s
```

where `s` is starting equity and `e` is ending equity.

out of the money amount

(Call Option) The strike price minus the price of an asset if the price is below the strike price, otherwise zero.

It is calculated as

```
OTM_{\text{call}} = \max(K - S,\, 0)
```

(Put Option) The price of an asset minus the strike price if the price is above the strike price, otherwise zero.

It is calculated as

$$OTM_{\text{put}} = \max(S - K,\, 0)$$

where S is the current price of the underlying asset and K is the strike price of the Option contract.

pattern day trader

A trader who executes four or more day trades in the US Equity market within five business days. FINRA requires pattern day traders to maintain a minimum account equity of $25,000.

payoff

The profit or loss that an Option buyer or seller makes from a trade. Payoff is determined by the difference between the Option's intrinsic value at expiration and the premium paid or received.

Pearson correlation

A measure of the linear relationship between two variables, ranging from -1 to 1.

It is calculated as

$$\rho_{XY} = \frac{\text{Cov}(X,\, Y)}{\sigma_X \sigma_Y}$$

where $\text{Cov}(X, Y)$ is the covariance of the two variables and σ_X, σ_Y are their standard deviations. A value of 1 indicates a perfect positive linear relationship, -1 indicates a perfect negative linear relationship, and 0 indicates no linear relationship.

Probabilistic Sharpe ratio

The probability that the estimated Sharpe ratio of an algorithm is greater than a benchmark.

It is calculated as

$$P\left(\hat{SR} > SR^{\ast}\right) = CDF\left(\frac{(\hat{SR} - SR^{\ast})\sqrt{n-1}}{\sqrt{1 - \hat{\gamma}_{3}\hat{SR} + \frac{\hat{\gamma}_{4}-1}{4}\hat{SR}^{2}}}\right)$$

where $SR^{\ast}$ is the Sharpe ratio of the benchmark, $\hat{SR}$ is the Sharpe ratio of the algorithm, n is the number of trading days, $\hat{\gamma}_{3}$ is the skewness of the algorithm's returns, $\hat{\gamma}_{4}$ is the kurtosis of the algorithm's returns, and CDF is the normal cumulative distribution function. For more information about the PSR, see Bailey and López de Prado (2012) .

profit loss ratio

The ratio of the average win rate to the average loss rate.

It is calculated as

$$PLR = \frac{\bar{W}}{|\bar{L}|}$$

where $\bar{W}$ is the average win and $\bar{L}$ is the average loss. A profit-loss ratio greater than 1 indicates that the average winning trade is larger than the average losing trade.

put call parity

A relationship between the prices of a European call Option, a European put Option, the underlying asset, and the risk-free rate.

It is defined as

$$C(t,K) - P(t,K) = e^{(q-r)t}(S_T - K)$$

where C is the call price, P is the put price, K is the strike price, S_T is the underlying asset price, r is the risk-free rate, q is the dividend yield, and t is the time to expiration.

return

The rate of return across the entire trading period.

It is calculated as

$$R = \frac{e - s}{s}$$

where s is starting equity and e is ending equity.

risk free interest rate

The interest rate an investor can expect to earn on an investment that carries zero risk, such as the interest paid on a 10-year highly rated government treasury note. The risk-free rate serves as a baseline for evaluating the performance of risky investments.

Sharpe ratio

A measure of the risk-adjusted return, developed by William Sharpe.

It is calculated as

$$SR = \frac{E[R_p - R_b]}{\sigma_p}$$

where R_p is the return of the portfolio, R_b is the return of the benchmark, and σ_p is the standard deviation of the portfolio's excess returns. By default, LEAN uses a 0% risk-free rate, so $R_b = 0$. For more information about the Sharpe ratio, see Sharpe (1994) .

Sortino ratio

A measure of the risk-adjusted return, developed by Frank Sortino. Unlike the Sharpe ratio, the Sortino ratio only penalizes returns falling below a user-specified target or required rate of return.

It is calculated as

$$S = \frac{R_p - R_f}{\sigma_d}$$

where R_p is the portfolio return, R_f is the risk-free rate, and σ_d is the downside deviation (the standard deviation of negative returns only). By using downside deviation, the Sortino ratio does not penalize upside volatility.

tail value at risk

The expected loss of a portfolio beyond the Value at Risk threshold, also known as Conditional Value at Risk (CVaR).

Assuming normally distributed returns, it is calculated as

$$\text{TVaR}_{\alpha} = \mu + \sigma \times \frac{\phi[\Phi^{-1}(\alpha)]}{1 - \alpha}$$

where μ is the mean return, σ is the standard deviation, α is the confidence level, ϕ is the standard normal density function, and Φ^{-1} is the inverse of the standard normal cumulative distribution function.

total fees

The total quantity of fees paid for all the transactions during the algorithm's trading period. Total fees include brokerage commissions, exchange fees, and other transaction costs.

total net profit

The rate of return across the entire trading period.

It is calculated as

$$\text{Total Net Profit} = \frac{e - s}{s}$$

where s is starting equity and e is ending equity.

total trades

The number of orders that were filled or partially filled during the algorithm's trading period.

tracking error

A measure of how closely a portfolio follows the index to which it is benchmarked.

It is calculated as

$$TE = \sigma(R_p - R_b)$$

where R_p is the portfolio return, R_b is the benchmark return, and σ denotes the standard deviation. A tracking error of 0 indicates a perfect match with the benchmark.

Treynor ratio

A measurement of the returns earned in excess of the risk-free rate per unit of benchmark risk, developed by Jack Treynor.

It is calculated as

$$T = \frac{R_p - R_f}{\beta}$$

where R_p is the portfolio return, R_f is the risk-free rate, and β is the portfolio's beta. Unlike the Sharpe ratio, which uses total risk (standard deviation), the Treynor ratio uses systematic risk (beta).

unrealized

The amount of profit a portfolio would capture if it liquidated all open positions and paid the fees for transacting and crossing the spread. Unrealized profit becomes realized profit when the positions are closed.

volume

The total value of assets traded for all of an algorithm's transactions during the trading period.

win rate

The proportion of trades that were profitable after transaction fees.

It is calculated as

$$W_r = \frac{n_W}{N}$$

where n_W is the number of profitable trades and N is the total number of trades.

z score

The number of standard deviations a data point is from the mean of a dataset.

It is calculated as

$$Z = \frac{x - \mu}{\sigma}$$

where x is the data point, μ is the mean, and σ is the standard deviation. A z-score of 0 indicates the data point equals the mean. Values beyond ± 3 are commonly considered outliers.

Initialization

Introduction

The `initialize` method is the entry point of your algorithm where you define a series of settings, including security subscriptions, starting cash balances, and warm-up periods. LEAN only calls the `initialize` method one time, at the start of your algorithm.

Set Dates

To set the date range of backtests, call the `set_start_date` and `set_end_date` methods. The dates you provide are based in the algorithm time zone. By default, the end date is yesterday, one millisecond before midnight. In live trading, LEAN ignores the start and end dates.

```
PY
# Set the start and end dates for the algorithm, defining the backtesting period.
self.set_start_date(2013, 1, 5)                 # Set the start date to January 5, 2013.
self.set_end_date(2015, 1, 5)                   # Set the end date to January 5, 2015.
self.set_end_date(datetime.now() - timedelta(7)) # Set the end date to last week.
```

Organization managers can enforce all backtests to end a certain number of months before the current date to reduce the chance of overfitting. For more information, see Out-of-Sample Period .

Set Account Currency

The algorithm equity curve, benchmark, and performance statistics are denominated in the account currency. To set the account currency and your starting cash, call the `set_account_currency` method. By default, the account currency is USD and your starting cash is $100,000. If you call the `set_account_currency` method, you must call it before you call the `set_cash` method or add data . If you call the `set_account_currency` method more than once, only the first call takes effect.

```
PY
# Set the account currency and your starting cash.
self.set_account_currency("BTC") # Set the account currency to Bitcoin and its quantity to 100,000 BTC.
self.set_account_currency("INR") # Set the account currency to Indian Rupees and its quantity to 100,000 INR.
self.set_account_currency("BTC", 10) # Set the account currency to Bitcoin and its quantity to 10 BTC.
```

Set Cash

To set your starting cash in backtests, call the `set_cash` method. By default, your starting cash is $100,000 USD. In live trading, LEAN ignores the `set_cash` method and uses the cash balances in your brokerage account instead.

```
PY
# Set the initial cash balance for the account for supported currencies.
self.set_cash(100000)       # Set the quantity of the account currency to 100,000.
self.set_cash("BTC", 10)    # Set the Bitcoin quantity to 10.
self.set_cash("EUR", 10000) # Set the EUR quantity to 10,000.
```

Set Brokerage and Cash Model

We model your algorithm with margin modeling by default, but you can select a cash account type. Cash accounts don't allow leveraged trading, whereas Margin accounts can support leverage on your account value. To set your brokerage and account type, call the `set_brokerage_model` method. For more information about each brokerage and the account types they support, see the brokerage integration documentation. For more information about the reality models that the brokerage models set, see Supported Models .

```
PY
# Set the brokerage model and account type to model fees, supported order types, and available margin.
self.set_brokerage_model(BrokerageName.INTERACTIVE_BROKERS_BROKERAGE, AccountType.MARGIN)
```

The `AccountType` enumeration has the following members:

Set Universe Settings

The universe settings of your algorithm configure some properties of the universe constituents, including derivatives such as futures and options.

The following table describes the properties of the `UniverseSettings` object:

Property: `asynchronous` Should the universe selection run asynchronously to boost speed? Data Type: `bool` | Default Value: `False`
Property: `extended_market_hours` Should assets also feed extended market hours? You only receive extended market hours data if you create the subscription with an intraday resolution. If you create the subscription with daily resolution, the daily bars only reflect the regular trading hours. Data Type: `bool` | Default Value: `False`
Property: `fill_forward` Should asset data fill forward? Data Type: `bool` | Default Value: `True`
Property: `minimum_time_in_universe` What's the minimum time assets should be in the universe? Data Type: `timedelta` | Default Value: `timedelta(1)`
Property: `resolution` What resolution should assets use? Data Type: `Resolution` | Default Value: `Resolution.MINUTE`
Method: `schedule.on` What days should universe selection run? If it's `None` , it's the data resolution. For example, US Equity fundamentals universes are daily at midnight. Argument Type: `IDateRule` | Default Value: `None`
Property: `contract_depth_offset` What offset from the current front month should be used for continuous Future contracts ? 0 uses the front month and 1 uses the back month contract. This setting is only available for Future assets. Data Type: `int` | Default Value: `0`
Property: `data_mapping_mode` How should continuous Future contracts be mapped? This setting is only available for Future assets. Data Type: `DataMappingMode` | Default Value: `DataMappingMode.OpenInterest`

Property: `data_normalization_mode` How should historical prices be adjusted? This setting is only available for Equity and Futures assets. Data Type: `DataNormalizationMode` | Default Value: `DataNormalizationMode.ADJUSTED`
Property: `leverage` What leverage should assets use in the universe? This setting is not available for derivative assets. Data Type: `float` | Default Value: `Security.NULL_LEVERAGE`

To set the `universe_settings` , update the preceding properties in the `initialize` method before you add the universe. These settings are globals, so they apply to all universes you create.

```py
# Request second resolution data. This will be slow!
self.universe_settings.resolution = Resolution.SECOND
self.add_universe(self.universe.top(50))
```

For more information about universe settings, see the related documentation for classic and framework algorithms.

Set Security Initializer

Instead of configuring global universe settings, you can individually configure the settings of each security in the universe with a security initializer. Security initializers let you apply any security-level reality model or special data requests on a per-security basis. To set the security initializer, in the `initialize` method, call the `set_security_initializer` method and then define the security initializer.

```py
# A custom security initializer can override default models such as
# setting new fee and fill models for the security.
self.set_security_initializer(self._custom_security_initializer)

def _custom_security_initializer(self, security: Security) -> None:
    security.set_fee_model(ConstantFeeModel(0, "USD"))
```

For simple requests, you can use the functional implementation of the security initializer. This style lets you configure the security object with one line of code.

```py
# Disable the trading fees for each security by using lambda function
# for the set_security_initializer argument.
self.set_security_initializer(lambda security: security.set_fee_model(ConstantFeeModel(0, "USD")))
```

If you call the `set_security_initializer` method, it overwrites the default security initializer. The default security initializer uses the security-level reality models of the brokerage model to set the following reality models of each security:

- Fill
- Slippage
- Fee
- Buying Power
- Settlement
- Short availability
- Margin Interest Rate

The default security initializer also sets the leverage of each security and intializes each security with a seeder function. To extend upon the default security initializer instead of overwriting it, call `add_security_initializer` before you create the subscriptions.

```
class AddSecurityInitializerExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the security initializer to set models of assets.
        self.add_security_initializer(self._custom_security_initializer)

    def _custom_security_initializer(self, security: Security) -> None:
        # Overwrite some of the reality models
        security.set_fee_model(ConstantFeeModel(0, "USD"))
```

Add Data

You can subscribe to asset, fundamental, alternative, and custom data. The Dataset Market provides 400TB of data that you can easily import into your algorithms.

Asset Data

To subscribe to asset data, call one of the asset subscription methods like `add_equity` or `add_forex` . Each asset class has its own method to create subscriptions. For more information about how to create subscriptions for each asset class, see Asset Classes .

```
self.add_equity("AAPL")  # Add Apple 1 minute bars (minute by default)
self.add_forex("EURUSD", Resolution.SECOND) # Add EURUSD 1 second bars
```

In live trading, you define the securities you want, but LEAN also gets the securities in your live portfolio and sets their resolution to the lowest resolution of the subscriptions you made. For example, if you create subscriptions in your algorithm for securities with Second, Minute, and Hour resolutions, the assets in your live portfolio are given a resolution of Second.

Alternative Data

To add alternative datasets to your algorithms, call the `add_data` method. For full examples, in the Datasets chapter, select a dataset and see the Requesting Data section.

Custom Data

To add custom data to your algorithms, call the `add_data` method. For more information about custom data, see Importing Data .

Limitations

There is no official limit to how much data you can add to your algorithms, but there are practical resource limitations. Each security subscription requires about 5MB of RAM, so larger machines let you run algorithms with bigger universes. For more information about our cloud nodes, see Resources .

Set Indicators and Consolidators

You can create and warm-up indicators in the `initialize` method.

```
self._symbol = self.add_equity("SPY").symbol
self._sma = self.sma(self._symbol, 20)
self.warm_up_indicator(self._symbol, self._sma)
```

Set Algorithm Settings

The following table describes the `AlgorithmSettings` properties:

Property: `automatic_indicator_warm_up` A flag that defines if automatic indicators are ready on creation. It does not account for built-in `RollingWindow` that stores their historical values , use the `warm_up_indicator` or the `indicator_history` method instead. Data Type: `bool` | Default Value: `False`

Property: `seed_initial_prices`

Determines whether to seed initial prices for all selected and manually added securities.

Data Type: `bool` | Default Value: `False`

Property: `daily_precise_end_time`

A flag that defines if daily bars should have an end_time that matches the market close time (`True`) or the following midnight (`False`).

Data Type: `bool` | Default Value: `True`

Property: `free_portfolio_value`

The buying power buffer value.

To successfully update the `free_portfolio_value` , you must update it after the `initialize` method.

Data Type: `float` | Default Value: `250`

Property: `free_portfolio_value_percentage`

The buying power buffer percentage value.

Data Type: `float` | Default Value: `0.0025`

Property: `ignore_unknown_asset_holdings`

Determines whether to terminate the algorithm when an asset holding is not supported by Lean or the brokerage.

Data Type: `bool` | Default Value: `True`

Property: `liquidate_enabled`

A flag to enable and disable the `liquidate` method.

Data Type: `bool` | Default Value: `True`

Property: `max_absolute_portfolio_target_percentage`

The absolute maximum valid total portfolio value target percentage.

Data Type: `float` | Default Value: `1000000000`

Property: `min_absolute_portfolio_target_percentage`

The absolute minimum valid total portfolio value target percentage.

Data Type: `float` | Default Value: `0.0000000001`

Property: `minimum_order_margin_portfolio_percentage` The minimum order margin portfolio percentage to ignore bad orders and orders with small sizes. Data Type: `float` | Default Value: `0.001`
Property: `performance_sample_period` Performance tracking sample period to use if any, useful to debug performance issues. See Performance Chart . Data Type: `timedelta` | Default Value: `timedelta(0)`
Property: `rebalance_portfolio_on_insight_changes` Rebalance the portfolio when you emit new insights or when insights expire. Data Type: `bool/NoneType` | Default Value: `True`
Property: `rebalance_portfolio_on_security_changes` Rebalance the portfolio when your universe changes. Data Type: `bool/NoneType` | Default Value: `True`
Property: `stale_price_time_span` The minimum time span elapsed to consider a market fill price as stale Data Type: `timedelta` | Default Value: `timedelta(hours=1)`
Property: `trading_days_per_year` Number of trading days per year for this algorithm's portfolio statistics . Data Type: `int` | Default Value: `252`
Property: `warm_up_resolution` The resolution to use during the warm-up period Data Type: `Resolution/NoneType` | Default Value: `None`

To change the `settings` , update some of the preceding properties.

```
# Set the algorithm behavior using the settings property on your algorithm.
self.settings.rebalance_portfolio_on_security_changes = False
self.settings.trading_days_per_year = 365
```

Set Benchmark

The benchmark performance is input to calculate several statistics on your algorithm, including alpha and beta . To set a benchmark for your algorithm, call the `set_benchmark` method. You can set the benchmark to a security, a constant value, or a value from a custom data source . If you don't set a brokerage model , the default benchmark is SPY. If you set a brokerage model, the model defines the default benchmark.

```
# Set the benchmark to IBM
self.set_benchmark("IBM")

# Set the benchmark to a constant value of 0
self.set_benchmark(lambda x: 0)

# Set the benchmark to a value from a custom data source
symbol = self.add_data(CustomData, "CustomData", Resolution.HOUR).symbol
self.set_benchmark(symbol)
```

If you pass a ticker to the `set_benchmark` method, LEAN checks if you have a subscription for it. If you have a subscription for it, LEAN uses the security subscription. If you don't have a subscription for it, LEAN creates a US Equity subscription with the ticker. Since the ticker you pass may not reference a US Equity, we recommend you subscribe to the benchmark security before you call the `set_benchmark` method.

Set Time Zone

LEAN supports international trading across multiple time zones and markets, so it needs a reference time zone for the algorithm to set the `time` . The default time zone is Eastern Time (ET), which is UTC-4 in summer and UTC-5 in winter. To set a different time zone, call the `set_time_zone` method. This method accepts either a string following the IANA Time Zone database convention or a NodaTime .DateTimeZone object. If you pass a string, the method converts it to a `NodaTime.DateTimeZone` object. The `TimeZones` class provides the following helper attributes to create `NodaTime.DateTimeZone` objects:

```
self.set_time_zone("Europe/London")
self.set_time_zone(TimeZones.CHICAGO)
```

The algorithm time zone may be different from the exchange time zone . If the time zones are different, it might appear like there is a lag between the algorithm time and the first bar of a history request, but this is just the difference in time zone. All the data is internally synchronized in Coordinated Universal Time (UTC) and arrives in the same Slice object. A slice is a sliver of time with all the data available for this moment.

To keep trades easy to compare between asset classes, we mark all orders in UTC time.

Set Warm Up Period

You may need some historical data at the start of your algorithm to prime technical indicators or populate historical data arrays. The warm-up period pumps data into your algorithm from before the start date. To set a warm-up period, call the `set_warm_up` method. The warm-up feature uses the subscriptions you add in `initialize` to gather the historical data that warms up the algorithm. If you don't create security subscriptions in the `initialize` method, the warm-up won't occur.

```
# Wind time back 7 days from the start date
self.set_warm_up(timedelta(7))

# Feed in 100 trading days worth of data before the start date
self.set_warm_up(100, Resolution.DAILY)

# If you don't provide a resolution argument, it uses the lowest resolution in your subscriptions
self.set_warm_up(100)
```

Set Name and Tags

You can categorize your backtest with a name and tags. To set the algorithm `name` , call the `set_name` method.

```
# Set the name of your backtest to help categorize your results.
self.set_name("Backtest Name")
```

The `set_name` method overwrites the names of backtests of an optimization , which contains the parameter values. To keep these values, create a name that includes them.

```
# Setting the backtest name to a mix of the parameters can help identify backtests in optimization results.
fast_period = self.get_parameter("fast_period", 100);
mid_period = self.get_parameter("mid_period", 200);
slow_period = self.get_parameter("slow_period", 300);
self.set_name(f"Backtest Name ({fast_period},{mid_period},{slow_period})");
```

To add tags to you algorithm, call the `add_tag` method.

```
# Add additional information to the algorithm with tags for better organization in the backtest results.
self.add_tag("Long Only")
self.add_tag("Momentum")
```

Your algorithm can add 20 tags. The name and each tag can have up to 200 characters or else they are truncated.

Post Initialization

After the `initialize` method, the `post_initialize` method performs post-initialization routines, so don't override it. To be notified when the algorithm is ready to begin trading, define an `on_warmup_finished` method. This method executes even if you don't set a warm-up period.

```
# Notify yourself when the algorithm is ready to begin trading.
def on_warmup_finished(self) -> None:
    self.log("Algorithm Ready")
```

Examples

The following examples demonstrate some common practices for initializing algorithms.

Example 1: Set the Data Seed

Some data feeds might not have data on its first fetch, making the algorithm prone to error. The following algorithm seeds the initial price of each asset to its last known price to avoid issues.

```
# Seed with the last known price of assets to prevent $0 security price errors.
def initialize(self):
    self.settings.seed_initial_prices = True
```

Example 2: Enable Extended Market Hours

Some traders use pre-market data for filtering assets. The following algorithm enables extended market hour data for assets in the universe.

```
# Add a universe of assets with extended market hours data.
def initialize(self):
    self.universe_settings.extended_market_hours = True
```

Example 3: Train Models When the Warm Up Finishes

The following algorithm uses the `on_warmup_finished` event handler to train a model with data from the warm-up period.

```
# Train machine learning models after the algorithm warm up is done, so your models
# are ready as soon as the algorithm starts trading.
def on_warmup_finished(self) -> None:
    self.train(self.my_training_method)
```

Securities

Securities

Key Concepts

Introduction

A security is an individual financial asset that you can trade on an exchange. LEAN models these unique assets with a `Security` object, which the `add_equity` , `add_crypto` , and similar methods return. The `securities` property of the `QCAlgorithm` class is a dictionary where the keys are `Symbol` objects and the values are `Security` objects. The `securities` dictionary contains all of the securities that have been in the algorithm during its lifetime.

```
PY
# Add the SPY.
self._symbol = self.add_equity("SPY").symbol
```

Price

To get the current price of a security, index the `securities` dictionary and then access the `price` member.

```
PY
# Get the price of the security.
price = self.securities[self._symbol].price
```

Holdings

The `Holdings` property of a `Security` object contains information about the investment state and history of the security.

```
PY
# Use the holdings object to get information on the asset position, such as the quantity and average price.
holdings = self.securities[self._symbol].holdings
quantity = holdings.quantity
```

Alternatively, you can get the current holdings of a security with the `portfolio` dictionary.

```
PY
# Get the quantity of a security you hold through the portfolio dictionary.
holdings = self.portfolio[self._symbol]
quantity = holdings.quantity
```

Reality Models

`Security` objects contain references to the security level reality models . To customize the behavior of each security, configure its reality models.

Tradable Status

The `is_tradable` property shows whether you can trade a security. The property value is true when the security is in the universe, even if the data starts at a later day. Indices, canonical Option securities, and continuous Futures contracts are not tradable. In live mode, custom data objects are also not tradable, even if the custom data represents a tradable asset.

```
PY
# Check if the security is tradable.
tradable = self.securities[self._symbol].is_tradable
```

Symbol Properties

The `symbol_properties` property of a `Security` contains properties for that specific security, such as the lot size and the minimum price variation.

```
# Round orders to a brokerage's lot size and minimum price variation using the symbol_properties.
symbol_properties = self.securities[self._symbol].symbol_properties
lot_size = symbol_properties.lot_size
minimum_price_variation = symbol_properties.minimum_price_variation
```

Market Hours

The `exchange` property of a `Security` contains information about the exchange that lists the security. For example, the `exchange.hours` property contains information on the trading days and hours .

```
# Using the exchange object, check if the exchange's regular trading hours are open at the given time.
exchange = self.securities[self._symbol].exchange
hours = exchange.hours
is_open_now = hours.is_open(self.time, extended_market_hours=False)
```

Custom Security Properties

You can add attributes to the `Security` object. For example, you can add an exponential moving average .

```
# Add an EMA indicator to the SPY Equity object.
equity = self.add_equity("SPY")
equity.ema = self.ema(equity.symbol, 10, Resolution.DAILY)
```

This feature is helpful because you can get the `Security` object from the `securities` object.

```
# Get the SPY Equity object from the securities object to get the EMA indicator.
ema = self.securities["SPY"].ema.current.value
```

Properties

The `Security` type has the following properties:

Examples

The following examples demonstrate some common practices for securities.

Example 1: Accessing Properties

The following example shows how to access various propeties of the `Security` object.

```
class SecuritiesUsageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        self.spy = self.add_equity("SPY")

    def on_data(self, slice: Slice) -> None:
        # OHLCV data.
        price = self.spy.close
        volume = self.spy.volume
        # Quote data.
        quote_size = self.spy.bid_size
        quote_price = self.spy.ask_price
        # Symbol Properties.
        lot_size = self.spy.symbol_properties.lot_size
        # Fundamentals cached data.
        pe_ratio = self.spy.fundamentals.valuation_ratios.pe_ratio
        # Properties, e.g. is tradeble, is market open, leverage, ...
        market_open = Extensions.is_market_open(self.spy, extended_market_hours=False)
        leverage = self.spy.leverage
        # Models, e.g. margin model, buying power model, ...
        margin_model = self.spy.margin_model
        # Portfolio Holdings reference.
        holding = self.spy.holdings
```

Securities

Requesting Data

Introduction

When you add a security to your algorithm, your algorithm creates a data subscription and receives data updates for that security or custom data source .

Add Assets

To create an Equity subscription, call the `add_equity` method and pass the `ticker` argument. The `ticker` argument represents the current ticker.

```py
# Add the SPY ETF.
equity = self.add_equity("SPY")
```

The `add_equity` method creates a subscription for a single Equity asset and adds it to your user-defined universe.

For more information about adding assets, see Asset Classes .

Add Universes

Universe selection is the process of selecting a basket of assets you may trade. When you add a universe to your algorithm, LEAN sends a large dataset into a filter function you define. LEAN automatically subscribes to these new assets and adds them to your algorithm.

```py
# Use the _fundamental_filter_function to add the 100 most liquid stocks to the universe.
class MyFundamentalUniverseAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.universe_settings.asynchronous = True
        self.add_universe(self._fundamental_filter_function)

    # Get the top 100 stocks by dollar volume.
    def _fundamental_filter_function(self, fundamental: List[Fundamental]) -> List[Symbol]:
        sorted_by_dollar_volume = sorted(fundamental, key=lambda x: x.dollar_volume, reverse=True)
        return [c.symbol for c in sorted_by_dollar_volume[:100]]
```

For more information about universes, see Universes .

Resolutions

Resolution is the duration of time that's used to sample a data source. Market data is sampled and saved in disk with five resolutions. The `Resolution` enumeration has the following members:

- `Resolution.TICK`
- `Resolution.SECOND`
- `Resolution.MINUTE`
- `Resolution.HOUR`
- `Resolution.DAILY`

For more information about the resolutions of each asset class, follow these steps:

1. Open the Asset Classes documentation.
2. Click an asset class.
3. Click Requesting Data .
4. Scroll down to the Resolutions section.

You can subscribe to daily resolution for an asset for updating indicator and subscribe to another asset for denser resolution for trading using the indicator.

```
def initialize(self):
    self.add_equity("VIX", Resolution.DAILY)
    self.add_equity("SPY", Resolution.MINUTE)
```

To get data with multiple or customizable resolutions for an asset, use consolidators .

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

For more information about how to enable and disable fill forward for each asset class, follow these steps:

1. Open the Asset Classes documentation.
2. Click an asset class.
3. Click Requesting Data .
4. Scroll down to the Fill Forward section.

Example: Disable Fill Forward Data

For some illiquid securities or alternative data, using forward filled data might not be an accurate estimation nor usable information. To avoid this, disable fill forward.

```
def initialize(self):
    self.add_data(BrainSentiment7Days, symbol, fill_forward=False)
```

Security Changed Events

When you add and remove assets, LEAN notifies your algorithm through the `on_securities_changed` event handler. The event handler receives a `SecurityChanges` object, which contains references to the added and removed securities. To access the added securities, iterate the `changes.added_securities` property. To get the removed securities, iterate the `changes.removed_securities` property.

```
# Use on_securities_changed to know when an asset is added or removed.
def on_securities_changed(self, changes: SecurityChanges) -> None:
    # Iterate through the added assets.
    for security in changes.added_securities:
        self.debug(f"{self.time}: Added {security.symbol}")

    # Iterate through the removed assets.
    for security in changes.removed_securities:
        self.debug(f"{self.time}: Removed {security.symbol}")

        if security.invested:
            self.liquidate(security.symbol, "Removed from Universe")
```

The preceding example liquidates securities that leave the universe. You can use this event to create indicators when a new security enters the universe.

Remove Subscriptions

To remove a security subscription, call the `remove_security` method.

```
# Remove the security subscription.
self.remove_security(self._symbol)
```

The `remove_security` method cancels your open orders for the security and liquidates your holdings.

Examples

The following examples demonstrate some common practices on the subject of requesting data.

Example 1: Add Linked Alternative Data for Universe Constituents

Many traders select universe constituents and then allocate positions with two independent sets of logic. Position sizing usually requires additional information, like alternative data factors. To manage alternative data subscriptions for all the universe constituents, subscribe and unsubscribe from the data in the `on_securities_changed` method. The following example demonstrates adds the KavoutCompositeFactorBundle when assets enter the universe.

```py
class RequestSecuritiesDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Add a universe of the 25 most liquid US Equities.
        self.add_universe(self.universe.top(25))

    def on_data(self, slice: Slice) -> None:
        # Invest by the updated Kavout Factor data.
        factor_data = slice.get(KavoutCompositeFactorBundle)
        if factor_data:
            sorted_by_factor_score = sorted(
                factor_data.items(),
                key=lambda x: x[1].growth + x[1].value_factor + x[1].quality + x[1].momentum + x[1].low_volatility,
                reverse=True
            )
            sorted_by_factor_score = [x for x in sorted_by_factor_score if self.securities[x[0].underlying].price][:10]
            top_factor_targets = [PortfolioTarget(x[0].underlying, 0.1) for x in sorted_by_factor_score]
            self.set_holdings(top_factor_targets, True)

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        # Iterate securities that entered the universe.
        for security in changes.added_securities:
            # Subscribe to the factor data for the new security.
            # Save the alternative data symbol in the security object.
            security.alt_data_symbol = self.add_data(KavoutCompositeFactorBundle, security.symbol, Resolution.DAILY).symbol

        # Iterate securities that left the universe.
        for security in changes.removed_securities:
            # Unsubscribe from the altnerative data updates.
            self.remove_security(security.alt_data_symbol)
```

Example 2: Add Linked Custom Data

QuantConnect Cloud has a lot of data, but not everything. To import some external data into your algorithm, define a custom data source . The following algorithm loads Bitstamp's BTCUSD trading activity from a CSV file and plots it:

PY

```
# Define the algorithm.
class LinkedCustomDataExampleAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add Bitcoin and the custom dataset.
        btc = self.add_crypto('BTCUSD')
        btc.data_symbol = self.add_data(Bitstamp, btc.symbol.value, Resolution.DAILY).symbol
        # Plot the price from the custom dataset.
        self.plot_indicator('BTC Price', self.identity(btc.data_symbol))

# Define the custom data source.
class Bitstamp(PythonData):
    # Define the get_source method to load the data from its location.
    def get_source(self, config, date, is_live_mode):
        source = "https://raw.githubusercontent.com/QuantConnect/Documentation/master/Resources/datasets/custom-data/bitstampusd.csv"
        # REMOTE_FILE in the next line means the data file in online storage.
        return SubscriptionDataSource(source, SubscriptionTransportMedium.REMOTE_FILE)

    # Define the reader method to parse the CSV rows.
    def reader(self, config, line, date, is_live_mode):
        # Ignore empty rows.
        if not line.strip():
            return None

        # Instantiate a new data object.
        coin = Bitstamp()
        coin.symbol = config.symbol

        # Ignore non-numeric lines.
        if not line[0].isdigit():
            return None

        # Split the CSV row by its commas.
        data = line.split(',')

        # Ignore invalid data.
        coin.value = float(data[4])
        if coin.value == 0:
            return None

        # Parse the row.
        coin.time = datetime.strptime(data[0], "%Y-%m-%d")
        coin.end_time = coin.time + timedelta(1)
        coin["Open"] = float(data[1])
        coin["High"] = float(data[2])
        coin["Low"] = float(data[3])
        coin["Close"] = coin.value
        coin["VolumeBTC"] = float(data[5])
        coin["VolumeUSD"] = float(data[6])
        coin["WeightedPrice"] = float(data[7])
        return coin
```

Securities

Handling Data

Introduction

If you create a data subscription, your algorithm receives data updates for that security or custom data source .

Get Prices

LEAN uses data updates to set the current prices of a security and compute the contribution of securities you hold to the portfolio value. To get the current prices of a security, find the `Security` object in the `securities` dictionary and access the price attributes.

```
PY
# Use the securities object as a dictionary to get the current ask and bid price of the SPY.
security = self.securities["SPY"]
price = security.price
bid_price = security.bid_price
ask_price = security.ask_price
```

Data Events

The `Slice` that LEAN passes to the `on_data` method represents all of the data for your subscriptions at a single point in time. The `Slice` object contains data like `Tick` objects, `TradeBar` objects, `QuoteBar` objects, corporate actions , and chains for Option and Future contracts. You can use the data in the `Slice` to make trading decisions.

To access data in the `Slice` , index it with the security `Symbol` . If you use the security ticker instead of the `Symbol` , LEAN automatically finds the `Symbol` .

```
PY
# Use the OnData method to get the data for a symbol in the current time slice.
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self._symbol):
        my_data = slice[self._symbol]
```

The following table shows the `Slice` property to index based on the data format you want:

Data Format	Slice Property
`TradeBar`	`bars`
`QuoteBar`	`quote_bars`
`Tick`	`ticks`

```
PY
# Get the tradebar from the slice.
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self._symbol):
        bar = slice.bars[self._symbol]
```

If you just index the `Slice` instead of the preceding properties, it returns the correct object. For instance, if your data subscription provides `QuoteBar` objects and you index the `Slice` with the security `Symbol` , it returns the `QuoteBar` .

For more information about the `Slice` class, see Timeslices .

Cache

To get the most recent data for a security, call the `get_last_data` method on the `Security` object.

```
# Get the most recent data for a security.
data = self.securities["SPY"].get_last_data()
```

The `cache` property of a `Security` object provides additional price information since you can access `TradeBar` , `QuoteBar` , and `Tick` data.

```
# Get additional price information for the security.
cache = self.securities["SPY"].cache
trade_bar = cache.get_data[TradeBar]()
quote_bar = cache.get_data[QuoteBar]()
ticks = cache.get_all[Tick]()
```

Market Session

The `Session` property of a `Security` object contains the open, high, low, close, volume, and open interest of trading sessions. The `Session` object is a `RollingWindow` object with size of zero by default. To enable market session tracking, set the size of the `Session` object to 2, so the previous session data is at index 1.

```
session = self.securities[self._symbol].session
session.size = 2
today_open = session.open
today_high = session.high
today_low = session.low
today_cumulative_volume = session.volume
if session.is_ready:
    yesterday_close = session[1].close
```

Increase the size of the `Session` object to store more session data. You can use cached data in the `Session` property instead of requesting historical daily data .

```
equity = self.add_equity("SPY")
# Increase the session lookback to 252 from default (0)
equity.session.size = 252
# Get all closing prices in the session history
closes = [x.close for x in session][::-1]
```

For more information about rolling windows, see Rolling Window .

Examples

The following examples demonstrate some common practices for handling data.

Example 1: Get QuoteBar Data

The following algorithm updates an indicator with the mid-price of a quote bar to increase the accuracy of the indicator values for illiquid assets. Then, make use of the SMA indicator to trade the SMA cross strategy.

```py
class HandlingSecuritiesDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        self._symbol = self.add_equity("SPY").symbol
        self._indicator = SimpleMovingAverage(250)

        self.set_warm_up(timedelta(350))

    def on_data(self, slice: Slice) -> None:
        # Check if the QuoteBars contain SPY quote data.
        if self._symbol not in slice.quote_bars:
            return
        quote_bar = slice.quote_bars[self._symbol]
        # Calculate the mid price by averaging the bid and ask price.
        mid_price = (quote_bar.bid.close + quote_bar.ask.close) * 0.5
        # Update the SMA indicator with the mid price.
        self._indicator.update(quote_bar.end_time, mid_price)

        # Wait for the algorithm and indicator to be warmed up.
        if self.is_warming_up or not self._indicator.is_ready:
            return
        # Trade SMA cross strategy.
        weight = -0.5 if self._indicator.current.value > mid_price else 0.5
        self.set_holdings(self._symbol, weight)
```

Example 2: Get Tick Data

The following algorithm calculates the bid and ask sizes of the latest SPY quote ticks and then trades at the top of each hour. During each rebalance, it buys SPY if bid size is greater than ask size since supply is greater than demand in this case. If bid size is smaller than ask size, it sells SPY since demand is greater than supply in this case.

```py
class BidAskSizeTickAlgorithm(QCAlgorithm):
    # Set up variables to save the bid and ask sizes.
    _bid_size = 0
    _ask_size = 0
    _hour = -1

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 10)
        # Seed the price of each asset with its last known price to
        # avoid trading errors.
        self.settings.seed_initial_prices = True
        self._symbol = self.add_equity('SPY', Resolution.TICK).symbol

    def on_data(self, slice: Slice) -> None:
        # Check if the Slice contain SPY tick data.
        ticks = slice.ticks.get(self._symbol)
        if ticks:
            # Iterate all the ticks to calculate the bid and ask sizes.
            for tick in ticks:
                # Make sure the tick data is a quote instead of a trade.
                if tick.tick_type == TickType.QUOTE:
                    # Update the bid and ask sizes.
                    self._bid_size += tick.bid_size
                    self._ask_size += tick.ask_size
        # Trade at the top of each hour.
        if slice.time.hour != self._hour:
            # Invest based on supply-demand relationship from all ticks.
            # If bid size is above ask size, supply is greater than
            # demand, which drives the price up. Otherwise, supply is
            # lower than demand, which drives the price down.
            self.set_holdings(
                self._symbol, 0.5 if self._bid_size > self._ask_size else -0.5
            )
            # Reset the bid and ask size variables.
            self._bid_size = 0
            self._ask_size = 0
            self._hour = slice.time.hour
```

Example 3: Get US Equity Fundamental Data

The following algorithm gets the latest fundamental data of all the US Equities in the algorithm. We invest in the stocks with the highest PE Ratio equally to ride on the popularity.

```
class HandlingSecuritiesDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Request data for a selected list of equities for trading.
        for ticker in ["AAPL", "MSFT", "TSLA", "GOOG", "AMZN"]:
            self.add_equity(ticker)

    def on_data(self, slice: Slice) -> None:
        pe_ratios = {}

        # Iterate active security objects.
        for kvp in self.active_securities:
            symbol = kvp.key
            security = kvp.value

            # Get the Fundamental cache.
            fundamental = security.fundamentals
            # Get the sector code.
            sector_code = fundamental.asset_classification.morningstar_sector_code

            pe_ratios[symbol] = fundamental.valuation_ratios.pe_ratio

        # Sort by PE ratio to get the most popular stocks.
        sorted_by_pe_ratio = sorted(pe_ratios.items(), key=lambda x: x[1])
        targets = [PortfolioTarget(x[0], 1/3) for x in sorted_by_pe_ratio[-3:]]
        targets.extend([PortfolioTarget(x[0], 0) for x in sorted_by_pe_ratio[:2]])
        # Invest equally in the highest PE Ratio stocks for evenly dissipate capital risk.
        self.set_holdings(targets)
```

Example 4: Get Option Greeks

The following algorithm gets SPY Option Greek values. Sell a straddle with the ATM options, selected by Option Delta (closest to 0.5).

```
class HandlingSecuritiesDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Add an SPY Option universe.
        option = self.add_option("SPY")
        # Set the Option universe filter.
        option.set_filter(lambda x: x.strikes(-5, 5).expiration(0, 60))
        # Save a reference of the canonical symbol.
        self._symbol = option.symbol

    def on_data(self, slice: Slice) -> None:
        # Try to get the Option contracts within the Option chain.
        chain = slice.option_chains.get(self._symbol)
        if not self.portfolio.invested and chain:
            for contract in chain:
                # Get the implied volatility and greeks of each Option contract.
                iv = contract.implied_volatility
                greeks = contract.greeks
                delta = greeks.delta
                gamma = greeks.gamma
                vega = greeks.vega
                theta = greeks.theta
                rho = greeks.rho

            # Invest in a straddle strategy to capitalize the volatility
            # Trade the ATM options with the closest expiry after 7 days.
            expiry = min(x.expiry for x in chain)
            selected = sorted([x for x in chain if x.expiry == expiry],
                key=lambda x: abs(x.greeks.delta - 0.5))[0]
            option_strategy = OptionStrategies.straddle(selected.symbol.canonical, selected.strike, selected.expiry)
            self.sell(option_strategy, 1)
```

Example 5: Get Asset Sentiment Values

The following example gets sentiment values from the Brain Sentiment Indicator dataset. It simply buys AAPL when the sentiment is positive and liquidates the position when the sentiment is negative.

```py
class HandlingSecuritiesDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Seed the price of AAPL with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Add the 7-day sentiment data for AAPL.
        self._symbol = self.add_equity("AAPL", Resolution.DAILY).symbol
        self._dataset_7day_symbol = self.add_data(BrainSentimentIndicator7Day, self._symbol).symbol

    def on_data(self, slice: Slice) -> None:
        # Check if the current slice contains the 7-day sentiment data.
        if slice.contains_key(self._dataset_7day_symbol):
            data_point = slice[self._dataset_7day_symbol]
            # Log the sentiment value.
            self.log(f"{self._dataset_7day_symbol} sentiment at {slice.time}: {data_point.sentiment}")

            # Invest if the sentiment score is above 0, which indicates positive sentiment.
            if data_point.sentiment > 0:
                self.market_order(self._symbol, 1)
            # Liquidate otherwise.
            elif data_point.sentiment < 0 and self.portfolio[self._symbol].invested:
                self.liquidate(self._symbol)
```

Example 6: Market Session as History

Using `Session` instead of history requests or rolling window to cache the last 252 OHLCV bars, the following algorithm buys SPY accordingly when the market opens above the 252-day max of closing prices.

```py
class MarketSessionAsDailyHistory(QCAlgorithm):
    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        equity = self.add_equity("SPY")

        # Increase the session lookback to 252 from default (0)
        # since our strategy break out the 252-day max of closing prices
        equity.session.size = 252
        # Warm up with daily data for speed
        self.set_warm_up(equity.session.size, Resolution.DAILY)

        self.schedule.on(self.date_rules.every_day("SPY"), self.time_rules.after_market_open("SPY", 1), self.trade_break_out)

    def trade_break_out(self):
        '''Break-out strategy. If the market opens above the 252-day max of closing prices,
        allocate all in SPY. Liquidate if it opens below the mean.
        '''
        session = self.securities["SPY"].session
        # The session is ready when the number of samples is greater than the size (252)
        if self.is_warming_up or not session.is_ready:
            return

        # Create a pandas Series of the closing prices of session
        # to use the max and mean methods
        closes = pd.Series([x.close for x in session][::-1])
        _open, _max, _mean = session.open, closes.max(), closes.mean()

        # Invest all in SPY if the open break out the 252-day max and liquidate below the mean
        if _open > _max:
            self.set_holdings("SPY", 1, tag=f'{_open=:.2f}, {_max=:.2f}')
        if _open < _mean:
            self.liquidate("SPY", tag=f'{_open=:.2f}, {_mean=:.2f}')
```

Securities

Market Hours

Introduction

The `exchange` property of a `Security` object contains information about the exchange that lists the security, including its time zone and the trading days and hours. To get the exchange market hours, use the `exchange.hours` property on a `Security` object.

```
# Get properties of the exchange that lists the security.
security_exchange_hours = self.securities["SPY"].exchange.hours
```

Market Status

To check if the exchange is open at a specific time, call the `is_open` method.

```
# Check if the exchange is currently open.
is_open_now = security_exchange_hours.is_open(self.time, extended_market_hours=False)

# Check if the exchange is open at any point in time over a specific interval.
is_open = security_exchange_hours.is_open(self.time, self.time + timedelta(days=1), extended_market_hours=False)
```

To check if the exchange is open on a specific date, call the `is_date_open` method.

```
# Check if the exchange is open at some time today.
is_open = security_exchange_hours.is_date_open(self.time, extended_market_hours=True)
```

To get the next market open time, call the `get_next_market_open` method.

```
# Get the next market open time.
market_open_time = security_exchange_hours.get_next_market_open(self.time, extended_market_hours=False)
```

To get the next market close time, call the `get_next_market_close` method.

```
# Get the next market close time.
market_close_time = security_exchange_hours.get_next_market_close(self.time, extended_market_hours=False)
```

To get the previous trading day, call the `get_previous_trading_day` method.

```
# Get the previous trading day.
day = security_exchange_hours.get_previous_trading_day(self.time)
```

To get the next trading day, call the `get_next_trading_day` method.

```
# Get the next trading day.
day = security_exchange_hours.get_next_trading_day(self.time)
```

Extended Market Hours

By default, your security subscriptions only cover regular trading hours. To subscribe to pre and post-market trading hours for a specific asset, enable the `extended_market_hours` argument when you create the security subscription.

```
self.add_equity("SPY", extended_market_hours=True)
```

You only receive extended market hours data if you create the subscription with minute, second, or tick resolution. If you create the subscription with daily or hourly resolution, the bars only reflect the regular trading hours.

Properties

The `SecurityExchange` object has the following attributes:

Examples

The follow examples demonstrate some common practices for trading with market hours data.

Example 1: Only Within 1 Hour Of Market Open And Close

Buying SPY shortly after market holidays or weekend breaks can be a profitable strategy. Historically, the market has tended to experience positive returns in the trading sessions immediately following extended market closures. This is often attributed to the release of pent-up demand and information during the downtime. By positioning into SPY at the open or within the first few trading hours after a holiday or weekend, investors may be able to capture this post-break bounce in the broader market.

```
class MarketHourExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.spy = self.add_equity("SPY", Resolution.HOUR)

    def on_data(self, slice: Slice) -> None:
        # Check if the previous day is holiday
        previous_day = self.time.replace(hour=0, minute=0) - timedelta(1)
        if previous_day in self.spy.exchange.hours.holidays:
            # Buy if it is a holiday a day before
            self.set_holdings(self.spy.symbol, 1)
        elif self.portfolio[self.spy.symbol].invested:
            # Liquidate otherwise if any open position
            self.liquidate(self.spy.symbol)
```

Example 2: Pre-market Short Limit Order

A pre-market short limit order is a type of order placed before the regular trading session begins. It allows a trader to take a short position at a price higher than the current market price, with the intention of selling the position shortly after the market opens and profiting from the expected price decline. This strategy is often used by traders who anticipate a decline in the asset's value and want to capitalize on it.

```
class MarketHourExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add SPY data with extended market hours.
        self._spy = self.add_equity("SPY", extended_market_hours=True)

    def on_data(self, slice: Slice) -> None:
        if self._spy.symbol not in slice.quote_bars:
            return
        # During pre-market hours, place an unmarketable limit order.
        if (not self._spy.invested and
            self._is_before_market_open_extended_hours(slice.time) and
            not list(self.transactions.get_open_order_tickets(self._spy.symbol))):
            self.limit_order(self._spy.symbol, -10, self._spy.bid_price * 1.005)
        # If we hold a position during regular trading hours, liquidate
        # it.
        elif (self._spy.invested and
            self._spy.exchange.hours.is_open(slice.time, False)):
            self.liquidate(self._spy.symbol)

    def _is_before_market_open_extended_hours(self, time: datetime) -> bool:
        return (
            # It's currently extended market hours.
            self._spy.exchange.hours.is_open(time, True) and
            # The next market open for regular trading hours is today.
            self._spy.exchange.hours.get_next_market_open(
                time, False
            ).day == time.day
        )
```

However, it is important to note that pre-market trading can be more volatile and riskier than regular trading, and the intended price may not be achieved on this strategy.

Example 3: Last Hour Trades

Establishing a scheduled trading event in the hour before market close can be an effective strategy. This allows the trader to analyze market conditions, identify potential trade opportunities, and prepare orders ahead of the close. By emitting their trading insights and planned actions to the market in this critical final hour, the trader can influence other market participants and potentially gain an edge.

```PY
class MarketHourExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.spy = self.add_equity("SPY")

        # Set up a portfolio construction model to handle insights for trading
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel(Expiry.END_OF_DAY))

        # Set up a scheduled event on 1-hour before market close to open position
        self.schedule.on(
            self.date_rules.every_day(self.spy.symbol),
            self.time_rules.before_market_close(self.spy.symbol, 60),
            self.last_hour_trade
        )

    def last_hour_trade(self) -> None:
        # Get the time of next market close
        market_close_time = self.spy.exchange.hours.get_next_market_close(self.time, extended_market_hours=False)
        # Emit an insight that expires 1 minutye before the next market close
        self.emit_insights(Insight.price(self.spy.symbol, market_close_time - timedelta(minutes=1), InsightDirection.UP))
```

Securities

Filtering Data

Introduction

Unfiltered raw data can be faulty for a number of reasons, including invalid data entry. Moreover, high-frequency traders can deploy bait-and-switch strategies by submitting bait orders to deceive other market participants, making raw data noisy and untradeable. To avoid messing up with our trading logic and model training, you can filter out suspicious raw data with a data filter.

Set Models

To set a data filter for a security, call the `set_data_filter` property on the `Security` object.

```
PY
# Use the set_data_filter method to use the SecurityDataFilter on the SPY ETF data.
spy = self.add_equity("SPY")
spy.set_data_filter(SecurityDataFilter())
```

You can also set the data filter model in a security initializer . If your algorithm has a universe, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `add_security_initializer` before you create the subscriptions.

```
PY
class AddSecurityInitializerExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the security initializer to set models of assets.
        self.add_security_initializer(self._custom_security_initializer)

    def _custom_security_initializer(self, security: Security) -> None:
        # Overwrite some of the reality models
        security.set_data_filter(SecurityDataFilter())
```

Default Behavior

The following table shows the default data filter for each security type:

Security Type	Default Filter
`Equity`	EquityDataFilter
`Option`	OptionDataFilter
`Forex`	ForexDataFilter
`Index`	IndexDataFilter
`Cfd`	CfdDataFilter
Others	SecurityDataFilter

None of the preceding filters filter out any data.

Model Structure

Data filtering models must implement a `filter` method, which receives `Security` and `BaseData` objects and then returns a `boolean` object that represents if the data point should be filtered out.

```
PY
# Include or exclude a data point from the algorithm.
class MyDataFilter(SecurityDataFilter):
    def filter(self, vehicle: Security, data: BaseData) -> bool:
        return True
```

Examples

The following examples demonstrate some common practices for filtering data.

Example 1: Filter Out Outliers

When analyzing high-frequency price data, it's important to filter out potential outliers and anomalies that may skew the analysis. One effective method is to use simple moving average (SMA) and standard deviation indicators to identify ticks that significantly deviate from the short-term trend. By comparing each tick to the indicator values, you can flag any data points that fall outside a threshold (for example, three standard deviations). This filtration process removes suspicious or erroneous price information from entering your algorithm, ensuring a cleaner dataset for trading.

```
PY
class CustomDataFilterAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 3)
        equity = self.add_equity("AAPL", Resolution.TICK)
        # Create the indicators.
        equity.sma = self.sma(equity.symbol, 100)
        equity.std = IndicatorExtensions.of(StandardDeviation(100), equity.sma, True)
        # Set the data filter.
        equity.set_data_filter(CustomDataFilter())

class CustomDataFilter(SecurityDataFilter):

    def filter(self, vehicle: Security, data: BaseData) -> bool:
        # Wait until the indicators are ready.
        security = vehicle
        if not (security.sma.is_ready and security.std.is_ready):
            return True # Keep the data point.
        # Check if the current value is within 3 standard deviations of the mean.
        # Return True (keep) or False (discard).
        sma = security.sma.current.value
        std = security.std.current.value
        return sma - 3*std <= data.value <= sma + 3*std
```

Example 2: Filter Out Major Exchanges

When you trade illiquid financial instruments, it can be advantageous to focus on the BATS exchange since its quote data may not fully reflect the fair market value. Due to the lower trading volume and visibility of BATS, the quotes there may lag behind the true value of illiquid assets. A carefully designed algorithm can analyze the BATS feed to identify situations where the quotes appears to be undervalued compared to the asset's intrinsic worth. By executing trades to capture this disconnect, rather than arbitraging between exchanges, you may be able to profit from the market inefficiencies present in the less liquid instrument. The following example demonstrates how to only consume data from the BATS exchange:

```
PY
class BatsDataFilterAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 3)
        equity = self.add_equity("AAPL", Resolution.TICK)
        # Set the data filter.
        equity.set_data_filter(BatsDataFilter())

class BatsDataFilter(SecurityDataFilter):

    def filter(self, vehicle: Security, data: BaseData) -> bool:
        # Get the tick object.
        tick = Tick(data)
        # Return True (keep) or False (discard).
        return tick and tick.exchange == Exchange.BATS.name
```

US Equity

Requesting Data

Introduction

Request US Equity data in your algorithm to receive a feed of asset prices in the `on_data` method.

Every stock traded in the US Securities Information Processors (SIP) CTA/UTP feed is available. Over-the-Counter (OTC) trades are not included. For more information about the specific dataset we use for backtests, see the US Equities dataset listing .

To trade US Equities live, you can use the QuantConnect data provider or one of the brokerage data providers .

Create Subscriptions

To create an Equity subscription, in the `initialize` method, call the `add_equity` method. The `add_equity` method returns an `Equity` object, which contains a `symbol` property. Save a reference to the `symbol` so you can use it in `on_data` to access the security data in the `Slice` .

```
PY
self._symbol = self.add_equity("SPY").symbol
```

The `add_equity` method creates a subscription for a single Equity asset and adds it to your user-defined universe. To create a dynamic universe of Equities, add an Equity universe or an Equity Universe Selection model .

To view the supported assets in the US Equities dataset, see the Data Explorer . It doesn't include Over-the-Counter (OTC) stocks.

Resolutions

The following table shows the available resolutions and data formats for Equity subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`TICK`			✓	✓
`SECOND`	✓	✓		
`MINUTE`	✓	✓		
`HOUR`	✓			
`DAILY`	✓			

The default resolution for Equity subscriptions is `Resolution.MINUTE` . To change the resolution, pass a `resolution` argument to the `add_equity` method.

```
PY
self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
```

To create custom resolution periods, see Consolidating Data .

Asset Primary Exchange

When a stock like Apple is listed, it's listed on Nasdaq. The open auction tick on Nasdaq is the price that's used as the official open of the day. NYSE, BATS, and other exchanges also have opening auctions, but the only official opening price for Apple is the opening auction on the exchange where it was listed.

Supported Markets

LEAN groups all of the US Equity exchanges under `Market.USA` . In live mode, the brokerage routes the orders to the exchange that provides the best price.

To set the market for a security, pass a `market` argument to the `add_equity` method.

```
self._symbol = self.add_equity("SPY", market=Market.USA).symbol
```

The brokerage models have a default market for each asset class. If you set a brokerage model, you may not need to specify the market to use.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fill_forward` argument to false when you create the security subscription.

```
self.add_equity("SPY", fill_forward=False)
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. In backtests, the default leverage for margin accounts is 2x leverage and leverage is not available for cash accounts. To change the amount of leverage you can use for a security, pass a `leverage` argument to the `add_equity` method.

```
self._symbol = self.add_equity("SPY", leverage=3).symbol
```

In live trading, the brokerage determines how much leverage you may use. For more information about the leverage they provide, see Brokerages .

Extended Market Hours

By default, your security subscriptions only cover regular trading hours. To subscribe to pre and post-market trading hours for a specific asset, enable the `extended_market_hours` argument when you create the security subscription.

```
self.add_equity("SPY", extended_market_hours=True)
```

You only receive extended market hours data if you create the subscription with minute, second, or tick resolution. If you create the subscription with daily or hourly resolution, the bars only reflect the regular trading hours.

To view the schedule of regular and extended market hours, see Market Hours .

Data Normalization

The data normalization mode defines how historical data is adjusted for corporate actions . The data normalization mode affects the data that LEAN passes to `on_data` and the data from history requests . By default, LEAN adjusts US Equity data for splits and dividends to produce a smooth price curve, but the following data normalization modes are available for Equity subscriptions:

If you use `ADJUSTED` , `SPLIT_ADJUSTED` , or `TOTAL_RETURN` , we use the entire split and dividend history to adjust historical prices. This process ensures you get the same adjusted prices, regardless of the backtest end date.

To set the data normalization mode for a security, pass a `data_normalization_mode` argument to the `add_equity` method.

```
self._symbol = self.add_equity("SPY", data_normalization_mode=DataNormalizationMode.RAW).symbol
```

The `SCALED_RAW` data normalization is only for history requests . When you use `SCALED_RAW` , we use the split and dividend history before the algorithm's current time to adjust historical prices. The `SCALED_RAW` data normalization model enables you to warm up indicators with adjusted data when you subscribe to `RAW` security data.

Properties

The `add_equity` method returns an `Equity` object, which have the following properties:

Examples

The following examples demonstrate some common practices for requesting US Equity data.

Example 1: Add Multiple Assets

The following algorithm adds multiple US Equities with extended market hours data. Extended market hours data enables you to monitor price movements during pre-market and after-hours trading sessions.

```py
class USEquityDemoAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Create a list of tickers you want to add.
        tickers = ["AAPL", "TSLA", "GOOG"]
        # Add extended market hours data for each US Equity.
        self._equities = [self.add_equity(ticker, extended_market_hours=True) for ticker in tickers]
```

Example 2: Import External Trade Signals

Say you source trading signals from outside your algorithm and organize them into a CSV file on Dropbox with the following structure:

```
#ticker,source1,source2,source3,source4,source5
AAPL,1.25,1.10,1.32,1.13,1.21
AMZN,1.15,1.05,1.07,1.11,1.03
GOOG,0.97,0.99,0.98,1.04,0.95
META,1.04,1.03,1.10,1.04,0.98
MSFT,0.92,0.96,0.98,1.01,0.98
```

The following algorithm uses a Scheduled Event to periodically pull the CSV file from Dropbox , parse its signals, and place trades. To determine the target weight for each asset, it takes the mean score from all the sources. If the mean score is greater than 1, it allocates 20% of the portfolio to the asset. Otherwise, it allocates -20% to the asset.

```py
from io import StringIO

class USEquityDemoAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        self.settings.seed_initial_prices = True

        # Add the US Equities.
        self.signal_by_ticker = {self.add_equity(ticker, Resolution.DAILY).symbol: 1
            for ticker in "AAPL,AMZN,GOOG,META,MSFT".split(',')}

        # Set up a Scheduled Event to download the data file and place orders.
        self.schedule.on(self.date_rules.month_start(), self.time_rules.midnight, self._download_data_and_place_orders)

    def _download_data_and_place_orders(self):
        # Download the file from DropBox.
        file_content = self.download("<DropBoxUrl>&dl=1")
        if file_content:
            # Convert the file content into trading signals.
            self.signal_by_ticker = pd.read_csv(StringIO(file_content), index_col=0).mean(axis=1)

        # Place orders according to the signals.
        targets = [
            PortfolioTarget(symbol, 0.2 if signal >= 1 else -0.2)
            for symbol, signal in self.signal_by_ticker.items()
        ]
        self.set_holdings(targets, True)
```

US Equity

Handling Data

Introduction

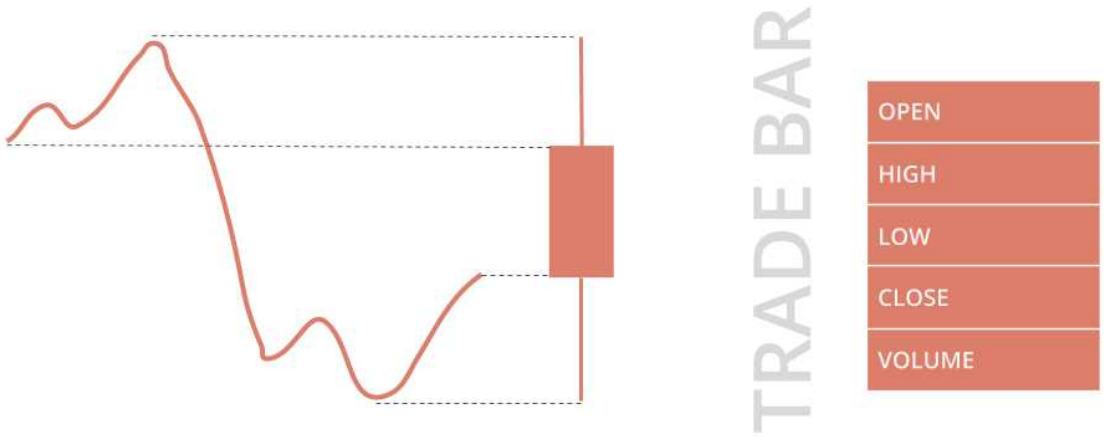
LEAN passes the data you request to the `on_data` method so you can make trading decisions. The `Slice` object that the `on_data` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `on_data` method, use the `current_slice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars` `DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the security ticker or `symbol` , but we recommend you use the `symbol` .

To view the resolutions that are available for US Equity data, see Resolutions .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `bars` property of the `Slice` with the security `symbol` . If the security doesn't actively trade or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `symbol` .

```
def on_data(self, slice: Slice) -> None:
    # Obtain the mapped TradeBar of the symbol if any
    trade_bar = slice.bars.get(self._symbol)   # None if not found
```

You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

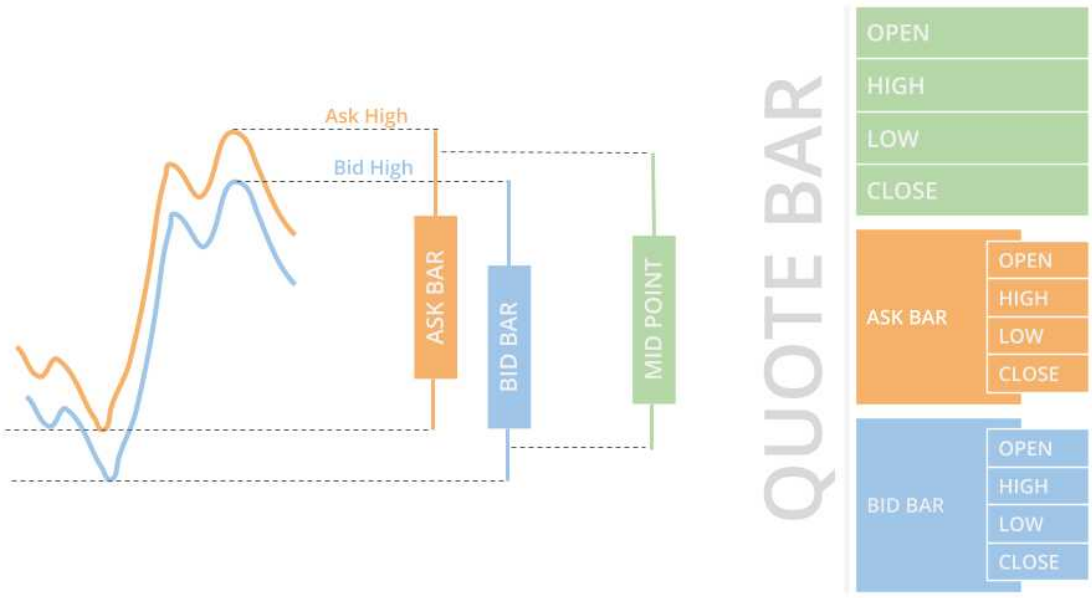
```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Symbol-TradeBar key-value pairs
    for symbol, trade_bar in slice.bars.items():
        close_price = trade_bar.close
```

`TradeBar` objects have the following properties:

We adjust the daily open and close price of bars to reflect the official auction prices .

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `open` , `high` , `low` , and `close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `open` , `high` , `low` , and `close` properties of the `QuoteBar` copy the values of either the `bid` or `ask` instead of taking their mean.



To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the security `symbol` . If the security doesn't actively get quotes or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `symbol` .

```
def on_data(self, slice: Slice) -> None:
    # Obtain the mapped QuoteBar of the symbol if any
    quote_bar = slice.quote_bars.get(self._symbol)   # None if not found
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Symbol-QuoteBar key-value pairs
    for symbol, quote_bar in slice.quote_bars.items():
        ask_price = quote_bar.ask.close
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

`QuoteBar` objects have the following properties:

Ticks

`Tick` objects represent a single trade or quote at a moment in time. A trade tick is a record of a transaction for the security. A quote tick is an offer to buy or sell the security at a specific price.

Trade ticks have a non-zero value for the `quantity` and `price` properties, but they have a zero value for the `bid_price` , `bid_size` , `ask_price` , and `ask_size` properties. Quote ticks have non-zero values for `bid_price` and `bid_size` properties or have non-zero values for `ask_price` and `ask_size` properties. To check if a tick is a trade or a quote, use the `ticktype` property.

In backtests, LEAN groups ticks into one millisecond buckets. In live trading, LEAN groups ticks into ~70-millisecond buckets. To get the `Tick` objects in the `Slice` , index the `Ticks` property of the `Slice` with a `symbol` . If the security doesn't actively trade or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for

your security before you index the `Slice` with the security `symbol` .

```
def on_data(self, slice: Slice) -> None:
    ticks = slice.ticks.get(self._symbol, [])   # Empty if not found
    for tick in ticks:
        price = tick.price
```

You can also iterate through the `Ticks` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `list[Tick]` objects.

```
def on_data(self, slice: Slice) -> None:
    for symbol, ticks in slice.ticks.items():
        for tick in ticks:
            price = tick.price
```

Tick data is raw and unfiltered, so it can contain bad ticks that skew your trade results. For example, some ticks come from dark pools, which aren't tradable. We recommend you only use tick data if you understand the risks and are able to perform your own online tick filtering.

`Tick` objects have the following properties:

If we detect a tick that may be suspicious , we set its `suspicious` flag to true.

Other Data Formats

For more information about data formats available for US Equities, see Corporate Actions .

Examples

The following examples demonstrate some common practices for handling US Equity data.

Example 1: Various Data Resolutions and Formats

The following algorithm handles three data resolutions (Daily, Minute, and Tick) and three data formats (TradeBar, QuoteBar, and Tick). The Equity subscriptions provide the ticks and daily TradeBar objects. To create the 5-minute QuoteBar objects, it consolidates the AAPL ticks.

The algorithm enters a long position in AAPL when the following conditions are met:

- The 16-day Fractal Adaptive Moving Average (FRAMA) of QQQ is increasing, which indicates the trend is up.
- The Relative Strength Index (RSI) of AAPL is above 70, which indicates AAPL has been rising from large buying pressure.

The algorithm enters a short position in AAPL when the following conditions are met:

- The 16-day FRAMA of QQQ is rising, which indicates the trend is down.
- The RSI of AAPL is above, which indicates AAPL has been declining from large selling pressure.

The algorithm liquidates the portfolio when the FRAMA changes direction.

PY

```
class USEquityExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 4)
        self.set_end_date(2024, 9, 10)
        # Add QQQ and AAPL data.
        self._qqq = self.add_equity("QQQ", Resolution.DAILY)
        self._aapl = self.add_equity("AAPL", Resolution.TICK)
        # Create the indicators.
        self._qqq.frama = self.frama(self._qqq.symbol, 16)
        self._aapl.rsi = RelativeStrengthIndex(10)
        # Create a 5-minute consolidator to aggregate AAPL tick data into quote bars.
        consolidator = TickQuoteBarConsolidator(timedelta(minutes=5))
        # Subscribe the consolidator for automatic updates.
        self.subscription_manager.add_consolidator(self._aapl.symbol, consolidator)
        # Attach an event handler handler to update the RSI indicator with the consolidated bars.
        consolidator.data_consolidated += lambda _, bar: self._aapl.rsi.update(bar.end_time, bar.close)
        # Warm up the indicators.
        self.warm_up_indicator(self._qqq.symbol, self._qqq.frama)
        for quote_bar in self.history[QuoteBar](self._aapl.symbol, 10, Resolution.MINUTE):
            self._aapl.rsi.update(quote_bar.end_time, quote_bar.close)

    def on_data(self, slice: Slice) -> None:
        # Ensure AAPL ticks are in the current slice.
        if self._aapl.symbol not in slice.ticks:
            return
        # Get the indicator values.
        frama = self._qqq.frama.current.value
        prev_frama = self._qqq.frama.previous.value
        rsi = self._aapl.rsi.current.value

        # Check if we have an AAPL position.
        if self._aapl.holdings.invested:
            # If there is divergence between our position and the Frama direction, exit the position.
            if (self._aapl.holdings.is_long and frama < prev_frama or
                self._aapl.holdings.is_short and frama > prev_frama):
                self.liquidate(self._aapl.symbol)
        # Look for a long entry.
        elif frama > prev_frama and rsi >= 70:
            self.set_holdings(self._aapl.symbol, 0.5)
        # Look for a short entry.
        elif frama < prev_frama and rsi <= 30:
            self.set_holdings(self._aapl.symbol, -0.5)
```

US Equity

Corporate Actions

Introduction

US Equity subscriptions provide notifications for splits, dividends, symbol changes, and delistings.

Splits

When a company does a stock split, the number of shares each shareholder owns increases and the price of each share decreases. When a company does a reverse stock split, the number of shares each shareholder owns decreases and the price of each share increases. A company may perform a stock split or a reverse stock split to adjust the price of their stock so that more investors trade it and the liquidity increases.

When a stock split or reverse stock split occurs for an Equity in your algorithm, LEAN sends a `Split` object to the `on_data` method. You receive `Split` objects when a split is in the near future and when it occurs. To know if the split occurs in the near future or now, check the `type` property.

If you backtest without the `RAW` data normalization mode , the splits are factored into the price and volume. If you backtest with the `RAW` data normalization mode or trade live, when a split occurs, LEAN automatically adjusts your positions based on the `split_factor` . If the post-split quantity isn't a valid lot size , LEAN credits the remaining value to your cashbook in your account currency. If you have indicators or consolidators in your algorithm, reset and warm-up them up with `SCALED_RAW` data when splits occur so that the data in your indicators and consolidators account for the price adjustments that the splits cause. For examples, see Reset Indicators or Reset Consolidators .

To get the `Split` objects, index the `splits` object with the security `symbol` . The `splits` object may not contain data for your `Symbol` . To avoid issues, check if the `splits` object contains data for your security before you index it with the security `Symbol` .

```
PY
def on_data(self, slice: Slice) -> None:
    split = slice.splits.get(self._symbol)
    if split:
        pass

def on_splits(self, splits: Splits) -> None:
    split = splits.get(self._symbol)
    if split:
        pass
```

You can also iterate through the `splits` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `Split` objects.

```
PY
def on_data(self, slice: Slice) -> None:
    for symbol, split in slice.splits.items():
        pass

def on_splits(self, splits: Splits) -> None:
    for symbol, split in splits.items():
        pass
```

To get historical splits, make a history request with the `Split` type.

```
PY
splits_df = self.history(Split, symbol, timedelta(4*365))
splits = self.history[Split](symbol, timedelta(4*365))
```

LEAN stores the data for stock splits in factor files. To view some example factor files, see the LEAN GitHub repository . In backtests, your algorithm receives `Split` objects at midnight. In live trading, your algorithm receives `Split` objects when the factor files are ready.

If you hold an Option contract for an underlying Equity when a split occurs, LEAN closes your Option contract position.

If a split event occurs before your order is filled, the unfilled portion of the order is adjusted automatically, where its quantity is multiplied by the split factor and the limit/stop/trigger price (if any) is divided by the split factor.

`Split` objects have the following properties:

Dividends

A dividend is a payment that a company gives to shareholders to distribute profits. When a dividend payment occurs for an Equity in your algorithm, LEAN sends a `Dividend` object to the `on_data` method.

If you backtest with the `ADJUSTED` or `TOTAL_RETURN` data normalization mode, the dividends are factored into the price. If you backtest with the other data normalization modes or trade live, when a dividend payment occurs, LEAN automatically adds the payment amount to your cashbook. If you have indicators or consolidators in your algorithm, reset and warm-up them up with `SCALED_RAW` data when dividend payments occur so that the data in your indicators and consolidators account for the price adjustments that the dividend causes. For examples, see Reset Indicators or Reset Consolidators .

To get the `Dividend` objects, index the `dividends` object with the security `symbol` . The `dividends` object may not contain data for your `symbol` . To avoid issues, check if the `dividends` object contains data for your security before you index it with the security `symbol` .

```
PY
def on_data(self, slice: Slice) -> None:
    dividend = slice.dividends.get(self._symbol)
    if dividend:
        pass

def on_dividends(self, dividends: Dividends) -> None:
    dividend = dividends.get(self._symbol)
    if dividend:
        pass
```

You can also iterate through the `dividends` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `Dividend` objects.

```
PY
def on_data(self, slice: Slice) -> None:
    for symbol, dividend in slice.dividends.items():
        pass

def on_dividends(self, dividends: Dividends) -> None:
    for symbol, dividend in dividends.items():
        pass
```

To get historical dividends, make a history request with the `Dividend` type.

```
PY
dividends_df = self.history(Dividend, symbol, timedelta(4*365))
dividends = self.history[Split](Dividend, timedelta(4*365))
```

For a full example, see the DividendAlgorithm in the LEAN GitHub repository.

`Dividend` objects have the following properties:

Symbol Changes

The benefit of the `Symbol` class is that it always maps to the same security, regardless of their trading ticker. When a company changes its trading ticker, LEAN sends a `SymbolChangedEvent` to the `on_data` method.

To get the `SymbolChangedEvent` objects, index the `symbol_changed_events` object with the security `symbol` . The `symbol_changed_events` object may not contain data for your `symbol` . To avoid issues, check if the `symbol_changed_events` object contains data for your security before you index it with the security `symbol` .

```
PY
def on_data(self, slice: Slice) -> None:
    symbol_changed_event = slice.symbol_changed_events.get(self._symbol)
    if symbol_changed_event:
        pass

def on_symbol_changed_events(self, symbol_changed_events: SymbolChangedEvents) -> None:
    symbol_changed_event = symbol_changed_events.get(self._symbol)
    if symbol_changed_event:
        pass
```

You can also iterate through the `symbol_changed_events` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `SymbolChangedEvent` objects.

```
def on_data(self, slice: Slice) -> None:
    for symbol, symbol_changed_event in slice.symbol_changed_events.items():
        pass

def on_symbol_changed_events(self, symbol_changed_events: SymbolChangedEvents) -> None:
    for symbol, symbol_changed_event in symbol_changed_events.items():
        pass
```

If you have an open order for a security when they change their ticker, LEAN cancels your order. To keep your order, in the `on_order_event` method, get the quantity and `Symbol` of the cancelled order and submit a new order.

```
def on_order_event(self, order_event: OrderEvent) -> None:
    if order_event.status == OrderStatus.CANCELED:
        ticket = self.transactions.get_order_ticket(order_event.order_id)
        if "symbol changed event" in ticket.tag:
            self.transactions.add_order(ticket.submit_request)
```

LEAN stores the data for ticker changes in map files. To view some example map files, see the LEAN GitHub repository .

`SymbolChangedEvent` objects have the following properties:

Delistings

When a company is delisting from an exchange, LEAN sends a `Delisting` object to the `on_data` method. You receive `Delisting` objects when a delisting is in the near future and when it occurs. To know if the delisting occurs in the near future or now, check the `Type` property.

To get the `Delisting` objects, index the `delistings` object with the security `symbol` . The `delistings` objects may not contain data for your `symbol` . To avoid issues, check if the `delistings` object contains data for your security before you index it with the security `symbol` .

```
def on_data(self, slice: Slice) -> None:
    delisting = slice.delistings.get(self._symbol)
    if delisting:
        pass

def on_delistings(self, delistings: Delistings) -> None:
    delisting = delistings.get(self._symbol)
    if delisting:
        pass
```

You can also iterate through the `delistings` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `Delisting` objects.

```
def on_data(self, slice: Slice) -> None:
    for symbol, delisting in slice.Delistings.items():
        pass

def on_delistings(self, delistings: Delistings) -> None:
    for symbol, delisting in delistings.items():
        pass
```

The delist warning occurs on the final trading day of the stock to give you time to gracefully exit out of positions before LEAN automatically liquidates them.

```
if delisting.type == DelistingType.WARNING:
    # Liquidate with MarketOnOpenOrder on delisting warning
    quantity = self.portfolio[symbol].quantity
    if quantity != 0:
        self.market_on_open_order(symbol, -quantity)
```

The `on_securities_changed` event notifies the algorithm when delisted assets are removed from the universe.

To improve iteration speed, LEAN removes delisted securities from the `securities` primary collection. To access all the securities, iterate the `securities.total` property.

```py
# Access all the securities.
for security in self.securities.total:
    pass

# Exclude delisted securities.
for security in self.securities.values():
    pass
```

For a full example, see the DelistingEventsAlgorithm in the LEAN GitHub repository.

`Delisting` objects have the following properties:

Live Trading Considerations

In backtesting, corporate actions occurs at midnight Eastern Time (ET). In live trading, the live data for corporate actions arrives at 6/7 AM ET, so that's when they occur.

Examples

The following examples demonstrate some common practices for US Equity corporate actions.

Example 1: Resetting Indicators on Split Events

The following algorithm adds raw TSLA data and uses it to update an Exponential Moving Average (EMA) indicator. When a split occurs, it resets and warms up the indicator with scaled raw data to ensure the indicator doesn't reflect price discontinuities.

```py
class USEquityCorporateActionExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add raw US Equity data.
        self._equity = self.add_equity("TSLA", Resolution.DAILY, data_normalization_mode=DataNormalizationMode.RAW)
        # Create an EMA indicator.
        self._equity.ema = self.ema(self._equity.symbol, 50)

    def on_splits(self, splits: Splits) -> None:
        # Wait until the split has occurred.
        split = splits[self._equity.symbol]
        if split.type != SplitType.SPLIT_OCCURRED:
            return
        # Reset the indicator.
        self._equity.ema.reset()
        # Warm up the indicator with scaled raw data.
        history = self.history[TradeBar](
            self._equity.symbol, self._equity.ema.warm_up_period,
            data_normalization_mode=DataNormalizationMode.SCALED_RAW
        )
        for bar in history:
            self._equity.ema.update(bar.end_time, bar.close)
```

Example 2: Reinvesting Dividend Payments

The following algorithm adds raw SPY data. It then holds the SPY and re-invests the dividend payments into additional shares.

PY

```
class USEquityCorporateActionExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add raw Equity data.
        self._spy = self.add_equity("SPY", data_normalization_mode=DataNormalizationMode.RAW)

    def on_data(self, slice: Slice) -> None:
        # Buy and hold.
        if not self._spy.holdings.invested:
            self.set_holdings(self._spy.symbol, 0.5)

    def on_dividends(self, dividends: Dividends) -> None:
        # Get the total dividend payment amount.
        total_dividend_amount = dividends[self._spy.symbol].distribution * self._spy.holdings.quantity
        # Calculate the number of shares you can buy with the dividend payment.
        quantity = np.floor(total_dividend_amount / self._spy.price)
        if quantity:
            # Place an order to re-invest the dividends.
            self.market_order(self._spy.symbol, quantity)
```

US Equity

Corporate Fundamentals

Introduction

Corporate fundamental data contains all the information on the underlying company of an Equity asset and the information in their financial statements. Since corporate data contains information not found in price and alternative data, adding corporate data to your trading strategies provides you with more information so you can make more informed trading decisions. Corporate fundamental data is available through the US Fundamental Data from Morningstar .

Direct Access

To get fundamental data for Equities in your algorithm, use the `fundamentals` property of the `Equity` objects. The fundamental data represent the company's fundamentals for the current algorithm time.

```
fundamentals = self.securities[self._symbol].fundamentals
```

To get fundamental data for Equities, regardless of whether or not you have subscribed to them in your algorithm, call the `fundamentals` method. If you pass one `Symbol` , the method returns a `Fundamental` object. If you pass a list of `Symbol` objects, the method returns a list of `Fundamental` objects. The fundamental data represents the corporate fundamentals for the current algorithm time.

```
# Single asset
ibm = Symbol.create("IBM", SecurityType.EQUITY, Market.USA)
ibm_fundamental = self.fundamentals(ibm)

# Multiple assets
nb = Symbol.create("NB", SecurityType.EQUITY, Market.USA)
fundamentals = self.fundamentals([ nb, ibm ])
```

Data Availability

Some assets don't have fundamentals (for example, ETFs) and the Morningstar dataset doesn't provide fundamentals for all US Equities. To check if fundamental data is available for an asset, use the `has_fundamental_data` property.

```
has_fundamental_data = self.securities[self._symbol].fundamentals.has_fundamental_data
```

Object References

If you save a reference to the `fundamentals` object or its properties, you can access the fundamental properties as they change over time.

```
self._fundamentals = self.securities[self._symbol].fundamentals
earning_ratios = self.fundamentals.earning_ratios
```

Universe Selection

You can access fundamental data in the selection function of your fundamental universe .

```
class MyUniverseAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.universe_settings.asynchronous = True
        self.add_universe(self._fundamental_function)

    def _fundamental_function(self, fundamental: List[Fundamental]) -> List[Symbol]:
        return [c.symbol for c in fundamental if c.has_fundamental_data]
```

Historical Data

To get historical fundamental data, call the `history` method. The return type depends on how you call the method.

```
PY
ibm = Symbol.create("IBM", SecurityType.EQUITY, Market.USA)

# DataFrame of fundamental data for a given asset
df_history = self.history(Fundamental, ibm, timedelta(30), flatten=True)

# Fundamental objects
fundamental_history = self.history[Fundamental](ibm, timedelta(30))

# Fundamentals objects for all US Equities (including delisted companies)
fundamentals_history = self.history[Fundamentals](timedelta(30))

# DataFrame of fundamental data for universe constituents
df_history = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series of fundamental data for universe constituents
series_history = self.history(self._universe, 30, Resolution.DAILY)
for (universe_symbol, time), fundamental in series_history.items():
    highest_market_cap = sorted(fundamental, key=lambda x: x.market_cap)[-5:]
```

For more information about historical fundamental data, see Equity Fundamental Data .

Data Updates

The US Fundamental dataset only provides the originally-reported figures. If there was a mistake in reporting a figure, the data value isn't fixed later. In live trading, new fundamental data is available to your algorithms at approximately 6/7 AM Eastern Time (ET) each day. The majority of the corporate data update occurs once per month, but the financial ratios update daily. If there is no new data for a period of time, the previous data is filled forward.

Properties

The US Fundamentals dataset provides Fundamental objects. To filter Fundamental objects, you can use the `MorningstarSectorCode` , `MorningstarIndustryGroupCode` , and `MorningstarIndustryCode` enumeration values.

Fundamentals Attributes

Fundamentals objects have the following attributes:

MorningstarSectorCode Enumeration

Sectors are large super categories of data. To access the sector of an Equity, use the **morningstar_sector_code** property.

```
PY
filtered = [x for x in fundamental if x.asset_classification.morningstar_sector_code == MorningstarSectorCode.TECHNOLOGY]
```

The **MorningstarSectorCode** enumeration has the following members:

MorningstarIndustryGroupCode Enumeration

Industry groups are clusters of related industries which tie together. To access the industry group of an Equity, use the **morningstar_industry_group_code** property.

```
PY
filtered = [x for x in fundamental if x.asset_classification.morningstar_industry_group_code ==
MorningstarIndustryGroupCode.APPLICATION_SOFTWARE]
```

The **MorningstarIndustryGroupCode** enumeration has the following members:

MorningstarIndustryCode Enumeration

Industries are the finest level of classification available and are the individual industries according to the Morningstar classification system. To access the industry group of an Equity, use the **morningstar_industry_code** property:

```
filtered = [x for x in fundamental if x.asset_classification.morningstar_industry_code == MorningstarIndustryCode.SOFTWARE_APPLICATION]
```

The **MorningstarIndustryCode** enumeration has the following members:

Exchange Id Values

Exchange Id is mapped to represent the exchange that lists the Equity. To access the exchange Id of an Equity, use the **primary_exchange_id** property.

```
filtered = [x for x in fundamental if x.company_reference.primary_exchange_id == "NAS"]
```

The exchanges are represented by the following string values:

String Representation	Exchange
NYS	New York Stock Exchange (NYSE)
NAS	NASDAQ
ASE	American Stock Exchange (AMEX)
TSE	Tokyo Stock Exchange
AMS	Amsterdam Internet Exchange
SGO	Santiago Stock Exchange
XMAD	Madrid Stock Exchange
ASX	Australian Securities Exchange
BVMF	B3 (stock exchange)
LON	London Stock Exchange
TKS	Istanbul Stock Exchange Settlement and Custody Bank
SHG	Shanghai Exchange
LIM	Lima Stock Exchange
FRA	Frankfurt Stock Exchange
JSE	Johannesburg Stock Exchange
MIL	Milan Stock Exchange
TAE	Tel Aviv Stock Exchange
STO	Stockholm Stock Exchange
ETR	Deutsche Boerse Xetra Core
PAR	Paris Stock Exchange
BUE	Buenos Aires Stock Exchange
KRX	Korea Exchange
SWX	SIX Swiss Exchange

PINX	Pink Sheets (OTC)
CSE	Canadian Securities Exchange
PHS	Philippine Stock Exchange
MEX	Mexican Stock Exchange
TAI	Taiwan Stock Exchange
IDX	Indonesia Stock Exchange
OSL	Oslo Stock Exchange
BOG	Colombia Stock Exchange
NSE	National Stock Exchange of India
HEL	Nasdaq Helsinki
MISX	Moscow Exchange
HKG	Hong Kong Stock Exchange
IST	Istanbul Stock Exchange
BOM	Bombay Stock Exchange
TSX	Toronto Stock Exchange
BRU	Brussels Stock Exchange
BATS	BATS Global Markets
ARCX	NYSE Arca
GREY	Grey Market (OTC)
DUS	Dusseldorf Stock Exchange
BER	Berlin Stock Exchange
ROCO	Taipei Exchange
CNQ	Canadian Trading and Quotation System Inc.
BSP	Bangko Sentral ng Pilipinas
NEOE	NEO Exchange

Examples

The following examples demonstrate some common practices for US Equity corporate fundamentals.

Example 1: Capturing the Overreaction to Financial Reports

The following algorithm is based on the hypothesis that investors overreact to new financial report releases. It buys TSLA stock on every new 10Q or 8K filing and then liquidates the position after seven days.

```py
class USEquityCorporateFundamentalsExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add Equity data.
        self._equity = self.add_equity("TSLA")
        # Add a member to track the last financial statement filing date.
        self._last_filing_date = None

    def on_data(self, slice: Slice) -> None:
        # Get the most recent filing date.
        last_filing_date = self._equity.fundamentals.financial_statements.file_date.value

        # When new financial statements are released, buy TSLA.
        if self._last_filing_date and last_filing_date != self._last_filing_date:
            self.set_holdings(self._equity.symbol, 1)
            self._exit_time = self.time + timedelta(7)

        # Liquidate the position after 1 week.
        if self._equity.holdings.invested and self.time >= self._exit_time:
            self.liquidate()

        # Update the last filing date to identify future changes.
        self._last_filing_date = last_filing_date
```

Example 2: Diversifying Across Sectors

The follow algorithm aims to reduce concentration risk in any one sector. It selects the 500 largest Equities at the start of each month and then forms a portfolio that gives equal weight to each sector and equal weight to the assets within each sector.

```py
class USEquityCorporateFundamentalsExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(10_000_000)
        # Define the universe settings.
        self.universe_settings.resolution = Resolution.DAILY
        self.universe_settings.schedule.on(self.date_rules.month_start('SPY'))
        # Add a universe of the 500 largest Equities.
        self._universe = self.add_universe(
            lambda fundamental: [
                f.symbol for f in sorted(fundamental, key=lambda f: f.market_cap)[-500:]
            ]
        )
        # Create a Scheduled Event to rebalance the portfolio each month.
        self.schedule.on(self.date_rules.month_start('SPY', 1), self.time_rules.midnight, self._rebalance)

    def _rebalance(self) -> None:
        # Wait until there are asset in the universe.
        if not self._universe.selected:
            return

        # Group the universe constituents by sector.
        symbols_by_sector = {}
        for symbol in self._universe.selected:
            equity = self.securities[symbol]
            if not equity.price:
                continue
            sector_code = equity.fundamentals.asset_classification.morningstar_sector_code
            if sector_code not in symbols_by_sector:
                symbols_by_sector[sector_code] = []
            symbols_by_sector[sector_code].append(symbol)

        # Create targets to invest equally in each sector and invest equally in the assets within each sector.
        targets = []
        sector_count = len(symbols_by_sector)
        for symbols in symbols_by_sector.values():
            weight = 1 / sector_count / len(symbols)
            targets.extend([PortfolioTarget(symbol, weight) for symbol in symbols])

        # Place the trades.
        self.set_holdings(targets, liquidate_existing_holdings=True)
```

US Equity

Shorting

Introduction

In a regular long position, you buy shares and then sell them later to close the trade. In a short position, you borrow shares, sell them, and then buy the shares back later to close the trade. Short positions let you profit when a security's price decreases while you have the position open, but there are risks involved. For example, you can get a margin call and you may incur borrowing costs.

Holdings Accounting

If you have an open long position, your portfolio has a positive quantity of shares for that security. In contrast, if you have an open short position, your portfolio has a negative quantity of shares for that security.

Short Availability

To short sell, you need to borrow the shares from another investor or your brokerage. The short availability is the number of shares available for you to borrow. If you don't model the short availability in backtests, you could have a strategy that performs well in backtesting but doesn't trade in live mode because the shares aren't available to borrow. If you assume your short orders are successful in backtests, your backtesting results likely won't represent the true performance of actually trading the strategy during the backtest period. To get the short availability in your algorithms, use the US Equities Short Availability dataset . For more information about this topic, see Short Availability .

Borrowing Costs

In live trading, your brokerage charges an interest fee when you borrow shares to short a security. In backtesting, use the ShortMarginInterestRateModel .

To get valid borrowing rates, use the InteractiveBrokersShortableProvider .

```py
def initialize(self) -> None:
    security = self.add_equity("SPY")
    # For US Equity, use the ShortMarginInterestRateModel with IB data
    security.set_shortable_provider(InteractiveBrokersShortableProvider())
    security.margin_interest_rate_model = ShortMarginInterestRateModel()
```

Examples

The following examples demonstrate some common practices for shorting US Equities:

Example 1: Shorting Penny Stock Top Gainers

The following algorithm adds a universe of penny stocks that have experienced the greatest upward momentum over the last two trading days. For each asset in the universe, it monitors an hourly Bollinger Bands indicator. When an asset breaks above the upper band, it shorts the asset. It exits each position when the asset drops 10% from the entry price or when the price reverts back below the middle Bollinger Band.

PY

```
class USEquityShortingExampleAlgorithm(QCAlgorithm):

    _roc_by_symbol = {}

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Enable automatic indicator warm-up.
        self.settings.automatic_indicator_warm_up = True
        # Add a universe of low-cap penny stocks that have high upward momentum.
        self.add_universe(self._select_assets)

    def _select_assets(self, fundamentals: List[Fundamental]) -> List[Symbol]:
        # Select all the penny stocks that have a momentum score.
        penny_stocks = []
        for f in fundamentals:
            # Create a RateOfChange indicator for each asset.
            self._roc_by_symbol[f.symbol] = self._roc_by_symbol.get(f.symbol, RateOfChange(1))
            # Update the indicator an ensure it's ready.
            # Filter out assets above $5M market cap or $1 share price.
            if not self._roc_by_symbol[f.symbol].update(f.end_time, f.price) or f.market_cap > 5e6 or f.price > 1:
                continue
            penny_stocks.append(f.symbol)

        # Select the 20 penny stocks with the greatest momentum.
        return sorted(penny_stocks, key=lambda symbol: self._roc_by_symbol[symbol].current.value)[-20:]

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        # Iterate through the assets that entered the universe.
        for security in changes.added_securities:
            # Set the shortable provider of the asset to ensure realistic short availability.
            security.set_shortable_provider(InteractiveBrokersShortableProvider())
            # Create a BollingerBand indicator for this asset.
            security.bbands = self.bb(security.symbol, 20, 2, resolution=Resolution.HOUR)
            # Attach an event handler to the indicator to track its updates.
            security.bbands.updated += self.on_bb_updated

        # Liquidate and remove the indicator updates for assets that leave the universe.
        for security in changes.removed_securities:
            self.deregister_indicator(security.bbands)
            self.liquidate(security.symbol)

    def on_bb_updated(self, bb: object, _: IndicatorDataPoint) -> None:
        # When the indicator updates, ensure it's ready.
        if not bb.is_ready:
            return
        security = self.securities[bb.current.symbol]
        # Short the asset if the price is above the upper band.
        if not security.holdings.invested and security.price > bb.upper_band.current.value:
            # Get the number of shares avaiable for shorting.
            shortable_quantity = security.shortable_provider.shortable_quantity(security.symbol, self.time)
            # Calculate the target quantity.
            quantity = max(self.calculate_order_quantity(security.symbol, -0.1), -shortable_quantity if shortable_quantity else 0)
            if quantity == 0: return
            # Short the asset.
            self.market_order(security.symbol, quantity)
            # Place a take-profit order 10% below the current price.
            self.limit_order(security.symbol, -quantity, 0.9 * security.bid_price)
        # If the limit order isn't hit before the price drops below the middle band,
        # exit the position and cancel the limit order.
        elif security.holdings.invested and security.price < bb.middle_band.current.value:
            self.liquidate(security.symbol)
```

US Equity

Data Preparation

Introduction

The US Equities dataset provides price data for backtests and live trading.

Sourcing

The QuantConnect data provider consolidates US Equity market data across all of the exchanges. Over-the-Counter (OTC) trades are excluded. The data is powered by the Securities Information Processor (SIP), so it has 100% market coverage. In contrast, free platforms that display data feeds like the Better Alternative Trading System (BATS) only have about 6-7% market coverage .

We provide live splits, dividends, and corporate actions for US companies. We deliver them to your algorithm before the trading day starts.

Bar Building

We aggregate ticks to build bars.

The bar-building process can exclude ticks. If a tick is excluded, its volume is aggregated in the bar but its price is not aggregated in the bar. Ticks are excluded if any of the following statements are true:

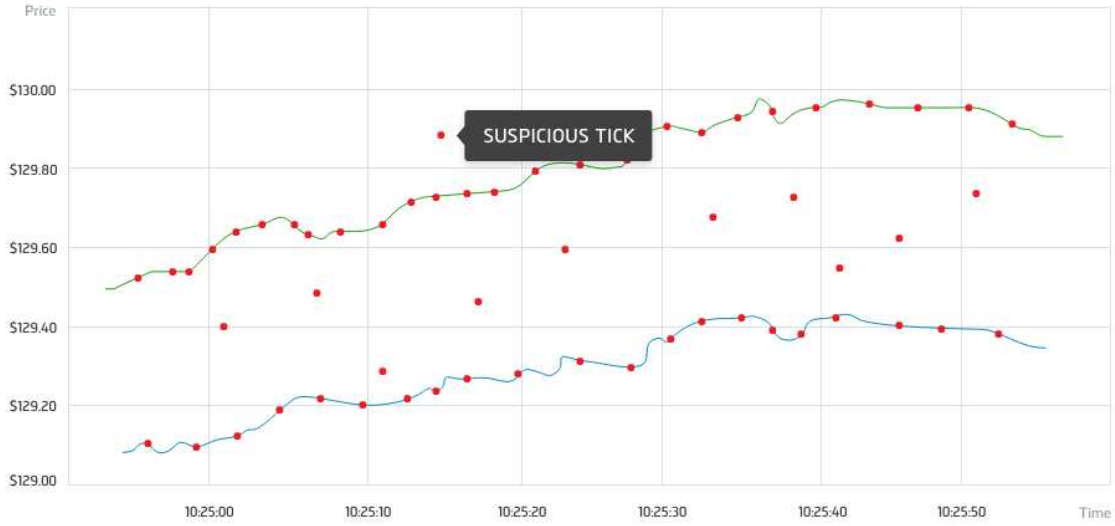
- The tick is suspicious.
- The tick is from the FINRA exchange and meets our price and volume thresholds.
- The trade has none of the following included `TradeConditionFlags` and at least one of the following excluded `TradeConditionFlags` :
- The quote has a size of less than 100 shares.
- The quote has none of the following included `QuoteConditionFlags` and at least one of the following excluded `QuoteConditionFlags` :
- The quote has one of the following `QuoteConditionFlags` :

In the preceding tables, Participant refers to the entities on page 19 of the Consolidated Tape System Multicast Output Binary Specification .

Suspicious Ticks

Tick price data is raw and unfiltered, so it can contain a lot of noise. If a tick is not tradable, we flag it as suspicious. This process makes the bars a more realistic representation of what you could execute in live trading. If you use tick data, avoid using suspicious ticks in your algorithms as informative data points. We recommend only using tick data if you understand the risks and are able to perform your own tick filtering. Ticks are flagged as suspicious in the following situations:

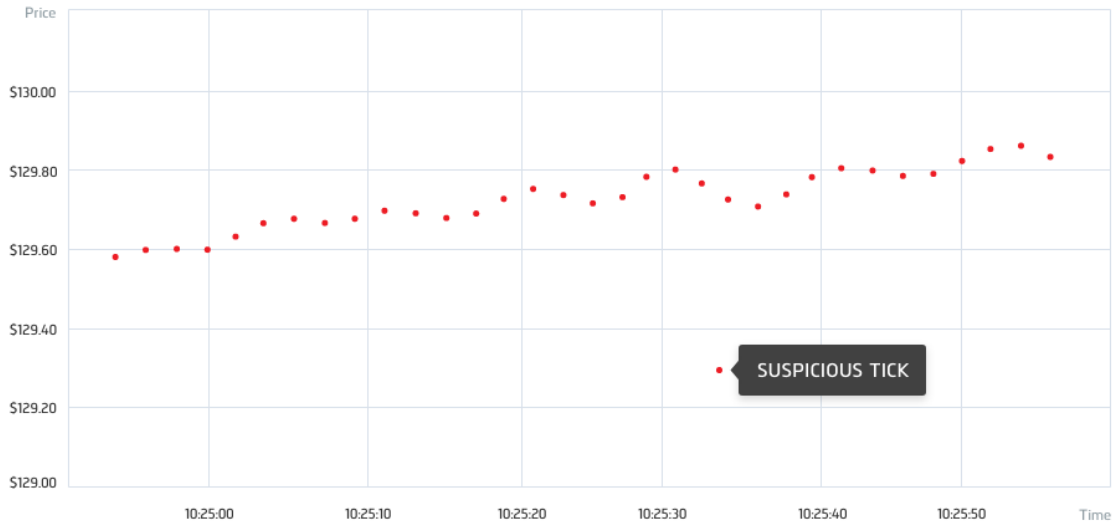
- The tick occurs below the best bid or above the best ask



This image shows a tick that occurred above the best ask price of a security. The green line represents the best ask of the security, the blue

line represents the best bid of the security, and the red dots represent trade ticks. The ticks between the best bid and ask occur from filling hidden orders. The tick that occurred above the best ask price is flagged as suspicious.

- The tick occurs far from the current market price



This image shows a tick that occurred far from the price of the security. The red dots represent trade ticks. The tick that occurred far from the market price is flagged as suspicious.

- The tick occurs on a dark pool
- The tick is rolled back
- The tick is reported late

Market Auction Prices

The opening and closing price of the day is set by very specific opening and closing auction ticks. When a stock like Apple is listed, it's listed on Nasdaq. The open auction tick on Nasdaq is the price that's used as the official open of the day. NYSE, BATS, and other exchanges also have opening auctions, but the only official opening price for Apple is the opening auction on the exchange where it was listed.

We set the opening and closing prices of the first and last bars of the day to the official auction prices. This process is used for second, minute, hour, and daily bars for the 9:30 AM and 4:00 PM Eastern Time (ET) prices. In contrast, other platforms might not be using the correct opening and closing prices.

The official auction prices are usually emitted 2-30 seconds after the market open and close. We do our best to use the official opening and closing prices in the bars we build, but the delay can be so large that there isn't enough time to update the opening and closing price of the bar before it's injected into your algorithms. For example, if you subscribe to second resolution data, we wait until the end of the second for the opening price but most second resolution data won't get the official opening price. If you subscribe to minute resolution data, we wait until the end of the minute for the opening auction price. Most of the time, you'll get the actual opening auction price with minute resolution data, but there are always exceptions. Nasdaq and NYSE can have delays in publishing the opening auction price, but we don't have control over those issues and we have to emit the data on time so that you get the bar you are expecting.

Live and Backtesting Differences

In live trading, bars are built using the exchange timestamps with microsecond accuracy. This microsecond-by-microsecond processing of the ticks can mean that the individual bars between live trading and backtesting can have slightly different ticks. As a result, it's possible for a tick to be counted in different bars between backtesting and live trading, which can lead to bars having slightly different open, high, low, close, and volume values.

Data Availability

In live trading, live data is available in real-time. In backtests, live data is available at the following pre-market trading session.

Examples

The following examples demonstrate some common practices related to our US Equity data preparation process.

Example 1: Trading at the Opening Auction

The following algorithm creates a Scheduled Event that places a Market On Open order , which fill at the official opening auction price.

```py
class USEquityDataPreparationExampleAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add Equity data.
        self._spy = self.add_equity("SPY", extended_market_hours=True).symbol
        # Create a Scheduled Event that rebalances with market on open orders.
        self.schedule.on(
            self.date_rules.every_day(self._spy),
            self.time_rules.before_market_open(self._spy, 30),
            self._rebalance
        )

    def _rebalance(self):
        quantity = self.calculate_order_quantity(self._spy, 0.1)
        if quantity:
            self.market_on_open_order(self._spy, quantity)
```

Example 2: Demonstrate Using Tick Flags to Identify Opening Auction Tick

This example demonstrates using the tick flags to identify the official opening price on the security primary exchange. All exchanges have an opening auction to determine the market on open price, but only the primary listed exchange is used as the official open price for the asset. The algorithm subscribes to the raw tick data of QQQ ETF and logs the auction price tick data of the asset.

```py
class USEquityDataPreparationExampleAlgorithm(QCAlgorithm):
    def initialize(self):
        self.set_start_date(2024, 9, 5)
        self.set_end_date(2024, 9, 5)
        # Subscribe to tick data of a security and find the exchange code.
        self._asset = self.add_equity(ticker = "QQQ", resolution = Resolution.TICK, extended_market_hours = True, data_normalization_mode
= DataNormalizationMode.RAW)
        # Define flags to help filter opening auctions in the OnData method.
        self.officialOpen = TradeConditionFlags.REGULAR | TradeConditionFlags.OFFICIAL_OPEN
        self.openingPrints = TradeConditionFlags.REGULAR | TradeConditionFlags.OPENING_PRINTS
        # Display exchange code and trade condition flags on the console.
        self.debug(f"Search Codes: Ex:{self._asset.primary_exchange.code} OO: {self.officialOpen} OP: {self.openingPrints}")

    def on_data(self, data):
        # Create a list of opening auction tick data.
        trades = [
            tick for tick in self._asset.cache.get_all[Tick]()
            if  tick.TickType == TickType.TRADE and
                tick.Price > 0 and
                tick.SaleCondition and
                (
                    tick.ParsedSaleCondition == self.officialOpen or
                    tick.ParsedSaleCondition == self.openingPrints
                )
        ]
        # Log the opening auction tick price
        for tick in trades:
            self.log(f"{self.Time},{tick.Price},{tick.Quantity},{tick.ParsedSaleCondition},{tick.ExchangeCode},{tick.Exchange}")
```

Introduction to Options
Applied Options

Equity Options

Requesting Data

Request Equity Options data in your algorithm to receive a feed of contract prices in the `on_data` method. For more information about the specific dataset we use for backtests, see the US Equity Options dataset listing . To trade Equity Options live, you can use one of the brokerage data providers . We currently only support American-style Options for US Equity Options.

To request Equity Options data, call one of the following methods:

- `self.add_option` to add a basket of contracts for a single underlying Equity
- `self.add_option_contract` to add individual contracts for an underlying Equity

Request and Filter Contracts for Option Strategies

Universes

Introduction

The `add_option` method enables you to select a basket of Option contracts for an underlying Equity. To form your universe of contracts, you can filter them down by their strike price and expiry or you can choose to a subset of the contracts that form popular Option strategies . If you want to subscribe to individual contracts one-by-one instead of a set of contracts, see Individual Contracts .

Create Universes

To add a universe of Equity Option contracts, in the `initialize` method, call the `add_option` method. This method returns an `Option` object, which has a `set_filter` method you can call to filter the set of tradable contract down to just the contracts you want.

```
PY
class BasicOptionAlgorithm(QCAlgorithm):

    def initialize(self):
        self.universe_settings.asynchronous = True
        option = self.add_option("SPY")
        option.set_filter(self._filter)
        self._symbol = option.symbol

    def _filter(self, universe):
        return universe.expiration(0, 7).delta(0.35, 0.75)

    def on_data(self, data):
        chain = data.option_chains.get(self._symbol)
        if chain:
            contract = sorted(chain, key=lambda x: (x.expiry, x.greeks.delta))[0]
```

For more information about the `add_option` method, see Create Universes .

Filter by Investment Strategy

Options trading strategies consist of simultaneously buying or selling one or more Option contracts of the same underlying Equity with different features.

```
PY
# Example 1: Select a Straddle
option.set_filter(lambda option_filter_universe: option_filter_universe.straddle(30))

# Example 2: Select the contracts (including weeklys) that expire in the next 30 days that form an Iron Condor
option.set_filter(lambda option_filter_universe: option_filter_universe.strikes(-20, 20).expiration(0, 30).iron_condor(30, 5, 10))

# Example 3: Select the 0DTE contracts that form an Strangle
option.set_filter(lambda option_filter_universe: option_filter_universe.expiration(0, 0).strangle(30, 5, -10))
```

The following table describes the filter methods of the `OptionFilterUniverse` class that select contracts for Option strategies:

`naked_call(min_days_till_expiry: int, strike_from_atm: float)` Selects a call contract to form Naked Call , Covered Call , or Protective Call Option strategies.
`naked_put(min_days_till_expiry: int, strike_from_atm: float)` Selects a put contract to form Naked Put , Covered Put , or Protective Put Option strategies.
`call_spread(min_days_till_expiry: int, higher_strike_from_atm: float, lower_strike_from_atm: float)` Selects two call contracts to form Bull Call Spread or Bear Call Spread Option strategies.

`put_spread(min_days_till_expiry: int, higher_strike_from_atm: float, lower_strike_from_atm: float)`

Selects two put contracts to form Bull Put Spread or Bear Put Spread Option strategies.

`call_calendar_spread(strike_from_atm: int, min_near_days_till_expiry: int, min_far_days_till_expiry: int)`

Selects two call contracts to form Long Call Calendar Spread or Short Call Calendar Spread Option strategies.

`put_calendar_spread(strike_from_atm: int, min_near_days_till_expiry: int, min_far_days_till_expiry: int)`

Selects two put contracts to form Long Put Calendar Spread or Short Put Calendar Spread Option strategies.

`strangle(min_days_till_expiry: int, higher_strike_from_atm: float, lower_strike_from_atm: float)`

Selects two contracts to form Long Strangle or Short Strangle Option strategies.

`straddle(min_days_till_expiry: int)`

Selects two contracts to form Long Straddle or Short Straddle Option strategies.

`protective_collar(min_days_till_expiry: int, higher_strike_from_atm: float, lower_strike_from_atm: float)`

Selects two contracts to form Protective Collar Option strategies.

`conversion(min_days_till_expiry: int, strike_from_atm: float)`

Selects two contracts to form Conversion or Reverse Conversion Option strategies.

`call_butterfly(min_days_till_expiry: int, strike_spread: float)`

Selects three contracts to form Long Call Butterfly or Short Call Butterfly Option strategies.

`put_butterfly(min_days_till_expiry: int, strike_spread: float)`

Selects three contracts to form Long Put Butterfly or Short Put Butterfly Option strategies.

`iron_butterfly(min_days_till_expiry: int, strike_spread: float)`

Selects four contracts to form Long Iron Butterfly or Short Iron Butterfly Option strategies.

`iron_condor(min_days_till_expiry: int, near_strike_spread: float, far_strike_spread: float)`

Selects four contracts to form Long Iron Condor or Short Iron Condor Option strategies.

`box_spread(min_days_till_expiry: int, strike_spread: float)`

Selects four contracts to form Box Spread or Short Box Spread Option strategies.

`jelly_roll(strike_from_atm: float, min_near_days_till_expiry: int, min_far_days_till_expiry: int)`

Selects four contracts to form Jelly Roll or Short Jelly Roll Option strategies.

`call_ladder(min_days_till_expiry: int, higher_strike_from_atm: float, middle_strike_from_atm: float, lower_strike_from_atm: float)`

Selects four contracts to form Bear Call Ladder or Bull Call Ladder Option strategies.

`put_ladder(min_days_till_expiry: int, higher_strike_from_atm: float, middle_strike_from_atm: float, lower_strike_from_atm: float)` Selects four contracts to form Bear Put Ladder or Bull Put Ladder Option strategies.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

Filter by Implied Volatility and Greeks

Option price models compute the theoretical price of Option contracts, their implied volatility, and their Greek values. Theoretical prices can help you detect undervalued and overvalued contracts, implied volatility can provide you insight into the upcoming volatility of the underlying security, and Greek values can help you hedge your portfolio.

```py
# Example 1: Select the contracts with delta between 0.25 and 0.75
option.set_filter(lambda option_filter_universe: option_filter_universe.delta(0.25, 0.75))

# Example 2: Select the contracts (including weeklys) that expire in the next 90 days with implied volatility below 20%
option.set_filter(lambda option_filter_universe: option_filter_universe.iv(0, 20).expiration(0, 90))

# Example 3: Select the contracts (including weeklys) that expire in the next 30 days with implied volatility below 20% that forms an Iron Condor
option.set_filter(lambda option_filter_universe: option_filter_universe.iv(0, 20).expiration(0, 30).iron_condor(30, 5, 10))
```

The following table describes the filter methods of the `OptionFilterUniverse` class that select contract for a range of implied volatility, Greek values, and open interest:

`iv(min: float, max: float)`
`implied_volatility(min: float, max: float)`
 	
Selects a contract with implied volatility within the range you set.

`d(min: float, max: float)`
`delta(min: float, max: float)`
 	
Selects a contract with delta within the range you set.

`g(min: float, max: float)`
`gamma(min: float, max: float)`
 	
Selects a contract with gamma within the range you set.

`r(min: float, max: float)`
`rho(min: float, max: float)`
 	
Selects a contract with rho within the range you set.

`v(min: float, max: float)`
`vega(min: float, max: float)`
 	
Selects a contract with vega within the range you set.

`t(min: float, max: float)`
`theta(min: float, max: float)`
 	
Selects a contract with theta within the range you set.

`oi(min: int, max: int)`
`open_interest(min: float, max: float)`
 	
Selects a contract with open interest within the range you set.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

To perform thorough filtering on the `OptionFilterUniverse` , define an isolated filter method.

```
# Select the put contracts with the lowest strike price.
option.set_filter(self._contract_selector)

def _contract_selector(self, option_filter_universe: OptionFilterUniverse) -> OptionFilterUniverse:
    return option_filter_universe \
        .delta(0.5, 1.5) \
        .gamma(0.0001, 0.0006) \
        .vega(0.01, 1.5) \
        .theta(-2.0, -0.5) \
        .rho(0.5, 3.0) \
        .implied_volatility(1, 3) \
        .open_interest(100,500)
```

Filter by Other Contract Properties

To set a contract filter, in the `initialize` method, call the `set_filter` method of the `Option` object.

```
# Select contracts that have a strike price within 1 strike level above and below the underlying price
option.set_filter(min_strike=-1, max_strike=1)

# Select contracts that expire within 30 days
option.set_filter(min_expiry=timedelta(days=0), maxExpiry=timedelta(days=30))

# Select contracts that have a strike price within 1 strike level and expire within 30 days
option.set_filter(min_strike=-1, max_strike=1, min_expiry=timedelta(days=0), maxExpiry=timedelta(days=30))

# Select call contracts
option.set_filter(lambda option_filter_universe: option_filter_universe.calls_only())
```

The following table describes the available filter techniques:

`set_filter(minStrike: int, maxStrike: int)` Selects the contracts that have a strike price within a minimum and maximum strike level relative to the underlying price. For example, say the underlying price is 302 and there are strikes at every 5. If you set `m_strike` to -1 and `max_strike` to 1, LEAN selects the contracts that have a strike of 300 or 305. This filter runs asynchronously by default.
`set_filter(minExpiry: timedelta, maxExpiry: timedelta)` Selects the contracts that expire within the range you set. This filter runs asynchronously by default.
`set_filter(minStrike: int, maxStrike: int, minExpiry: timedelta, maxExpiry: timedelta)` Selects the contracts that expire and have a strike within the range you set. This filter runs asynchronously by default.
`set_filter(universeFunc: Callable[[OptionFilterUniverse], OptionFilterUniverse])` Selects the contracts that a function selects.

The following table describes the filter methods of the `OptionFilterUniverse` class:

`strikes(min_strike: int, max_strike: int)` Selects contracts that are within `m_strike` strikes below the underlying price and `max_strike` strikes above the underlying price.
`calls_only()` Selects call contracts.
`puts_only()` Selects put contracts.
`standards_only()` Selects standard contracts.
`weeklys_only()` Selects weekly contracts.
`front_month()` Selects the front month contract.
`back_months()` Selects the non-front month contracts.
`back_month()` Selects the back month contracts.
`expiration(min_expiryDays: int, max_expiryDays: int)` Selects contracts that expire within a range of dates relative to the current day.
`contracts(contracts: list[Symbol])` Selects a list of contracts.
`contracts(contract_selector: Callable[[list[Symbol]], list[Symbol]])` Selects contracts that a selector function selects.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

```
# Example 1: Select the front month call contracts
option.set_filter(lambda option_filter_universe: option_filter_universe.calls_only().front_month())

# Example 2: Select the contracts (including weeklys) that expire in the next 90 days
option.set_filter(lambda option_filter_universe: option_filter_universe.strikes(-20, 20).expiration(0, 90))
```

Some of the preceding filter methods only set an internal enumeration in the `OptionFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `OptionFilterUniverse` .

Default Filter

By default, LEAN subscribes to the Option contracts that have the following characteristics:

- Standard and weeklys
- Within 1 strike price of the underlying asset price
- Expire within 35 days

To adjust the universe of contracts, set a filter. The filter usually runs at the first bar of every day. When the filter selects a contract that isn't currently in your universe, LEAN adds the new contract data to the next `Slice` that it passes to the `on_data` method.

Historical Data

To get historical chains for an Equity Option, see Historical Data .

Examples

Example 1: Selecting for 0DTE Contracts

0DTE Options are Option contracts that expire on the same day you trade them. To create an universe with 0DTE Options, call the `set_filter` method with expiration set. In order to trade with the contracts with most liquidity, limit the strike range from 10 strikes above and below the current price level.

```
class EquityOptionAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        option = self.add_option("SPY")
        # Filter for 0-DTE contracts within +/-10 strike range.
        # They have the highest volatility but low premium, providing sufficient liquidity and higher profit margin.
        option.set_filter(lambda u: u.expiration(0, 0).strikes(-10, 10))
```

Example 2: Straddle

You can also create an universe that return the option contracts that form an option strategy . In this example, we demonstrate filtering for a long straddle strategy that expires 30 days later.

```
class EquityOptionAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        option = self.add_option("SPY")
        self._symbol = option.symbol
        # Using straddle() method, it will only return the best-matched ATM call and put contracts expiring after 30 days.
        # It provides better accuracy in filtering, and subscribe only to the needed contracts to save computation resources.
        option.set_filter(lambda u: u.straddle(30))

    def on_data(self, slice: Slice) -> None:
        # Only wants the option chain of the selected symbol.
        chain = slice.option_chains.get(self._symbol)
        if not self.portfolio.invested and chain:
            # There should only be 1 expiry and 1 strike from the 2 contracts returned, getting from either contract is fine.
            expiry = list(chain)[0].expiry
            strike = list(chain)[0].strike

            # Forms a long straddle option strategy using abstraction method ensure accuracy.
            long_straddle = OptionStrategies.straddle(self._symbol, strike, expiry)
            self.buy(long_straddle, 1)
```

Example 3: Custom Selector

Using a custom selection function, you can filter the option universe to obtain the contracts that you need without subscribing the redundants. This can ensure the accuracy of the filter, as well as avoiding unnecessary subscriptions that drag the algorithm computational performance. In this example, we try to obtain a put contract that expires 30 days later that is 5 below the current underlying price and a call contract that expires 60 days later that is 10 above the current underlying price.

PY

```
class EquityOptionAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Seed the price with last known price to ensure the underlying price data is available on initial option contract filtering.
        self.settings.seed_initial_prices = True
        self.underlying = self.add_equity("SPY", data_normalization_mode=DataNormalizationMode.RAW)
        # Subscribe to underlying data for ATM calculation using the update underlying price.
        # Set data normalization mode to raw is required to ensure strike price and underlying price is comparable.
        option = self.add_option(self.underlying.symbol)
        option.set_filter(lambda u: u.contracts(self.selection))

    def selection(self, contracts: List[Symbol]) -> List[Symbol]:
        selected = []

        # Select the best-match put contracts that expires 30 days later that is $5 below the current underlying price.
        # We should first filter the hard requirement, then sort the reminders for faster computation.
        puts = [x for x in contracts
            if x.id.option_right == OptionRight.PUT and \
            x.id.date >= self.time + timedelta(30) and \
            x.id.strike_price <= self.underlying.price - 5
        ]
        if len(puts) > 0:
            expiry = min(x.id.date for x in puts)
            put = sorted([x for x in puts if x.id.date == expiry],
                key=lambda x: x.id.strike_price,
                reverse=True)[0]
            selected.append(put)

        # Select the best-match call contract that expires 60 days later that is $10 above the current underlying price.
        calls = [x for x in contracts
            if x.id.option_right == OptionRight.CALL and \
            x.id.date >= self.time + timedelta(60) and \
            x.id.strike_price >= self.underlying.price + 10
        ]
        if len(calls) > 0:
            expiry = min(x.id.date for x in calls)
            call = sorted([x for x in calls if x.id.date == expiry],
                key=lambda x: x.id.strike_price)[0]
            selected.append(call)

        return selected
```

Requesting Data

Individual Contracts

Introduction

The `add_option_contract` method enables you to add an individual Option contract to your algorithm. To check which contracts are currently available to add to your algorithm, use the `option_chain` method. If you want to subscribe to a set of contracts instead of individual contracts one-by-one, see Universes .

Create Subscriptions

Before you can subscribe to an Option contract, you must configure the underlying Equity and get the contract `Symbol` .

```
class BasicOptionAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self._underlying = self.add_equity('SPY', data_normalization_mode=DataNormalizationMode.RAW).symbol
        self._contract_symbol = None

    def on_data(self, data):
        if self._contract_symbol:
            return
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        expiry = chain.expiry.min()
        self._contract_symbol = chain[
            (chain.expiry == expiry) &
            (chain.right == OptionRight.CALL) &
            (chain.delta < 0.7) &
            (chain.delta > 0.3)
        ].sort_values('openinterest').index[-1]
        self.add_option_contract(self._contract_symbol)
```

Configure the Underlying Equity

If you want to subscribe to the underlying Equity in the `initialize` method, set the Equity data normalization to `DataNormalizationMode.RAW` .

```
self._underlying = self.add_equity("SPY", data_normalization_mode=DataNormalizationMode.RAW).symbol
```

If your algorithm has a dynamic universe of Equities, before you add the Equity universe in the `initialize` method, set the universe data normalization mode to `DataNormalizationMode.RAW` .

```
self.universe_settings.data_normalization_mode = DataNormalizationMode.RAW
```

Get Contract Symbols

To subscribe to an Option contract, you need the contract `Symbol` . The preferred method to getting Option contract `Symbol` objects is to use the `option_chain` method. This method returns an `OptionChain` object, which represent an entire chain of Option contracts for a single underlying security. You can even format the chain data into a DataFrame where each row in the DataFrame represents a single contract. With the chain, sort and filter the data to find the specific contract(s) you want to trade.

```
# Get the contracts available to trade (in DataFrame format).
chain = self.option_chain(self._underlying, flatten=True).data_frame

# Select a contract.
expiry = chain.expiry.min()
self._contract_symbol = chain[
    # Select call contracts with the closest expiry.
    (chain.expiry == expiry) &
    (chain.right == OptionRight.CALL) &
    # Select contracts with a 0.3-0.7 delta.
    (chain.delta > 0.3) &
    (chain.delta < 0.7)
    # Select the contract with the largest open interest.
].sort_values('openinterest').index[-1]
```

Alternatively, you can create a Option contract `Symbol` object directly parsing its OSI ticker using the `SymbolRepresentation.parse_option_ticker_osi` method.

```
# Create the contract Symbol for the SPY Call 564 3 Sept 2024.
self._contract_symbol = SymbolRepresentation.parse_option_ticker_osi('SPY 240903C00564000')
```

Subscribe to Contracts

To create an Equity Option contract subscription, pass the contract `Symbol` to the `add_option_contract` method. Save a reference to the contract `symbol` so you can easily access the Option contract in the OptionChain that LEAN passes to the `on_data` method. This method returns an `Option` object. To override the default pricing model of the Option, set a pricing model .

```
option = self.add_option_contract(self._contract_symbol)
option.price_model = OptionPriceModels.binomial_cox_ross_rubinstein()
```

The `add_option_contract` method creates a subscription for a single Option contract and adds it to your user-defined universe. To create a dynamic universe of Option contracts, add an Equity Options universe or an Options Universe Selection model .

Warm Up Contract Prices

If you subscribe to an Option contract with `add_option_contract` , you'll need to wait until the next `Slice` to receive data and trade the contract. To trade the contract in the same time step you subscribe to the contract, set the current price of the contract in a security initializer .

```
self.settings.seed_initial_prices = True
```

Supported Assets

To view the supported assets in the US Equities dataset, see the Data Explorer .

Resolutions

The following table shows the available resolutions and data formats for Equity Option contract subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`TICK`				
`SECOND`				
`MINUTE`	✓	✓		
`HOUR`	✓	✓		
`DAILY`	✓	✓		

The default resolution for Option contract subscriptions is `Resolution.MINUTE` . To change the resolution, pass a `resolution` argument to the

`add_option_contract` method.

```
self.add_option_contract(self._contract_symbol, Resolution.MINUTE)
```

To create custom resolution periods, see Consolidating Data .

Supported Markets

LEAN groups all of the US Equity exchanges under `Market.USA` . You don't need to pass a `market` argument to the `add_option_contract` method because the contract `symbol` already contains the market.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fill_forward` argument to false when you create the security subscription.

```
self.add_option_contract(self._contract_symbol, fill_forward=False)
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. Options are already leveraged products, so you can't change their leverage.

Extended Market Hours

By default, your security subscriptions only cover regular trading hours. To subscribe to pre and post-market trading hours for a specific asset, enable the `extended_market_hours` argument when you create the security subscription.

```
self.add_option_contract(self._contract_symbol, extended_market_hours=True)
```

You only receive extended market hours data if you create the subscription with minute, second, or tick resolution. If you create the subscription with daily or hourly resolution, the bars only reflect the regular trading hours.

To view the schedule of regular and extended market hours, see Market Hours .

Data Normalization

The data normalization mode doesn't affect the data that LEAN passes to `on_data` or the data from history request . By default, LEAN doesn't adjust Equity Options data for splits and dividends of their underlying. If you change the data normalization mode, it won't change the outcome.

If you hold an Option contract when a corporate action occurs for the underlying Equity, LEAN automatically closes your position.

Remove Subscriptions

To remove a contract subscription that you created with `add_option_contract` , call the `remove_option_contract` method. This method is an alias for `remove_security` .

```
self.remove_option_contract(self._contract_symbol)
```

The `remove_option_contract` method cancels your open orders for the contract and liquidates your holdings.

Properties

The `add_option_contract` method returns an `Option` object, which have the following properties:

Helper Methods

The `Option` object provides methods you can use for basic calculations. These methods require the underlying price. To get the `Option` object and

the `Security` object for its underlying in any function, use the Option `symbol` to access the value in the `securities` object.

```
option = self.securities[self._contract_symbol]
underlying = self.securities[self._contract_symbol.underlying]
underlying_price = underlying.price
```

To get the Option payoff , call the `get_pay_off` method.

```
pay_off = option.get_pay_off(underlying_price)
```

To get the Option intrinsic value , call the `get_intrinsic_value` method.

```
intrinsic_value = option.get_intrinsic_value(underlying_price)
```

To get the Option out-of-the-money amount , call the `out_of_the_money_amount` method.

```
otm_amount = option.out_of_the_money_amount(underlying_price)
```

To check whether the Option can be automatic exercised, call the `is_auto_exercised` method.

```
is_auto_exercised = option.is_auto_exercised(underlying_price)
```

Exceptions and Edge Cases

The following sections explain exceptions and edge cases with subscribing to individual Option contracts.

Manually Creating Option Symbol Objects

To subscribe to an Option contract, you need the contract `Symbol` . You can get the contract `Symbol` from the `create_option` or `option_chain` methods. If you use the `create_option` method, you need to provide the details of an existing contract.

```
self._contract_symbol = Symbol.create_option(self._underlying, Market.USA,
    OptionStyle.AMERICAN, OptionRight.CALL, 365, datetime(2022, 6, 17))
```

Default Underlying Subscription Settings

If you subscribe to an Equity Option contract but don't have a subscription to the underlying Equity, LEAN automatically subscribes to the underlying Equity with the following settings:

Setting	Value
Fill forward	Same as the Option contract
Leverage	0
Extended Market Hours	Same as the Option contract
Data Normalization	`DataNormalizationMode.RAW`

In this case, you still need the Equity `Symbol` to subscribe to Equity Option contracts. If you don't have access to it, create it.

```
self._underlying = Symbol.create("SPY", SecurityType.EQUITY, Market.USA)
```

Overriding the Initial Implied Volatility Guess

To override the initial guess of implied volatility , set and warm up the underlying volatility model .

Examples

The following examples demonstrate some common practices for requesting individual Equity Option contract data.

Example 1: Covered Call

A cover call consists of a short call and with a lot of the underlying equity. Although it capped the maximum profit if the underlying skyrocketted, it also provide extra credit received while speculating the underlying will rise.

```PY
class EquityOptionExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self._chain = pd.DataFrame()
        # Seed the security price to ensure the retrieval of the ATM calls at the initial filtering.
        self.settings.seed_initial_prices = True
        # Set the data normalization mode as raw for option strike-price comparability.
        self.aapl = self.add_equity("AAPL", data_normalization_mode=DataNormalizationMode.RAW).symbol

        # Filter an updated option list at market open everyday by a scheduled event.
        self.schedule.on(
            self.date_rules.every_day(self.aapl),
            self.time_rules.at(9, 0),
            self.refresh_option_list
        )

    def refresh_option_list(self) -> None:
        # Get all tradable option contracts for AAPL at the current time for filtering.
        chain = self.option_chain(self.aapl, flatten=True).data_frame
        if chain.empty:
            return
        # Select the calls expires within 30 days and within $5 strike from ATM as leg of the covered call.
        # $5 buffer is given on selecting the ATM call due to price movement.
        expiry_threshold = self.time + timedelta(30)
        self._chain = chain[
            (chain.expiry < expiry_threshold) &
            (chain.right == OptionRight.CALL) &
            (abs(chain.strike - chain.underlyinglastprice) <= 5)
        ]
        for symbol in self._chain.index:
            self.add_option_contract(symbol)

    def on_data(self, slice: Slice) -> None:
        if not self.portfolio.invested and self.aapl in slice.bars and not self._chain.empty:
            # To form a covered call, get the contract closest to ATM and expiry.
            self._chain['abs_moneyness'] = abs(self._chain.strike - slice.bars[self.aapl].price)
            expiry = self._chain.expiry.min()
            contract = self._chain[self._chain.expiry == expiry].sort_values('abs_moneyness').index[0]

            # Covered call involves shorting 1 ATM call and ordering 1 lot of underlying.
            self.market_order(contract, -1)
            self.market_order(self.aapl, self.securities[contract].symbol_properties.contract_multiplier)

    def on_order_event(self, order_event: OrderEvent) -> None:
        # Close AAPL position if the short call is not exercised (OTM).
        # If it is exercised, the underlying will be used to settle the contract automatically.
        if order_event.ticket.order_type == OrderType.OPTION_EXERCISE \
        and not order_event.is_in_the_money:
            self.market_order(self.aapl, -self.securities[order_event.symbol].symbol_properties.contract_multiplier)
```

Example 2: 0-DTE Bull Put Spread

0DTE options often trades with high volume and volatility, providing arbitration opportunities and higher profit margin on spread type trading. In this example, we make use of 0-DTE SPY options to trade bull put spread option strategy.

```
class EquityOptionExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1);
        self.set_end_date(2024, 12, 27)
        self.legs = []
        # Seed the underlying security price to ensure accurate filtering for puts of $5 above/below current market price.
        self.settings.seed_initial_prices = True
        # Set the data normalization mode as raw for option strike-price comparability.
        self.spy = self.add_equity("SPY", data_normalization_mode=DataNormalizationMode.RAW).symbol

        # Filter an updated option list at market open everyday by a scheduled event.
        self.schedule.on(self.date_rules.every_day(self.spy), self.time_rules.before_market_open(self.spy, 10), self.refresh_option_list)

        # Use a scheduled event to close all positions before market close.
        self.schedule.on(self.date_rules.every_day(self.spy), self.time_rules.before_market_close(self.spy, 1), self.exit_position)

    def refresh_option_list(self) -> None:
        # Get all tradable option contracts for SPY at the current time for filtering.
        contracts = self.option_chain(self.spy)
        # Select the 0-DTE puts by setting expiry within 1 day.
        filtered_contracts = [x for x in contracts
            if x.expiry < self.time + timedelta(1) and x.right == OptionRight.PUT]
        # Ensure at least 2 contracts available to form a put spread.
        if len(filtered_contracts) < 2:
            self.legs = []
            return

        # To form a put spread, select and subscribe to put contracts $5 above and below from the current underlying price.
        underlying_price = self.securities[self.spy].price
        itm_put = sorted(filtered_contracts, key=lambda x: abs(x.strike - underlying_price - 5))[0]
        otm_put = sorted(filtered_contracts, key=lambda x: abs(x.strike - underlying_price + 5))[0]
        def get_leg(contract, quantity):
            self.add_option_contract(contract.symbol)
            return Leg.create(contract.symbol, quantity)
        self.legs = [get_leg(itm_put, -1), get_leg(otm_put, 1)]

    def on_data(self, slice: Slice) -> None:
        # To avoid over-trading, limit the position opening to before 3pm.
        # To ensure the put spread formed correctly, make sure at least 2 contracts selected.
        if not self.portfolio.invested and self.time.hour < 15 and len(self.legs) == 2:
            # A bull put spread involves buying a lower-strike put and selling a high-strike put
            [self.market_order(leg.symbol, leg.quantity) for leg in self.legs]

    def exit_position(self) -> None:
        # Exit all positions by removing the contract before market close to avoid option assignment and overnight risk.
        [self.remove_option_contract(leg.symbol, f'Exit position') for leg in self.legs]
        self.legs = []
```

Example 3: Select Option Contracts by Greeks

The following algorithm creates a weekly Scheduled Event that adds a universe of contracts with a Delta >= 0.99. This universe is useful for creating a hedge replicate portfolio for arbitrage.

```
class EquityOptionExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add the underlying asset with raw data to enable Option strike-price comparability.
        self._underlying = self.add_equity("SPY", data_normalization_mode=DataNormalizationMode.RAW).symbol
        # Add a Scheduled Event to select the Option contracts to trade each week.
        self.schedule.on(
            self.date_rules.week_start(self._underlying),
            self.time_rules.at(7, 30),
            self._add_contracts
        )

    def _add_contracts(self) -> None:
        self._universe = []
        # Get all the tradable Option contracts for SPY at the current time.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if not chain.empty:
            # Add the contracts that have the nearest expiry after 7 days and a delta >= 0.99.
            expiry_threshold = self.time + timedelta(7)
            expiry = chain[chain.expiry >= expiry_threshold].expiry.min()
            self._universe = [
                self.add_option_contract(symbol)
                for symbol in chain[(chain.expiry == expiry) & (chain.delta >= 0.99)].index
            ]
        # Plot the number of contracts in the universe.
        self.plot('Universe', 'Size', len(self._universe))
```

Example 4: Wheel Strategy

The Wheel strategy is a popular trading strategy for Options that enables traders to build a steady flow of income from Equity assets they want to hold for the long term.

```py
class EquityOptionExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 5)
        self.set_end_date(2024, 9, 5)
        self.set_cash(1000000000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Set the data normalization mode as raw for option strike-price comparability.
        self.spy = self.add_equity("SPY", data_normalization_mode=DataNormalizationMode.RAW).symbol
        # Set OTM threshold for wheel strategy profit margin.
        self.otm_threshold = 0.05

    def on_data(self, slice: Slice) -> None:
        # To use the latest underlying price to filter the option contract, ensure the SPY in the bar data.
        # Open short put contract position only when the last wheel is completed.
        if not self.portfolio.invested and self.spy in slice.bars:
            # Initiate the wheel by shorting a least-OTM put contract that the strike is below the threshold.
            symbol = self.get_target_contract(OptionRight.PUT, slice.bars[self.spy].price * (1 - self.otm_threshold))
            self.set_holdings(symbol, -0.2)
        # Open short call contract position only when the put is assigned (portfolio with the underlying) to close the wheel and
underlying position by the call assignment.
        elif self.portfolio[self.spy].invested and self.spy in slice.bars:
            # Short the corresponding number of a least-OTM call contract that the strike is above the threshold.
            symbol = self.get_target_contract(OptionRight.CALL, slice.bars[self.spy].price * (1 + self.otm_threshold))
            self.market_order(symbol, self.portfolio[self.spy].quantity /
self.securities[self.spy].symbol_properties.contract_multipliers)

    def get_target_contract(self, right: OptionRight, target_price: float) -> Symbol:
        # Get all tradable option contracts for SPY at the current time for filtering.
        contract_symbols = self.option_chain(self.spy)
        if not contract_symbols:
            return
        # Filter for the least-OTM contract that is off by the threshold to form the wheel.
        # Expiry is set to be at least 30 days to earn the time decay, which is highest in the last month.
        expiry = min(x.id.date for x in contract_symbols)
        filtered = [x for x in contract_symbols \
            if x.id.date == expiry \
            and x.id.option_right == right \
            and (x.id.strike_price >= target_price if right == OptionRight.CALL else x.id.strike_price <= target_price)]
        sorted_by_strikes = sorted(filtered, key=lambda x: x.id.strike_price)
        selected = sorted_by_strikes[0] if right == OptionRight.CALL else sorted_by_strikes[-1]
        # Request the selected contract data for trading.
        return self.add_option_contract(selected).symbol
```

For more details, refer to the Wheel Strategy research post .

Example 5: Scan and Update Option Chain Every 5 Minutes

The following example shows how to update the Option chain every five minutes. The `OptionChainManager` class implements the selection logic and manages the contract subscriptions.

```py
class OptionChainFullExample(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(100000)

        self.universe_settings.asynchronous = True
        self.universe_settings.minimum_time_in_universe = timedelta(minutes=0)
        # Seed the security price to ensure the underlying price data is ready at the initial filtering
        self.settings.seed_initial_prices = True
        # Set the data normalization mode as raw for option strike-price comparability
        spy = self.add_equity("SPY", data_normalization_mode=DataNormalizationMode.RAW).symbol
        # Set up a OptionChainManager to filter the contracts based on latest data by request
        self._chain_manager = {
            Symbol.create_canonical_option(spy): OptionChainManager(-10, 10, 0, 7)
        }
        # Daily population of the available contracts to ensure the contracts are tradable
        self._populate_option_chain()
        self.schedule.on(
            self.date_rules.every_day(spy), self.time_rules.after_market_open(spy, 1), self._populate_option_chain
        )
        # Filter for contract in every 5 minutes interval through scheduled event
        self.schedule.on(self.date_rules.every_day(spy), self.time_rules.every(timedelta(minutes=5)), self._filter)

    def _populate_option_chain(self):
        # The contract list is updated daily, so we can get it and apply
        # the expiration filter as soon as the market opens.
        for symbol, manager in self._chain_manager.items():
            manager.set_chain(self.option_chain(symbol), self.time)
        self._filter()
```

```
        self._filter()

    def _filter(self):
        for symbol, manager in self._chain_manager.items():
            manager.select(self, symbol)

    def on_data(self, slice: Slice) -> None:
        # Iterate the saved symbol and chain manager to obtain only the contract wanted
        for symbol, _ in self._chain_manager.items():
            chain = slice.option_chains.get(symbol)
            if not chain:
                continue
            expiry = min([x.expiry for x in chain])
            contracts = [
                x for x in chain
                if x.expiry == expiry and x.right == OptionRight.CALL and self.securities[x.symbol].is_tradable
            ]
            if not contracts:
                continue
            atm_call = sorted(contracts, key=lambda x: abs(chain.underlying.price-x.strike))[0]

            if not self.portfolio[atm_call.symbol].invested:

        for symbol in symbols - self._symbols:
            self._symbols.add(symbol)
            algorithm.add_option_contract(symbol)
```

Equity Options

Handling Data

Introduction

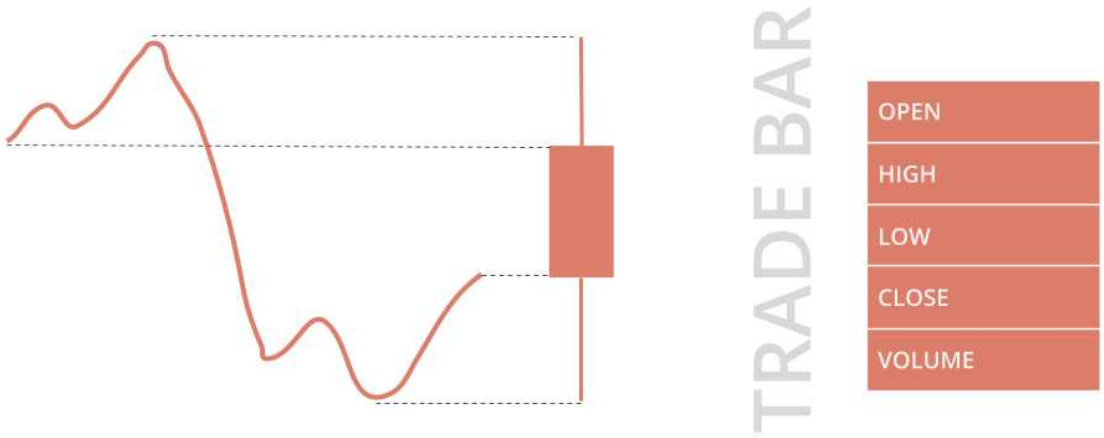
LEAN passes the data you request to the `on_data` method so you can make trading decisions. The `Slice` object that the `on_data` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `on_data` method, use the `current_slice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars` `DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the contract ticker or `symbol` , but we recommend you use the `symbol` .

To view the resolutions that are available for Equity Options data, see Resolutions .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `bars` property of the `Slice` with the contract `symbol` . If the contract doesn't actively trade or you are in the same time step as when you added the contract subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for your contract before you index the `Slice` with the contract `symbol` .

```
def on_data(self, slice: Slice) -> None:
    # Obtain the mapped TradeBar of the symbol if any
    trade_bar = slice.bars.get(self._contract_symbol)   # None if not found
```

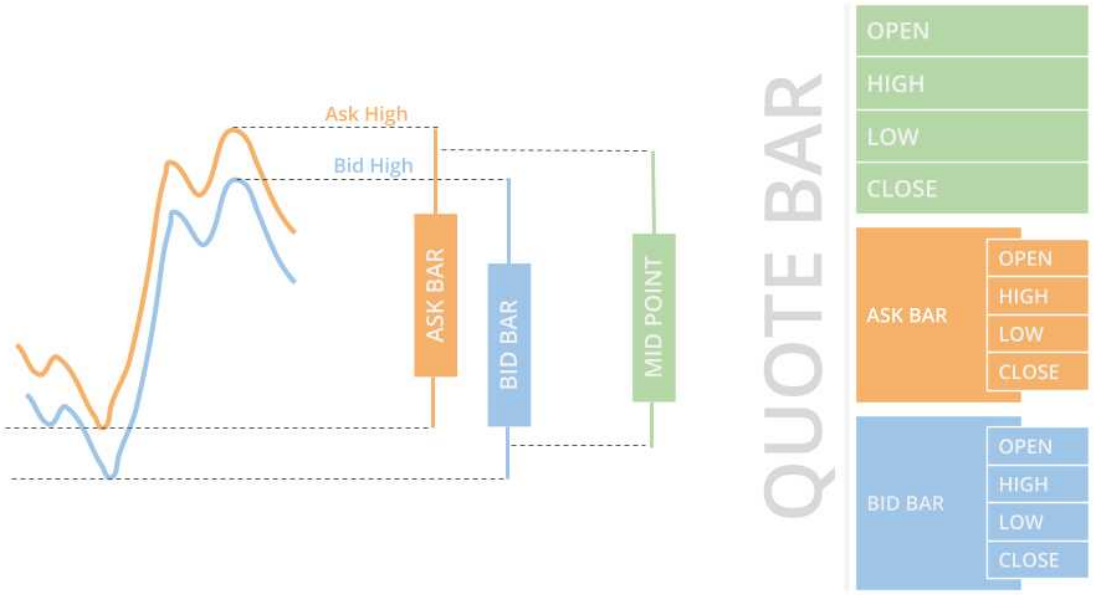
You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Symbol-TradeBar key-value pairs
    for symbol, trade_bar in slice.bars.items():
        close_price = trade_bar.close
```

`TradeBar` objects have the following properties:

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `open` , `high` , `low` , and `close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `open` , `high` , `low` , and `close` properties of the `QuoteBar` copy the values of either the `bid` or `ask` instead of taking their mean.



To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the contract `symbol` . If the contract doesn't actively get quotes or you are in the same time step as when you added the contract subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for your contract before you index the `Slice` with the contract `symbol` .

```
def on_data(self, slice: Slice) -> None:
    # Obtain the mapped QuoteBar of the symbol if any
    quote_bar = slice.quote_bars.get(self._contract_symbol)   # None if not found
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Symbol-QuoteBar key-value pairs
    for symbol, quote_bar in slice.quote_bars.items():
        ask_price = quote_bar.ask.close
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

`QuoteBar` objects have the following properties:

Option Chains

`OptionChain` objects represent an entire chain of Option contracts for a single underlying security.

To get the `OptionChain` , index the `option_chains` property of the `Slice` with the canonical `Symbol` .

```
def on_data(self, slice: Slice) -> None:
    # Try to get the OptionChain using the canonical symbol (None if no OptionChain return)
    chain = slice.option_chains.get(self._contract_symbol.Canonical)
    if chain:
        # Get all contracts if the OptionChain contains any member
        contracts = chain.contracts
```

You can also loop through the `option_chains` property to get each `OptionChain` .

```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Canonical Symbol-OptionChain key-value pairs
    for canonical_symbol, chain in slice.option_chains.items():
        contracts = chain.contracts
```

`OptionChain` objects have the following properties:

Option Contracts

`OptionContract` objects represent the data of a single Option contract in the market. To get the Option contracts in the `Slice` , use the `contracts` property of the `OptionChain` .

```
def on_data(self, slice: Slice) -> None:
    # Try to get the OptionChain using the canonical symbol
    chain = slice.option_chains.get(self._contract_symbol.canonical)
    if chain:
        # Get individual contract data
        contract = chain.contracts.get(self._contract_symbol)
        if contract:
            price = contract.price
```

Greeks and Implied Volatility

To get the Greeks and implied volatility of an Option contract, use the `greeks` and `implied_volatility` members.

```
def on_data(self, slice: Slice) -> None:
    # Try to get the OptionChain using the canonical symbol
    chain = slice.option_chains.get(self._contract_symbol.canonical)
    if chain:
        # Get individual contract data
        contract = chain.contracts.get(self._contract_symbol)
        if contract:
            # Get greeks data of the selected contract
            delta = contract.greeks.delta
            iv = contract.implied_volatility
```

LEAN only calculates Greeks and implied volatility when you request them because they are expensive operations. If you invoke the `greeks` property, the Greeks aren't calculated. However, if you invoke the `greeks.delta` , LEAN calculates the delta. To avoid unecessary computation in your algorithm, only request the Greeks and implied volatility when you need them. For more information about the Greeks and implied volatility, see Options Pricing .

Open Interest

Open interest is the number of outstanding contracts that haven't been settled. It provides a measure of investor interest and the market liquidity, so it's a popular metric to use for contract selection. Open interest is calculated once per day. To get the latest open interest value, use the `open_interest` property of the `Option` or `option_contract` .

```
def on_data(self, slice: Slice) -> None:
    # Try to get the option_chains using the canonical symbol
    chain = slice.option_chains.get(self._contract_symbol.canonical)
    if chain:
        # Get individual contract data
        contract = chain.contracts.get(self._contract_symbol)
        if contract:
            # Get the open interest of the selected contracts
            open_interest = contract.open_interest
```

Properties

`OptionContract` objects have the following properties:

Examples

Example 1: Get Mid Price For Individual Contracts

This example shows how to handle `QuoteBar` data for shortlisted Equity Option contracts to calculate mid price using bid close and ask close data,

while filter individual option contracts and request data using `self.option_chain` method for the contracts that expires within the current week. Using mid price, we can examine the market fair value of the Option and compare with model theoretical price.

```
class EquityOptionHandlingDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)

        self.contracts = []

        # Seed the price with last known price to ensure the underlying price data is available on initial option contract filtering.
        self.settings.seed_initial_prices = True
        # Subscribe to underlying data for ATM calculation using the update underlying price.
        # Set data normalization mode to raw is required to ensure strike price and underlying price is comparable.
        self.spy = self.add_equity("SPY", data_normalization_mode=DataNormalizationMode.RAW).symbol

        # Update the tradable contracts daily before market open since the option contract list provider populate them daily.
        self.schedule.on(
            self.date_rules.every_day(self.spy),
            self.time_rules.at(9, 0),
            self.update_contracts
        )

    def update_contracts(self) -> None:
        # Get all contracts that expiring this week to trade with, subscribe to data for trading need.
        contracts = self.option_chain(self.spy)
        self.contracts = [self.add_option_contract(x).symbol for x in contracts
            if x.id.date < Expiry.end_of_week(self.time)]

    def on_data(self, slice: Slice) -> None:
        # Only focus on filtered list of option contracts to trade.
        for contract in self.contracts:
            # Mid price can only be calculated when quote bar data is available.
            quote = slice.quote_bars.get(contract)
            if quote and quote.bid is not None and quote.ask is not None:
                # Mid price = average of bid close price and ask close price.
                mid_price = (quote.bid.close + quote.ask.close) * 0.5
```

Example 2: Get Mid Price For Universe

This example shows how to handle `QuoteBar` data for shortlisted Equity Option contracts to calculate mid price using bid close and ask close data, while request data through universe selection function using `set_filter` method for the contracts that expires within the current week. Using mid price, we can examine the market fair value of the Option and compare with model theoretical price.

```
class EquityOptionHandlingDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)

        # Seed the price with last known price to ensure the underlying price data is available on initial option contract filtering.
        self.settings.seed_initial_prices = True
        # Subscribe to underlying data for ATM calculation using the update underlying price.
        # Set data normalization mode to raw is required to ensure strike price and underlying price is comparable.
        spy = self.add_equity("SPY", data_normalization_mode=DataNormalizationMode.RAW).symbol
        # Subscribe to SPY option data.
        option = self.add_option(spy)
        self._symbol = option.symbol
        # We wish to only trade the contracts expiring within the same week since they have the highest volume.
        option.set_filter(lambda u: u.contracts(lambda x: [s for s in x if s.id.date <= Expiry.end_of_week(self.time)]))

    def on_data(self, slice: Slice) -> None:
        # Only want to obtain the option chain of the selected symbol.
        chain = slice.option_chains.get(self._symbol)
        if not chain:
            return

        for contract in chain:
            # Mid price = average of bid close price and ask close price
            mid_price = (contract.bid_price + contract.ask_price) * 0.5
```

Example 3: Get Instant Delta

The option greeks change rapidly, so we need to obtain the instant greeks to accurately calculate the hedge size for arbitration or replication portfolio. You can call the `Greeks` property from the `OptionChain` data to access various greeks. In this example, we will demonstrate how to obtain the contract with delta closest to 0.4 among all call contracts expiring the same week.

```py
class EquityOptionHandlingDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 5)
        self.set_end_date(2024, 9, 5)

        # Seed the price with last known price to ensure the underlying price data is available on initial option contract filtering.
        self.settings.seed_initial_prices = True
        # Subscribe to underlying data for ATM calculation using the update underlying price.
        # Set data normalization mode to raw is required to ensure strike price and underlying price is comparable.
        spy = self.add_equity("SPY", data_normalization_mode=DataNormalizationMode.RAW).symbol
        # Subscribe to SPY option data.
        option = self.add_option(spy)
        self._symbol = option.symbol
        # We wish to only trade the contracts expiring within the same week since they have the highest volume.
        # 0.4 Delta will only appear in call contracts.
        option.set_filter(lambda u: u.delta(0.2, 0.6).contracts(lambda x: [s for s in x if s.id.date <= Expiry.end_of_week(self.time)]))

    def on_data(self, slice: Slice) -> None:
        # Only want to obtain the option chain of the selected symbol.
        chain = slice.option_chains.get(self._symbol)
        if not chain:
            return

        # Get the contract with Delta closest to 0.4 to trade.
        # The arbitary delta criterion might be set due to hedging need or risk adjustment.
        selected = sorted(chain, key=lambda x: abs(x.greeks.delta - 0.4))[0]
```

Example 4: Delta-Hedged Short Straddle

This example demonstrates a delta-hedged short straddle strategy that sells an at-the-money (ATM) straddle with 7-30 days to expiration and continuously neutralizes the portfolio delta using the underlying shares. The `StraddleSelector` helper class picks the farthest expiry within the DTE range and the strike closest to the spot price. On each slice , the combined Option delta is accumulated from the `OptionChain` and the net portfolio delta is computed by adding the underlying position. The `DeltaHedger` helper enforces a minimum share threshold and a rehedge band to avoid over-trading, and applies a time delay between successive hedges. A Scheduled Event closes the straddle on expiration day and assignment events are handled to keep the underlying position clean.

```py
class DeltaHedgedStraddleAlgo(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1_000_000)
        self.settings.seed_initial_prices = True
        self._spy = self.add_equity("SPY", data_normalization_mode=DataNormalizationMode.RAW)
        # Initialize the straddle selector with 7-30 day DTE range.
        self._straddle_selector = StraddleSelector(min_dte=7, max_dte=30)
        # Initialize the delta hedger with 30 share minimum, 20 share rehedge band, and 4 hour delay.
        self._hedger = DeltaHedger(30, 20, timedelta(hours=4))
        self._canonical_option = Symbol.create_canonical_option(self._spy)
        # Set the straddle position size to 50% of portfolio value.
        self._straddle_weight = 0.5
        self._short_straddle = None
        self._exit_day = None
        # Schedule the rebalance method to run 30 minutes after market open.
        self.schedule.on(
            self.date_rules.every_day(self._spy),
            self.time_rules.after_market_open(self._spy, 30),
            self._rebalance
        )
        # Schedule the close expiring method to run 60 minutes before market close.
        self.schedule.on(
            self.date_rules.every_day(self._spy),

```

Equity Options

Greeks and Implied Volatility

The Greeks are measures that describe the sensitivity of an Option's price to various factors like underlying price changes (Delta), time decay (Theta), volatility (Vega), and interest rates (Rho), while Implied Volatility (IV) represents the market's expectation of the underlying asset's volatility over the life of the Option.

Greeks and Implied Volatility

Key Concepts

Introduction

LEAN provides multiple ways for you to get the Greeks and implied volatility (IV) of Option contracts. There is a daily, pre-calculated dataset based on the end of the previous trading day. There is also a stream of values that are calculated on-the-fly as your algorithm runs.

Greeks on Universes

The Greeks and IV values in the filter function are the daily, pre-calculated values based on the end of the previous trading day.

```py
def initialize(self):
    option = self.add_option("SPY")
    option.set_filter(lambda universe: universe.delta(0.3, 0.7).expiration(0,7))
```

To calculate the values, we use our implementation of the forward tree pricing model, which accounts for the interest rate and dividend payments.

You can't customize the Greeks and IV values that the filter function receives. However, you can create indicators to customize how the Greeks and IV are calculated for the contracts already in your universe.

Greek History

The Greeks and IV values that you get from a history request of the Option universe are the daily, pre-calculated values based on the end of the previous trading day.

```py
class OptionHistoryAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        option = self.add_option('SPY')
        # DataFrame example:
        history_df = self.history(option.symbol, 5, flatten=True)
        # OptionUniverse objects example:
        history = self.history[OptionUniverse](option.symbol, 5)
        for chain in history:
            end_time = chain.end_time
            filtered_contracts = [c for c in chain if c.greeks.delta > 0.3]
            for contract in filtered_contracts:
                symbol = contract.symbol
                expiry = contract.id.date
                strike = contract.id.strike_price
                price = contract.close
                iv = contract.implied_volatility
```

You can't customize the Greeks and IV values that you get from a history request. However, you can create indicators to customize how the Greeks and IV are calculated for the contracts already in your universe.

Greeks on Data Events

The Greeks and IV values that you get from the current Slice are from the price model calculations. These values aren't the same as the values you get in the universe filter function.

```
class OptionDataEventsAlgorithm(QCAlgorithm):

    def initialize(self):
        option = self.add_option("GOOG")
        option.price_model = OptionPriceModels.binomial_cox_ross_rubinstein()

    def on_data(self, data):
        for canonical_symbol, chain in data.option_chains.items():
            for contract in chain:
                iv = contract.implied_volatility
                delta = contract.greeks.delta
```

To view all the models LEAN supports, see Supported Models .

Greek Indicators

The Greeks and IV values that you get from the indicators are calculated in the same way as the values you get in the filter function, but they can reflect intraday prices instead of just the daily closing prices.

For Equity Options, the `indicator_history` uses the `SCALED_RAW` data normalization mode when requesting historical prices.

Examples

For detailed examples on using Option Greeks and Implied Volatility indicators in algorithm, you may refer to the Greeks Indicators page examples.

Greeks and Implied Volatility

Indicators

Introduction

Option indicators enable you to calculate daily and intraday values for the Greeks and implied volatility of Option contracts. This page explains the most popular Option indicators and how to use them with LEAN.

Parameters

The following table describes the arguments that the automatic Option indicators methods accept:

Argument	Data Type	Description	Default Value
`symbol`	`Symbol`	The contract to use when calculating the indicator values.	
`mirror_option`	`Symbol`	The mirror contract to use in parity type calculations.	`None`
`risk_free_rate`	`float`	The risk-free interest rate. If you don't provide a value, the default value is the US primary credit rate from the Interest Rate Provider Model .	`None`
`dividend_yield`	`float`	The dividend yield rate. If you don't provide a value, the default value comes from the Dividend Yield Provider Model .	`None`
`option_model`	`OptionPricingModelType`	The Option pricing model that's used to calculate the Greeks. If you don't provide a value, the default value is `OptionPricingModelType.BinomialCoxRossRubinstein` for Equity Options.	`None`
`resolution`	`Resolution`	The resolution of the indicator data. If you don't provide a value, the default value is the resolution of the subscription you have for the Option contract(s).	`None`

To perform implied volatility (IV) smoothing with a put-call pair, pass one of the contracts as the `symbol` argument and pass the other contract in the pair as the `mirror_option` argument. The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, call the `set_smoothing_function` method of the `ImpliedVolatility` class/property.

Several different Option pricing models are supported to calculate the IV and Greeks. The following table describes the `OptionPricingModelType` enumeration members:

Implied Volatility

Implied volatility, , is the market's expectation for the future volatility of an asset and is implied by the price of the assets's Options contracts. You can't observe it in the market but you can derive it from the price of an Option. For more information about implied volatility, see Implied Volatility .

Automatic Indicators

To create an automatic indicator for implied volatility, call the `QCAlgorithm.iv` method with the Option contract `symbol` object(s).

```
class AutomaticImpliedVolatilityIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_equity('SPY', data_normalization_mode=DataNormalizationMode.RAW).symbol

        # Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )
        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]

        # Get the ImpliedVolatility indicator of each contract.
        for canonical, chain in slice.option_chains.items():
            for symbol in chain:
                option = self.securities[symbol]
                indicator = option.iv
        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

For more information about the `iv` method, see Parameters and Using IV Indicator .

Manual Indicators

To create a manual indicator for implied volatility, call the `ImpliedVolatility` constructor.

```
class ManualImpliedVolatilityIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset
```

```
        # Subscribe to the underlying asset.
        self._underlying = self.add_equity('SPY', data_normalization_mode=DataNormalizationMode.RAW).symbol
        # Set up the dividend yield provider for the underlying.
        self._dividend_yield_provider = DividendYieldProvider(self._underlying)
        # Define the Option pricing model.
        self._option_pricing_model = OptionPricingModelType.FORWARD_TREE

        # Set up a Scheduled Event to select contract and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )

        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index

                    option.id.strike_price, option.id.date
                )
                # Check if price data is available for both contracts and the underlying asset.
                q = slice.quote_bars
                b = slice.bars
                if option in q and mirror in q and underlying in b:
                    data_points = [
                        IndicatorDataPoint(option, q[option].end_time, q[option].close),
                        IndicatorDataPoint(mirror, q[mirror].end_time, q[mirror].close),
                        IndicatorDataPoint(
                            underlying, b[underlying].end_time, b[underlying].close
                        )
                    ]
                    for data_point in data_points:
                        indicator.update(data_point)

                    # Get the current value of the ImpliedVolatility indicator.
                    value = indicator.current.value

        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if not self._underlying and self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

For more information about the `ImpliedVolatility` constructor, see Using IV Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirror_option` argument to the `iv` method or `ImpliedVolatility` constructor and then call the `set_smoothing_function` method of the resulting `ImpliedVolatility` object. The follow table describes the arguments of the custom function:

Argument	Data Type	Description
`iv`	`float`	The IV of the Option contract.
`mirror_iv`	`float`	The IV of the mirror Option contract.

The method must return a `float` as the smoothened IV.

```
def initialize(self):
    option = Symbol.create_option("AAPL", Market.USA, OptionStyle.AMERICAN, OptionRight.PUT, 505, datetime(2014, 6, 27))
    self.add_option_contract(option)

    mirror_option = Symbol.create_option("AAPL", Market.USA, OptionStyle.AMERICAN, OptionRight.CALL, 505, datetime(2014, 6, 27))
    self.add_option_contract(mirror_option)

    self._iv = self.iv(option, mirror_option)
    # Example: The average of the call-put pair.
    self._iv.set_smoothing_function(lambda iv, mirror_iv: (iv + mirror_iv) * 0.5)
```

PY

Delta

Delta, , is the rate of change of the Option price with respect to the price of the underlying asset. It measures the first-order sensitivity of the price to a movement in underlying price. For example, an Option delta of 0.4 means that if the underlying asset moves by 1%, then the value of the Option moves by 0.4 1% = 0.4%. For more information about delta, see Delta .

Automatic Indicators

To create an automatic indicator for delta, call the `QCAlgorithm.d` method with the Option contract `symbol` object(s).

```py
class AutomaticDeltaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_equity('SPY', data_normalization_mode=DataNormalizationMode.RAW).symbol

        # Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )
        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_option_contract(call)
            contract2 = self.add_option_contract(put)

            # Create and save the automatic Delta indicators.
            contract1.d = self.d(call, put)
            contract2.d = self.d(put, call)

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Get the Delta indicator of each contract.
        for canonical, chain in slice.option_chains.items():
            for symbol in chain:
                option = self.securities[symbol]
                indicator = option.d
        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

The follow table describes the arguments that the `d` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`iv_model`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating Delta. If you don't provide a value, the default value is to match the `option_model` parameter.	`None`

For more information about the `d` method, see Using D Indicator .

Manual Indicators

To create a manual indicator for delta, call the `Delta` constructor.

```py
class ManualDeltaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_equity('SPY', data_normalization_mode=DataNormalizationMode.RAW).symbol
        # Set up the dividend yield provider for the underlying.
        self._dividend_yield_provider = DividendYieldProvider(self._underlying)
        # Define the Option pricing model.
        self._option_pricing_model = OptionPricingModelType.FORWARD_TREE

        # Set up a Scheduled Event to select contract and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )

        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_option_contract(call)
            contract2 = self.add_option_contract(put)

            # Create and save the automatic Delta indicators.
            for contract_a, contract_b in [(contract1, contract2), (contract2, contract1)]:
                contract_a.Delta = Delta(
                        contract_a.symbol, self.risk_free_interest_rate_model,
                        self._dividend_yield_provider, contract_b.symbol, self._option_pricing_model
                    )

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Iterate through the indicators.
        for canonical, chain in slice.option_chains.items():
            for option in chain:
                underlying = option.symbol.underlying
                indicator = self.securities[option].Delta
                mirror = Symbol.create_option(
                    underlying.value, option.id.market, option.id.option_style,
                    OptionRight.Call if option.id.option_right == OptionRight.PUT else OptionRight.PUT,
                    option.id.strike_price, option.id.date
                )
                # Check if price data is available for both contracts and the underlying asset.
                q = slice.quote_bars
                b = slice.bars
                if option in q and mirror in q and underlying in b:
                    data_points = [
                        IndicatorDataPoint(option, q[option].end_time, q[option].close),
                        IndicatorDataPoint(mirror, q[mirror].end_time, q[mirror].close),
                        IndicatorDataPoint(
                            underlying, b[underlying].end_time, b[underlying].close
                        )
```

```
                    ]
                    for data_point in data_points:
                        indicator.update(data_point)

                    # Get the current value of the Delta indicator.
                    value = indicator.current.value

        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if not self._underlying and self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

For more information about the `Delta` constructor, see Using D Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirror_option` argument to the indicator method or constructor and then call the `set_smoothing_function` method of the `implied_volatility` property of the indicator.

```
PY
# Example: Average IV of the call-put pair.
delta_indicator.implied_volatility.set_smoothing_function(lambda iv, mirror_iv: (iv + mirror_iv) * 0.5)
```

Gamma

Gamma, , is the rate of change of the portfolio's delta with respect to the underlying asset's price. It represents the second-order sensitivity of the Option to a movement in the underlying asset's price. For more information about Gamma, see Gamma .

Automatic Indicators

To create an automatic indicator for gamma, call the `QCAlgorithm.g` method with the Option contract `symbol` object(s).

```py
class AutomaticGammaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_equity('SPY', data_normalization_mode=DataNormalizationMode.RAW).symbol

        # Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),

            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_option_contract(call)
            contract2 = self.add_option_contract(put)

            # Create and save the automatic Gamma indicators.
            contract1.g = self.g(call, put)
            contract2.g = self.g(put, call)

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Get the Gamma indicator of each contract.
        for canonical, chain in slice.option_chains.items():
            for symbol in chain:
                option = self.securities[symbol]
                indicator = option.g
        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

The follow table describes the arguments that the `g` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`iv_model`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating Gamma. If you don't provide a value, the default value is to match the `option_model` parameter.	`None`

For more information about the `g` method, see Using G Indicator .

Manual Indicators

To create a manual indicator for gamma, call the `Gamma` constructor.

```py
class ManualGammaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_equity('SPY', data_normalization_mode=DataNormalizationMode.RAW).symbol
        # Set up the dividend yield provider for the underlying.
        self._dividend_yield_provider = DividendYieldProvider(self._underlying)
        # Define the Option pricing model.
        self._option_pricing_model = OptionPricingModelType.FORWARD_TREE

        # Set up a Scheduled Event to select contract and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )

        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_option_contract(call)
            contract2 = self.add_option_contract(put)

            # Create and save the automatic Gamma indicators.
            for contract_a, contract_b in [(contract1, contract2), (contract2, contract1)]:
                contract_a.Gamma = Gamma(
                        contract_a.symbol, self.risk_free_interest_rate_model,
                        self._dividend_yield_provider, contract_b.symbol, self._option_pricing_model
                    )

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Iterate through the indicators.
        for canonical, chain in slice.option_chains.items():
            for option in chain:
                underlying = option.symbol.underlying
                indicator = self.securities[option].Gamma
                mirror = Symbol.create_option(
                    underlying.value, option.id.market, option.id.option_style,
                    OptionRight.Call if option.id.option_right == OptionRight.PUT else OptionRight.PUT,
                    option.id.strike_price, option.id.date
                )
                # Check if price data is available for both contracts and the underlying asset.
                q = slice.quote_bars
                b = slice.bars
                if option in q and mirror in q and underlying in b:
                    data_points = [
                        IndicatorDataPoint(option, q[option].end_time, q[option].close),
                        IndicatorDataPoint(mirror, q[mirror].end_time, q[mirror].close),
                        IndicatorDataPoint(
                            underlying, b[underlying].end_time, b[underlying].close
                        )
```

```
                    ]
                    for data_point in data_points:
                        indicator.update(data_point)

                    # Get the current value of the Gamma indicator.
                    value = indicator.current.value

        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if not self._underlying and self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

For more information about the `Gamma` constructor, see Using G Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirror_option` argument to the indicator method or constructor and then call the `set_smoothing_function` method of the `implied_volatility` property of the indicator.

```
PY
# Example: Average IV of the call-put pair.
gamma_indicator.implied_volatility.set_smoothing_function(lambda iv, mirror_iv: (iv + mirror_iv) * 0.5)
```

Vega

Vega, , is the rate of change in the value of the Option with respect to the volatility of the underlying asset. For more information about vega, see Vega .

Automatic Indicators

To create an automatic indicator for vega, call the `QCAlgorithm.v` method with the Option contract `symbol` object(s).

```
class AutomaticVegaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_equity('SPY', data_normalization_mode=DataNormalizationMode.RAW).symbol

        # Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )
        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_option_contract(call)
            contract2 = self.add_option_contract(put)

            # Create and save the automatic Vega indicators.
            contract1.v = self.v(call, put)
            contract2.v = self.v(put, call)

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Get the Vega indicator of each contract.
        for canonical, chain in slice.option_chains.items():
            for symbol in chain:
                option = self.securities[symbol]
                indicator = option.v
        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

The follow table describes the arguments that the `v` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`iv_model`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating Vega. If you don't provide a value, the default value is to match the `option_model` parameter.	`None`

For more information about the `v` method, see Using V Indicator .

Manual Indicators

To create a manual indicator for vega, call the Vega constructor.

PY

```
class ManualVegaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_equity('SPY', data_normalization_mode=DataNormalizationMode.RAW).symbol
        # Set up the dividend yield provider for the underlying.
        self._dividend_yield_provider = DividendYieldProvider(self._underlying)
        # Define the Option pricing model.
        self._option_pricing_model = OptionPricingModelType.FORWARD_TREE

        # Set up a Scheduled Event to select contract and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )

        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.

        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_option_contract(call)
            contract2 = self.add_option_contract(put)

            # Create and save the automatic Vega indicators.
            for contract_a, contract_b in [(contract1, contract2), (contract2, contract1)]:
                contract_a.Vega = Vega(
                        contract_a.symbol, self.risk_free_interest_rate_model,
                        self._dividend_yield_provider, contract_b.symbol, self._option_pricing_model
                    )

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Iterate through the indicators.
        for canonical, chain in slice.option_chains.items():
            for option in chain:
                underlying = option.symbol.underlying
                indicator = self.securities[option].Vega
                mirror = Symbol.create_option(
                    underlying.value, option.id.market, option.id.option_style,
                    OptionRight.Call if option.id.option_right == OptionRight.PUT else OptionRight.PUT,
                    option.id.strike_price, option.id.date
                )
                # Check if price data is available for both contracts and the underlying asset.
                q = slice.quote_bars
                b = slice.bars
                if option in q and mirror in q and underlying in b:
                    data_points = [
                        IndicatorDataPoint(option, q[option].end_time, q[option].close),
                        IndicatorDataPoint(mirror, q[mirror].end_time, q[mirror].close),
                        IndicatorDataPoint(
                            underlying, b[underlying].end_time, b[underlying].close
                        )
```

```
                    ]
                    for data_point in data_points:
                        indicator.update(data_point)

                    # Get the current value of the Vega indicator.
                    value = indicator.current.value

        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if not self._underlying and self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

For more information about the `Vega` constructor, see Using V Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirror_option` argument to the indicator method or constructor and then call the `set_smoothing_function` method of the `implied_volatility` property of the indicator.

```
PY
# Example: Average IV of the call-put pair.
vega_indicator.implied_volatility.set_smoothing_function(lambda iv, mirror_iv: (iv + mirror_iv) * 0.5)
```

Theta

Theta, , is the rate of change of the value of the Option with respect to the passage of time. It is also known to as the time decay of an Option. For more information about theta, see Theta .

Automatic Indicators

To create an automatic indicator for theta, call the `QCAlgorithm.t` method with the Option contract `symbol` object(s).

```py
class AutomaticThetaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_equity('SPY', data_normalization_mode=DataNormalizationMode.RAW).symbol

        # Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )
        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_option_contract(call)
            contract2 = self.add_option_contract(put)

            # Create and save the automatic Theta indicators.
            contract1.t = self.t(call, put)
            contract2.t = self.t(put, call)

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Get the Theta indicator of each contract.
        for canonical, chain in slice.option_chains.items():
            for symbol in chain:
                option = self.securities[symbol]
                indicator = option.t
        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

The follow table describes the arguments that the `t` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`iv_model`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating theta. If you don't provide a value, the default value is to match the `option_model` parameter.	`None`

For more information about the `t` method, see Using T Indicator .

Manual Indicators

To create a manual indicator for theta, call the `Theta` constructor.

```py
class ManualThetaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_equity('SPY', data_normalization_mode=DataNormalizationMode.RAW).symbol
        # Set up the dividend yield provider for the underlying.
        self._dividend_yield_provider = DividendYieldProvider(self._underlying)
        # Define the Option pricing model.
        self._option_pricing_model = OptionPricingModelType.FORWARD_TREE

        # Set up a Scheduled Event to select contract and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )

        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_option_contract(call)
            contract2 = self.add_option_contract(put)

            # Create and save the automatic Theta indicators.
            for contract_a, contract_b in [(contract1, contract2), (contract2, contract1)]:
                contract_a.Theta = Theta(
                        contract_a.symbol, self.risk_free_interest_rate_model,
                        self._dividend_yield_provider, contract_b.symbol, self._option_pricing_model
                    )

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Iterate through the indicators.
        for canonical, chain in slice.option_chains.items():
            for option in chain:
                underlying = option.symbol.underlying
                indicator = self.securities[option].Theta
                mirror = Symbol.create_option(
                    underlying.value, option.id.market, option.id.option_style,
                    OptionRight.Call if option.id.option_right == OptionRight.PUT else OptionRight.PUT,
                    option.id.strike_price, option.id.date
                )
                # Check if price data is available for both contracts and the underlying asset.
                q = slice.quote_bars
                b = slice.bars
                if option in q and mirror in q and underlying in b:
                    data_points = [
                        IndicatorDataPoint(option, q[option].end_time, q[option].close),
                        IndicatorDataPoint(mirror, q[mirror].end_time, q[mirror].close),
                        IndicatorDataPoint(
                            underlying, b[underlying].end_time, b[underlying].close
                        )
```

```
                    ]
                    for data_point in data_points:
                        indicator.update(data_point)

                    # Get the current value of the Theta indicator.
                    value = indicator.current.value

        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if not self._underlying and self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

For more information about the `Theta` constructor, see Using T Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirror_option` argument to the indicator method or constructor and then call the `set_smoothing_function` method of the `implied_volatility` property of the indicator.

```
PY
# Example: Average IV of the call-put pair.
theta_indicator.implied_volatility.set_smoothing_function(lambda iv, mirror_iv: (iv + mirror_iv) * 0.5)
```

Rho

Rho, , is the rate of change of the value of a derivative with respect to the interest rate . It is usually small and not a big issue in practice unless the Option is deep in-the-money and has a long horizon. In this case, the interest rate matters because you need to discount a larger cash flow over a longer horizon. For more information about rho, see Rho .

Automatic Indicators

To create an automatic indicator for rho, call the `QCAlgorithm.r` method with the Option contract `symbol` object(s).

```py
class AutomaticRhoIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_equity('SPY', data_normalization_mode=DataNormalizationMode.RAW).symbol

        # Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )
        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_option_contract(call)
            contract2 = self.add_option_contract(put)

            # Create and save the automatic Rho indicators.
            contract1.r = self.r(call, put)
            contract2.r = self.r(put, call)

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Get the Rho indicator of each contract.
        for canonical, chain in slice.option_chains.items():
            for symbol in chain:
                option = self.securities[symbol]
                indicator = option.r
        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

The follow table describes the arguments that the `r` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`iv_model`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating rho If you don't provide a value, the default value is to match the `option_model` parameter.	`None`

For more information about the `r` method, see Using R Indicator .

Manual Indicators

To create a manual indicator for rho, call the Rho constructor.

```py
class ManualRhoIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_equity('SPY', data_normalization_mode=DataNormalizationMode.RAW).symbol
        # Set up the dividend yield provider for the underlying.
        self._dividend_yield_provider = DividendYieldProvider(self._underlying)
        # Define the Option pricing model.
        self._option_pricing_model = OptionPricingModelType.FORWARD_TREE

        # Set up a Scheduled Event to select contract and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )

        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_option_contract(call)
            contract2 = self.add_option_contract(put)

            # Create and save the automatic Rho indicators.
            for contract_a, contract_b in [(contract1, contract2), (contract2, contract1)]:
                contract_a.Rho = Rho(
                        contract_a.symbol, self.risk_free_interest_rate_model,
                        self._dividend_yield_provider, contract_b.symbol, self._option_pricing_model
                    )

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Iterate through the indicators.
        for canonical, chain in slice.option_chains.items():
            for option in chain:
                underlying = option.symbol.underlying
                indicator = self.securities[option].Rho
                mirror = Symbol.create_option(
                    underlying.value, option.id.market, option.id.option_style,
                    OptionRight.Call if option.id.option_right == OptionRight.PUT else OptionRight.PUT,
                    option.id.strike_price, option.id.date
                )
                # Check if price data is available for both contracts and the underlying asset.
                q = slice.quote_bars
                b = slice.bars
                if option in q and mirror in q and underlying in b:
                    data_points = [
                        IndicatorDataPoint(option, q[option].end_time, q[option].close),
                        IndicatorDataPoint(mirror, q[mirror].end_time, q[mirror].close),
                        IndicatorDataPoint(
                            underlying, b[underlying].end_time, b[underlying].close
                        )
```

```
                    ]
                    for data_point in data_points:
                        indicator.update(data_point)

                    # Get the current value of the Rho indicator.
                    value = indicator.current.value

        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if not self._underlying and self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

For more information about the `Rho` constructor, see Using R Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirror_option` argument to the indicator method or constructor and then call the `set_smoothing_function` method of the `implied_volatility` property of the indicator.

```
PY
# Example: Average IV of the call-put pair.
rho_indicator.implied_volatility.set_smoothing_function(lambda iv, mirror_iv: (iv + mirror_iv) * 0.5)
```

Crypto

Requesting Data

Introduction

Request Crypto data in your algorithm to receive a feed of asset prices in the `on_data` method. For more information about the specific datasets we use for backtests, see the CoinAPI datasets . To trade Crypto live, you can use the QuantConnect data provider .

Create Subscriptions

To create a Crypto subscription, in the `initialize` method, call the `add_crypto` method. The `add_crypto` method returns a `Crypto` object, which contains a `symbol` property. Save a reference to the `symbol` so you can use it in `on_data` to access the security data in the `Slice` .

```
self._symbol = self.add_crypto("BTCUSD").symbol
```

The `add_crypto` method creates a subscription for a single Crypto asset and adds it to your user-defined universe. To create a dynamic universe of Crypto assets, add a Crypto universe .

To view the supported assets, see the CoinAPI datasets .

Fungible Assets

Fungible assets are assets that are interchangeable with each other. For example, every Bitcoin is effectively identical to every other Bitcoin. In contrast, non-fungible tokens (NFTs) are non-fungible because each one is unique. An example of an NFT is the Bored Ape Yacht Club collection. LEAN doesn't currently support trading NFTs.

Resolutions

The following table shows the available resolutions and data formats for Crypto subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`TICK`			✓	✓
`SECOND`	✓	✓		
`MINUTE`	✓	✓		
`HOUR`	✓	✓		
`DAILY`	✓	✓		

The default resolution for Crypto subscriptions is `Resolution.MINUTE` . To change the resolution, pass a `resolution` argument to the `add_crypto` method.

```
self._symbol = self.add_crypto("BTCUSD", Resolution.DAILY).symbol
```

To create custom resolution periods, see Consolidating Data .

Supported Markets

The following `Market` enumeration members are available for Crypto:

To set the market for a security, pass a `market` argument to the `add_crypto` method.

```
self._symbol = self.add_crypto("BTCUSD", market=Market.COINBASE).symbol
```

The brokerage models have a default market for each asset class. If you set a brokerage model, you may not need to specify the market to use.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fill_forward` argument to false when you create the security subscription.

```
self._symbol = self.add_crypto("BTCUSD", fill_forward=False).symbol
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. The amount of leverage available to you depends on the brokerage you use. To change the amount of leverage you can use for a security, pass a `leverage` argument to the `add_crypto` method.

```
self._symbol = self.add_crypto("BTCUSD", leverage=3).symbol
```

For more information about the leverage each brokerage provides, see Brokerages .

Data Normalization

The data normalization mode doesn't affect the data that LEAN passes to `on_data` or the data from history request . If you change the data normalization mode, it won't change the outcome.

Properties

The `add_crypto` method returns a `Crypto` object, which have the following properties:

Examples

The following examples demonstrate some common practices for requesting Crypto data.

Example 1: Initialize Binance Algorithms

The following algorithm requests data for the BTC/USDT and ETH/USDT Crypto pairs on Binance. The Binance brokerage model provides realistic fee and fill modeling for the backtest. Since the quote currency of both pairs is USDT, set the account currency to USDT instead of USD. Otherwise, some order will fail since the brokerage doesn't automatically convert USD to USDT for you.

```
class CryptoExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Set the brokerage and account type for accurate fee and margin behavior.
        self.set_brokerage_model(BrokerageName.BINANCE, AccountType.CASH)

        # In some Crypto brokerages, USD is not a valid currency to trade.
        # Therefore, set the account currency to USDT and add the starting cash.
        self.set_account_currency("USDT", 100000)

        # Subscribe to the Crypto pairs.
        # You don't need to specify the market because the Binance brokerage model already does that.
        self.add_crypto("BTCUSDT", market=Market.BINANCE)
        self.add_crypto("ETHUSDT", market=Market.BINANCE)
```

Crypto

Handling Data

Introduction

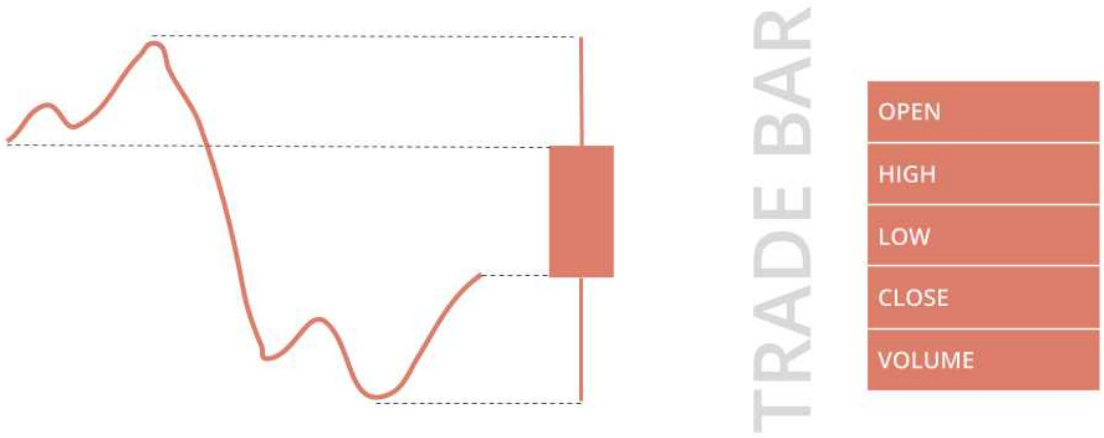
LEAN passes the data you request to the `on_data` method so you can make trading decisions. The `Slice` object that the `on_data` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `on_data` method, use the `current_slice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars` `DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the security ticker or `symbol` , but we recommend you use the `symbol` .

To view the resolutions that are available for Crypto data, see Resolutions .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `bars` property of the `Slice` with the security `symbol` . If the security doesn't actively trade or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `symbol` .

```
def on_data(self, slice: Slice) -> None:
    # Obtain the mapped TradeBar of the symbol if any
    trade_bar = slice.bars.get(self._symbol)   # None if not found
```

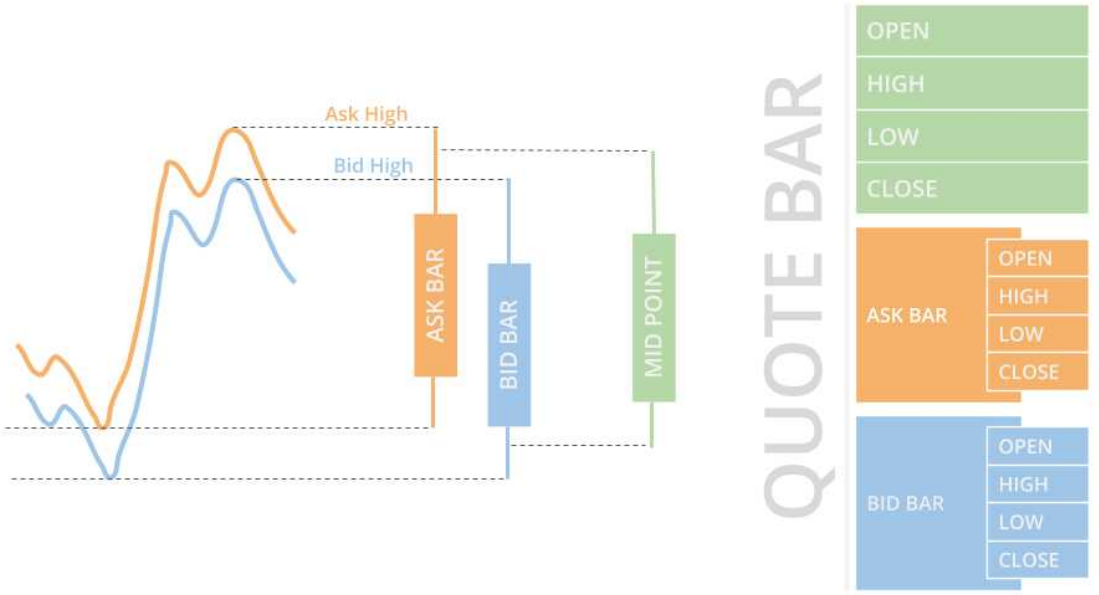
You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Symbol-TradeBar key-value pairs
    for symbol, trade_bar in slice.bars.items():
        close_price = trade_bar.close
```

`TradeBar` objects have the following properties:

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `open` , `high` , `low` , and `close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `open` , `high` , `low` , and `close` properties of the `QuoteBar` copy the values of either the `bid` or `ask` instead of taking their mean.



To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the security `symbol` . If the security doesn't actively get quotes or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `symbol` .

```
def on_data(self, slice: Slice) -> None:
    # Obtain the mapped QuoteBar of the symbol if any
    quote_bar = slice.quote_bars.get(self._symbol)   # None if not found
```

PY

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Symbol-QuoteBar key-value pairs
    for symbol, quote_bar in slice.quote_bars.items():
        ask_price = quote_bar.ask.close
```

PY

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

`QuoteBar` objects have the following properties:

Ticks

`Tick` objects represent a single trade or quote at a moment in time. A trade tick is a record of a transaction for the security. A quote tick is an offer to buy or sell the security at a specific price.

Trade ticks have a non-zero value for the `quantity` and `price` properties, but they have a zero value for the `bid_price` , `bid_size` , `ask_price` , and `ask_size` properties. Quote ticks have non-zero values for `bid_price` and `bid_size` properties or have non-zero values for `ask_price` and `ask_size` properties. To check if a tick is a trade or a quote, use the `ticktype` property.

In backtests, LEAN groups ticks into one millisecond buckets. In live trading, LEAN groups ticks into ~70-millisecond buckets. To get the `Tick` objects in the `Slice` , index the `Ticks` property of the `Slice` with a `symbol` . If the security doesn't actively trade or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `symbol` .

```
def on_data(self, slice: Slice) -> None:
    ticks = slice.ticks.get(self._symbol, [])   # Empty if not found
    for tick in ticks:
        price = tick.price
```

You can also iterate through the `Ticks` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `list[Tick]` objects.

```
def on_data(self, slice: Slice) -> None:
    for symbol, ticks in slice.ticks.items():
        for tick in ticks:
            price = tick.price
```

Tick data is raw and unfiltered, so it can contain bad ticks that skew your trade results. For example, some ticks come from dark pools, which aren't tradable. We recommend you only use tick data if you understand the risks and are able to perform your own online tick filtering.

`Tick` objects have the following properties:

Examples

The following examples demonstrate some common practices for handling Crypto data.

Example 1: Dollar Cost Average BTC

Dollar cost averaging (DCA) is where you consistently invest a fixed dollar amount into an asset on a regular basis (for example, monthly), regardless of the asset's price. It can reduce the volatility in your PnL due to slowly increasing the position size over time. The following algorithm demonstrates a DCA investment into BTC. It buys $3,000 USD worth of BTC every midnight for 30 consecutive days.

```
class CryptoExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Set a day count variable for counting the days of the DCA trade.
        self._day_count = 0
        # Set the brokerage and account type to match your brokerage environment for accurate fee and margin behavior.
        self.set_brokerage_model(BrokerageName.BITFINEX, AccountType.CASH)
        # For daily DCA purchases, subscribe to daily asset data.
        self._symbol = self.add_crypto("BTCUSD", Resolution.DAILY, Market.BITFINEX).symbol

    def on_data(self, slice: Slice) -> None:
        # If you haven't invested for 30 consecutive days yet, continue buying.
        if self._symbol in slice.bars and self._day_count < 30:
            # Increase the day count.
            self._day_count += 1
            # Calculate the order size for $3,000 USD using the current price.
            quantity = 3_000 / slice.bars[self._symbol].close
            # Round down to observe the lot size.
            lot_size = self.securities[self._symbol].symbol_properties.lot_size
            quantity = int(quantity / lot_size) * lot_size
            if quantity:
                self.market_order(self._symbol, quantity)
```

Example 2: Inter-Market Spread

There is always a small discrepancy in the price of the same Crypto pair trading on different exchanges. Although you can't currently live trade on algorithm with multiple brokerages, you can study the cointegration pattern and implement 2 live nodes to capture the arbitrage opportunity. The following algorithm demonstrates how to obtain the spread between the BTCUSD pair on Kraken and on Coinbase:

PY

```
class CryptoExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Subscribe to BTC/USD on 2 different exchanges.
        self.kraken_btc = self.add_crypto("BTCUSD", market=Market.KRAKEN).symbol
        self.coinbase_btc = self.add_crypto("BTCUSD", market=Market.COINBASE).symbol

    def on_data(self, slice: Slice) -> None:
        # Only calculate the spread if the prices on both exchanges are in the current Slice.
        if self.kraken_btc in slice.bars and self.coinbase_btc in slice.bars:
            # Calculate the spread between the 2 exchanges, making sure the comparison is always in the same direction.
            spread = slice.bars[self.kraken_btc].close - slice.bars[self.coinbase_btc].close
```

Crypto

Holdings

Introduction

Crypto holdings require special consideration because not all brokerages track your positions in each currency pair.

Cash vs Margin Brokerage Accounts

Some of the Crypto brokerages integrated into QuantConnect support cash and margin accounts while some only support cash accounts. If you want to short Crypto assets or use leverage, you need a margin account. Follow these steps to view which account types each brokerage supports:

1. Open the brokerage guides .
2. Click a Crypto brokerage.
3. Scroll down to the Account Types section.

Virtual Pairs

All fiat and Crypto currencies are individual assets. When you buy a pair like BTCUSD, you trade USD for BTC. In this case, LEAN removes some USD from your portfolio cashbook and adds some BTC. The virtual pair BTCUSD represents your position in that trade, but the virtual pair doesn't actually exist. It simply represents an open trade. If you call the Liquidate method with the `symbol` of a virtual pair, the method only liquidates the quantity in your virtual pair. For more information about liquidating Crypto postitions, see Crypto Trades .

Access Cypto Holdings

The `cash_book` stores the quantity of your Crypto holdings. To access your Crypto holdings, index the `cash_book` with the currency ticker. The values of the `CashBook` dictionary are `Cash` objects, which have the following properties:

```
btc_quantity = self.portfolio.cash_book['BTC'].amount
btc_value = self.portfolio.cash_book['BTC'].value_in_account_currency
```

To access the virtual pair of your Crypto trades, index the `portfolio` object with the pair `symbol` .

```
security_holding  = self.portfolio[self._btc_usd_symbol]
```

Stateful Redeployments

When you make a trade inside of a running algorithm, LEAN tracks the virtual position state for you, but it won't survive between deployments. Some brokerages save your virtual pairs, so you can load them into your algorithm when you stop and redeploy it. Depending on the brokerage you select, you may be able to manually add virtual pairs when you deploy live algorithms with the LEAN CLI or cloud deployment wizard .

Examples

The following examples demonstrate some common practices for crypto holdings.

Example 1: ETH-BTC Proxy Trading

The following algorithm trades trend-following of the ETHBTC crypto pair using a 20-day EMA indicator. To reduce friction (e.g. slippage), we trade the more liquid and popular BTCUSDT and ETHUSDT pair instead. For example, if ETHBTC is above EMA (uptrend), we sell all BTCUSDT holdings and buy ETHUSDT with the same USDT value, going flat on BTC while holding ETH.

PY

```
class CryptoHoldingsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_account_currency("USDT", 1000000)

        # We would like to trade the EMA cross between 2 popular cryptos: BTC & ETH,
        # so we request ETHBTC data to find trading opportunities.
        self.ethbtc = self.add_crypto("ETHBTC", Resolution.DAILY, market=Market.COINBASE).symbol
        # Trade through BTCUSDT & ETHUSDT, though, since stable coin trades have lower friction costs and higher liquidity.
        btcusdt = self.add_crypto("BTCUSDT", Resolution.DAILY, market=Market.COINBASE)
        ethusdt = self.add_crypto("ETHUSDT", Resolution.DAILY, market=Market.COINBASE)
        self.btcusdt = btcusdt.symbol
        self.ethusdt = ethusdt.symbol

        # Simulate an account with various crypto cash through holdings.
        # Set the cash book directly with the crypto amounts
        btcusdt.holdings.set_holdings(btcusdt.price, 5)
        btcusdt.base_currency.add_amount(5)
        ethusdt.holdings.set_holdings(ethusdt.price, 22.5)
        ethusdt.base_currency.add_amount(22.5)

        # Add automatic updating of the EMA indicator for trend trade signal emission.
        self._ema = self.ema(self.ethbtc, 20, Resolution.DAILY)
        # Warm up the indicator for its readiness usage immediately.
        self.warm_up_indicator(self.ethbtc, self._ema, Resolution.DAILY)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self.ethbtc)
        btc = slice.bars.get(self.btcusdt)
        eth = slice.bars.get(self.ethusdt)

        if bar and self._ema.is_ready and btc and eth:
            ema = self._ema.current.value
            btc_holdings = self.portfolio.cash_book["BTC"].amount
            eth_holdings = self.portfolio.cash_book["ETH"].amount

            # ETHBTC's current price is higher than EMA, suggesting an uptrend.
            if bar.close > ema and not self.portfolio[self.btcusdt].is_short:
                # To follow the up trend of ETHBTC, sell ALL BTCUSDT and buy ETHUSDT with the same value.
                if btc_holdings > 0:
                    btc_value = btc_holdings * btc.close
                    # Sell all BTC
                    self.market_order(self.btcusdt, -btc_holdings)
                    # Buy ETH with the same USDT value
                    eth_size = btc_value / eth.close
                    self.market_order(self.ethusdt, eth_size)
            # ETHBTC's current price is below the EMA, suggesting a downtrend.
            elif bar.close < ema and not self.portfolio[self.btcusdt].is_long:
                # To follow the downtrend of ETHBTC, sell ALL ETHUSDT and buy BTCUSDT with the same value.
                if eth_holdings > 0:
                    eth_value = eth_holdings * eth.close
                    # Sell all ETH
                    self.market_order(self.ethusdt, -eth_holdings)
                    # Buy BTC with the same USDT value
                    btc_size = eth_value / btc.close
                    self.market_order(self.btcusdt, btc_size)
```

Crypto

Market Hours

Introduction

The Crypto markets are open 24/7. There are no pre-market hours, post-market hours, holidays, late opens, or early closes.

Asset Classes

Crypto Futures

Crypto Perpetual Futures are derivative financial contracts that obligate parties to buy or sell an asset at an unspecified future date.

Crypto Futures

Requesting Data

Introduction

Request Crypto Futures data in your algorithm to receive a feed of asset prices in the `on_data` method. For more information about the specific datasets we use for backtests, see the Binance Crypto Future Price Data dataset listing . To trade Crypto Futures live, you can use the QuantConnect data provider .

Create Subscriptions

To create a Crypto Futures subscription, in the `initialize` method, call the `add_crypto_future` method. The `add_crypto_future` method returns a `CryptoFuture` object, which contains a `symbol` property. Save a reference to the `symbol` so you can use it in `on_data` to access the security data in the `Slice` .

```
self._symbol = self.add_crypto_future("BTCUSD").symbol
```
PY

The `add_crypto_future` method creates a subscription for a single Crypto Futures asset and adds it to your user-defined universe.

To view the supported assets in the Crypto Futures dataset, see Supported Assets .

Resolutions

The following table shows the available resolutions and data formats for Crypto Futures contract subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`TICK`			✓	✓
`SECOND`	✓	✓		
`MINUTE`	✓	✓		
`HOUR`	✓	✓		
`DAILY`	✓	✓		

The default resolution for Crypto Futures subscriptions is `Resolution.MINUTE` . To change the resolution, pass a `resolution` argument to the `add_crypto_future` method.

```
self._symbol = self.add_crypto_future("BTCUSD", Resolution.DAILY).symbol
```
PY

To create custom resolution periods, see Consolidating Data .

Supported Markets

The following `Market` enumeration members are available for Cryptofuture:

```
self._symbol = self.add_crypto_future("BTCUSD", market=Market.BINANCE).symbol
```
PY

The brokerage models have a default market for each asset class. If you set a brokerage model, you may not need to specify the market to use.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you

disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fill_forward` argument to false when you create the security subscription.

```
PY
self._symbol = self.add_crypto_future("BTCUSD", fill_forward=False).symbol
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. The amount of leverage available to you depends on the brokerage you use. To change the amount of leverage you can use for a security, pass a `leverage` argument to the `add_crypto_future` method.

```
PY
self._symbol = self.add_crypto_future("BTCUSD", leverage=3).symbol
```

For more information about the leverage each brokerage provides, see Brokerages .

Data Normalization

The data normalization mode doesn't affect the data that LEAN passes to `on_data` or the data from history request . If you change the data normalization mode, it won't change the outcome.

Properties

The `add_crypto_future` method returns a `CryptoFuture` object, which have the following properties:

Examples

The following examples demonstrate some common practices for requesting Crypto Futures data.

Example 1: Respect Lot Sizes

Like Futures, Crypto Futures contracts have a fixed discrete lot size to trade instead of fractional like spot Crypto pairs. The following algorithm demonstrates how to place orders that respect the lot size to avoid rounding errors.

```
PY
class CryptoFutureAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Set brokerage and account type to match your brokerage environment for accurate fee and margin behavior.
        self.set_brokerage_model(BrokerageName.BINANCE, AccountType.MARGIN)
        # In the Binance brokerage, you can't trade with USD.
        # Set the account currency as USDT and add the starting cash.
        self.set_account_currency("USDT", 100_000)
        # Subscribe to the BTCUSDT perpetual Future contract.
        self._symbol = self.add_crypto_future("BTCUSDT").symbol

    def on_data(self, slice: Slice) -> None:
        # Only place orders when market is open since market on open orders aren't supported.
        if not self.portfolio.invested and self.is_market_open(self._symbol):
            # Get the lot size from the symbol properties. Placing an order that respects the lot size
            # ensures the order is valid and allows accurate profit and risk calculations for the whole portfolio.
            lot_size = self.securities[self._symbol].symbol_properties.lot_size
            # This example demonstrates an initial desired order size of 2.5 contracts, which will be rounded
            # to 2 contracts since the lot size is 1.
            quantity = 2.5 // lot_size * lot_size
            self.market_order(self._symbol, quantity)
```

Crypto Futures

Handling Data

Introduction

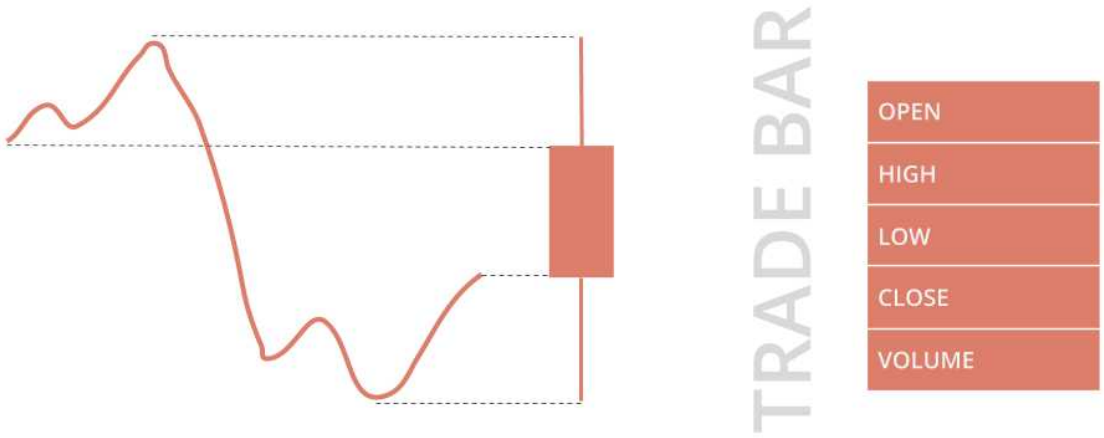
LEAN passes the data you request to the `on_data` method so you can make trading decisions. The `Slice` object that the `on_data` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `on_data` method, use the `current_slice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars` `DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the security ticker or `symbol` , but we recommend you use the `symbol` .

To view the resolutions that are available for Crypto Futures data, see Resolutions .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `bars` property of the `Slice` with the security `symbol` . If the security doesn't actively trade or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `symbol` .

```
def on_data(self, slice: Slice) -> None:
    # Obtain the mapped TradeBar of the symbol if any
    trade_bar = slice.bars.get(self._symbol)   # None if not found
```

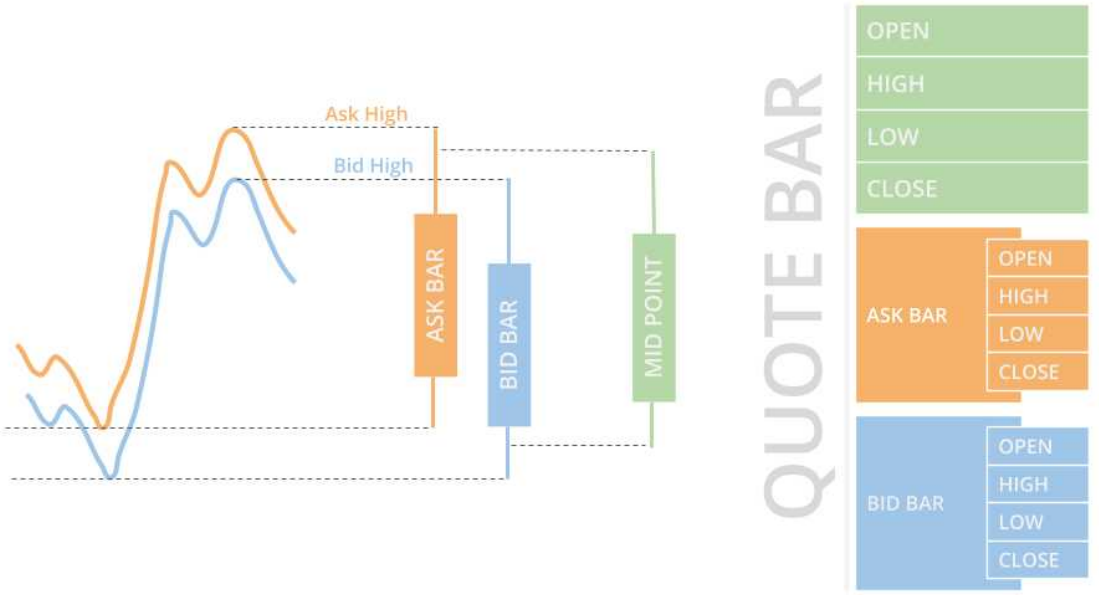
You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Symbol-TradeBar key-value pairs
    for symbol, trade_bar in slice.bars.items():
        close_price = trade_bar.close
```

`TradeBar` objects have the following properties:

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `open` , `high` , `low` , and `close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `open` , `high` , `low` , and `close` properties of the `QuoteBar` copy the values of either the `bid` or `ask` instead of taking their mean.



To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the security `symbol` . If the security doesn't actively get quotes or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `symbol` .

```
def on_data(self, slice: Slice) -> None:
    # Obtain the mapped QuoteBar of the symbol if any
    quote_bar = slice.quote_bars.get(self._symbol)   # None if not found
```

PY

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Symbol-QuoteBar key-value pairs
    for symbol, quote_bar in slice.quote_bars.items():
        ask_price = quote_bar.ask.close
```

PY

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

`QuoteBar` objects have the following properties:

Ticks

`Tick` objects represent a single trade or quote at a moment in time. A trade tick is a record of a transaction for the security. A quote tick is an offer to buy or sell the security at a specific price.

Trade ticks have a non-zero value for the `quantity` and `price` properties, but they have a zero value for the `bid_price` , `bid_size` , `ask_price` , and `ask_size` properties. Quote ticks have non-zero values for `bid_price` and `bid_size` properties or have non-zero values for `ask_price` and `ask_size` properties. To check if a tick is a trade or a quote, use the `ticktype` property.

In backtests, LEAN groups ticks into one millisecond buckets. In live trading, LEAN groups ticks into ~70-millisecond buckets. To get the `Tick` objects in the `Slice` , index the `Ticks` property of the `Slice` with a `symbol` . If the security doesn't actively trade or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `symbol` .

```
def on_data(self, slice: Slice) -> None:
    ticks = slice.ticks.get(self._symbol, [])   # Empty if not found
    for tick in ticks:
        price = tick.price
```

You can also iterate through the `Ticks` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `list[Tick]` objects.

```
def on_data(self, slice: Slice) -> None:
    for symbol, ticks in slice.ticks.items():
        for tick in ticks:
            price = tick.price
```

Tick data is raw and unfiltered, so it can contain bad ticks that skew your trade results. For example, some ticks come from dark pools, which aren't tradable. We recommend you only use tick data if you understand the risks and are able to perform your own online tick filtering.

`Tick` objects have the following properties:

Margin Interest Rates

`MarginInterestRate` objects contain the margin interest rate, which is a cost associated with trading on margin. To get the `MarginInterestRate` objects in the `Slice` , index the `margin_interest_rates` property of the `Slice` with the Crypto Future `Symbol` . The `margin_interest_rates` property of the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the property contains data for your Crypto Future before you index it with the Crypto Future `Symbol` .

```
def on_data(self, slice: Slice) -> None:
    margin_interest_rate = slice.margin_interest_rates.get(self._symbol)
    if margin_interest_rate:
        interest_rate = margin_interest_rate.interest_rate
```

You can also iterate through the `margin_interest_rates` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `margin_interest_rate` objects.

```
def on_data(self, slice: Slice) -> None:
    for symbol, margin_interest_rate in slice.margin_interest_rates.items():
        interest_rate = margin_interest_rate.interest_rate
```

`MarginInterestRate` objects have the following properties:

Examples

The following examples demonstrate some common practices for handling Crypto Futures data.

Example 1: Adjust Holdings on Margin Payments

Perpetual futures have a mechanism called funding , where if you're holding a position at certain times (the funding timestamp), you might have to pay or receive funding based on the difference between the perpetual contract price and the spot price. This example demonstrates how to adjust your position in Crypto Future based on the funding rate. The funding is settled in the quote currency, which is USDT in this case. When you receive USDT, the algorithm increases its position size in BTCUSDT. When you pay USDT, the algorithm decreases its position size.

```py
class CryptoFutureAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Set brokerage and account type to match your brokerage environment for accurate fee and margin behavior.
        self.set_brokerage_model(BrokerageName.BINANCE, AccountType.MARGIN)
        # In the Binance brokerage, you can't trade with USD.
        # Set the account currency as USDT and add the starting cash.
        self.set_account_currency("USDT", 1000000)
        # Subscribe to the BTCUSDT perpetual Future contract.
        btcusdt = self.add_crypto_future("BTCUSDT")
        self._symbol = btcusdt.symbol
        # Save the lot size to avoid order errors.
        self._lot_size = btcusdt.symbol_properties.lot_size
        # Set the starting BTC balance to 10.
        btcusdt.base_currency.set_amount(10)
        # Create a member to track the current day.
        self._day = -1

    def on_data(self, slice: Slice) -> None:
        # Only place orders when the market is open since market on open orders aren't supported.
        if not self.portfolio.invested and self.is_market_open(self._symbol):
            # Open a long position in the perpetual Crypto Future.
            self.market_order(self._symbol, 10)
        # Only run the following logic once per day.
        if self._day == self.time.day:
            return
        # Get the current margin interest rate.
        interest_rate = slice.margin_interest_rates.get(self._symbol)
        if not interest_rate:
            return
        # Calculate the funding payment.
        holding = self.portfolio[self._symbol]
        position_value = holding.get_quantity_value(holding.quantity).amount
        interest_rate = slice.margin_interest_rates[self._symbol].interest_rate
        funding = interest_rate * position_value / holding.security.price
        # Increase/decrease the position size based on the funding payment.
        quantity = -funding // self._lot_size * self._lot_size
        if quantity:
            self.market_order(self._symbol, quantity)
            # Plot the portfolio state.
            self.plot("CashBook", "USDT", self.portfolio.cash_book['USDT'].amount)
            self.plot("CashBook", "BTC", self.portfolio.cash_book['BTC'].amount)
            self.plot("Quantity", "BTCUSDT", self.portfolio[self._symbol].quantity)
        self._day = self.time.day
```

Example 2: Future-Spot Arbitrage

Long-short arbitrage involves simultaneously trading BTCUSDT in the spot market and BTCUSDT Futures with the same size but in the opposite direction. The following algorithm monitors the spread between these markets. If the spot price exceeds the Future price by a threshold, it shorts the spot market and buys the Future contract (and vice vera for the other way around), assuming their discrepancies will be wiped out within a short period due to market efficiency. It closes the positions after the spread inverts.

PY

```
class CryptoFutureArbitrageAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Set brokerage and account type to match your brokerage
        # environment for accurate fee and margin behavior.
        self.set_brokerage_model(BrokerageName.BINANCE, AccountType.MARGIN)
        # In the Binance brokerage, you can't trade with USD.
        # Set the account currency to USDT and add the starting cash.
        self.set_account_currency("USDT", 50_000_000)
        # Add the BTCUSDT spot and Futures markets.
        self._spot = self.add_crypto(
            "BTCUSDT", fill_forward=False, market=Market.BINANCE
        )
        self._future = self.add_crypto_future(
            "BTCUSDT", fill_forward=False, market=Market.BINANCE
        )
        self._multiplier = self._future.symbol_properties.contract_multiplier
        self._threshold = 1.005  # 0.5%

    def on_data(self, slice: Slice) -> None:
        # Wait for there to be a TradeBar for each asset, so we know
        # the prices are up-to-date.
        for security in [self._spot, self._future]:
            if security.symbol not in slice.bars:
                return
        spot = self._spot.price
        future = self._future.price
        # Buy low sell high: If one's price is above another by the
        # set threshold, sell it and buy the other security. The
        # threshold ensures there is enough profit potential to overcome
        # the fees and slippage. Make sure to equalize the actual order
        # size with the contract multiplier.
        if not self._spot.invested:
            if spot >= future * self._threshold:
                self._enter(-1, 1)
            elif future >= spot * self._threshold:
                self._enter(1, -1)
            return
        # When the mispricing converges, close both positions to earn
        # the spread.
        if ((self._spot.holdings.is_short and spot < future) or
            (self._spot.holdings.is_long and spot > future)):
            # Liquidate the spot position.
            quantity = min(
                self._spot.holdings.quantity,
                self._spot.base_currency.amount
            )
            if quantity < 0:
                quantity /= (1 - 0.001)  # To cover the taker fees.
            lot_size = self._spot.symbol_properties.lot_size
            quantity = -round(quantity / lot_size) * lot_size
            self.market_order(self._spot.symbol, quantity, tag='Liquidate Spot')
            # Liquidate the Future position.
            self.liquidate(self._future.symbol, tag='Liquidate Future')

    def _enter(self, spot_sign, future_sign):
        quantity = self.calculate_order_quantity(self._future.symbol, 0.5)
        if not quantity:
            return
        # Enter the spot position.
        spot_quantity = spot_sign * quantity * self._multiplier
        self.market_order(self._spot.symbol, spot_quantity, tag='Spot')
        # Enter the Future position.
        self.market_order(self._future, future_sign * quantity, tag='Future')
```

Forex

Requesting Data

Introduction

Request Forex data in your algorithm to receive a feed of exchange rates in the `on_data` method. For more information about the specific dataset we use for backtests, see the FOREX dataset listing . To trade Forex live, you can use the QuantConnect data provider .

Create Subscriptions

To create a Forex pair subscription, in the `initialize` method, call the `add_forex` method. The `add_forex` method returns a `Forex` object, which contains a `symbol` property. Save a reference to the `symbol` so you can use it in `on_data` to access the security data in the `Slice` .

```
self._symbol = self.add_forex("EURUSD").symbol
```

PY

To view the supported Forex pairs, see Supported Assets .

Resolutions

The following table shows the available resolutions and data formats for Forex subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`TICK`				✓
`SECOND`		✓		
`MINUTE`		✓		
`HOUR`		✓		
`DAILY`		✓		

The default resolution for Forex subscriptions is `Resolution.MINUTE` . To change the resolution, pass a `resolution` argument to the `add_forex` method.

```
self._symbol = self.add_forex("EURUSD", Resolution.DAILY).symbol
```

PY

To create custom resolution periods, see Consolidating Data .

Supported Markets

The only market available for Forex pairs is `Market.OANDA` , so you don't need to pass a `market` argument to the `add_forex` method.

```
self._symbol = self.add_forex("EURUSD", market=Market.OANDA).symbol
```

PY

The brokerage models have a default market for each asset class. If you set a brokerage model, you may not need to specify the market to use.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fill_forward` argument to false when you create the security subscription.

```
self._symbol = self.add_forex("EURUSD", fill_forward=False).symbol
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. The OANDA brokerage let's you use up to 50x leverage on margin accounts. To change the amount of leverage you can use for a Forex pair, pass a `leverage` argument to the `add_forex` method.

```
self._symbol = self.add_forex("EURUSD", leverage=35).symbol
```

Data Normalization

The data normalization mode doesn't affect the data that LEAN passes to `on_data` or the data from history request . If you change the data normalization mode, it won't change the outcome.

Properties

The `add_forex` method returns a `Forex` object, which have the following properties:

Examples

The following examples demonstrate some common practices for requesting Forex data.

Example 1: Add All Forex Pairs

The following algorithm adds all the Forex pairs that trade on the OANDA exchange . To get all of the pairs from the Symbol Properties Database , call the `symbol_properties_database.get_symbol_properties_list` method. Adding all of the pairs is particularly useful for spotting arbitrage opportunities among the pairs.

```
class ForexExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self._forex_pairs = [
            # Add all of the pairs. You don't need to specify the market because the Symbol object already does.
            self.add_forex(x.key.symbol, Resolution.DAILY)
            # Get all of the OANDA Forex pairs from the Symbol Properties Database.
            for x in self.symbol_properties_database.get_symbol_properties_list(Market.OANDA, SecurityType.FOREX)
        ]
```

Forex

Handling Data

Introduction

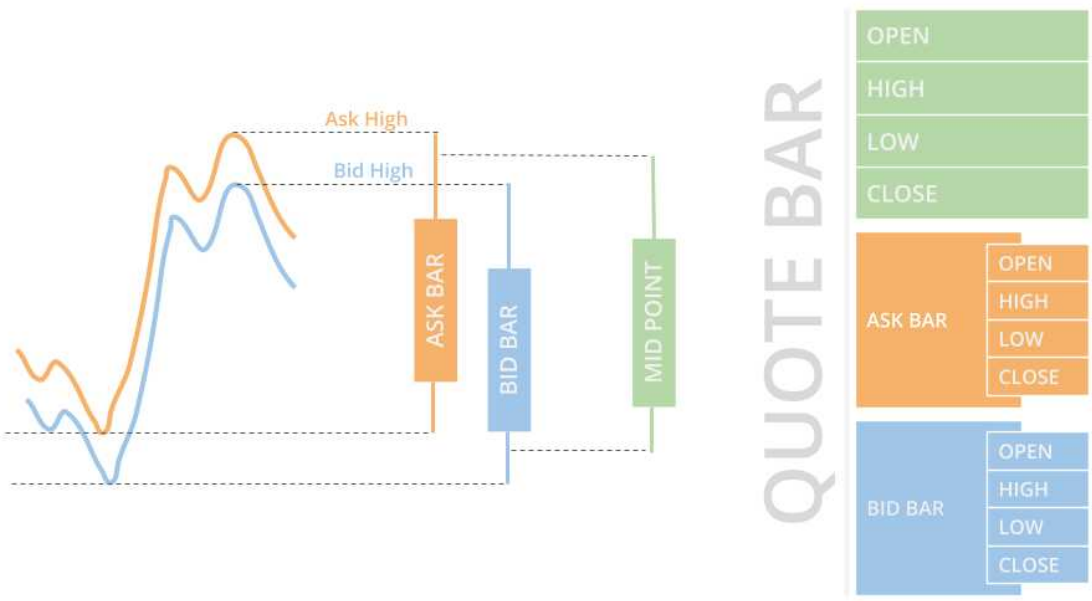
LEAN passes the data you request to the `on_data` method so you can make trading decisions. The `Slice` object that the `on_data` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `on_data` method, use the `current_slice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `QuoteBars` `DataDictionary` is made up of `QuoteBar` objects. To access individual data points in the dictionary, you can index the dictionary with the Forex pair ticker or `symbol` , but we recommend you use the `symbol` .

To view the resolutions that are available for Forex data, see Resolutions .

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `open` , `high` , `low` , and `close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `open` , `high` , `low` , and `close` properties of the `QuoteBar` copy the values of either the `bid` or `ask` instead of taking their mean.



To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the Forex pair `symbol` . If the Forex pair doesn't actively get quotes or you are in the same time step as when you added the Forex pair subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for your Forex pair before you index the `Slice` with the Forex pair `symbol` .

```
def on_data(self, slice: Slice) -> None:
    # Obtain the mapped QuoteBar of the symbol if any
    quote_bar = slice.quote_bars.get(self._symbol)   # None if not found
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Symbol-QuoteBar key-value pairs
    for symbol, quote_bar in slice.quote_bars.items():
        ask_price = quote_bar.ask.close
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

`QuoteBar` objects have the following properties:

Ticks

`Tick` objects represent a single trade or quote at a moment in time. A trade tick is a record of a transaction for the Forex pair. A quote tick is an offer to buy or sell the Forex pair at a specific price.

Trade ticks have a non-zero value for the `quantity` and `price` properties, but they have a zero value for the `bid_price` , `bid_size` , `ask_price` , and `ask_size` properties. Quote ticks have non-zero values for `bid_price` and `bid_size` properties or have non-zero values for `ask_price` and `ask_size` properties. To check if a tick is a trade or a quote, use the `ticktype` property.

In backtests, LEAN groups ticks into one millisecond buckets. In live trading, LEAN groups ticks into ~70-millisecond buckets. To get the `Tick` objects in the `Slice` , index the `Ticks` property of the `Slice` with a `symbol` . If the Forex pair doesn't actively trade or you are in the same time step as when you added the Forex pair subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for your Forex pair before you index the `Slice` with the Forex pair `symbol` .

```
def on_data(self, slice: Slice) -> None:
    ticks = slice.ticks.get(self._symbol, [])   # Empty if not found
    for tick in ticks:
        price = tick.price
```

You can also iterate through the `Ticks` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `list[Tick]` objects.

```
def on_data(self, slice: Slice) -> None:
    for symbol, ticks in slice.ticks.items():
        for tick in ticks:
            price = tick.price
```

Tick data is raw and unfiltered, so it can contain bad ticks that skew your trade results. For example, some ticks come from dark pools, which aren't tradable. We recommend you only use tick data if you understand the risks and are able to perform your own online tick filtering.

`Tick` objects have the following properties:

Examples

The following examples demonstrate some common practices for handling Forex data.

Example 1: Trade the USDJPY Spread

USDJPY is a Forex pair where the reserve banks of the base currency and quote currency act at different time, which results in a 12-hour period of seasonal peak volume. To reduce slippage costs, place orders when bid-ask spread is relatively low. The following algorithm demonstrates how to utilize the Minimum indicator to check for a narrow spread.

```py
class ForexExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add the USDJPY trading pair.
        self._forex = self.add_forex("USDJPY")
        # Create a Minimum indicator to track the lowest bid-ask spread for the past 12 hours.
        self._forex.spread_low = Minimum(12*60)
        # Warm up the indicator so it's immediately ready to use.
        self.warm_up_indicator(self._forex.symbol, self._forex.spread_low)

    def on_data(self, slice: Slice) -> None:
        # Ensure we have quote data for USDJPY in the current slice.
        if self._forex.symbol not in slice.quote_bars:
            return
        quote_bar = slice.quote_bars[self._forex.symbol]
        # Bid-ask spread = Ask price - Bid price
        bid_ask_spread = quote_bar.ask.close = quote_bar.bid.close
        # Update the spread minimum indicator to calculate the lowest bid-ask spread over the last 12 hours.
        self._forex.spread_low.update(quote_bar.end_time, bid_ask_spread)

        # Trade if the current spread is the lowest bid-ask spread, since it is the most efficient,
        # liquid price with lowest slippage.
        if not self.portfolio.invested and bid_ask_spread == self._forex.spread_low.current.value:
            self.market_order(self._forex.symbol, 1000)

        # Plot the bid-ask spread to validate the minimum bid-ask spread calculation.
        self.plot("Bid-Ask Spread", "spread", bid_ask_spread)
```

Example 2: 5-Minute EURUSD Trend Reversal

The following algorithm applies a mean reveral strategy to EURUSD. To smooth out the noise of minute resolution data, it consolidates the data into 5-minute bars and then calculates their 200-bar Exponential Moving Average (EMA). After every time the indicator updates, the algorithm checks for a trading opportuniity. When the current EURUSD price is below the EMA, it takes a long position. Otherwise, it takes a short position.

```py
class ForexExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Add EURUSD minute data.
        self._forex = self.add_forex("EURUSD")
        # Create an EMA indicator to estimate the trend of EURUSD.
        self._forex.ema = ExponentialMovingAverage(200)
        # Attach an event handler to the indicator to track its updates.
        self._forex.ema.updated += self.on_updated
        # Create a consolidator that produces 5-minute quote bars to reduce reduce noise.
        consolidator = QuoteBarConsolidator(timedelta(minutes=5))
        # Define the consolidator handler so it updates the EMA with the consoildated bars.
        consolidator.DataConsolidated += lambda _, bar: self._forex.ema.update(bar.end_time, bar.close)
        # Warm up the indicator with historical data.
        for bar in self.history[QuoteBar](self._forex.symbol, 1000):
            consolidator.update(bar)
        # Subscribe the consolidator for automatic updates.
        self.subscription_manager.add_consolidator(self._forex.symbol, consolidator)

    def on_updated(self, sender: object, point: IndicatorDataPoint) -> None:
        # Wait until the indicator is ready and the Forex pair has a price.
        if not self._forex.ema.is_ready or not self._forex.price:
            return
        # Rebalance the portfolio. If the current price is below the EMA, long. Otherwise, short.
        self.set_holdings(self._forex.symbol, 0.5 if self._forex.price <= point.value else -0.5)
```

Example 3: New York Time Alignment

The following algorithm creates daily Forex bars that close at 4:30 PM Eastern Time (ET). This technique is helpful when you want to align the daily bars with the close of the New York.

PY

```
class ForexExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add EURUSD minute data.
        self._forex = self.add_forex("EURUSD")
        # Create a daily bar consolidator with a custom period (4:30 PM-4:30 PM Eastern Time).
        consolidator = QuoteBarConsolidator(self._consolidation_period)
        # Attach a consolidation handler to plot the consolidated bars.
        consolidator.data_consolidated += lambda _, bar: self.plot("Consolidated Bar", "Close", bar.close)
        # Subscribe the consolidator for automatic updates.
        self.subscription_manager.add_consolidator(self._forex.symbol, consolidator)

    def _consolidation_period(self, dt: datetime) -> CalendarInfo:
        # Set the start time to be 4:30 PM of the previous day.
        start = dt.replace(hour=16, minute=30, second=0, microsecond=0)
        period = timedelta(1)
        if dt.hour < 17:
            start -= period
        # Set the period to 1 day to make daily bars.
        return CalendarInfo(start, period)
```

Universes

Introduction

The `add_future` method enables you to select a basket of Future contracts for an underlying Future. To form your universe of contracts, you can filter them down by their expiry. If you want to subscribe to individual contracts one-by-one instead of a set of contracts, see Individual Contracts .

Create Universes

To add a universe of Future contracts, in the `initialize` method, call the `add_future` method. This method returns an `Future` object, which has a `set_filter` method you can call to filter the set of tradable contract down to just the contracts you want.

```
PY
class BasicFutureAlgorithm(QCAlgorithm):

    def initialize(self):
        self.future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            Resolution.DAILY,
            extended_market_hours=True,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0
        )
        self.future.set_filter(0, 182)

    def on_data(self, data):
        for continuous_symbol, chain in data.future_chains.items():
            for symbol, contract in chain.contracts.items():
                expiry = contract.expiry
```

For more information about the `add_future` method, see Create Universes .

Continous Contracts

By default, LEAN only subscribes to the continuous Future contract. A continuous Future contract represents a series of separate contracts stitched together to form a continuous price. If you need a lot of historical data to warm up an indicator, apply the indicator to the continuous contract price series. The `Future` object has a `symbol` property and a `mapped` property. The price of the `symbol` property is the adjusted price of the continuous contract. The price of the `mapped` property is the raw price of the currently selected contract in the continuous contract series.

```
PY
# Get the adjusted price of the continuous contract.
adjusted_price = self.securities[self._future.symbol].price

# Get the raw price of the currently selected contract in the continuous contract series.
raw_price = self.securities[self._future.mapped].price
```

The continuous Futures contract isn't a tradable security . You must place orders for a specific Futures contract. To access the currently selected contract in the continuous contract series, use the `mapped` property of the `Future` object.

```
PY
# Place a market order for the currently selected contract in the continuous contract series.
self.market_order(self._future.mapped, 1)
```

For more information, see Continous Contracts .

Filter by Contract Properties

To set a contract filter, in the `initialize` method, call the `set_filter` method of the `Future` object. The following table describes the available filter techniques:

`set_filter(minExpiry: int, maxExpiry: int)` Selects the contracts that expire within the range you set. This filter runs asynchronously by default.
`set_filter(universeFunc: Callable[[FutureFilterUniverse], FutureFilterUniverse])` Selects the contracts that a function selects.

```
# Select the contracts that expire within 182 days.
self._future.set_filter(0, 182)

# Select the front month contract.
self._future.set_filter(lambda future_filter_universe: future_filter_universe.front_month())
```

The following table describes the filter methods of the `FutureFilterUniverse` class:

`standards_only()` Selects standard contracts
`front_month()` Selects the front month contract
`back_months()` Selects the non-front month contracts
`back_month()` Selects the back month contracts
`expiration(min_expiry: timedelta, max_expiry: timedelta)` Selects contracts that expire within a range of dates relative to the current day
`expiration(min_expiry_days: int, max_expiry_days: int)` Selects contracts that expire within a range of dates relative to the current day
`contracts(contracts: list[Symbol])` Selects a list of contracts
`contracts(contractSelector: Callable[[list[Symbol]], list[Symbol]])` Selects contracts that a selector function selects

The preceding methods return an `FutureFilterUniverse` , so you can chain the methods together.

```
# Select the front month standard contracts
self._future.set_filter(lambda future_filter_universe: future_filter_universe.standards_only().front_month())
```

You can also define an isolated filter method.

```
# In Initialize
self._future.set_filter(self._contract_selector)

def _contract_selector(self,
    future_filter_universe: Callable[[FutureFilterUniverse], FutureFilterUniverse]) -> FutureFilterUniverse:
    return future_filter_universe.standards_only().front_month()
```

Default Filter

By default, LEAN doesn't add any contracts to the FuturesChain it passes to the `on_data` method.

Historical Data

To get historical data for a Futures universe, see Historical Data .

Examples

The following examples demonstrate some common practices for requesting Futures universe data.

Example 1: Rollover

Future contracts expire monthly or quarterly in most cases. Hence, if we hold Future position in month or quarter end, we must consider rolling over to the mapped contract. The following algorithm shows how to buy and roll over to the next front month Future contract. We make use of the universe selection filter to select the front month contract and order the next mapped contract during the previous one expires.

```
class FutureExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Seed the price with last known price to ensure the contract price data is available for the limit order.
        self.settings.seed_initial_prices = True
        future = self.add_future(Futures.Indices.SP_500_E_MINI, extended_market_hours=True)
        self._future = future.symbol
        # We only want to hold position of the front month contract.
        future.set_filter(lambda u: u.front_month())

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        # Liquidate if expired (or not being the front month contract anymore) and exit universe.
        for removed in changes.removed_securities:
            self.liquidate(removed.symbol)

        for added in changes.added_securities:
            # Make sure the newly added contract is an actual mapped tradable contract.
            if not added.symbol.is_canonical():
                # Roll over by ordering the same quantity.
                # Use limit order since market on open order is not supported on Future and avoid extreme quote filling.
                self.limit_order(added.symbol, 1, added.price)
```

Example 2: Continuous Future Indicator

One of the major applications of Continuous Futures is to obtain a smooth price series to feed into indicators. This technique ensures the indicator gets the price data that is comparable to the current contract in the continuous contract series. This example demonstrates a Exponential Moving Average crossover strategy based on the continuous ES contract data.

```py
class FutureEMACrossAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1_000_000)
        # Seed the price of each asset with its last known price to
        # avoid trading errors.
        self.settings.seed_initial_prices = True
        # Define a threshold for the EMA crossover.
        self._threshold = 0.01  # 1% above/below the EMA.
        # Use backward ratio normalization for the continuous contract
        # so the indicator receives a smooth price series.
        self._future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
        )
        # Only add the front-month contract.
        self._future.set_filter(lambda u: u.front_month())
        # Create a 252-day EMA indicator as a trend estimator.
        self._future.ema = self.ema(self._future.symbol, 252, Resolution.DAILY)
        # Warm up the EMA indicator to so we can trade right away.
        self.warm_up_indicator(self._future.symbol, self._future.ema)

    def on_data(self, slice: Slice) -> None:
        # Ensure the TradeBar data is available for the Future before
        # placing trades.
        bar = slice.bars.get(self._future.symbol)
        if not bar:
            return
        # Buy the mapped contract if the trend is estimated to go up
        # (price above the EMA).
        if bar.close >= self._future.ema.current.value * (1+self._threshold):
            self.set_holdings(self._future.mapped, 0.1)
        # Short the mapped contract if the trend is estimated to go down
        # (price below the EMA).
        elif bar.close <= self._future.ema.current.value * (1-self._threshold):
            self.set_holdings(self._future.mapped, -0.1)

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        # Liquidate the contract when it is no longer the front-month
        # contract (expired).
        for contract in changes.removed_securities:
            self.liquidate(contract.symbol)
```

Example 3: Contango

In Future trading, contango refers to the far-to-expiry Future contract price is higher than the spot price due to various reasons, such as storage fee and insurance of the commodities. The following example shows a contango trading by shorting the far contract that the price is above a threshold compared to the front month contract price and buying the front month contract to earn the premium in between.

```py
class FutureExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add Gold Futures.
        future = self.add_future(Futures.Metals.GOLD)
        self._future = future.symbol
        # Limit the expiration to within 6 months, as the longer the expiration, the higher the price uncertainty.
        future.set_filter(lambda u: u.expiration(0, 183))

    def on_data(self, slice: Slice) -> None:
        # Get Future chain only for the selected Future contract.
        chain = slice.future_chains.get(self._future)
        if not self.portfolio.invested and chain:
            # It takes 2 contracts with different expiries to form a horizontal spread arbitration to earn price difference in contango.
            if len(list(chain)) < 2:
                return
            sorted_by_expiry = sorted(chain, key=lambda x: x.expiry)
            far_contract = sorted_by_expiry[-1]
            near_contract = sorted_by_expiry[0]

            # Check if the far contract price is 1% higher than the near one.
            # If so, short the far contract and buy the near one to earn the horizontal spread premium.
            if far_contract.bid_price >= near_contract.ask_price * 1.01:
                self.market_order(far_contract.symbol, -1)
                self.market_order(near_contract.symbol, 1)

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        # Liquidate if expired (or not being the front month contract anymore) and exit universe.
        for removed in changes.removed_securities:
            self.liquidate()
```

Requesting Data

Individual Contracts

Introduction

The `add_future_contract` method enables you to add an individual Future contract to your algorithm. To check which contracts are currently available to add to your algorithm, call the `futures_chain` method. If you want to subscribe to a set of contracts instead of individual contracts one-by-one, see Universes .

Create Subscriptions

Before you can subscribe to a Future contract, you must have the underlying Future `Symbol` to get the contract `Symbol` .

```
class BasicFutureAlgorithm(QCAlgorithm):
    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self._continuous = self.add_future(Futures.Indices.SP_500_E_MINI).symbol
        self._contract_symbol = None

    def on_data(self, data):
        if not self._contract_symbol:
            self._contract_symbol = list(self.futures_chain(self._continuous))[0].symbol
            self.add_future_contract(self._contract_symbol)
```

Get Contract Symbols

To subscribe to a Future contract, you need the contract `Symbol` . The preferred method to getting Future contract `Symbol` objects is to use the `futures_chain` method. This method returns a `FuturesChain` object, which represent an entire chain of Option contracts for a single underlying security. You can even format the chain data into a DataFrame where each row in the DataFrame represents a single contract. With the chain, sort and filter the data to find the specific contract(s) you want to trade.

```
# Select the first contract in the chain, which is the front-month contract.
self._contract_symbol = list(self.futures_chain(self._continuous))[0].symbol
```

Alternatively, you can create a Future contract `Symbol` object directly parsing its ticker using the `SymbolRepresentation.parse_future_symbol` method.

```
# Create the contract Symbol for the December 2025 E-mini S&P 500 Future.
self._contract_symbol = SymbolRepresentation.parse_future_symbol('ESZ25')
# Create the contract Symbol using the 1-digit year format.
self._contract_symbol = SymbolRepresentation.parse_future_symbol('ESZ5')
# To avoid ambiguity, specify the 4-digit year.
self._contract_symbol = SymbolRepresentation.parse_future_symbol('ESZ5', 2015)
```

Subscribe to Contracts

To create an Future contract subscription, pass the contract `Symbol` to the `add_future_contract` method. Save a reference to the contract `symbol` so you can easily access the Future contract in the FutureChain that LEAN passes to the `on_data` method. This method returns an `Future` object.

```
self.add_future_contract(self._contract_symbol)
```

The `add_future_contract` method creates a subscription for a single Future contract and adds it to your user-defined universe. To create a dynamic universe of Futures contracts, add an Future universe or an Future Universe Selection model .

Warm Up Contract Prices

If you subscribe to an Future contract with `add_future_contract` , you'll need to wait until the next `Slice` to receive data and trade the contract. To trade the contract in the same time step you subscribe to the contract, set the current price of the contract in a security initializer .

```
self.settings.seed_initial_prices = True
```

Supported Assets

To view the supported assets in the Futures dataset, see the Supported Assets .

Resolutions

The following table shows the available resolutions and data formats for Futures subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`TICK`			✓	✓
`SECOND`	✓	✓		
`MINUTE`	✓	✓		
`HOUR`	✓	✓		
`DAILY`	✓	✓		

The default resolution for Futures contract subscriptions is `Resolution.MINUTE` . To change the resolution, pass a `resolution` argument to the `add_future_contract` method.

```
self.add_future_contract(self._contract_symbol, Resolution.DAILY)
```

To create custom resolution periods, see Consolidating Data .

Supported Markets

The following `Market` enumeration members are available for Futures:

Historical data for backtesting is unavailable for `ICE` , `INDIA` , `SGX` and `NYSELIFFE` . In live trading, LEAN sources this data from your brokerage or a third-party data provider .

You don't need to pass a `market` argument to the `add_future_contract` method because the contract `Symbol` already contains the market.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fill_forward` argument to false when you create the security subscription.

```
self.add_future_contract(self._contract_symbol, fill_forward=False)
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. Futures are already leveraged products, so you can't change their leverage with the default margin model .

Extended Market Hours

By default, your security subscriptions only cover regular trading hours. To subscribe to pre and post-market trading hours for a specific asset, enable the `extended_market_hours` argument when you create the security subscription.

```
self.add_future_contract(self._contract_symbol, extended_market_hours=True)
```

You only receive extended market hours data if you create the subscription with minute, second, or tick resolution. If you create the subscription with daily or hourly resolution, the bars only reflect the regular trading hours.

To view the schedule of regular and extended market hours, see Market Hours .

In general, we model most Futures market hours with the following segments:

Market Segment	Time
Pre-market	00:00:00 to 09:30:00
Market	09:30:00 to 17:00:00
Post-market	18:00:00 to 00:00:00

We model it this way because some Futures, like VIX, have pre- and post-market hours, so we standardized it. With this segmentation, if you set a Scheduled Events for the market open, it's set for 9:30 AM instead of midnight.

Continuous Contracts

A continuous Futures contract represents a single contract that maps to other contracts over time as the rollover rules are met. For more information about continuous Futures contracts, see Continuous Contracts .

Data Normalization

The data normalization mode doesn't affect the data that LEAN passes to `on_data` or the data from history request for Futures contracts. If you change the data normalization mode, it won't change the outcome.

The following data normalization modes are available for continuous Futures contracts :

Properties

The `add_future_contract` method returns a `Future` object, which have the following properties:

Examples

The following examples demonstrate common practices for requesting individual Future contract data.

Example 1: Add the Front-Month Contract

The following algorithm adds the front-month contract, with a two-day buffer, for the E-Mini S&P 500 Future and plots the daily closing price of the contract three days before month end. Then, trade an EMA cross strategy.

PY

```
class FutureExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Request the future underlying data for ATM strike selection.
        self._future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            extended_market_hours=True,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
        ).symbol

        # Create an EMA indicator for trade signal generation.
        self._ema = self.ema(self._future, 20, Resolution.DAILY)
        # Warm up the indicator for immediate readiness to trade with.
        self.warm_up_indicator(self._future, self._ema, Resolution.DAILY)

        # Set a scheduled event to select the option contract periodically.
        self.schedule.on(
            # 3 days offset to select in prior.
            self.date_rules.month_end(3),
            self.time_rules.at(0, 1),
            self.select_contract
        )
        self.select_contract()

    def select_contract(self) -> None:
        # Get all the contracts that are currently tradable.
        chain = self.futures_chain(self._future)
        # Select the front-month contract due to liquidity, with a 2-day buffer to avoid volatility.
        contracts = [c for c in chain if c.expiry >= self.time + timedelta(2)]
        if not contracts:
            return
        contract = contracts[0].symbol
        # Request the Futures contract for trading.
        self._contract_symbol = self.add_future_contract(contract).symbol

    def on_data(self, slice: Slice) -> None:
        # Trade based on updated data.
        bar = slice.bars.get(self._contract_symbol)
        if bar and self.is_market_open(self._contract_symbol):
            # Trade trend-following strategy with EMA cross.
            if bar.close > self._ema.current.value and not self.portfolio[self._future].is_long:
                self.set_holdings(self._contract_symbol, 0.5)
            elif bar.close < self._ema.current.value and not self.portfolio[self._future].is_short:
                self.set_holdings(self._contract_symbol, -0.5)
```

Futures

Handling Data

Introduction

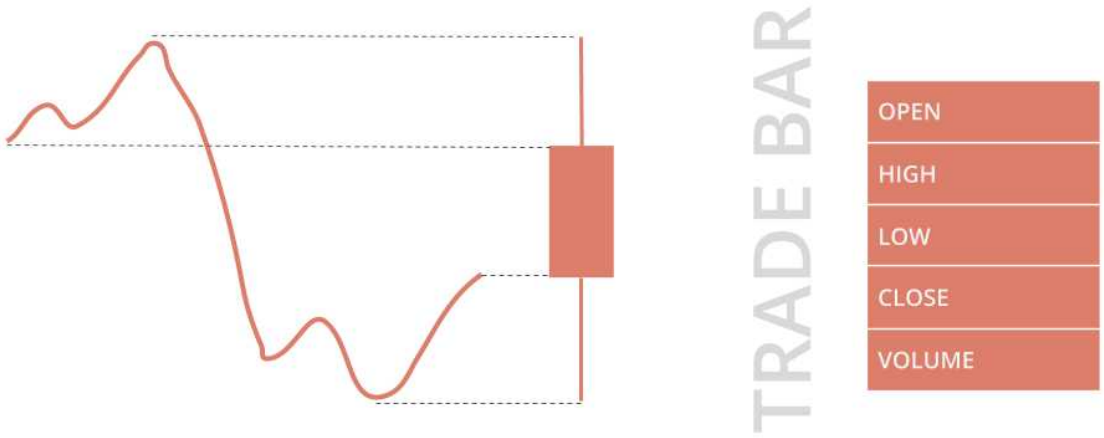
LEAN passes the data you request to the `on_data` method so you can make trading decisions. The `Slice` object that the `on_data` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `on_data` method, use the `current_slice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars` `DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the contract ticker or `symbol` , but we recommend you use the `symbol` .

To view the resolutions that are available for Futures data, see Resolutions .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `bars` property of the `Slice` with the contract `symbol` . If the contract doesn't actively trade or you are in the same time step as when you added the contract subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for your contract before you index the `Slice` with the contract `symbol` .

```
def on_data(self, slice: Slice) -> None:
    # Obtain the mapped TradeBar of the symbol if any
    trade_bar = slice.bars.get(self._contract_symbol)   # None if not found
```

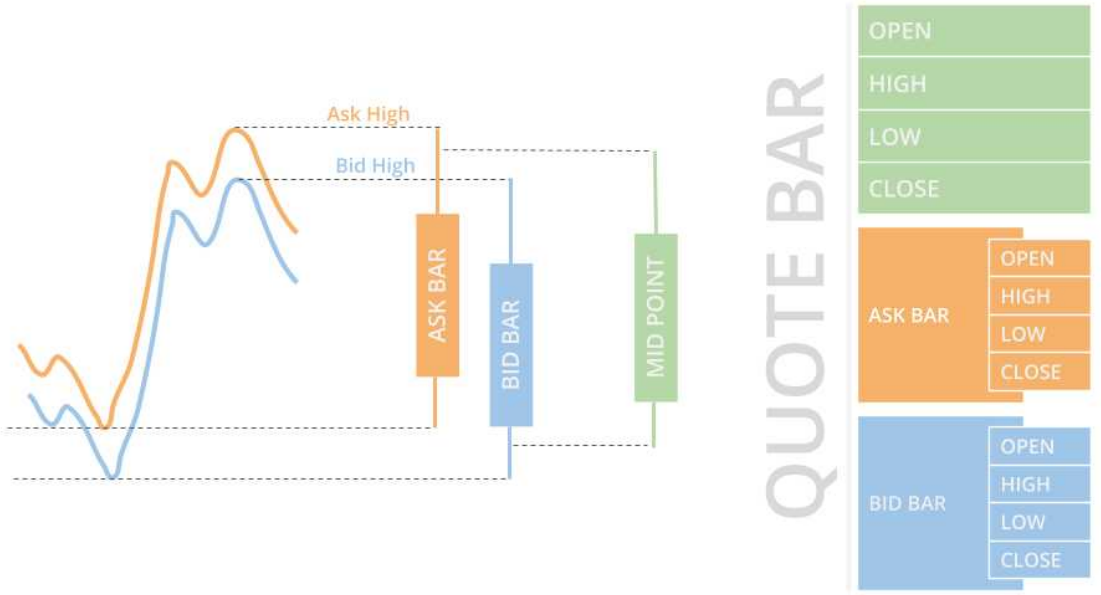
You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Symbol-TradeBar key-value pairs
    for symbol, trade_bar in slice.bars.items():
        close_price = trade_bar.close
```

`TradeBar` objects have the following properties:

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `open` , `high` , `low` , and `close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `open` , `high` , `low` , and `close` properties of the `QuoteBar` copy the values of either the `bid` or `ask` instead of taking their mean.



To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the contract `symbol` . If the contract doesn't actively get quotes or you are in the same time step as when you added the contract subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for your contract before you index the `Slice` with the contract `symbol` .

```
def on_data(self, slice: Slice) -> None:
    # Obtain the mapped QuoteBar of the symbol if any
    quote_bar = slice.quote_bars.get(self._contract_symbol)   # None if not found
```

PY

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Symbol-QuoteBar key-value pairs
    for symbol, quote_bar in slice.quote_bars.items():
        ask_price = quote_bar.ask.close
```

PY

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

`QuoteBar` objects have the following properties:

Ticks

`Tick` objects represent a single trade or quote at a moment in time. A trade tick is a record of a transaction for the contract. A quote tick is an offer to buy or sell the contract at a specific price.

Trade ticks have a non-zero value for the `quantity` and `price` properties, but they have a zero value for the `bid_price` , `bid_size` , `ask_price` , and `ask_size` properties. Quote ticks have non-zero values for `bid_price` and `bid_size` properties or have non-zero values for `ask_price` and `ask_size` properties. To check if a tick is a trade or a quote, use the `ticktype` property.

In backtests, LEAN groups ticks into one millisecond buckets. In live trading, LEAN groups ticks into ~70-millisecond buckets. To get the `Tick` objects in the `Slice` , index the `Ticks` property of the `Slice` with a `symbol` . If the contract doesn't actively trade or you are in the same time step as when you added the contract subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for your contract before you index the `Slice` with the contract `symbol` .

```
def on_data(self, slice: Slice) -> None:
    ticks = slice.ticks.get(self._contract_symbol, [])   # Empty if not found
    for tick in ticks:
        price = tick.price
```

You can also iterate through the `Ticks` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `list[Tick]` objects.

```
def on_data(self, slice: Slice) -> None:
    for symbol, ticks in slice.ticks.items():
        for tick in ticks:
            price = tick.price
```

Tick data is raw and unfiltered, so it can contain bad ticks that skew your trade results. For example, some ticks come from dark pools, which aren't tradable. We recommend you only use tick data if you understand the risks and are able to perform your own online tick filtering.

`Tick` objects have the following properties:

Futures Chains

`FuturesChain` objects represent an entire chain of contracts for a single underlying Future. To get the `FuturesChain`, index the `futures_chains` property of the `Slice` with the continuous contract `Symbol`.

```
def on_data(self, slice: Slice) -> None:
    # Try to get the FutureChain using the canonical symbol (None if no FutureChain return)
    chain = slice.futures_chains.get(self._contract_symbol.canonical)
    if chain:
        # Get all contracts if the FutureChain contains any member
        contracts = chain.contracts
```

You can also loop through the `futures_chains` property to get each `FuturesChain`.

```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Canonical Symbol-FutureChain key-value pairs
    for continuous_contract_symbol, chain in slice.futures_chains.items():
        contracts = chain.contracts
```

`FuturesChain` objects have the following properties:

Futures Contracts

`FuturesContract` objects represent the data of a single Futures contract in the market. To get the Futures contracts in the `Slice`, use the `contracts` property of the `FuturesChain`.

```
def on_data(self, slice: Slice) -> None:
    # Try to get the FutureChain using the canonical symbol
    chain = slice.future_chains.get(self._contract_symbol.canonical)
    if chain:
        # Get individual contract data (None if not contained)
        contract = chain.contracts.get(self._contract_symbol)
        if contract:
            price = contract.last_price
```

Open interest is the number of outstanding contracts that haven't been settled. It provides a measure of investor interest and the market liquidity, so it's a popular metric to use for contract selection. Open interest is calculated once per day. To get the latest open interest value, use the `open_interest` property of the `Future` or `future_contract`.

```
def on_data(self, slice: Slice) -> None:
    # Try to get the futures_chains using the canonical symbol
    chain = slice.futures_chains.get(self._contract_symbol.canonical)
    if chain:
        # Get individual contract data
        contract = chain.contracts.get(self._contract_symbol)
        if contract:
            # Get the open interest of the selected contracts
            open_interest = contract.open_interest
```

`FuturesContract` objects have the following properties:

Symbol Changes

When the continuous contract rolls over, LEAN passes a `SymbolChangedEvent` to your `on_data` method, which contains the old contract `Symbol` and the new contract `Symbol` . To get the `SymbolChangedEvent` , use the `symbol_changed_events` property of the `Slice` . You can use the `SymbolChangedEvent` to roll over contracts.

```
def on_data(self, slice: Slice) -> None:
    for symbol, changed_event in  slice.symbol_changed_events.items():
        old_symbol = changed_event.old_symbol
        new_symbol = changed_event.new_symbol
        tag = f"Rollover - Symbol changed at {self.time}: {old_symbol} -> {new_symbol}"
        quantity = self.portfolio[old_symbol].quantity

        # Rolling over: to liquidate any position of the old mapped contract and switch to the newly mapped contract
        self.liquidate(symbol=old_symbol, tag=tag)
        if quantity: self.market_order(new_symbol, quantity, tag=tag)
        self.log(tag)
```

LEAN passes a `SymbolChangedEvent` to your `on_symbol_changed_events` method as well. LEAN only invokes this method when the continuous contract rolls over.

```
def on_symbol_changed_events(self, symbol_changed_events: SymbolChangedEvents) -> None:
    for symbol, changed_event in symbol_changed_events.items():
        old_symbol = changed_event.old_symbol
        new_symbol = changed_event.new_symbol
        tag = f"Rollover - Symbol changed at {self.time}: {old_symbol} -> {new_symbol}"
        quantity = self.portfolio[old_symbol].quantity

        # Rolling over: to liquidate any position of the old mapped contract and switch to the newly mapped contract
        self.liquidate(symbol=old_symbol, tag=tag)
        if quantity: self.market_order(new_symbol, quantity, tag=tag)
        self.log(tag)
```

In backtesting, the `SymbolChangedEvent` occurs at midnight Eastern Time (ET). In live trading, the live data for continuous contract mapping arrives at 6/7 AM ET, so that's when it occurs.

`SymbolChangedEvent` objects have the following properties:

Examples

The following examples demonstrate some common practices for handling Futures data.

Example 1: Rollovers

Spot Future is referred to as the continuous Future contract, which is usually mapped by the front month contract or the contract with the most open interest. When a contract expires or is very close to expiring, traders usually rollover from the current contract to the next contract to avoid price settlement and remain invested. The following algorithm demonstrates rolling over with limit orders .

```py
class FutureExampleAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add the E-mini Futures and set the continuous contract mapping criteria for the rollovers.
        self._future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            extended_market_hours=True,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0
        )
        self._future.set_filter(0, 182)

    def on_data(self, data):
        # Place the initial order so you can start rolling over contracts later.
        if not self.portfolio.invested and not self.transactions.get_open_orders():
            # Buy the contract that's currently selected in the continous contract series.
            self.market_order(self._future.mapped, 1)

    # Track rollover events.
    def on_symbol_changed_events(self, symbol_changed_events):
        for symbol, changed_event in symbol_changed_events.items():
            old_symbol = changed_event.old_symbol
            new_symbol = changed_event.new_symbol
            # The quantity to roll over should be consistent.
            quantity = self.portfolio[old_symbol].quantity
            # Rolling over: Liquidate the old mapped contract and switch to the newly mapped contract.
            tag = f"Rollover: {old_symbol} -> {new_symbol}"
            self.liquidate(old_symbol, tag=tag)
            if quantity:
                # Place a limit order to avoid extreme quote filling.
                new_contract = self.securities[new_symbol]
                self.limit_order(
                    new_symbol, quantity,
                    # To avoid warnings, round the target limit price to a price that respects
                    # the minimum price variation for the Future.
                    self._get_limit_price(new_contract, new_contract.price),
                    tag=tag
                )

    def _get_limit_price(self, security, target_limit_price, round_up=True):
        parameters = GetMinimumPriceVariationParameters(security, target_limit_price)
        pip = security.price_variation_model.get_minimum_price_variation(parameters)
        return (int(target_limit_price / pip) + int(round_up)) * pip
```

Example 2: Micro Gold vs Gold

The following example demonstrates how to use the `SymbolPropertiesDatabase` to obtain the contract multipliers of both Micro Gold and Gold Future contracts. The algorithm uses it to invest $500k of nominal value into each contract.

PY

```
class FutureNominalBuysAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1_000_000)
        # Set the continuous contract mapping criteria for both Futures
        # since we want to trade the most liquid contracts.
        self._futures = []
        for ticker in [Futures.Metals.GOLD, Futures.Metals.MICRO_GOLD]:
            future = self.add_future(
                ticker,
                extended_market_hours=True,
                data_mapping_mode=DataMappingMode.OPEN_INTEREST,
                data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
                contract_depth_offset=0
            )
            future.set_filter(0, 180)
            self._futures.append(future)

    def on_data(self, slice: Slice) -> None:
        # Wait until we aren't invested and we have bars for all Futures.
        if (not self.portfolio.invested and
            all(future.symbol in slice.bars for future in self._futures)):
            for future in self._futures:
                # Calculate the order size for $500k. Get the quotient
                # after dividing by the contract multiplier since the
                # order size must be whole number.
                quantity = (
                    500_000
                    / future.price
                    // future.symbol_properties.contract_multiplier
                )
                if not quantity:
                    continue
                self.market_order(future.mapped, quantity)
```

Future Options

Requesting Data

Request Future Options data in your algorithm to receive a feed of contract prices in the `on_data` method. For more information about the specific dataset we use for backtests, see the US Future Options dataset listing . To trade Future Options live, you can use one of the brokerage data providers . We currently only support European-style Options for US Future Options.

To request Future Options data, call one of the following methods:

- `self.add_future_option` to add a basket of contracts for a single underlying Future
- `self.add_future_option_contract` to add individual contracts for an underlying Future

Request and Filter Contracts for Option Strategies

Universes

Introduction

The `add_future_option` method enables you to select a basket of Option contracts for an underlying Future. To form your universe of contracts, you can filter them down by their strike price and expiry or you can choose a subset of the contracts that form popular Option strategies . If you want to subscribe to individual contracts one-by-one instead of a set of contracts, see Individual Contracts .

Create Universes

To add a universe of Future Option contracts, in the `initialize` method, call the `add_future_option` method. Pass the `option_filter` argument to filter the set of tradable contract down to just the contracts you want.

```
PY
class BasicFutureOptionAlgorithm(QCAlgorithm):
    def initialize(self):
        self._future = self.add_future(Futures.Indices.SP_500_E_MINI,
            extended_market_hours=True,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0)
        self._future.set_filter(0, 182)

        self.add_future_option(self._future.symbol, lambda option_filter_universe: option_filter_universe.strikes(-1, 1))

    def on_data(self, data):
        # Iterate all Option chains to find the desired future and future options contracts
        for canonical_symbol, chain in data.option_chains.items():
            future_contract = canonical_symbol.underlying
            for symbol, contract in chain.contracts.items():
                strike = contract.strike

        # Get the Option chain for the mapped contract
        mapped_chain = data.option_chains.get(Symbol.create_canonical_option(self._future.mapped))
        if mapped_chain:
            for symbol, contract in mapped_chain.contracts.items():
                strike = contract.strike
```

For more information about the `add_future_option` method, see Create Universes .

Filter by Investment Strategy

Options trading strategies consist of simultaneously buying or selling one or more Option contracts of the same underlying Future with different features. The following table describes the filter methods of the `OptionFilterUniverse` class that select contract for Option strategies.

The following table describes the filter methods of the `OptionFilterUniverse` class that select contracts for Option strategies:

`naked_call(min_days_till_expiry: int, strike_from_atm: float)` Selects a call contract to form Naked Call , Covered Call , or Protective Call Option strategies.
`naked_put(min_days_till_expiry: int, strike_from_atm: float)` Selects a put contract to form Naked Put , Covered Put , or Protective Put Option strategies.
`call_spread(min_days_till_expiry: int, higher_strike_from_atm: float, lower_strike_from_atm: float)` Selects two call contracts to form Bull Call Spread or Bear Call Spread Option strategies.
`put_spread(min_days_till_expiry: int, higher_strike_from_atm: float, lower_strike_from_atm: float)` Selects two put contracts to form Bull Put Spread or Bear Put Spread Option strategies.

`call_calendar_spread(strike_from_atm: int, min_near_days_till_expiry: int, min_far_days_till_expiry: int)`

Selects two call contracts to form Long Call Calendar Spread or Short Call Calendar Spread Option strategies.

`put_calendar_spread(strike_from_atm: int, min_near_days_till_expiry: int, min_far_days_till_expiry: int)`

Selects two put contracts to form Long Put Calendar Spread or Short Put Calendar Spread Option strategies.

`strangle(min_days_till_expiry: int, higher_strike_from_atm: float, lower_strike_from_atm: float)`

Selects two contracts to form Long Strangle or Short Strangle Option strategies.

`straddle(min_days_till_expiry: int)`

Selects two contracts to form Long Straddle or Short Straddle Option strategies.

`protective_collar(min_days_till_expiry: int, higher_strike_from_atm: float, lower_strike_from_atm: float)`

Selects two contracts to form Protective Collar Option strategies.

`conversion(min_days_till_expiry: int, strike_from_atm: float)`

Selects two contracts to form Conversion or Reverse Conversion Option strategies.

`call_butterfly(min_days_till_expiry: int, strike_spread: float)`

Selects three contracts to form Long Call Butterfly or Short Call Butterfly Option strategies.

`put_butterfly(min_days_till_expiry: int, strike_spread: float)`

Selects three contracts to form Long Put Butterfly or Short Put Butterfly Option strategies.

`iron_butterfly(min_days_till_expiry: int, strike_spread: float)`

Selects four contracts to form Long Iron Butterfly or Short Iron Butterfly Option strategies.

`iron_condor(min_days_till_expiry: int, near_strike_spread: float, far_strike_spread: float)`

Selects four contracts to form Long Iron Condor or Short Iron Condor Option strategies.

`box_spread(min_days_till_expiry: int, strike_spread: float)`

Selects four contracts to form Box Spread or Short Box Spread Option strategies.

`jelly_roll(strike_from_atm: float, min_near_days_till_expiry: int, min_far_days_till_expiry: int)`

Selects four contracts to form Jelly Roll or Short Jelly Roll Option strategies.

`call_ladder(min_days_till_expiry: int, higher_strike_from_atm: float, middle_strike_from_atm: float, lower_strike_from_atm: float)`

Selects four contracts to form Bear Call Ladder or Bull Call Ladder Option strategies.

`put_ladder(min_days_till_expiry: int, higher_strike_from_atm: float, middle_strike_from_atm: float, lower_strike_from_atm: float)`

Selects four contracts to form Bear Put Ladder or Bull Put Ladder Option strategies.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

```
PY

# Example 1: Select a Straddle
self.add_future_option(self._future.symbol, lambda option_filter_universe: option_filter_universe.straddle(30, 5, 10))

# Example 2: Select the contracts (including weeklys) that expire in the next 30 days that form an Iron Condor
self.add_future_option(self._future.symbol, lambda option_filter_universe: option_filter_universe.strikes(-20, 20).expiration(0,
30).iron_condor(30, 5, 10))

# Example 3: Select the front month contracts that form an Strangle
self.add_future_option(self._future.symbol, lambda option_filter_universe: option_filter_universe.front_month().strangle(30, 5, -10))
```

Filter by Other Contract Properties

To set a contract filter, in the `initialize` method, call the `add_future_option` method and pass the `option_filter` argument.

```
PY

# Select contracts that have a strike price within 1 strike level above and below the underlying price
self.add_future_option(self._future.symbol, lambda option_filter_universe: option_filter_universe.strikes(-1,1))

# Select contracts that expire within 30 days
self.add_future_option(self._future.symbol, lambda option_filter_universe: option_filter_universe.expiration(0,30))

# Select contracts that have a strike price within 1 strike level and expire within 30 days
self.add_future_option(self._future.symbol, lambda option_filter_universe: option_filter_universe.strikes(-1,1).expiration(0,30))

# Select call contracts
self.add_future_option(self._future.symbol, lambda option_filter_universe: option_filter_universe.calls_only())
```

The following table describes the filter methods of the `OptionFilterUniverse` class:

`strikes(min_strike: int, max_strike: int)` Selects contracts that are within `m_strike` strikes below the underlying price and `max_strike` strikes above the underlying price.
`calls_only()` Selects call contracts.
`puts_only()` Selects put contracts.
`standards_only()` Selects standard contracts.
`weeklys_only()` Selects weekly contracts. This filter doesn't currently work. To add this functionality to our roadmap , react to this GitHub Issue with a thumbs up emoji.
`front_month()` Selects the front month contract.
`back_months()` Selects the non-front month contracts.
`back_month()` Selects the back month contracts.
`expiration(min_expiryDays: int, max_expiryDays: int)` Selects contracts that expire within a range of dates relative to the current day.
`contracts(contracts: list[Symbol])` Selects a list of contracts.
`contracts(contract_selector: Callable[[list[Symbol]], list[Symbol]])` Selects contracts that a selector function selects.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

PY

```
# Example 1: Select the front month call contracts
self.add_future_option(self._future.symbol, lambda option_filter_universe: option_filter_universe.calls_only().front_month())

# Example 2: Select the contracts that expire in the next 90 days
self.add_future_option(self._future.symbol, lambda option_filter_universe: option_filter_universe.strikes(-20, 20).expiration(0, 90))
```

To perform thorough filtering on the `OptionFilterUniverse` , define an isolated filter method.

```py
class BasicFutureOptionAlgorithm(QCAlgorithm):
    def initialize(self):
        self.add_future_option(self._future.symbol, self._selector)

    def _selector(self, option_filter_universe: OptionFilterUniverse) -> OptionFilterUniverse:
        symbols = list(option_filter_universe.puts_only())
        strike = min([symbol.id.strike_price for symbol in symbols])
        symbols = [symbol for symbol in symbols if symbol.id.strike_price == strike]
        return option_filter_universe.contracts(symbols)
```

Some of the preceding filter methods only set an internal enumeration in the `OptionFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `OptionFilterUniverse` .

Default Filter

By default, LEAN subscribes to the Option contracts that have the following characteristics:

- Standard and weeklys
- Within 1 strike price of the underlying asset price
- Expire within 35 days

To adjust the universe of contracts, set a filter. The filter usually runs at the first bar of every day. When the filter selects a contract that isn't currently in your universe, LEAN adds the new contract data to the next `Slice` that it passes to the `on_data` method.

Historical Data

To get historical data for a Future Options universe, see Historical Data .

Examples

The following examples demonstrate some common practices for requesting Future Option data through universe filtering.

Example 1: Call Spread

The following example demonstrates how to implement a bull call spread option strategy using universe filtering. We have to first subscribe to the underlying Future (with filtering), then call `self.add_future_option` with the underlying `Symbol` and the filtering function. We use `call_spread` method in the `OptionFilterUniverse` object to return only the 2 best match call contracts that forms a bull call spread.

```py
class FutureOptionAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Filter the underlying continuous Futures to narrow the FOP spectrum.
        self.underlying = self.add_future(Futures.Indices.SP_500_E_MINI,
            extended_market_hours=True,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0)
        self.underlying.set_filter(0, 182)
        # Use CallSpread filter to obtain the 2 best-matched contracts that forms a call spread.
        # It simplifies from further filtering and reduce computation on redundant subscription.
        self.add_future_option(self.underlying.symbol, lambda u: u.call_spread(5, 5, -5))

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested:
            return
        # Create canonical symbol for the mapped future contract, since we need that to access the option chain.
        symbol = Symbol.create_canonical_option(self.underlying.mapped)

        # Get option chain data for the mapped future only.
        # It requires 2 contracts with different strikes to form a call spread, so we make sure at least 2 contracts are present.
        chain = slice.option_chains.get(symbol)
        if not chain or len(list(chain)) < 2:
            return

        # Separate the contracts by strike, as we need to access their strike.
        expiry = min([x.expiry for x in chain])
        sorted_by_strike = sorted([x.strike for x in chain])
        itm_strike = sorted_by_strike[0]
        otm_strike = sorted_by_strike[-1]

        # Use abstraction method to order a bull call spread to avoid manual error.
        option_strategy = OptionStrategies.bull_call_spread(symbol, itm_strike, otm_strike, expiry)
        self.buy(option_strategy, 1)
```

Note that since both the underlying Future and the Future Option are expiring on the same day and are cash-settling in most cases, Lean can exercise the Future Option into account cash automatically at expiry and we do not need to handle the option exercise/assignment event.

Requesting Data

Individual Contracts

Introduction

The `add_future_option_contract` method enables you to add an individual Option contract to your algorithm. To check which contracts are currently available to add to your algorithm, use the `option_chain` method. If you want to subscribe to a set of contracts instead of individual contracts one-by-one, see Universes .

Create Subscriptions

Before you can subscribe to an Option contract, you must configure the underlying Future and get the contract `Symbol` .

```
class BasicFutureOptionAlgorithm(QCAlgorithm):
    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self._future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            extended_market_hours=True,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0
        )
        self._future.set_filter(0, 182)
        self._contract_symbol = None

    def on_data(self, data):
        if not self._contract_symbol:
            # Method 1: Add the desired option chain for the mapped contract
            self._contract_symbol = self._select_option_contract(self._future.mapped)
            self.add_future_option_contract(self._contract_symbol)

            # Method 2: Get all future contracts from the Future chain provider
            future_contract_symbol = list(self.futures_chain(self._future.symbol))[0].symbol
            symbol = self._select_option_contract(future_contract_symbol)
            self.add_future_option_contract(symbol)

            # Method 3: Iterate all Future chains to find the desired future options contracts
            for symbol, chain in data.future_chains.items():
                expiry = min([contract.expiry for contract in chain])
                future_contract = next(contract for contract in chain if contract.expiry == expiry)
                symbol = self._select_option_contract(future_contract.symbol)
                self.add_future_option_contract(symbol)

    def _select_option_contract(self, future_contract_symbol):
        chain = self.option_chain(future_contract_symbol, flatten=True).data_frame
        expiry = chain.expiry.min()
        return chain[
            (chain.expiry == expiry) & (chain.right == OptionRight.CALL)
        ].sort_values('strike').index[-1]
```

Configure the Underlying Futures Contracts

In most cases, you should subscribe to the underlying Futures contract before you subscribe to a Futures Option contract.

```
self._future = self.add_future(
    Futures.Indices.SP_500_E_MINI,
    extended_market_hours=True,
    data_mapping_mode=DataMappingMode.OPEN_INTEREST,
    data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
    contract_depth_offset=0
)
```

To get a `Symbol` of a specific Futures contract, use the `mapped` property of the `Future` object or the `symbol` property of the `FutureContract` objects in the `Slice.future_chains` collection.

Get Contract Symbols

To subscribe to a Future Option contract, you need the contract `Symbol` . The preferred method to getting Option contract `Symbol` objects is to use

the option_chain method. This method returns an OptionChain object, which represent an entire chain of Option contracts for a single underlying security. You can even format the chain data into a DataFrame where each row in the DataFrame represents a single contract. With the chain, sort and filter the data to find the specific contract(s) you want to trade.

```
PY
# Get the contracts available to trade (in DataFrame format).
chain = self.option_chain(future_contract_symbol, flatten=True).data_frame

# Select a contract.
expiry = chain.expiry.min()
self._contract_symbol = chain[
    # Select call contracts with the closest expiry.
    (chain.expiry == expiry) & (chain.right == OptionRight.CALL)
    # Select the contract with the lowest strike price.
].sort_values('strike').index[0]
```

Alternatively, you can create a Future Option contract Symbol object directly parsing its OSI ticker using the SymbolRepresentation.parse_option_ticker_osi method.

```
PY
# Create the contract Symbol for the Sept 2024 E-mini S&P 500 Call 7900 20 Sept 2024.
self._contract_symbol = SymbolRepresentation.parse_option_ticker_osi('ESU24 240920C07900000', SecurityType.FUTURE_OPTION,
OptionStyle.AMERICAN, Market.CME)
# Create the contract Symbol using the 1-digit year format.
self._contract_symbol = SymbolRepresentation.parse_option_ticker_osi('ESU4 240920C07900000', SecurityType.FUTURE_OPTION,
OptionStyle.AMERICAN, Market.CME)
```

Subscribe to Contracts

To create a Future Option contract subscription, pass the contract Symbol to the add_future_option_contract method. Save a reference to the contract symbol so you can easily access the Option contract in the OptionChain that LEAN passes to the on_data method. This method returns an Option object. To override the default pricing model of the Option, set a pricing model .

```
PY
option = self.add_future_option_contract(self._contract_symbol)
option.price_model = OptionPriceModels.binomial_cox_ross_rubinstein()
```

Warm Up Contract Prices

If you subscribe to a Future Option contract with add_future_option_contract , you'll need to wait until the next Slice to receive data and trade the contract. To trade the contract in the same time step you subscribe to the contract, set the current price of the contract in a security initializer .

```
PY
self.settings.seed_initial_prices = True
```

Supported Assets

To view the supported assets in the US Future Options dataset, see the Supported Assets .

Resolutions

The following table shows the available resolutions and data formats for Future Option contract subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
TICK				
SECOND				
MINUTE	✓	✓		
HOUR	✓	✓		
DAILY	✓	✓		

There is only one resolution option, so you don't need to pass a `resolution` argument to the `add_future_option_contract` method.

```
self.add_future_option_contract(self._option_contract_symbol, Resolution.MINUTE)
```

To create custom resolution periods, see Consolidating Data .

Supported Markets

The following `Market` enumeration members are available for Future Options:

You don't need to pass a `Market` argument to the `add_future_option_contract` method because the contract `Symbol` already contains the market.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fill_forward` argument to false when you create the security subscription.

```
self.add_future_option_contract(self._option_contract_symbol, fill_forward=False)
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. Future Options are already leveraged products, so you can't change their leverage.

Extended Market Hours

By default, your security subscriptions only cover regular trading hours. To subscribe to pre and post-market trading hours for a specific asset, enable the `extended_market_hours` argument when you create the security subscription.

```
self.add_future_option_contract(self._option_contract_symbol, extended_market_hours=True)
```

You only receive extended market hours data if you create the subscription with minute, second, or tick resolution. If you create the subscription with daily or hourly resolution, the bars only reflect the regular trading hours.

To view the schedule of regular and extended market hours, see Market Hours .

Data Normalization

The data normalization mode doesn't affect the data that LEAN passes to `on_data` or the data from history request . If you change the data normalization mode, it won't change the outcome.

Remove Subscriptions

To remove a contract subscription that you created with `add_future_option_contract` , call the `remove_option_contract` method. This method is an alias for `remove_security` .

```
self.remove_option_contract(self._option_contract_symbol)
```

The `remove_option_contract` method cancels your open orders for the contract and liquidates your holdings.

Properties

The `add_future_option_contract` method returns an `Option` object, which have the following properties:

Helper Methods

The `Option` object provides methods you can use for basic calculations. These methods require the underlying price. To get the `Option` object and the `Security` object for its underlying in any function, use the Option `symbol` to access the value in the `securities` object.

```py
option = self.securities[self._option_contract_symbol]
underlying = self.securities[self._option_contract_symbol.underlying]
underlying_price = underlying.price
```

To get the Option payoff , call the `get_pay_off` method.

```py
pay_off = option.get_pay_off(underlying_price)
```

To get the Option intrinsic value , call the `get_intrinsic_value` method.

```py
intrinsic_value = option.get_intrinsic_value(underlying_price)
```

To get the Option out-of-the-money amount , call the `out_of_the_money_amount` method.

```py
otm_amount = option.out_of_the_money_amount(underlying_price)
```

To check whether the Option can be automatic exercised, call the `is_auto_exercised` method.

```py
is_auto_exercised = option.is_auto_exercised(underlying_price)
```

Future Options

Handling Data

Introduction

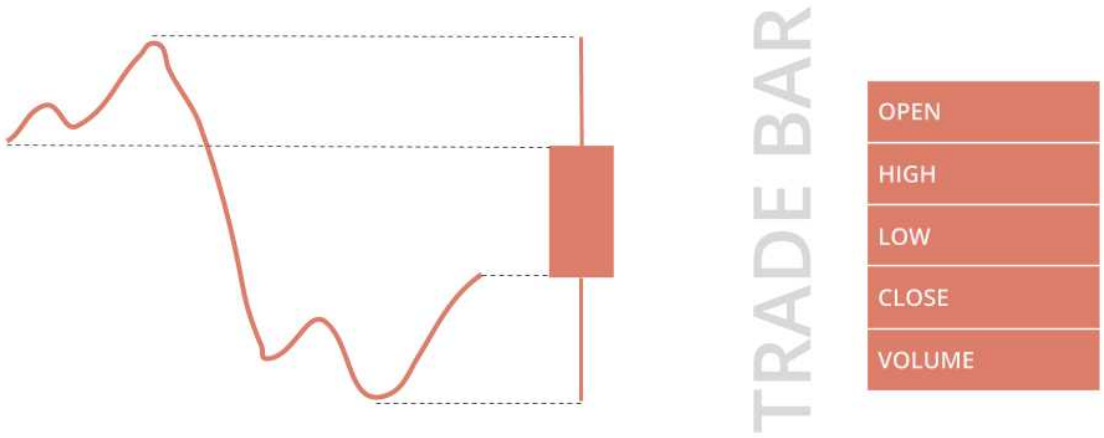
LEAN passes the data you request to the `on_data` method so you can make trading decisions. The `Slice` object that the `on_data` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `on_data` method, use the `current_slice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars` `DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the Futures Option contract ticker or `symbol` , but we recommend you use the `symbol` .

To view the resolutions that are available for Future Options data, see Resolutions .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `bars` property of the `Slice` with the Option contract `symbol` . If the Option contract doesn't actively trade or you are in the same time step as when you added the Option contract subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for your Option contract before you index the `Slice` with the Option contract `symbol` .

```
def on_data(self, slice: Slice) -> None:
    # Obtain the mapped TradeBar of the symbol if any
    trade_bar = slice.bars.get(self._option_contract_symbol)   # None if not found
```

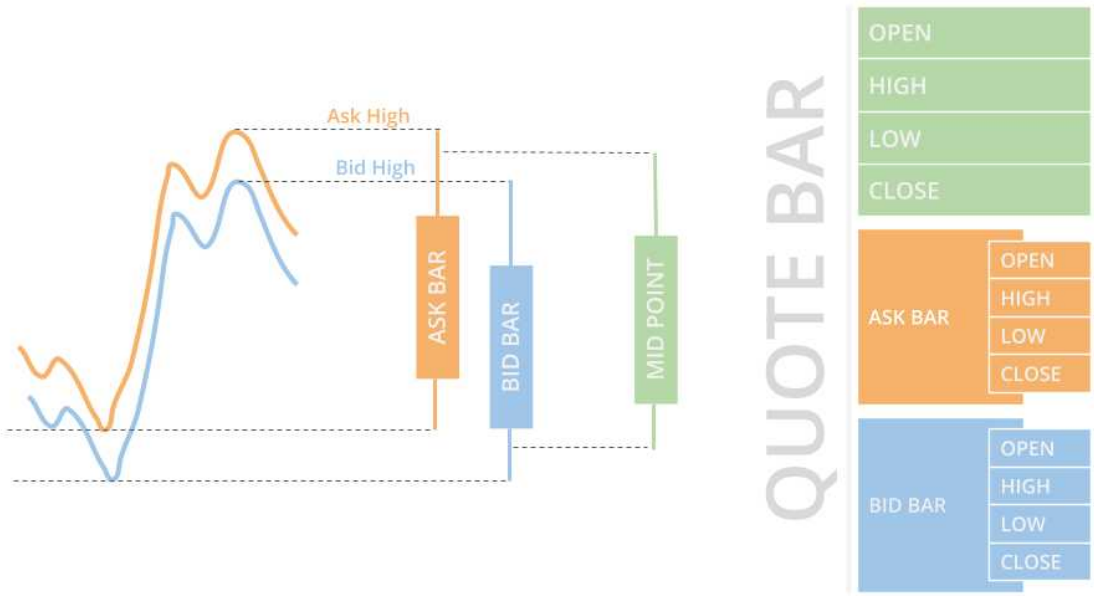
You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Symbol-TradeBar key-value pairs
    for symbol, trade_bar in slice.bars.items():
        close_price = trade_bar.close
```

`TradeBar` objects have the following properties:

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `open` , `high` , `low` , and `close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `open` , `high` , `low` , and `close` properties of the `QuoteBar` copy the values of either the `bid` or `ask` instead of taking their mean.



To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the Option contract `symbol` . If the Option contract doesn't actively get quotes or you are in the same time step as when you added the Option contract subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for your Option contract before you index the `Slice` with the Option contract `symbol` .

```
def on_data(self, slice: Slice) -> None:
    # Obtain the mapped QuoteBar of the symbol if any
    quote_bar = slice.quote_bars.get(self._option_contract_symbol)   # None if not found
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Symbol-QuoteBar key-value pairs
    for symbol, quote_bar in slice.quote_bars.items():
        ask_price = quote_bar.ask.close
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

`QuoteBar` objects have the following properties:

Futures Chains

`FuturesChain` objects represent an entire chain of contracts for a single underlying Future. To get the `FuturesChain` , index the `futures_chains` property of the `Slice` with the continuous contract `Symbol` .

```
def on_data(self, slice: Slice) -> None:
    # Try to get the FutureChain using the canonical symbol (None if no FutureChain return)
    chain = slice.futures_chains.get(self._future_contract_symbol.canonical)
    if chain:
        # Get all contracts if the FutureChain contains any member
        contracts = chain.contracts
```

You can also loop through the `futures_chains` property to get each `FuturesChain` .

```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Canonical Symbol-FutureChain key-value pairs
    for continuous_contract_symbol, chain in slice.futures_chains.items():
        contracts = chain.contracts
```

`FuturesChain` objects have the following properties:

Futures Contracts

`FuturesContract` objects represent the data of a single Futures contract in the market. To get the Futures contracts in the `Slice` , use the `contracts` property of the `FuturesChain` .

```
def on_data(self, slice: Slice) -> None:
    # Try to get the FutureChain using the canonical symbol
    chain = slice.future_chains.get(self._future_contract_symbol.canonical)
    if chain:
        # Get individual contract data (None if not contained)
        contract = chain.contracts.get(self._future_contract_symbol)
        if contract:
            price = contract.last_price
```

`FuturesContract` objects have the following properties:

Option Chains

`OptionChain` objects represent an entire chain of Option contracts for a single underlying security.

To get the `OptionChain` , index the `option_chains` property of the `Slice` with the canonical `Symbol` .

```
def on_data(self, slice: Slice) -> None:
    # Try to get the OptionChain using the canonical symbol (None if no OptionChain return)
    chain = slice.option_chains.get(self._option_contract_symbol.Canonical)
    if chain:
        # Get all contracts if the OptionChain contains any member
        contracts = chain.contracts
```

You can also loop through the `option_chains` property to get each `OptionChain` .

```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Canonical Symbol-OptionChain key-value pairs
    for canonical_fop_symbol, chain in slice.option_chains.items():
        contracts = chain.contracts
```

`OptionChain` objects have the following properties:

Option Contracts

`OptionContract` objects represent the data of a single Option contract in the market. To get the Option contracts in the `Slice` , use the `contracts` property of the `OptionChain` .

```
def on_data(self, slice: Slice) -> None:
    # Try to get the OptionChain using the canonical symbol
    chain = slice.option_chains.get(self._option_contract_symbol.canonical)
    if chain:
        # Get individual contract data
        contract = chain.contracts.get(self._option_contract_symbol)
        if contract:
            price = contract.price
```

You can also iterate through the `futures_chains` first.

```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Canonical Symbol-FuturesChain key-value pairs
    for continuous_future_symbol, futures_chain in slice.futures_chains.items():
        # Select a Future Contract and create its canonical FOP Symbol
        futures_contract = [contract for contract in futures_chain][0]
        canonical_fop_symbol = Symbol.create_canonical_option(futures_contract.symbol)
        # Try to get the OptionChain using the canonical FOP symbol
        option_chain = slice.option_chains.get(canonical_fop_symbol)
        if option_chain:
            # Get individual contract data
            option_contract = option_chain.contracts.get(self._option_contract_symbol)
            if option_contract:
                price = option_contract.price
```

Greeks and Implied Volatility

To get the Greeks and implied volatility of an Option contract, use the `greeks` and `implied_volatility` members.

```
def on_data(self, slice: Slice) -> None:
    # Try to get the OptionChain using the canonical symbol
    chain = slice.option_chains.get(self._option_contract_symbol.canonical)
    if chain:
        # Get individual contract data
        contract = chain.contracts.get(self._option_contract_symbol)
        if contract:
            # Get greeks data of the selected contract
            delta = contract.greeks.delta
            iv = contract.implied_volatility
```

LEAN only calculates Greeks and implied volatility when you request them because they are expensive operations. If you invoke the `greeks` property, the Greeks aren't calculated. However, if you invoke the `greeks.delta` , LEAN calculates the delta. To avoid unecessary computation in your algorithm, only request the Greeks and implied volatility when you need them. For more information about the Greeks and implied volatility, see Options Pricing .

Open Interest

Open interest is the number of outstanding contracts that haven't been settled. It provides a measure of investor interest and the market liquidity, so it's a popular metric to use for contract selection. Open interest is calculated once per day. To get the latest open interest value, use the `open_interest` property of the `Option` or `option_contract` .

```
def on_data(self, slice: Slice) -> None:
    # Try to get the option_chains using the canonical symbol
    chain = slice.option_chains.get(self._contract_symbol.canonical)
    if chain:
        # Get individual contract data
        contract = chain.contracts.get(self._contract_symbol)
        if contract:
            # Get the open interest of the selected contracts
            open_interest = contract.open_interest
```

Properties

`OptionContract` objects have the following properties:

Examples

The following examples demonstrate some common practices for handling Future Option data.

Example 1: Monthly Protective Put

The following algorithm shows how to perform monthly selection on individual ES Future Option contract to implement a protective put option strategy to hedge speculation on S&P500 Future. It is a useful tool to hedge the excessive risk on leverage using Futures to trade.

```
class FutureOptionExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000000000)

        # Seed the security price to ensure the underlying price is available at the initial filtering.
        self.settings.seed_initial_prices = True
        # Set data normalization mode to raw for fair strike price comparison.
        self.universe_settings.data_normalization_mode = DataNormalizationMode.RAW
        # Subscribe the underlying since the updated price is needed for filtering.
        self.underlying = self.add_future(Futures.Indices.SP_500_E_MINI,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.RAW,
            contract_depth_offset=0)
        # Filter the underlying continuous Futures to narrow the FOP spectrum.
        self.underlying.set_filter(0, 31)

        # Schedule a monthly event on selection of future-future option pair, since the portfolio rebalance on a monthly basis.
        self.schedule.on(
            self.date_rules.month_start(self.underlying.symbol),
            self.time_rules.after_market_open(self.underlying.symbol, 0),
            self.selection_and_rebalance
        )

    def selection_and_rebalance(self) -> None:
        # Get all available put FOP contract for the mapped underlying contract, since the trade liquidity and volatility is the highest.
        contract_symbols = self.option_chain(self.underlying.mapped)
        contract_symbols = [symbol for symbol in contract_symbols if symbol.id.option_right == OptionRight.PUT]
        # Select the ATM put expires the same date as the underlying. The max expiry of the FOP will expire the same time as the front
month future.
        expiry = max(symbol.id.date for symbol in contract_symbols)
        filtered_symbols = [symbol for symbol in contract_symbols if symbol.id.date == expiry]
        selected = sorted(filtered_symbols, key=lambda symbol: abs(symbol.id.strike_price -
self.securities[self.underlying.mapped].price))[0]
        # Request the FOP contract data for trading.
        contract = self.add_future_option_contract(selected)

        # A Protective Put consists of long a lot of the underlying, and long a put contract.
        self.market_order(self.underlying.mapped, contract.symbol_properties.contract_multiplier)
        self.market_order(contract.symbol, 1)
```

Example 2: Weekly Covered Call

The below example demonstrates a weekly-renewing covered call strategy to collect credit of selling the option. It filters the ATM call contract that expires within the current week at week start using `set_filter` filtering function.

```
class FutureOptionExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000000000)
        # Set data normalization mode to raw for fair strike price comparison.
        self.universe_settings.data_normalization_mode = DataNormalizationMode.RAW

        # Subscribe the underlying since the updated price is needed for filtering.
        self.underlying = self.add_future(Futures.Indices.SP_500_E_MINI,
            extended_market_hours=True,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.RAW,
            contract_depth_offset=0)
        # Filter the underlying continuous Futures to narrow the FOP spectrum.
        self.underlying.set_filter(0, 182)
        # Filter for the current-week-expiring calls to formulate a covered call that expires at the end of week.
        self.add_future_option(self.underlying.symbol, lambda u: u.calls_only().expiration(0, 5))

    def on_data(self, slice: Slice) -> None:
        # Create canonical symbol for the mapped future contract, since option chains are mapped by canonical symbol.
        symbol = Symbol.create_canonical_option(self.underlying.mapped)

        # Get option chain data for the mapped future, as both the underlying and FOP have the highest liquidity among all other
contracts.
        chain = slice.option_chains.get(symbol)
        if not self.portfolio.invested and chain:
            # Obtain the ATM call that expires at the end of week, such that both underlying and the FOP expires the same time.
            expiry = max(x.expiry for x in chain)
            atm_call = sorted([x for x in chain if x.expiry == expiry],
                key=lambda x: abs(x.strike - x.underlying_last_price))[0]

            # Use abstraction method to order a covered call to avoid manual error.
            option_strategy = OptionStrategies.covered_call(symbol, atm_call.strike,expiry)
            self.buy(option_strategy, 1)
```

Note that since both the underlying Future and the Future Option are expiring on the same day and are cash-settling in most cases, Lean can

exercise the Future Option into account cash automatically at expiry and we do not need to handle the option exercise/assignment event.

Future Options

Greeks and Implied Volatility

The Greeks are measures that describe the sensitivity of an Option's price to various factors like underlying price changes (Delta), time decay (Theta), volatility (Vega), and interest rates (Rho), while Implied Volatility (IV) represents the market's expectation of the underlying asset's volatility over the life of the Option.

Greeks and Implied Volatility

Key Concepts

Introduction

LEAN provides multiple ways for you to get the Greeks and implied volatility (IV) of Option contracts. There is a daily, pre-calculated dataset based on the end of the previous trading day. There is also a stream of values that are calculated on-the-fly as your algorithm runs.

Greeks on Universes

This feature is coming soon for Future Options.

Greek History

This feature is coming soon for Future Options.

Greeks on Data Events

The Greeks and IV values that you get from the current Slice are from the price model calculations. These values aren't the same as the values you get in the universe filter function.

```py
class BasicFutureOptionAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.settings.seed_initial_prices = True
        self.add_security_initializer(self._custom_security_initializer)
        self._future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0
        )
        self._future.set_filter(0, 182)
        self.add_future_option(self._future.symbol, lambda universe: universe.strikes(-5, 5))

    def on_data(self, data):
        for chain in data.option_chains.values():
            for contract in chain:
                iv = contract.implied_volatility
                delta = contract.greeks.delta

    def _custom_security_initializer(self, security: Security) -> None:
        if security.type == SecurityType.FUTURE_OPTION:
            security.price_model = OptionPriceModels.binomial_cox_ross_rubinstein()
```

To view all the models LEAN supports, see Supported Models .

Greek Indicators

Option indicators provide daily and intraday values for the Greeks and implied volatility of Future Option contracts.

Examples

For detailed examples on using Option Greeks and Implied Volatility indicators in algorithm, you may refer to the Greeks Indicators page examples.

Greeks and Implied Volatility

Indicators

Introduction

Option indicators enable you to calculate daily and intraday values for the Greeks and implied volatility of Option contracts. This page explains the most popular Option indicators and how to use them with LEAN.

Parameters

The following table describes the arguments that the automatic Option indicators methods accept:

Argument	Data Type	Description	Default Value
`symbol`	`Symbol`	The contract to use when calculating the indicator values.	
`mirror_option`	`Symbol`	The mirror contract to use in parity type calculations.	`None`
`risk_free_rate`	`float`	The risk-free interest rate. If you don't provide a value, the default value is the US primary credit rate from the Interest Rate Provider Model .	`None`
`dividend_yield`	`float`	The dividend yield rate. If you don't provide a value, the default value comes from the Dividend Yield Provider Model .	`None`
`option_model`	`OptionPricingModelType`	The Option pricing model that's used to calculate the Greeks. If you don't provide a value, the default value is `OptionPricingModelType.BlackScholes` for European-style Options.	`None`
`resolution`	`Resolution`	The resolution of the indicator data. If you don't provide a value, the default value is the resolution of the subscription you have for the Option contract(s).	`None`

To perform implied volatility (IV) smoothing with a put-call pair, pass one of the contracts as the `symbol` argument and pass the other contract in the pair as the `mirror_option` argument. The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, call the `set_smoothing_function` method of the `ImpliedVolatility` class/property.

Several different Option pricing models are supported to calculate the IV and Greeks. The following table describes the `OptionPricingModelType` enumeration members:

Implied Volatility

Implied volatility, , is the market's expectation for the future volatility of an asset and is implied by the price of the assets's Options contracts. You can't observe it in the market but you can derive it from the price of an Option. For more information about implied volatility, see Implied Volatility .

Automatic Indicators

To create an automatic indicator for implied volatility, call the `QCAlgorithm.iv` method with the Option contract `symbol` object(s).

```py
class AutomaticImpliedVolatilityIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0
        )
        self._future.set_filter(0, 182)

        # Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._future.symbol),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )
        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._future.mapped is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._future.mapped, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_future_option_contract(call)
            contract2 = self.add_future_option_contract(put)

            # Create and save the automatic ImpliedVolatility indicators.
            contract1.iv = self.iv(call, put)
            contract2.iv = self.iv(put, call)

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Get the ImpliedVolatility indicator of each contract.
        for canonical, chain in slice.option_chains.items():
            for symbol in chain:
                option = self.securities[symbol]
                indicator = option.iv
        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if self.portfolio[self._future.mapped].invested:
            self.liquidate(self._future.mapped)
```

For more information about the `iv` method, see Parameters and Using IV Indicator .

Manual Indicators

To create a manual indicator for implied volatility, call the `ImpliedVolatility` constructor.

```py
class ManualImpliedVolatilityIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
```

```
    def Initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0
        )
        self._future.set_filter(0, 182)
        # Set up the dividend yield provider for the underlying.
        self._dividend_yield_provider = ConstantDividendYieldModel(0)
        # Define the Option pricing model.
        self._option_pricing_model = OptionPricingModelType.FORWARD_TREE

        # Set up a Scheduled Event to select contract and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._future.symbol),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )

        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._future.mapped is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._future.mapped, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]

            contract1 = self.add_future_option_contract(call)
            contract2 = self.add_future_option_contract(put)

            # Create and save the automatic ImpliedVolatility indicators.
            for contract_a, contract_b in [(contract1, contract2), (contract2, contract1)]:
                contract_a.ImpliedVolatility = ImpliedVolatility(
                        contract_a.symbol, self.risk_free_interest_rate_model,
                        self._dividend_yield_provider, contract_b.symbol, self._option_pricing_model
                    )

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Iterate through the indicators.
        for canonical, chain in slice.option_chains.items():
            for option in chain:
                underlying = option.symbol.underlying
                indicator = self.securities[option].ImpliedVolatility
                mirror = Symbol.create_option(
                    underlying.value, option.id.market, option.id.option_style,
                    OptionRight.Call if option.id.option_right == OptionRight.PUT else OptionRight.PUT,
                    option.id.strike_price, option.id.date
                ).value
                # Check if price data is available for both contracts and the underlying asset.
                q = slice.quote_bars
                b = slice.bars
                if option in q and mirror in q and underlying in b:
                    data_points = [
                        IndicatorDataPoint(option, q[option].end_time, q[option].close),
                        IndicatorDataPoint(mirror, q[mirror].end_time, q[mirror].close),
                        IndicatorDataPoint(
                            underlying, b[underlying].end_time, b[underlying].close
                        )
                    ]
                    for data_point in data_points:
                        indicator.update(data_point)
```

```
                # Get the current value of the ImpliedVolatility indicator.
                value = indicator.current.value

        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if not self._future.mapped and self.portfolio[self._future.mapped].invested:
            self.liquidate(self._future.mapped)
```

For more information about the `ImpliedVolatility` constructor, see Using IV Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirror_option` argument to the `iv` method or `ImpliedVolatility` constructor and then call the `set_smoothing_function` method of the resulting `ImpliedVolatility` object. The follow table describes the arguments of the custom function:

Argument	Data Type	Description
`iv`	`float`	The IV of the Option contract.
`mirror_iv`	`float`	The IV of the mirror Option contract.

The method must return a `float` as the smoothened IV.

PY

```
def initialize(self):
    option = Symbol.create_option("AAPL", Market.USA, OptionStyle.AMERICAN, OptionRight.PUT, 505, datetime(2014, 6, 27))
    self.add_option_contract(option)

    mirror_option = Symbol.create_option("AAPL", Market.USA, OptionStyle.AMERICAN, OptionRight.CALL, 505, datetime(2014, 6, 27))
    self.add_option_contract(mirror_option)

    self._iv = self.iv(option, mirror_option)
    # Example: The average of the call-put pair.
    self._iv.set_smoothing_function(lambda iv, mirror_iv: (iv + mirror_iv) * 0.5)
```

Delta

Delta, , is the rate of change of the Option price with respect to the price of the underlying asset. It measures the first-order sensitivity of the price to a movement in underlying price. For example, an Option delta of 0.4 means that if the underlying asset moves by 1%, then the value of the Option moves by 0.4 1% = 0.4%. For more information about delta, see Delta .

Automatic Indicators

To create an automatic indicator for delta, call the `QCAlgorithm.d` method with the Option contract `symbol` object(s).

```py
class AutomaticDeltaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0
        )
        self._future.set_filter(0, 182)

        # Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._future.symbol),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )
        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._future.mapped is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._future.mapped, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_future_option_contract(call)
            contract2 = self.add_future_option_contract(put)

            # Create and save the automatic Delta indicators.
            contract1.d = self.d(call, put)
            contract2.d = self.d(put, call)

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Get the Delta indicator of each contract.
        for canonical, chain in slice.option_chains.items():
            for symbol in chain:
                option = self.securities[symbol]
                indicator = option.d
        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if self.portfolio[self._future.mapped].invested:
            self.liquidate(self._future.mapped)
```

The follow table describes the arguments that the `d` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`iv_model`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating Delta. If you don't provide a value, the default value is to match the `option_model` parameter.	`None`

For more information about the `d` method, see Using D Indicator .

Manual Indicators

To create a manual indicator for delta, call the `Delta` constructor.

```py
class ManualDeltaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0
        )
        self._future.set_filter(0, 182)
        # Set up the dividend yield provider for the underlying.
        self._dividend_yield_provider = ConstantDividendYieldModel(0)
        # Define the Option pricing model.
        self._option_pricing_model = OptionPricingModelType.FORWARD_TREE

        # Set up a Scheduled Event to select contract and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._future.symbol),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )

        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._future.mapped is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._future.mapped, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_future_option_contract(call)
            contract2 = self.add_future_option_contract(put)

            # Create and save the automatic Delta indicators.
            for contract_a, contract_b in [(contract1, contract2), (contract2, contract1)]:
                contract_a.Delta = Delta(
                        contract_a.symbol, self.risk_free_interest_rate_model,
                        self._dividend_yield_provider, contract_b.symbol, self._option_pricing_model
                    )

            self._options = (call, put)
```

```
    def on_data(self, slice: Slice) -> None:
        # Iterate through the indicators.
        for canonical, chain in slice.option_chains.items():
            for option in chain:
                underlying = option.symbol.underlying
                indicator = self.securities[option].Delta
                mirror = Symbol.create_option(
                    underlying.value, option.id.market, option.id.option_style,
                    OptionRight.Call if option.id.option_right == OptionRight.PUT else OptionRight.PUT,
                    option.id.strike_price, option.id.date
                ).value
                # Check if price data is available for both contracts and the underlying asset.
                q = slice.quote_bars
                b = slice.bars
                if option in q and mirror in q and underlying in b:
                    data_points = [
                        IndicatorDataPoint(option, q[option].end_time, q[option].close),
                        IndicatorDataPoint(mirror, q[mirror].end_time, q[mirror].close),
                        IndicatorDataPoint(
                            underlying, b[underlying].end_time, b[underlying].close
                        )
                    ]
                    for data_point in data_points:
                        indicator.update(data_point)

                    # Get the current value of the Delta indicator.
                    value = indicator.current.value

        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if not self._future.mapped and self.portfolio[self._future.mapped].invested:
            self.liquidate(self._future.mapped)
```

For more information about the `Delta` constructor, see Using D Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirror_option` argument to the indicator method or constructor and then call the `set_smoothing_function` method of the `implied_volatility` property of the indicator.

```
PY
# Example: Average IV of the call-put pair.
delta_indicator.implied_volatility.set_smoothing_function(lambda iv, mirror_iv: (iv + mirror_iv) * 0.5)
```

Gamma

Gamma, , is the rate of change of the portfolio's delta with respect to the underlying asset's price. It represents the second-order sensitivity of the Option to a movement in the underlying asset's price. For more information about Gamma, see Gamma .

Automatic Indicators

To create an automatic indicator for gamma, call the `QCAlgorithm.g` method with the Option contract `symbol` object(s).

```py
class AutomaticGammaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0
        )
        self._future.set_filter(0, 182)

        # Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._future.symbol),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )
        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._future.mapped is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._future.mapped, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_future_option_contract(call)
            contract2 = self.add_future_option_contract(put)

            # Create and save the automatic Gamma indicators.
            contract1.g = self.g(call, put)
            contract2.g = self.g(put, call)

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Get the Gamma indicator of each contract.
        for canonical, chain in slice.option_chains.items():
            for symbol in chain:
                option = self.securities[symbol]
                indicator = option.g
        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if self.portfolio[self._future.mapped].invested:
            self.liquidate(self._future.mapped)
```

The follow table describes the arguments that the `g` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
iv_model	OptionPricingModelType	The Option pricing model to use to estimate the IV when calculating Gamma. If you don't provide a value, the default value is to match the option_model parameter.	None

For more information about the g method, see Using G Indicator .

Manual Indicators

To create a manual indicator for gamma, call the Gamma constructor.

```py
class ManualGammaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0
        )
        self._future.set_filter(0, 182)
        # Set up the dividend yield provider for the underlying.
        self._dividend_yield_provider = ConstantDividendYieldModel(0)
        # Define the Option pricing model.
        self._option_pricing_model = OptionPricingModelType.FORWARD_TREE

        # Set up a Scheduled Event to select contract and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._future.symbol),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )

        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._future.mapped is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._future.mapped, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_future_option_contract(call)
            contract2 = self.add_future_option_contract(put)

            # Create and save the automatic Gamma indicators.
            for contract_a, contract_b in [(contract1, contract2), (contract2, contract1)]:
                contract_a.Gamma = Gamma(
                        contract_a.symbol, self.risk_free_interest_rate_model,
                        self._dividend_yield_provider, contract_b.symbol, self._option_pricing_model
                    )

            self._options = (call, put)
```

```
    def on_data(self, slice: Slice) -> None:
        # Iterate through the indicators.
        for canonical, chain in slice.option_chains.items():
            for option in chain:
                underlying = option.symbol.underlying
                indicator = self.securities[option].Gamma
                mirror = Symbol.create_option(
                    underlying.value, option.id.market, option.id.option_style,
                    OptionRight.Call if option.id.option_right == OptionRight.PUT else OptionRight.PUT,
                    option.id.strike_price, option.id.date
                ).value
                # Check if price data is available for both contracts and the underlying asset.
                q = slice.quote_bars
                b = slice.bars
                if option in q and mirror in q and underlying in b:
                    data_points = [
                        IndicatorDataPoint(option, q[option].end_time, q[option].close),
                        IndicatorDataPoint(mirror, q[mirror].end_time, q[mirror].close),
                        IndicatorDataPoint(
                            underlying, b[underlying].end_time, b[underlying].close
                        )
                    ]
                    for data_point in data_points:
                        indicator.update(data_point)

                    # Get the current value of the Gamma indicator.
                    value = indicator.current.value

        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if not self._future.mapped and self.portfolio[self._future.mapped].invested:
            self.liquidate(self._future.mapped)
```

For more information about the `Gamma` constructor, see Using G Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirror_option` argument to the indicator method or constructor and then call the `set_smoothing_function` method of the `implied_volatility` property of the indicator.

```
PY
# Example: Average IV of the call-put pair.
gamma_indicator.implied_volatility.set_smoothing_function(lambda iv, mirror_iv: (iv + mirror_iv) * 0.5)
```

Vega

Vega, , is the rate of change in the value of the Option with respect to the volatility of the underlying asset. For more information about vega, see Vega .

Automatic Indicators

To create an automatic indicator for vega, call the `QCAlgorithm.v` method with the Option contract `symbol` object(s).

PY

```
class AutomaticVegaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0
        )
        self._future.set_filter(0, 182)

        # Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._future.symbol),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )
        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._future.mapped is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._future.mapped, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_future_option_contract(call)
            contract2 = self.add_future_option_contract(put)

            # Create and save the automatic Vega indicators.
            contract1.v = self.v(call, put)
            contract2.v = self.v(put, call)

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Get the Vega indicator of each contract.
        for canonical, chain in slice.option_chains.items():
            for symbol in chain:
                option = self.securities[symbol]
                indicator = option.v
        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if self.portfolio[self._future.mapped].invested:
            self.liquidate(self._future.mapped)
```

The follow table describes the arguments that the v method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
iv_model	OptionPricingModelType	The Option pricing model to use to estimate the IV when calculating Vega. If you don't provide a value, the default value is to match the option_model parameter.	None

For more information about the v method, see Using V Indicator .

Manual Indicators

To create a manual indicator for vega, call the Vega constructor.

```py
class ManualVegaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0
        )
        self._future.set_filter(0, 182)
        # Set up the dividend yield provider for the underlying.
        self._dividend_yield_provider = ConstantDividendYieldModel(0)
        # Define the Option pricing model.
        self._option_pricing_model = OptionPricingModelType.FORWARD_TREE

        # Set up a Scheduled Event to select contract and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._future.symbol),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )

        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._future.mapped is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._future.mapped, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_future_option_contract(call)
            contract2 = self.add_future_option_contract(put)

            # Create and save the automatic Vega indicators.
            for contract_a, contract_b in [(contract1, contract2), (contract2, contract1)]:
                contract_a.Vega = Vega(
                        contract_a.symbol, self.risk_free_interest_rate_model,
                        self._dividend_yield_provider, contract_b.symbol, self._option_pricing_model
                    )

            self._options = (call, put)
```

```
    def on_data(self, slice: Slice) -> None:
        # Iterate through the indicators.
        for canonical, chain in slice.option_chains.items():
            for option in chain:
                underlying = option.symbol.underlying
                indicator = self.securities[option].Vega
                mirror = Symbol.create_option(
                    underlying.value, option.id.market, option.id.option_style,
                    OptionRight.Call if option.id.option_right == OptionRight.PUT else OptionRight.PUT,
                    option.id.strike_price, option.id.date
                ).value
                # Check if price data is available for both contracts and the underlying asset.
                q = slice.quote_bars
                b = slice.bars
                if option in q and mirror in q and underlying in b:
                    data_points = [
                        IndicatorDataPoint(option, q[option].end_time, q[option].close),
                        IndicatorDataPoint(mirror, q[mirror].end_time, q[mirror].close),
                        IndicatorDataPoint(
                            underlying, b[underlying].end_time, b[underlying].close
                        )
                    ]
                    for data_point in data_points:
                        indicator.update(data_point)

                    # Get the current value of the Vega indicator.
                    value = indicator.current.value

        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if not self._future.mapped and self.portfolio[self._future.mapped].invested:
            self.liquidate(self._future.mapped)
```

For more information about the `Vega` constructor, see Using V Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirror_option` argument to the indicator method or constructor and then call the `set_smoothing_function` method of the `implied_volatility` property of the indicator.

```
PY
# Example: Average IV of the call-put pair.
vega_indicator.implied_volatility.set_smoothing_function(lambda iv, mirror_iv: (iv + mirror_iv) * 0.5)
```

Theta

Theta, , is the rate of change of the value of the Option with respect to the passage of time. It is also known to as the time decay of an Option. For more information about theta, see Theta .

Automatic Indicators

To create an automatic indicator for theta, call the `QCAlgorithm.t` method with the Option contract `symbol` object(s).

```py
class AutomaticThetaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0
        )
        self._future.set_filter(0, 182)

        # Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._future.symbol),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )
        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._future.mapped is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._future.mapped, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_future_option_contract(call)
            contract2 = self.add_future_option_contract(put)

            # Create and save the automatic Theta indicators.
            contract1.t = self.t(call, put)
            contract2.t = self.t(put, call)

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Get the Theta indicator of each contract.
        for canonical, chain in slice.option_chains.items():
            for symbol in chain:
                option = self.securities[symbol]
                indicator = option.t
        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if self.portfolio[self._future.mapped].invested:
            self.liquidate(self._future.mapped)
```

The follow table describes the arguments that the `t` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`iv_model`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating theta. If you don't provide a value, the default value is to match the `option_model` parameter.	`None`

For more information about the `t` method, see Using T Indicator .

Manual Indicators

To create a manual indicator for theta, call the `Theta` constructor.

```py
class ManualThetaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0
        )
        self._future.set_filter(0, 182)
        # Set up the dividend yield provider for the underlying.
        self._dividend_yield_provider = ConstantDividendYieldModel(0)
        # Define the Option pricing model.
        self._option_pricing_model = OptionPricingModelType.FORWARD_TREE

        # Set up a Scheduled Event to select contract and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._future.symbol),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )

        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._future.mapped is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._future.mapped, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_future_option_contract(call)
            contract2 = self.add_future_option_contract(put)

            # Create and save the automatic Theta indicators.
            for contract_a, contract_b in [(contract1, contract2), (contract2, contract1)]:
                contract_a.Theta = Theta(
                        contract_a.symbol, self.risk_free_interest_rate_model,
                        self._dividend_yield_provider, contract_b.symbol, self._option_pricing_model
                    )

            self._options = (call, put)
```

```
    def on_data(self, slice: Slice) -> None:
        # Iterate through the indicators.
        for canonical, chain in slice.option_chains.items():
            for option in chain:
                underlying = option.symbol.underlying
                indicator = self.securities[option].Theta
                mirror = Symbol.create_option(
                    underlying.value, option.id.market, option.id.option_style,
                    OptionRight.Call if option.id.option_right == OptionRight.PUT else OptionRight.PUT,
                    option.id.strike_price, option.id.date
                ).value
                # Check if price data is available for both contracts and the underlying asset.
                q = slice.quote_bars
                b = slice.bars
                if option in q and mirror in q and underlying in b:
                    data_points = [
                        IndicatorDataPoint(option, q[option].end_time, q[option].close),
                        IndicatorDataPoint(mirror, q[mirror].end_time, q[mirror].close),
                        IndicatorDataPoint(
                            underlying, b[underlying].end_time, b[underlying].close
                        )
                    ]
                    for data_point in data_points:
                        indicator.update(data_point)

                    # Get the current value of the Theta indicator.
                    value = indicator.current.value

        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if not self._future.mapped and self.portfolio[self._future.mapped].invested:
            self.liquidate(self._future.mapped)
```

For more information about the `Theta` constructor, see Using T Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirror_option` argument to the indicator method or constructor and then call the `set_smoothing_function` method of the `implied_volatility` property of the indicator.

```
# Example: Average IV of the call-put pair.
theta_indicator.implied_volatility.set_smoothing_function(lambda iv, mirror_iv: (iv + mirror_iv) * 0.5)
```

Rho

Rho, , is the rate of change of the value of a derivative with respect to the interest rate . It is usually small and not a big issue in practice unless the Option is deep in-the-money and has a long horizon. In this case, the interest rate matters because you need to discount a larger cash flow over a longer horizon. For more information about rho, see Rho .

Automatic Indicators

To create an automatic indicator for rho, call the `QCAlgorithm.r` method with the Option contract `symbol` object(s).

```py
class AutomaticRhoIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0
        )
        self._future.set_filter(0, 182)

        # Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._future.symbol),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )
        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._future.mapped is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._future.mapped, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_future_option_contract(call)
            contract2 = self.add_future_option_contract(put)

            # Create and save the automatic Rho indicators.
            contract1.r = self.r(call, put)
            contract2.r = self.r(put, call)

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Get the Rho indicator of each contract.
        for canonical, chain in slice.option_chains.items():
            for symbol in chain:
                option = self.securities[symbol]
                indicator = option.r
        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if self.portfolio[self._future.mapped].invested:
            self.liquidate(self._future.mapped)
```

The follow table describes the arguments that the `r` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`iv_model`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating rho If you don't provide a value, the default value is to match the `option_model` parameter.	`None`

For more information about the `r` method, see Using R Indicator .

Manual Indicators

To create a manual indicator for rho, call the `Rho` constructor.

PY

```
class ManualRhoIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0
        )
        self._future.set_filter(0, 182)
        # Set up the dividend yield provider for the underlying.
        self._dividend_yield_provider = ConstantDividendYieldModel(0)
        # Define the Option pricing model.
        self._option_pricing_model = OptionPricingModelType.FORWARD_TREE

        # Set up a Scheduled Event to select contract and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._future.symbol),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )

        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._future.mapped is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._future.mapped, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index

                    )

            self._options = (call, put)
```

```
    def on_data(self, slice: Slice) -> None:
        # Iterate through the indicators.
        for canonical, chain in slice.option_chains.items():
            for option in chain:
                underlying = option.symbol.underlying
                indicator = self.securities[option].Rho
                mirror = Symbol.create_option(
                    underlying.value, option.id.market, option.id.option_style,
                    OptionRight.Call if option.id.option_right == OptionRight.PUT else OptionRight.PUT,
                    option.id.strike_price, option.id.date
                ).value
                # Check if price data is available for both contracts and the underlying asset.
                q = slice.quote_bars
                b = slice.bars
                if option in q and mirror in q and underlying in b:
                    data_points = [
                        IndicatorDataPoint(option, q[option].end_time, q[option].close),
                        IndicatorDataPoint(mirror, q[mirror].end_time, q[mirror].close),
                        IndicatorDataPoint(
                            underlying, b[underlying].end_time, b[underlying].close
                        )
                    ]
                    for data_point in data_points:
                        indicator.update(data_point)

                    # Get the current value of the Rho indicator.
                    value = indicator.current.value

        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if not self._future.mapped and self.portfolio[self._future.mapped].invested:
            self.liquidate(self._future.mapped)
```

For more information about the `Rho` constructor, see Using R Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirror_option` argument to the indicator method or constructor and then call the `set_smoothing_function` method of the `implied_volatility` property of the indicator.

```
PY
# Example: Average IV of the call-put pair.
rho_indicator.implied_volatility.set_smoothing_function(lambda iv, mirror_iv: (iv + mirror_iv) * 0.5)
```

Future Options

Market Hours

Introduction

The Future Option markets have the same hours as the Futures market. For more information, see the supported contracts and the market hours of Future markets .

Asset Classes

Index

There are cash Indices and volatility Indices. The former is a hypothetical portfolio that represents a segment of the financial market and the latter shows the expected level of price fluctuation in an Index Option.

Index

Requesting Data

Introduction

Request Index data in your algorithm to receive a feed of Index prices in the `on_data` method. For more information about the specific dataset we use for backtests, see the US Cash Indices dataset listing . To trade live with Index data, you can use one of the brokerage data providers .

Create Subscriptions

To create an Index subscription, in the `initialize` method, call the `add_index` method. The `add_index` method returns an `Index` object, which contains a `symbol` property. Save a reference to the `symbol` so you can use it in `on_data` to access the security data in the `Slice` .

```
self._symbol = self.add_index("VIX").symbol
```

PY

To view the supported assets in the US Cash Indices dataset, see the Supported Indices .

Resolutions

The following table shows the available resolutions and data formats for Index subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`TICK`				
`SECOND`				
`MINUTE`	✓			
`HOUR`	✓			
`DAILY`	✓			

The default resolution for Index subscriptions is `Resolution.MINUTE` . To change the resolution, pass a `resolution` argument to the `add_index` method.

```
self._symbol = self.add_index("VIX", Resolution.DAILY).symbol
```

PY

To create custom resolution periods, see Consolidating Data .

Supported Markets

The only market available for Indices is `Market.USA` , so you don't need to pass a `market` argument to the `add_index` method.

```
self._symbol = self.add_index("VIX", market=Market.USA).symbol
```

PY

The brokerage models have a default market for each asset class. If you set a brokerage model, you may not need to specify the market to use.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fill_forward` argument to false when you create the security subscription.

```
self._symbol = self.add_index("VIX", fill_forward=False).symbol
```

Data Normalization

The data normalization mode doesn't affect the data that LEAN passes to `on_data` or the data from history request . If you change the data normalization mode, it won't change the outcome.

Properties

The `add_index` method returns an `Index` object, which have the following properties:

Examples

The following examples demonstrate some common practices for requesting Index data.

Example 1: VIX EMA Cross

The following algorithm adds daily VIX Index data and uses the Exponential Moving Average (EMA) indicator to create trading signals. The algorithm uses a 30-day slow EMA and a 15-day fast EMA. It enters a long SPY position when the fast EMA crosses above the slow EMA and liquidates the position when the fast EMA crosses below the slow EMA.

```
class IndexDemoAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add the daily VIX and SPY data.
        self._vix = self.add_index("VIX", Resolution.DAILY).symbol
        self._spy = self.add_equity("SPY", Resolution.DAILY).symbol
        # Create the fast and slow EMA indicators.
        self._ema_fast = self.ema(self._vix, 15)
        self._ema_slow = self.ema(self._vix, 30)
        # Define a small tolerance to reduce trading churn.
        self._tolerance = 0.00015

    def on_data(self, slice: Slice) -> None:
        # Check if the indicators are ready.
        if not self._ema_slow.is_ready:
            return
        # When the fast VIX EMA crosses above the slow EMA, buy SPY.
        if (not self.portfolio.invested and
            self._ema_fast.current.value > self._ema_slow.current.value * (1 + self._tolerance)):
            self.set_holdings(self._spy, 0.8)
        # When the fast VIX EMA crosses below the slow EMA, liquidate the position.
        elif (self.portfolio.invested and
            self._ema_fast.current.value < self._ema_slow.current.value * (1 - self._tolerance)):
            self.liquidate(self._spy)
```

Index

Handling Data

Introduction

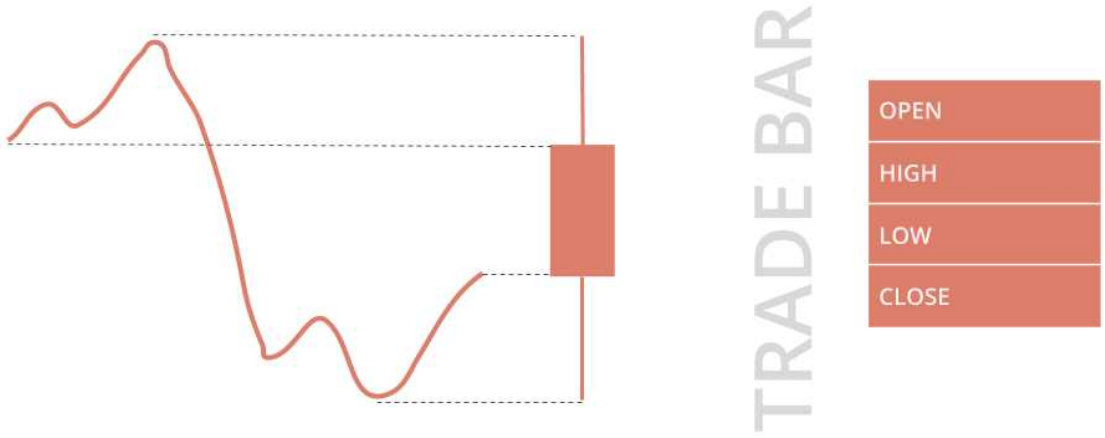
LEAN passes the data you request to the `on_data` method so you can make trading decisions. The `Slice` object that the `on_data` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `on_data` method, use the `current_slice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `Ticks` `DataDictionary` is made up of `Tick` objects. To access individual data points in the dictionary, you can index the dictionary with the Index ticker or `symbol` , but we recommend you use the `symbol` .

To view the resolutions that are available for Index data, see Resolutions .

Bars

You can't trade Indices, but `TradeBar` objects are bars that represent the open, high, low, and close of an Index price over a period of time.



To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `bars` property of the `Slice` with the Index `Symbol` . The `Slice` may not contain data for your `Symbol` at every time step. To avoid issues, check if the `Slice` contains data for your Index before you index the `Slice` with the Index `Symbol` .

```
def on_data(self, slice: Slice) -> None:
    if self._symbol in slice.bars:
        trade_bar = slice.bars[self._symbol]
        value = trade_bar.value
```

`TradeBar` objects have the following properties:

Examples

The following examples demonstrate some common practices for handling Index data.

Example 1: Trading ES Futures Based on the SPX Index RSI

The following algorithm adds daily data for the SPX Index and uses the Relative Strength Index (RSI) indicator to generate trading signals for the E-Mini S&P 500 Future. When the RSI crosses below 30, it buys the front-month ES contract. When the RSI crosses above 70, it liquidates the portfolio.

PY

```
class IndexDemoAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add daily SPX Index data.
        self._spx = self.add_index("SPX", Resolution.DAILY)
        # Create an RSI indicator for the SPX index.
        self._spx.rsi = self.rsi(self._spx.symbol, 15)
        # Add the ES front-month Futures contract.
        self._es = self.add_future(Futures.Indices.SP_500_E_MINI, data_mapping_mode=DataMappingMode.OPEN_INTEREST)
        self._es.set_filter(lambda future_filter_universe: future_filter_universe.standards_only().front_month())

    def on_data(self, slice: Slice) -> None:
        # Check if the indicator is ready and we have the front-month contract data.
        if not self._spx.rsi.is_ready or self._es.mapped not in slice.bars:
            return

        # If the SPX RSI is <30, buy the ES.
        if not self.portfolio.invested and self._spx.rsi.current.value < 30:
            self.set_holdings(self._es.mapped, 0.5)

        # If the SPX RSI is >70, liquidate the portfolio.
        elif self.portfolio.invested and self._spx.rsi.current.value > 70:
            self.liquidate()
```

Index Options

Requesting Data

Request Index Options data in your algorithm to receive a feed of contract prices in the `on_data` method. For more information about the specific dataset we use for backtests, see the US Index Options dataset listing . To trade Index Options live, you can use one of the brokerage data providers . Index Options are exclusively European-style Options.

To request Index Options data, call one of the following methods:

- `self.add_index_option` to add a basket of contracts for a single underlying Index
- `self.add_index_option_contract` to add individual contracts for an underlying Index

Universes

Introduction

The `add_index_option` method enables you to select a basket of Option contracts for an underlying Index. To form your universe of contracts, you can filter them down by their strike price and expiry or you can choose to a subset of the contracts that form popular Option strategies . If you want to subscribe to individual contracts one-by-one instead of a set of contracts, see Individual Contracts .

Create Universes

To add a universe of Index Option contracts, in the `initialize` method, call the `add_index_option` method. This method returns an `Option` object, which has a `set_filter` method you can call to filter the set of tradable contract down to just the contracts you want.

```
PY
class BasicIndexOptionAlgorithm(QCAlgorithm):
    def initialize(self):
        self.universe_settings.asynchronous = True
        option = self.add_index_option("SPX","SPXW")
        option.set_filter(self._filter)
        self._symbol = option.symbol

    def _filter(self, universe):
        return universe.expiration(0, 7).delta(0.35, 0.75)

    def on_data(self, data):
        chain = data.option_chains.get(self._symbol)
        if chain:
            contract = sorted(chain, key=lambda x: (x.expiry, x.greeks.delta))[0]
```

For more information about the `add_index_option` method, see Create Universes .

Filter by Investment Strategy

Options trading strategies consist of simultaneously buying or selling one or more Option contracts of the same underlying Index with different features. The following table describes the filter methods of the `OptionFilterUniverse` class that select contract for Option strategies.

The following table describes the filter methods of the `OptionFilterUniverse` class that select contracts for Option strategies:

`naked_call(min_days_till_expiry: int, strike_from_atm: float)` Selects a call contract to form Naked Call , Covered Call , or Protective Call Option strategies.
`naked_put(min_days_till_expiry: int, strike_from_atm: float)` Selects a put contract to form Naked Put , Covered Put , or Protective Put Option strategies.
`call_spread(min_days_till_expiry: int, higher_strike_from_atm: float, lower_strike_from_atm: float)` Selects two call contracts to form Bull Call Spread or Bear Call Spread Option strategies.
`put_spread(min_days_till_expiry: int, higher_strike_from_atm: float, lower_strike_from_atm: float)` Selects two put contracts to form Bull Put Spread or Bear Put Spread Option strategies.
`call_calendar_spread(strike_from_atm: int, min_near_days_till_expiry: int, min_far_days_till_expiry: int)` Selects two call contracts to form Long Call Calendar Spread or Short Call Calendar Spread Option strategies.

`put_calendar_spread(strike_from_atm: int, min_near_days_till_expiry: int, min_far_days_till_expiry: int)` Selects two put contracts to form Long Put Calendar Spread or Short Put Calendar Spread Option strategies.
`strangle(min_days_till_expiry: int, higher_strike_from_atm: float, lower_strike_from_atm: float)` Selects two contracts to form Long Strangle or Short Strangle Option strategies.
`straddle(min_days_till_expiry: int)` Selects two contracts to form Long Straddle or Short Straddle Option strategies.
`protective_collar(min_days_till_expiry: int, higher_strike_from_atm: float, lower_strike_from_atm: float)` Selects two contracts to form Protective Collar Option strategies.
`conversion(min_days_till_expiry: int, strike_from_atm: float)` Selects two contracts to form Conversion or Reverse Conversion Option strategies.
`call_butterfly(min_days_till_expiry: int, strike_spread: float)` Selects three contracts to form Long Call Butterfly or Short Call Butterfly Option strategies.
`put_butterfly(min_days_till_expiry: int, strike_spread: float)` Selects three contracts to form Long Put Butterfly or Short Put Butterfly Option strategies.
`iron_butterfly(min_days_till_expiry: int, strike_spread: float)` Selects four contracts to form Long Iron Butterfly or Short Iron Butterfly Option strategies.
`iron_condor(min_days_till_expiry: int, near_strike_spread: float, far_strike_spread: float)` Selects four contracts to form Long Iron Condor or Short Iron Condor Option strategies.
`box_spread(min_days_till_expiry: int, strike_spread: float)` Selects four contracts to form Box Spread or Short Box Spread Option strategies.
`jelly_roll(strike_from_atm: float, min_near_days_till_expiry: int, min_far_days_till_expiry: int)` Selects four contracts to form Jelly Roll or Short Jelly Roll Option strategies.
`call_ladder(min_days_till_expiry: int, higher_strike_from_atm: float, middle_strike_from_atm: float, lower_strike_from_atm: float)` Selects four contracts to form Bear Call Ladder or Bull Call Ladder Option strategies.
`put_ladder(min_days_till_expiry: int, higher_strike_from_atm: float, middle_strike_from_atm: float, lower_strike_from_atm: float)` Selects four contracts to form Bear Put Ladder or Bull Put Ladder Option strategies.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

```py
# Example 1: Select a Straddle
option.set_filter(lambda option_filter_universe: option_filter_universe.straddle(30))

# Example 2: Select the contracts (including weeklys) that expire in the next 30 days that form an Iron Condor
option.set_filter(lambda option_filter_universe: option_filter_universe.strikes(-20, 20).expiration(0, 30).iron_condor(30, 5, 10))

# Example 3: Select the 0DTE contracts that form an Strangle
option.set_filter(lambda option_filter_universe: option_filter_universe.expiration(0, 0).strangle(30, 5, -10))
```

Filter by Implied Volatility and Greeks

Option price models compute the theoretical price of Option contracts, their implied volatility, and their Greek values. Theoretical prices can help you detect undervalued and overvalued contracts, implied volatility can provide you insight into the upcoming volatility of the underlying security, and Greek values can help you hedge your portfolio. The following table describes the filter methods of the `OptionFilterUniverse` class that select contract for a range of implied volatility, Greek values, and open interest.

The following table describes the filter methods of the `OptionFilterUniverse` class that select contract for a range of implied volatility, Greek values, and open interest:

`iv(min: float, max: float)`
`implied_volatility(min: float, max: float)`
 	
Selects a contract with implied volatility within the range you set.

`d(min: float, max: float)`
`delta(min: float, max: float)`
 	
Selects a contract with delta within the range you set.

`g(min: float, max: float)`
`gamma(min: float, max: float)`
 	
Selects a contract with gamma within the range you set.

`r(min: float, max: float)`
`rho(min: float, max: float)`
 	
Selects a contract with rho within the range you set.

`v(min: float, max: float)`
`vega(min: float, max: float)`
 	
Selects a contract with vega within the range you set.

`t(min: float, max: float)`
`theta(min: float, max: float)`
 	
Selects a contract with theta within the range you set.

`oi(min: int, max: int)`
`open_interest(min: float, max: float)`
 	
Selects a contract with open interest within the range you set.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

```py
# Example 1: Select the contracts with delta between 0.25 and 0.75
option.set_filter(lambda option_filter_universe: option_filter_universe.delta(0.25, 0.75))

# Example 2: Select the contracts (including weeklys) that expire in the next 90 days with implied volatility below 20%
option.set_filter(lambda option_filter_universe: option_filter_universe.iv(0, 20).expiration(0, 90))

# Example 3: Select the contracts (including weeklys) that expire in the next 30 days with implied volatility below 20% that forms an
Iron Condor
option.set_filter(lambda option_filter_universe: option_filter_universe.iv(0, 20).expiration(0, 30).iron_condor(30, 5, 10))
```

Filter by Other Contract Properties

To set a contract filter, in the `initialize` method, call the `set_filter` method of the `Option` object.

```py
# Select contracts that have a strike price within 1 strike level above and below the underlying price
option.set_filter(min_strike=-1, max_strike=1)

# Select contracts that expire within 30 days
option.set_filter(min_expiry=timedelta(days=0), maxExpiry=timedelta(days=30))

# Select contracts that have a strike price within 1 strike level and expire within 30 days
option.set_filter(min_strike=-1, max_strike=1, min_expiry=timedelta(days=0), maxExpiry=timedelta(days=30))

# Select call contracts
option.set_filter(lambda option_filter_universe: option_filter_universe.calls_only())
```

The following table describes the available filter techniques:

`set_filter(minStrike: int, maxStrike: int)` Selects the contracts that have a strike price within a minimum and maximum strike level relative to the underlying price. For example, say the underlying price is 302 and there are strikes at every 5. If you set `m_strike` to -1 and `max_strike` to 1, LEAN selects the contracts that have a strike of 300 or 305. This filter runs asynchronously by default.
`set_filter(minExpiry: timedelta, maxExpiry: timedelta)` Selects the contracts that expire within the range you set. This filter runs asynchronously by default.
`set_filter(minStrike: int, maxStrike: int, minExpiry: timedelta, maxExpiry: timedelta)` Selects the contracts that expire and have a strike within the range you set. This filter runs asynchronously by default.
`set_filter(universeFunc: Callable[[OptionFilterUniverse], OptionFilterUniverse])` Selects the contracts that a function selects.

The following table describes the filter methods of the `OptionFilterUniverse` class:

`strikes(min_strike: int, max_strike: int)` Selects contracts that are within `m_strike` strikes below the underlying price and `max_strike` strikes above the underlying price.
`calls_only()` Selects call contracts.
`puts_only()` Selects put contracts.
`standards_only()` Selects standard contracts.
`weeklys_only()` Selects weekly contracts.
`front_month()` Selects the front month contract.
`back_months()` Selects the non-front month contracts.
`back_month()` Selects the back month contracts.
`expiration(min_expiryDays: int, max_expiryDays: int)` Selects contracts that expire within a range of dates relative to the current day.
`contracts(contracts: list[Symbol])` Selects a list of contracts.
`contracts(contract_selector: Callable[[list[Symbol]], list[Symbol]])` Selects contracts that a selector function selects.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

```
# Example 1: Select the front month call contracts
option.set_filter(lambda option_filter_universe: option_filter_universe.calls_only().front_month())

# Example 2: Select the contracts (including weeklys) that expire in the next 90 days
option.set_filter(lambda option_filter_universe: option_filter_universe.strikes(-20, 20).expiration(0, 90))
```

Some of the preceding filter methods only set an internal enumeration in the `OptionFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `OptionFilterUniverse` .

Default Filter

By default, LEAN subscribes to the Option contracts that have the following characteristics:

- Standard and weeklys
- Within 1 strike price of the underlying asset price
- Expire within 35 days

To adjust the universe of contracts, set a filter. The filter usually runs at the first bar of every day. When the filter selects a contract that isn't currently in your universe, LEAN adds the new contract data to the next `Slice` that it passes to the `on_data` method.

Historical Data

To get historical chains for an Index Option, see Historical Data .

Examples

The following examples demonstrate some common practices for requesting Index Options universe data.

Example 1: Selecting for 0DTE Contracts

0DTE Options are option contracts that expire on the same day they are traded. To create a universe with 0DTE options, call the or `set_filter` method. In this example, we will select 0DTE contracts within 1 strike price level and a Delta between 0.25 and 0.75. Then, we will go long on the highest strike price call contract of the SPX index and hold until expiry.

```py
class BasicIndexOptionAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100_000)
        # Subscribe to the option chain.
        self._option = self.add_index_option("SPX", "SPXW")
        # Filter the option universe to only select 0DTE options.
        self._option.set_filter(lambda u: u.expiration(0, 0).strikes(-1, 1))
        # Filter the option universe by Delta. The last set_filter call prevails.
        # self._option.set_filter(lambda option_filter_universe: option_filter_universe.delta(0.25, 0.75))

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested:
            return
        # Get the option chain data.
        chain = slice.option_chains.get(self._option.symbol)
        if not chain:
            return
        # Sorted the call Option contracts according to their strike prices.
        calls = sorted([contract for contract in chain if contract.right == OptionRight.CALL], key=lambda x: x.strike)
        if not calls:
            return
        # Buy 1 0DTE call option contract for the SPX index.
        self.Buy(calls[0].symbol, 1)
```

Requesting Data

Individual Contracts

Introduction

The `add_option_contract` method enables you to add an individual Option contract to your algorithm. To check which contracts are currently available to add to your algorithm, use the `option_chain` method. If you want to subscribe to a set of contracts instead of individual contracts one-by-one, see Universes .

Create Subscriptions

Before you can subscribe to an Index Option contract, you must configure the underlying Index and get the contract `symbol` .

```
class BasicIndexOptionAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self._underlying = self.add_index("SPX").symbol
        self._contract_symbol = None

    def on_data(self, data):
        if self._contract_symbol:
            return
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        expiry = chain.expiry.min()
        self._contract_symbol = chain[
            (chain.expiry == expiry) &
            (chain.right == OptionRight.CALL) &
            (chain.delta < 0.7) &
            (chain.delta > 0.3)
        ].sort_values('openinterest').index[-1]
        self.add_option_contract(self._contract_symbol)
```

PY

Configure the Underlying Index

In most cases, you should subscribe to the underlying Index before you subscribe to an Index Option contract.

```
self._underlying = self.add_index("SPX").symbol
```

PY

Get Contract Symbols

To subscribe to an Option contract, you need the contract `Symbol` . The preferred method to getting Option contract `Symbol` objects is to use the `option_chain` method. This method returns an `OptionChain` object, which represent an entire chain of Option contracts for a single underlying security. You can even format the chain data into a DataFrame where each row in the DataFrame represents a single contract. With the chain, sort and filter the data to find the specific contract(s) you want to trade.

```
# Get the contracts available to trade (in DataFrame format).
#   Option A: Standard contracts.
chain = self.option_chain(
    Symbol.create_canonical_option(self._underlying, Market.USA, "?SPX"), flatten=True
).data_frame

#  Option B: Weekly contracts.
#chain = self.option_chain(
#    Symbol.create_canonical_option(self._underlying, "SPXW", Market.USA, "?SPXW"), flatten=True
#).data_frame

# Select a contract.
expiry = chain.expiry.min()
self._contract_symbol = chain[
    # Select call contracts with the closest expiry.
    (chain.expiry == expiry) &
    (chain.right == OptionRight.CALL) &
    # Select contracts with a 0.3-0.7 delta.
    (chain.delta < 0.7) &
    (chain.delta > 0.3)
    # Select the contract with the largest open interest.
].sort_values('openinterest').index[-1]
```

Alternatively, you can create a Index Option contract `Symbol` object directly parsing its OSI ticker using the `SymbolRepresentation.parse_option_ticker_osi` method.

```
# Create the contract Symbol for the SPX Call 5650 3 Sept 2024.
self._contract_symbol = SymbolRepresentation.parse_option_ticker_osi('SPXW 240903C05650000', SecurityType.INDEX_OPTION,
OptionStyle.EUROPEAN, Market.USA)
```

Subscribe to Contracts

To create an Index Option contract subscription, pass the contract `Symbol` to the `add_index_option_contract` method. Save a reference to the contract `Symbol` so you can easily access the contract in the OptionChain that LEAN passes to the `on_data` method. To override the default pricing model of the Option, set a pricing model .

```
option = self.add_index_option_contract(self._contract_symbol)
option.PriceModel = OptionPriceModels.black_scholes()
```

The `add_index_option_contract` method creates a subscription for a single Index Option contract and adds it to your user-defined universe. To create a dynamic universe of Index Option contracts, add an Index Option universe .

Warm Up Contract Prices

If you subscribe to an Index Option contract with `add_index_option_contract` , you'll need to wait until the next `Slice` to receive data and trade the contract. To trade the contract in the same time step you subscribe to the contract, set the current price of the contract in a security initializer .

```
self.settings.seed_initial_prices = True
```

Supported Assets

To view the supported assets in the US Index Options dataset, see Supported Assets .

Resolutions

The following table shows the available resolutions and data formats for Index Option contract subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
TICK				
SECOND				
MINUTE	✓	✓		
HOUR	✓	✓		
DAILY	✓	✓		

The default resolution for Index Option subscriptions is `Resolution.MINUTE` . To change the resolution, pass a `resolution` argument to the `add_index_option_contract` method.

```
self.add_index_option_contract(self._contract_symbol, Resolution.HOUR)
```

To create custom resolution periods, see Consolidating Data .

Supported Markets

The only market available for Index Options is `Market.USA` . You don't need to pass a `market` argument to the `add_index_option_contract` method because the contract `Symbol` already contains the market.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fill_forward` argument to false when you create the security subscription.

```
self.add_index_option_contract(self._contract_symbol, fill_forward=False)
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. Options are already leveraged products, so you can't change their leverage.

Data Normalization

The data normalization mode doesn't affect the data that LEAN passes to `on_data` or the data from history request . If you change the data normalization mode, it won't change the outcome.

Remove Subscriptions

To remove a contract subscription that you created with `add_index_option_contract` , call the `remove_option_contract` method. This method is an alias for `remove_security` .

```
self.remove_option_contract(self._contract_symbol)
```

The `remove_option_contract` method cancels your open orders for the contract and liquidates your holdings.

Properties

The `add_index_option_contract` method returns an `Option` object, which have the following properties:

Helper Methods

The `Option` object provides methods you can use for basic calculations. These methods require the underlying price. To get the `Option` object and the `Security` object for its underlying in any function, use the Option `symbol` to access the value in the `securities` object.

```
option = self.securities[self._contract_symbol]
underlying = self.securities[self._contract_symbol.underlying]
underlying_price = underlying.price
```

To get the Option payoff , call the `get_pay_off` method.

```
pay_off = option.get_pay_off(underlying_price)
```

To get the Option intrinsic value , call the `get_intrinsic_value` method.

```
intrinsic_value = option.get_intrinsic_value(underlying_price)
```

To get the Option out-of-the-money amount , call the `out_of_the_money_amount` method.

```
otm_amount = option.out_of_the_money_amount(underlying_price)
```

To check whether the Option can be automatic exercised, call the `is_auto_exercised` method.

```
is_auto_exercised = option.is_auto_exercised(underlying_price)
```

Exceptions and Edge Cases

The following sections explain exceptions and edge cases with subscribing to individual Option contracts.

Manually Creating Option Symbol Objects

To subscribe to an Option contract, you need the contract `Symbol` . To get Index Option contract `Symbol` objects, call the `create_option` or `option_chain` methods. If you use the `create_option` method, you need to know the specific contract details.

```
# Standard contracts
self._contract_symbol = Symbol.create_option(self._underlying, Market.USA,
    OptionStyle.EUROPEAN, OptionRight.CALL, 3650, datetime(2022, 6, 17))

# Weekly contracts
self._weekly_contract_symbol = Symbol.create_option(self._underlying, "SPXW", Market.USA,
    OptionStyle.EUROPEAN, OptionRight.CALL, 3650, datetime(2022, 6, 17))
```

Default Underlying Subscription Settings

If you subscribe to an Index Option contract but don't have a subscription to the underlying Index, LEAN automatically subscribes to the underlying Index and sets its fill forward property to match that of the Index Option contract. In this case, you still need the Index `symbol` to subscribe to Index Option contracts. If you don't have access to it, create it.

```
self._underlying = Symbol.create("SPX", SecurityType.INDEX, Market.USA)
```

Overriding the Initial Implied Volatility Guess

To override the initial guess of implied volatility , set and warm up the underlying volatility model .

Examples

The following examples demonstrate common practices for requesting individual index option contract data.

Example 1: 5-Minute Option Chain

The following example shows how to update the Option chain every five minutes. The custom `OptionChainManager` class implements the selection

logic and manages the contract subscriptions.

```py
class OptionChainFullExample(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 10, 31)
        self.set_cash(500000)
        self.universe_settings.asynchronous = True
        self.universe_settings.minimum_time_in_universe = timedelta(minutes=0)

        # Seed the last price to ensure filtering using the underlying price is available immediately.
        self.settings.seed_initial_prices = True

        # Request the index underlying data for filtering.
        spx = self.add_index("SPX").symbol
        # Create the 5-minute option chain manager on SPXW weekly index option.
        self._chain_manager = {
            Symbol.create_canonical_option(spx, "SPXW", Market.USA, "?SPXW"): OptionChainManager(-10, 10, 0, 1)
        }
        # Populate the updated option chain immediately to trade with.
        self._populate_option_chain()

        # Set schedule event to populate the option chain at market open, since the option contracts are updating daily.
        self.schedule.on(
            self.date_rules.every_day(spx), self.time_rules.after_market_open(spx, 1), self._populate_option_chain
        )
        # Set a scheduled event to filter the closed ATM calls every 5 minutes.
        self.schedule.on(self.date_rules.every_day(spx), self.time_rules.every(timedelta(minutes=5)), self._filter)

    def _populate_option_chain(self) -> None:
        # The contract list is updated daily, so we can get it and apply
        # the expiration filter as soon as the market opens.
        for symbol, manager in self._chain_manager.items():
            manager.set_chain(self.option_chain(symbol), self.time)
        self._filter()

    def _filter(self) -> None:
        for symbol, manager in self._chain_manager.items():
            manager.select(self, symbol)

    def on_data(self, slice: Slice) -> None:
        for symbol, _ in self._chain_manager.items():
            # Only trade on updated data.
            chain = slice.option_chains.get(symbol)
            if not chain:
                continue

            # Filter the closest ATM call contract and trade.
            expiry = min([x.expiry for x in chain])
            contracts = [
                x for x in chain
                if x.expiry == expiry and x.right == OptionRight.CALL and self.securities[x.symbol].is_tradable
            ]
            if not contracts:
                continue
            atm_call = sorted(contracts, key=lambda x: abs(chain.underlying.price-x.strike))[0]
            if not self.portfolio[atm_call.symbol].invested:
                self.market_order(atm_call.symbol, 1)

class OptionChainManager:
    _chain = []
    _symbols = set([])

    def __init__(self, min_strike: int, max_strike: int, min_expiry: int, max_expiry: int) -> None:
        self._min_strike = min_strike
        self._max_strike = max_strike
        self._min_expiry = min_expiry
        self._max_expiry = max_expiry

    def set_chain(self, chain:OptionChain, time: datetime) -> None:
        # Filter the expiry daily only since contract list is updated daily.
        self._chain = [x for x in chain if self._min_expiry <= (x.expiry - time).days <= self._max_expiry]

    def select(self, algorithm: QCAlgorithm, symbol: Symbol) -> None:
        if not self._chain:
            return
        if symbol.is_canonical():
            symbol = symbol.underlying

        # Filter the contracts with strike range spread between the preset level.
        strikes = sorted(set(x.strike for x in self._chain))
        spot = algorithm.securities[symbol].price
        atm = sorted(strikes, key=lambda x: abs(spot-x))[0]
        index = strikes.index(atm)
        min_strike = strikes[max(0, index + self._min_strike)]
        max_strike = strikes[min(len(strikes) - 1, index + self._max_strike)]
        symbols = set(x.symbol for x in self._chain if min_strike <= x.strike <= max_strike)

        # Remove subscriptions if the contracts are not being ATM anymore.
        for symbol in self._symbols - symbols:
```

```
        for symbol in self._symbols - symbols:
            if algorithm.remove_option_contract(symbol):
                self._symbols.remove(symbol)
        # Request data of the newly identified ATM contracts.
        for symbol in symbols - self._symbols:
            self._symbols.add(symbol)
            algorithm.add_option_contract(symbol)
```

Index Options

Handling Data

Introduction

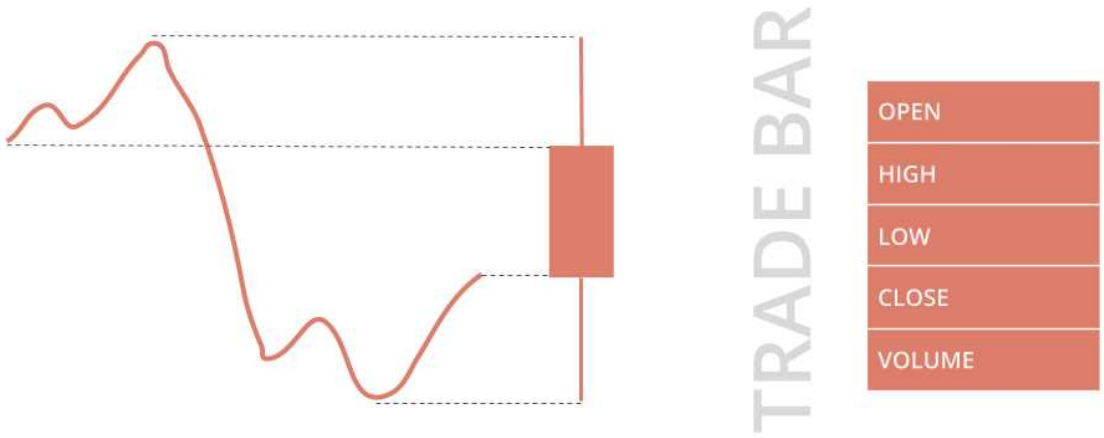
LEAN passes the data you request to the `on_data` method so you can make trading decisions. The `Slice` object that the `on_data` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `on_data` method, use the `current_slice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars` `DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the contract ticker or `symbol` , but we recommend you use the `symbol` .

To view the resolutions that are available for Index Options data, see Resolutions .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `bars` property of the `Slice` with the contract `symbol` . If the contract doesn't actively trade or you are in the same time step as when you added the contract subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for your contract before you index the `Slice` with the contract `symbol` .

```
def on_data(self, slice: Slice) -> None:
    # Obtain the mapped TradeBar of the symbol if any
    trade_bar = slice.bars.get(self._contract_symbol)   # None if not found
```

PY

You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

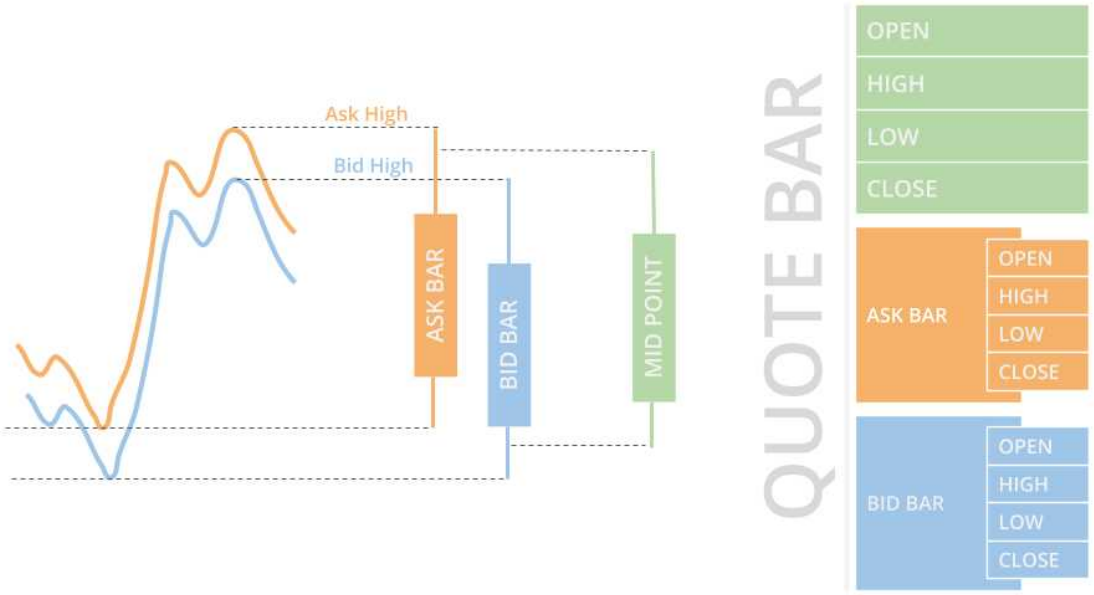
```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Symbol-TradeBar key-value pairs
    for symbol, trade_bar in slice.bars.items():
        close_price = trade_bar.close
```

PY

`TradeBar` objects have the following properties:

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `open` , `high` , `low` , and `close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `open` , `high` , `low` , and `close` properties of the `QuoteBar` copy the values of either the `bid` or `ask` instead of taking their mean.



To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the contract `symbol` . If the contract doesn't actively get quotes or you are in the same time step as when you added the contract subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for your contract before you index the `Slice` with the contract `symbol` .

```
def on_data(self, slice: Slice) -> None:
    # Obtain the mapped QuoteBar of the symbol if any
    quote_bar = slice.quote_bars.get(self._contract_symbol)   # None if not found
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Symbol-QuoteBar key-value pairs
    for symbol, quote_bar in slice.quote_bars.items():
        ask_price = quote_bar.ask.close
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

`QuoteBar` objects have the following properties:

Option Chains

`OptionChain` objects represent an entire chain of Option contracts for a single underlying security.

To get the `OptionChain` , index the `option_chains` property of the `Slice` with the canonical `Symbol` .

```
def on_data(self, slice: Slice) -> None:
    # Try to get the OptionChain using the canonical symbol (None if no OptionChain return)
    chain = slice.option_chains.get(self._contract_symbol.Canonical)
    if chain:
        # Get all contracts if the OptionChain contains any member
        contracts = chain.contracts
```

You can also loop through the `option_chains` property to get each `OptionChain` .

```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Canonical Symbol-OptionChain key-value pairs
    for canonical_symbol, chain in slice.option_chains.items():
        contracts = chain.contracts
```

`OptionChain` objects have the following properties:

Option Contracts

`OptionContract` objects represent the data of a single Option contract in the market. To get the Option contracts in the `Slice` , use the `contracts` property of the `OptionChain` .

```
def on_data(self, slice: Slice) -> None:
    # Try to get the OptionChain using the canonical symbol
    chain = slice.option_chains.get(self._contract_symbol.canonical)
    if chain:
        # Get individual contract data
        contract = chain.contracts.get(self._contract_symbol)
        if contract:
            price = contract.price
```

Greeks and Implied Volatility

To get the Greeks and implied volatility of an Option contract, use the `greeks` and `implied_volatility` members.

```
def on_data(self, slice: Slice) -> None:
    # Try to get the OptionChain using the canonical symbol
    chain = slice.option_chains.get(self._contract_symbol.canonical)
    if chain:
        # Get individual contract data
        contract = chain.contracts.get(self._contract_symbol)
        if contract:
            # Get greeks data of the selected contract
            delta = contract.greeks.delta
            iv = contract.implied_volatility
```

LEAN only calculates Greeks and implied volatility when you request them because they are expensive operations. If you invoke the `greeks` property, the Greeks aren't calculated. However, if you invoke the `greeks.delta` , LEAN calculates the delta. To avoid unecessary computation in your algorithm, only request the Greeks and implied volatility when you need them. For more information about the Greeks and implied volatility, see Options Pricing .

Open Interest

Open interest is the number of outstanding contracts that haven't been settled. It provides a measure of investor interest and the market liquidity, so it's a popular metric to use for contract selection. Open interest is calculated once per day. To get the latest open interest value, use the `open_interest` property of the `Option` or `option_contract` .

```
def on_data(self, slice: Slice) -> None:
    # Try to get the option_chains using the canonical symbol
    chain = slice.option_chains.get(self._contract_symbol.canonical)
    if chain:
        # Get individual contract data
        contract = chain.contracts.get(self._contract_symbol)
        if contract:
            # Get the open interest of the selected contracts
            open_interest = contract.open_interest
```

Properties

`OptionContract` objects have the following properties:

Examples

The following examples demonstrate some common practices for handling Index Options.

Example 1: Supply-Demand Pressure Of Individual Contract

This example shows how to handle `QuoteBar` data for the SPXW Index Option contracts to trade based on the supply-demand pressure, while filter individual option contracts and request data using `self.option_chain` method for the contracts that expire that day.

```py
class IndexOptionHandlingDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000000)

        self.contracts = []

        # Subscribe to underlying data for ATM calculation using the updated underlying price.
        # Set data normalization mode to raw is required to ensure the strike and underlying prices are comparable.
        self.spxw = self.add_index_option("SPX", "SPXW")
        self.spxw.set_filter(lambda x: x.expiration(0, 3).strikes(-5, 5))

        # Update the tradable contracts daily before the market opens since the option contract list provider populates them daily.
        self.schedule.on(
            self.date_rules.every_day(self.spxw.symbol),
            self.time_rules.at(9, 0),
            self.update_contracts
        )

    def update_contracts(self) -> None:
        # Get all contracts that expire today, and subscribe to data for trading needs.
        # We do not need to liquidate or handle settlement since all contracts are cash-settled after market close.
        # We only get the strike contracts within $10 of the underlying for higher liquidity and less slippage.
        contracts = self.option_chain(self.spxw.symbol)
        self.contracts = [x.symbol for x in contracts
            if x.expiry < self.time + timedelta(1) and\
            abs(x.underlying_last_price - x.strike) < 10]

    def on_data(self, slice: Slice) -> None:
        # Only focus on a filtered list of option contracts to trade and select the ATM call.
        calls = [x for x in self.contracts if x.id.option_right == OptionRight.CALL]
        if not calls:
            return
        contract = sorted(
            calls,
            key=lambda x: abs(self.securities[x.underlying].price - x.id.strike_price)
        )[0]

        # Trade based on the updated data.
        quote = slice.quote_bars.get(contract)
        if quote and quote.bid is not None and quote.ask is not None and not self.portfolio.invested:
            # if the last trading price is close to the ask price, the sell pressure is higher, so we short.
            diff = quote.ask.close - 2 * quote.close + quote.bid.close
            if diff < 0:
                self.set_holdings(contract, -0.05)
            else:
                self.set_holdings(contract, 0.05)
```

Example 2: Supply-Demand Pressure Of Universe

This example shows how to handle `QuoteBar` data for shortlisted Index Option contracts to calculate mid-price using bid close and ask close data, while request data through universe selection function using `set_filter` method for the contracts that expire within the current week. Using mid-price, we can examine the market fair value of the Option and compare it with the model theoretical price.

```py
class IndexOptionHandlingDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 15)
        self.set_cash(100000000)

        # Subscribe to SPXW option data.
        option = self.add_index_option("SPX", "SPXW")
        self._symbol = option.symbol
        # We wish only to trade the contracts expiring within the same week since they have the highest volume.
        option.set_filter(lambda u: u.contracts(lambda x: [s for s in x if s.id.date <= Expiry.end_of_week(self.time)]))

    def on_data(self, slice: Slice) -> None:
        # Only want to obtain the option chain of the selected symbol.
        chain = slice.option_chains.get(self._symbol)
        if not chain:
            return

        # Select the ATM call to trade.
        contract = sorted(
            [x for x in chain if x.right == OptionRight.CALL],
            key=lambda x: abs(x.underlying_last_price - x.strike)
        )[0]

        # If the last trading price is close to the asking price, the selling pressure is higher, so we are short.
        diff = contract.ask_price - 2 * contract.last_price + contract.bid_price
        if diff < 0:
            self.set_holdings(contract, -0.05)
        else:
            self.set_holdings(contract, 0.05)
```

Example 3: Get Instant Delta

The option Greeks change rapidly, so we need to obtain the instant Greeks to calculate the hedge size for arbitration or replication portfolio accurately. You can call the `Greeks` property from the `OptionChain` data to access various Greeks. In this example, we will demonstrate how to obtain a contract with a Delta closest to 0.4 among all call contracts expiring the same week.

```py
class IndexOptionHandlingDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Subscribe to SPXW option data.
        option = self.add_index_option("SPX", "SPXW")
        self._symbol = option.symbol
        # We wish only to trade the contracts expiring within the same week since they have the highest volume.
        # 0.4 Delta will only appear in call contracts.
        option.set_filter(lambda u: u.delta(0.2, 0.6).contracts(lambda x: [s for s in x if s.id.date <= Expiry.end_of_week(self.time)]))

    def on_data(self, slice: Slice) -> None:
        # Only want to obtain the option chain of the selected symbol.
        chain = slice.option_chains.get(self._symbol)
        if not chain or self.portfolio.invested:
            return

        # Get the contract with Delta closest to 0.4 to trade.
        # The arbitrary delta criterion might be set due to hedging need or risk adjustment.
        selected = sorted(chain, key=lambda x: abs(x.greeks.delta - 0.4))[0]

        # Hold a naked call on the selected contract to speculate an uprise of the SPX index with leverage.
        self.market_order(selected.symbol, 1)
```

Index Options

Greeks and Implied Volatility

The Greeks are measures that describe the sensitivity of an Option's price to various factors like underlying price changes (Delta), time decay (Theta), volatility (Vega), and interest rates (Rho), while Implied Volatility (IV) represents the market's expectation of the underlying asset's volatility over the life of the Option.

Greeks and Implied Volatility

Key Concepts

Introduction

LEAN provides multiple ways for you to get the Greeks and implied volatility (IV) of Option contracts. There is a daily, pre-calculated dataset based on the end of the previous trading day. There is also a stream of values that are calculated on-the-fly as your algorithm runs.

Greeks on Universes

The Greeks and IV values in the filter function are the daily, pre-calculated values based on the end of the previous trading day.

```py
def initialize(self):
    option = self.add_index_option("SPX")
    option.set_filter(lambda universe: universe.delta(0.3, 0.7).expiration(0,7))
```

To calculate the values, we use our implementation of the Black-Scholes pricing model, which accounts for the interest rate and dividend payments when applicable. For example, VIX doesn't have dividends. We use SPY for SPX and QQQ for NDX.

You can't customize the Greeks and IV values that the filter function receives. However, you can create indicators to customize how the Greeks and IV are calculated for the contracts already in your universe.

Greek History

The Greeks and IV values that you get from a history request of the Option universe are the daily, pre-calculated values based on the end of the previous trading day.

```py
class OptionHistoryAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        option = self.add_index_option('SPX')
        # DataFrame example:
        history_df = self.history(option.symbol, 5, flatten=True)
        # OptionUniverse objects example:
        history = self.history[OptionUniverse](option.symbol, 5)
        for chain in history:
            end_time = chain.end_time
            filtered_contracts = [c for c in chain if c.greeks.delta > 0.3]
            for contract in filtered_contracts:
                symbol = contract.symbol
                expiry = contract.id.date
                strike = contract.id.strike_price
                price = contract.close
                iv = contract.implied_volatility
```

You can't customize the Greeks and IV values that you get from a history request. However, you can create indicators to customize how the Greeks and IV are calculated for the contracts already in your universe.

Greeks on Data Events

The Greeks and IV values that you get from the current Slice are from the price model calculations. These values aren't the same as the values you get in the universe filter function.

```
class OptionDataEventsAlgorithm(QCAlgorithm):

    def initialize(self):
        option = self.add_index_option("VIX", "VIXW")
        option.price_model = OptionPriceModels.binomial_cox_ross_rubinstein()

    def on_data(self, data):
        for canonical_symbol, chain in data.option_chains.items():
            for contract in chain:
                iv = contract.implied_volatility
                delta = contract.greeks.delta
```

PY

To view all the models LEAN supports, see Supported Models .

Greek Indicators

The Greeks and IV values that you get from the indicators are calculated in the same way as the values you get in the filter function, but they can reflect intraday prices instead of just the daily closing prices.

Examples

For detailed examples on using Option Greeks and Implied Volatility indicators in algorithm, you may refer to the Greeks Indicators page examples.

Greeks and Implied Volatility

Indicators

Introduction

Option indicators enable you to calculate daily and intraday values for the Greeks and implied volatility of Option contracts. This page explains the most popular Option indicators and how to use them with LEAN.

Parameters

The following table describes the arguments that the automatic Option indicators methods accept:

Argument	Data Type	Description	Default Value
`symbol`	`Symbol`	The contract to use when calculating the indicator values.	
`mirror_option`	`Symbol`	The mirror contract to use in parity type calculations.	`None`
`risk_free_rate`	`float`	The risk-free interest rate. If you don't provide a value, the default value is the US primary credit rate from the Interest Rate Provider Model .	`None`
`dividend_yield`	`float`	The dividend yield rate. If you don't provide a value, the default value comes from the Dividend Yield Provider Model .	`None`
`option_model`	`OptionPricingModelType`	The Option pricing model that's used to calculate the Greeks. If you don't provide a value, the default value is `OptionPricingModelType.BlackScholes` for Index Options.	`None`
`resolution`	`Resolution`	The resolution of the indicator data. If you don't provide a value, the default value is the resolution of the subscription you have for the Option contract(s).	`None`

To perform implied volatility (IV) smoothing with a put-call pair, pass one of the contracts as the `symbol` argument and pass the other contract in the pair as the `mirror_option` argument. The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, call the `set_smoothing_function` method of the `ImpliedVolatility` class/property.

Several different Option pricing models are supported to calculate the IV and Greeks. The following table describes the `OptionPricingModelType` enumeration members:

Implied Volatility

Implied volatility, , is the market's expectation for the future volatility of an asset and is implied by the price of the assets's Options contracts. You can't observe it in the market but you can derive it from the price of an Option. For more information about implied volatility, see Implied Volatility .

Automatic Indicators

To create an automatic indicator for implied volatility, call the `QCAlgorithm.iv` method with the Option contract `symbol` object(s).

```py
class AutomaticImpliedVolatilityIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_index('SPX').symbol

        # Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )
        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_index_option_contract(call)
            contract2 = self.add_index_option_contract(put)

            # Create and save the automatic ImpliedVolatility indicators.
            contract1.iv = self.iv(call, put)
            contract2.iv = self.iv(put, call)

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Get the ImpliedVolatility indicator of each contract.
        for canonical, chain in slice.option_chains.items():
            for symbol in chain:
                option = self.securities[symbol]
                indicator = option.iv
        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

For more information about the `iv` method, see Parameters and Using IV Indicator .

Manual Indicators

To create a manual indicator for implied volatility, call the `ImpliedVolatility` constructor.

```py
class ManualImpliedVolatilityIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
```

```
        # Subscribe to the underlying asset.
        self._underlying = self.add_index('SPX').symbol
        # Set up the dividend yield provider for the underlying.
        self._dividend_yield_provider = DividendYieldProvider(self._underlying)
        # Define the Option pricing model.
        self._option_pricing_model = OptionPricingModelType.FORWARD_TREE

        # Set up a Scheduled Event to select contract and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )

        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_index_option_contract(call)
            contract2 = self.add_index_option_contract(put)

            # Create and save the automatic ImpliedVolatility indicators.
            for contract_a, contract_b in [(contract1, contract2), (contract2, contract1)]:
                contract_a.ImpliedVolatility = ImpliedVolatility(
                        contract_a.symbol, self.risk_free_interest_rate_model,
                        self._dividend_yield_provider, contract_b.symbol, self._option_pricing_model
                    )

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Iterate through the indicators.
        for canonical, chain in slice.option_chains.items():
            for option in chain:
                underlying = option.symbol.underlying
                indicator = self.securities[option].ImpliedVolatility
                mirror = Symbol.create_option(
                    underlying.value, option.id.market, option.id.option_style,
                    OptionRight.Call if option.id.option_right == OptionRight.PUT else OptionRight.PUT,
                    option.id.strike_price, option.id.date
                )
                # Check if price data is available for both contracts and the underlying asset.
                q = slice.quote_bars
                b = slice.bars
                if option in q and mirror in q and underlying in b:
                    data_points = [
                        IndicatorDataPoint(option, q[option].end_time, q[option].close),
                        IndicatorDataPoint(mirror, q[mirror].end_time, q[mirror].close),
                        IndicatorDataPoint(
                            underlying, b[underlying].end_time, b[underlying].close
                        )
                    ]
                    for data_point in data_points:
                        indicator.update(data_point)

                    # Get the current value of the ImpliedVolatility indicator.
                    value = indicator.current.value

        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if not self._underlying and self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

For more information about the `ImpliedVolatility` constructor, see Using IV Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirror_option` argument to the `iv` method or `ImpliedVolatility` constructor and then call the `set_smoothing_function` method of the resulting `ImpliedVolatility` object. The follow table describes the arguments of the custom function:

Argument	Data Type	Description
`iv`	`float`	The IV of the Option contract.
`mirror_iv`	`float`	The IV of the mirror Option contract.

The method must return a `float` as the smoothened IV.

```
def initialize(self):
    option = Symbol.create_option("AAPL", Market.USA, OptionStyle.AMERICAN, OptionRight.PUT, 505, datetime(2014, 6, 27))
    self.add_option_contract(option)

    mirror_option = Symbol.create_option("AAPL", Market.USA, OptionStyle.AMERICAN, OptionRight.CALL, 505, datetime(2014, 6, 27))
    self.add_option_contract(mirror_option)

    self._iv = self.iv(option, mirror_option)
    # Example: The average of the call-put pair.
    self._iv.set_smoothing_function(lambda iv, mirror_iv: (iv + mirror_iv) * 0.5)
```

PY

Delta

Delta, , is the rate of change of the Option price with respect to the price of the underlying asset. It measures the first-order sensitivity of the price to a movement in underlying price. For example, an Option delta of 0.4 means that if the underlying asset moves by 1%, then the value of the Option moves by 0.4 1% = 0.4%. For more information about delta, see Delta .

Automatic Indicators

To create an automatic indicator for delta, call the `QCAlgorithm.d` method with the Option contract `symbol` object(s).

```py
class AutomaticDeltaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_index('SPX').symbol

        # Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )
        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_index_option_contract(call)
            contract2 = self.add_index_option_contract(put)

            # Create and save the automatic Delta indicators.
            contract1.d = self.d(call, put)
            contract2.d = self.d(put, call)

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Get the Delta indicator of each contract.
        for canonical, chain in slice.option_chains.items():
            for symbol in chain:
                option = self.securities[symbol]
                indicator = option.d
        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

The follow table describes the arguments that the `d` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`iv_model`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating Delta. If you don't provide a value, the default value is to match the `option_model` parameter.	`None`

For more information about the `d` method, see Using D Indicator .

Manual Indicators

To create a manual indicator for delta, call the `Delta` constructor.

```py
class ManualDeltaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_index('SPX').symbol
        # Set up the dividend yield provider for the underlying.
        self._dividend_yield_provider = DividendYieldProvider(self._underlying)
        # Define the Option pricing model.
        self._option_pricing_model = OptionPricingModelType.FORWARD_TREE

        # Set up a Scheduled Event to select contract and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )

        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_index_option_contract(call)
            contract2 = self.add_index_option_contract(put)

            # Create and save the automatic Delta indicators.
            for contract_a, contract_b in [(contract1, contract2), (contract2, contract1)]:
                contract_a.Delta = Delta(
                        contract_a.symbol, self.risk_free_interest_rate_model,
                        self._dividend_yield_provider, contract_b.symbol, self._option_pricing_model
                    )

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Iterate through the indicators.
        for canonical, chain in slice.option_chains.items():
            for option in chain:
                underlying = option.symbol.underlying
                indicator = self.securities[option].Delta
                mirror = Symbol.create_option(
                    underlying.value, option.id.market, option.id.option_style,
                    OptionRight.Call if option.id.option_right == OptionRight.PUT else OptionRight.PUT,
                    option.id.strike_price, option.id.date
                )
                # Check if price data is available for both contracts and the underlying asset.
                q = slice.quote_bars
                b = slice.bars
                if option in q and mirror in q and underlying in b:
                    data_points = [
                        IndicatorDataPoint(option, q[option].end_time, q[option].close),
                        IndicatorDataPoint(mirror, q[mirror].end_time, q[mirror].close),
                        IndicatorDataPoint(
                            underlying, b[underlying].end_time, b[underlying].close
                        )
```

```
                    ]
                    for data_point in data_points:
                        indicator.update(data_point)

                    # Get the current value of the Delta indicator.
                    value = indicator.current.value

        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if not self._underlying and self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

For more information about the `Delta` constructor, see Using D Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirror_option` argument to the indicator method or constructor and then call the `set_smoothing_function` method of the `implied_volatility` property of the indicator.

```
PY
# Example: Average IV of the call-put pair.
delta_indicator.implied_volatility.set_smoothing_function(lambda iv, mirror_iv: (iv + mirror_iv) * 0.5)
```

Gamma

Gamma, , is the rate of change of the portfolio's delta with respect to the underlying asset's price. It represents the second-order sensitivity of the Option to a movement in the underlying asset's price. For more information about Gamma, see Gamma .

Automatic Indicators

To create an automatic indicator for gamma, call the `QCAlgorithm.g` method with the Option contract `symbol` object(s).

```py
class AutomaticGammaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_index('SPX').symbol

        # Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )
        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_index_option_contract(call)
            contract2 = self.add_index_option_contract(put)

            # Create and save the automatic Gamma indicators.
            contract1.g = self.g(call, put)
            contract2.g = self.g(put, call)

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Get the Gamma indicator of each contract.
        for canonical, chain in slice.option_chains.items():
            for symbol in chain:
                option = self.securities[symbol]
                indicator = option.g
        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

The follow table describes the arguments that the `g` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`iv_model`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating Gamma. If you don't provide a value, the default value is to match the `option_model` parameter.	`None`

For more information about the `g` method, see Using G Indicator .

Manual Indicators

To create a manual indicator for gamma, call the `Gamma` constructor.

```py
class ManualGammaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_index('SPX').symbol
        # Set up the dividend yield provider for the underlying.
        self._dividend_yield_provider = DividendYieldProvider(self._underlying)
        # Define the Option pricing model.
        self._option_pricing_model = OptionPricingModelType.FORWARD_TREE

        # Set up a Scheduled Event to select contract and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )

        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_index_option_contract(call)
            contract2 = self.add_index_option_contract(put)

            # Create and save the automatic Gamma indicators.
            for contract_a, contract_b in [(contract1, contract2), (contract2, contract1)]:
                contract_a.Gamma = Gamma(
                        contract_a.symbol, self.risk_free_interest_rate_model,
                        self._dividend_yield_provider, contract_b.symbol, self._option_pricing_model
                    )

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Iterate through the indicators.
        for canonical, chain in slice.option_chains.items():
            for option in chain:
                underlying = option.symbol.underlying
                indicator = self.securities[option].Gamma
                mirror = Symbol.create_option(
                    underlying.value, option.id.market, option.id.option_style,
                    OptionRight.Call if option.id.option_right == OptionRight.PUT else OptionRight.PUT,
                    option.id.strike_price, option.id.date
                )
                # Check if price data is available for both contracts and the underlying asset.
                q = slice.quote_bars
                b = slice.bars
                if option in q and mirror in q and underlying in b:
                    data_points = [
                        IndicatorDataPoint(option, q[option].end_time, q[option].close),
                        IndicatorDataPoint(mirror, q[mirror].end_time, q[mirror].close),
                        IndicatorDataPoint(
                            underlying, b[underlying].end_time, b[underlying].close
                        )
```

```
                    ]
                    for data_point in data_points:
                        indicator.update(data_point)

                    # Get the current value of the Gamma indicator.
                    value = indicator.current.value

        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if not self._underlying and self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

For more information about the `Gamma` constructor, see Using G Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirror_option` argument to the indicator method or constructor and then call the `set_smoothing_function` method of the `implied_volatility` property of the indicator.

```
PY
# Example: Average IV of the call-put pair.
gamma_indicator.implied_volatility.set_smoothing_function(lambda iv, mirror_iv: (iv + mirror_iv) * 0.5)
```

Vega

Vega, , is the rate of change in the value of the Option with respect to the volatility of the underlying asset. For more information about vega, see Vega .

Automatic Indicators

To create an automatic indicator for vega, call the `QCAlgorithm.v` method with the Option contract `symbol` object(s).

```
class AutomaticVegaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_index('SPX').symbol

        # Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )
        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_index_option_contract(call)
            contract2 = self.add_index_option_contract(put)

            # Create and save the automatic Vega indicators.
            contract1.v = self.v(call, put)
            contract2.v = self.v(put, call)

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Get the Vega indicator of each contract.
        for canonical, chain in slice.option_chains.items():
            for symbol in chain:
                option = self.securities[symbol]
                indicator = option.v
        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

The follow table describes the arguments that the `v` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`iv_model`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating Vega. If you don't provide a value, the default value is to match the `option_model` parameter.	`None`

For more information about the `v` method, see Using V Indicator .

Manual Indicators

To create a manual indicator for vega, call the Vega constructor.

```py
class ManualVegaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_index('SPX').symbol
        # Set up the dividend yield provider for the underlying.
        self._dividend_yield_provider = DividendYieldProvider(self._underlying)
        # Define the Option pricing model.
        self._option_pricing_model = OptionPricingModelType.FORWARD_TREE

        # Set up a Scheduled Event to select contract and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )

        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_index_option_contract(call)
            contract2 = self.add_index_option_contract(put)

            # Create and save the automatic Vega indicators.
            for contract_a, contract_b in [(contract1, contract2), (contract2, contract1)]:
                contract_a.Vega = Vega(
                        contract_a.symbol, self.risk_free_interest_rate_model,
                        self._dividend_yield_provider, contract_b.symbol, self._option_pricing_model
                    )

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Iterate through the indicators.
        for canonical, chain in slice.option_chains.items():
            for option in chain:
                underlying = option.symbol.underlying
                indicator = self.securities[option].Vega
                mirror = Symbol.create_option(
                    underlying.value, option.id.market, option.id.option_style,
                    OptionRight.Call if option.id.option_right == OptionRight.PUT else OptionRight.PUT,
                    option.id.strike_price, option.id.date
                )
                # Check if price data is available for both contracts and the underlying asset.
                q = slice.quote_bars
                b = slice.bars
                if option in q and mirror in q and underlying in b:
                    data_points = [
                        IndicatorDataPoint(option, q[option].end_time, q[option].close),
                        IndicatorDataPoint(mirror, q[mirror].end_time, q[mirror].close),
                        IndicatorDataPoint(
                            underlying, b[underlying].end_time, b[underlying].close
                        )
```

```
                    ]
                    for data_point in data_points:
                        indicator.update(data_point)

                    # Get the current value of the Vega indicator.
                    value = indicator.current.value

        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if not self._underlying and self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

For more information about the `Vega` constructor, see Using V Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirror_option` argument to the indicator method or constructor and then call the `set_smoothing_function` method of the `implied_volatility` property of the indicator.

PY

```
# Example: Average IV of the call-put pair.
vega_indicator.implied_volatility.set_smoothing_function(lambda iv, mirror_iv: (iv + mirror_iv) * 0.5)
```

Theta

Theta, , is the rate of change of the value of the Option with respect to the passage of time. It is also known to as the time decay of an Option. For more information about theta, see Theta .

Automatic Indicators

To create an automatic indicator for theta, call the `QCAlgorithm.t` method with the Option contract `symbol` object(s).

```py
class AutomaticThetaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_index('SPX').symbol

        # Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )
        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_index_option_contract(call)
            contract2 = self.add_index_option_contract(put)

            # Create and save the automatic Theta indicators.
            contract1.t = self.t(call, put)
            contract2.t = self.t(put, call)

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Get the Theta indicator of each contract.
        for canonical, chain in slice.option_chains.items():
            for symbol in chain:
                option = self.securities[symbol]
                indicator = option.t
        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

The follow table describes the arguments that the `t` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`iv_model`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating theta. If you don't provide a value, the default value is to match the `option_model` parameter.	`None`

For more information about the `t` method, see Using T Indicator .

Manual Indicators

To create a manual indicator for theta, call the `Theta` constructor.

```py
class ManualThetaIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_index('SPX').symbol
        # Set up the dividend yield provider for the underlying.
        self._dividend_yield_provider = DividendYieldProvider(self._underlying)
        # Define the Option pricing model.
        self._option_pricing_model = OptionPricingModelType.FORWARD_TREE

        # Set up a Scheduled Event to select contract and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )

        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_index_option_contract(call)
            contract2 = self.add_index_option_contract(put)

            # Create and save the automatic Theta indicators.
            for contract_a, contract_b in [(contract1, contract2), (contract2, contract1)]:
                contract_a.Theta = Theta(
                        contract_a.symbol, self.risk_free_interest_rate_model,
                        self._dividend_yield_provider, contract_b.symbol, self._option_pricing_model
                    )

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Iterate through the indicators.
        for canonical, chain in slice.option_chains.items():
            for option in chain:
                underlying = option.symbol.underlying
                indicator = self.securities[option].Theta
                mirror = Symbol.create_option(
                    underlying.value, option.id.market, option.id.option_style,
                    OptionRight.Call if option.id.option_right == OptionRight.PUT else OptionRight.PUT,
                    option.id.strike_price, option.id.date
                )
                # Check if price data is available for both contracts and the underlying asset.
                q = slice.quote_bars
                b = slice.bars
                if option in q and mirror in q and underlying in b:
                    data_points = [
                        IndicatorDataPoint(option, q[option].end_time, q[option].close),
                        IndicatorDataPoint(mirror, q[mirror].end_time, q[mirror].close),
                        IndicatorDataPoint(
                            underlying, b[underlying].end_time, b[underlying].close
                        )
```

```
                    ]
                    for data_point in data_points:
                        indicator.update(data_point)

                    # Get the current value of the Theta indicator.
                    value = indicator.current.value

        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if not self._underlying and self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

For more information about the `Theta` constructor, see Using T Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirror_option` argument to the indicator method or constructor and then call the `set_smoothing_function` method of the `implied_volatility` property of the indicator.

```
PY
# Example: Average IV of the call-put pair.
theta_indicator.implied_volatility.set_smoothing_function(lambda iv, mirror_iv: (iv + mirror_iv) * 0.5)
```

Rho

Rho, , is the rate of change of the value of a derivative with respect to the interest rate . It is usually small and not a big issue in practice unless the Option is deep in-the-money and has a long horizon. In this case, the interest rate matters because you need to discount a larger cash flow over a longer horizon. For more information about rho, see Rho .

Automatic Indicators

To create an automatic indicator for rho, call the `QCAlgorithm.r` method with the Option contract `symbol` object(s).

```py
class AutomaticRhoIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_index('SPX').symbol

        # Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )
        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_index_option_contract(call)
            contract2 = self.add_index_option_contract(put)

            # Create and save the automatic Rho indicators.
            contract1.r = self.r(call, put)
            contract2.r = self.r(put, call)

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Get the Rho indicator of each contract.
        for canonical, chain in slice.option_chains.items():
            for symbol in chain:
                option = self.securities[symbol]
                indicator = option.r
        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

The follow table describes the arguments that the `r` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`iv_model`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating rho If you don't provide a value, the default value is to match the `option_model` parameter.	`None`

For more information about the `r` method, see Using R Indicator .

Manual Indicators

To create a manual indicator for rho, call the Rho constructor.

```py
class ManualRhoIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 30)
        self.set_cash(500_000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Subscribe to the underlying asset.
        self._underlying = self.add_index('SPX').symbol
        # Set up the dividend yield provider for the underlying.
        self._dividend_yield_provider = DividendYieldProvider(self._underlying)
        # Define the Option pricing model.
        self._option_pricing_model = OptionPricingModelType.FORWARD_TREE

        # Set up a Scheduled Event to select contract and create the indicators every day before market open.
        self.schedule.on(
            self.date_rules.every_day(self._underlying),
            self.time_rules.at(9, 0),
            self._update_contracts_and_greeks
        )

        self._options = None

    def _update_contracts_and_greeks(self) -> None:
        if self._underlying is None:
            return
        # Get all the tradable Option contracts.
        chain = self.option_chain(self._underlying, flatten=True).data_frame
        if chain.empty:
            return

        # Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        chain = chain[chain.expiry > self.time + timedelta(30)]
        expiry = chain.expiry.min()
        chain = chain[chain.expiry == expiry]
        chain.loc[:, 'abs_strike_delta'] = abs(chain['strike'] - chain['underlyinglastprice'])
        abs_strike_delta = chain['abs_strike_delta'].min()
        chain = chain[chain['abs_strike_delta'] == abs_strike_delta]

        # Group the contracts into call/put pairs.
        contracts_pair_sizes = chain.groupby(['expiry', 'strike']).count()['right']
        paired_contracts = contracts_pair_sizes[contracts_pair_sizes == 2].index
        expiries = [x[0] for x in paired_contracts]
        strikes = [x[1] for x in paired_contracts]
        symbols = [
            idx[-1] for idx in chain[
                chain['expiry'].isin(expiries) & chain['strike'].isin(strikes)
            ].reset_index().groupby(['expiry', 'strike', 'right', 'symbol']).first().index
        ]
        pairs = [(symbols[i], symbols[i+1]) for i in range(0, len(symbols), 2)]

        for call, put in pairs:
            # Subscribe to both contracts.
            contract1 = self.add_index_option_contract(call)
            contract2 = self.add_index_option_contract(put)

            # Create and save the automatic Rho indicators.
            for contract_a, contract_b in [(contract1, contract2), (contract2, contract1)]:
                contract_a.Rho = Rho(
                        contract_a.symbol, self.risk_free_interest_rate_model,
                        self._dividend_yield_provider, contract_b.symbol, self._option_pricing_model
                    )

            self._options = (call, put)

    def on_data(self, slice: Slice) -> None:
        # Iterate through the indicators.
        for canonical, chain in slice.option_chains.items():
            for option in chain:
                underlying = option.symbol.underlying
                indicator = self.securities[option].Rho
                mirror = Symbol.create_option(
                    underlying.value, option.id.market, option.id.option_style,
                    OptionRight.Call if option.id.option_right == OptionRight.PUT else OptionRight.PUT,
                    option.id.strike_price, option.id.date
                )
                # Check if price data is available for both contracts and the underlying asset.
                q = slice.quote_bars
                b = slice.bars
                if option in q and mirror in q and underlying in b:
                    data_points = [
                        IndicatorDataPoint(option, q[option].end_time, q[option].close),
                        IndicatorDataPoint(mirror, q[mirror].end_time, q[mirror].close),
                        IndicatorDataPoint(
                            underlying, b[underlying].end_time, b[underlying].close
                        )
```

```
                    ]
                    for data_point in data_points:
                        indicator.update(data_point)

                    # Get the current value of the Rho indicator.
                    value = indicator.current.value

        # Sell straddle as an example to trade.
        if not self.portfolio.invested and self._options:
            self.sell(self._options[0], 1)
            self.sell(self._options[1], 1)
        # Liquidate any assigned positions.
        if not self._underlying and self.portfolio[self._underlying].invested:
            self.liquidate(self._underlying)
```

For more information about the `Rho` constructor, see Using R Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirror_option` argument to the indicator method or constructor and then call the `set_smoothing_function` method of the `implied_volatility` property of the indicator.

```
PY
# Example: Average IV of the call-put pair.
rho_indicator.implied_volatility.set_smoothing_function(lambda iv, mirror_iv: (iv + mirror_iv) * 0.5)
```

CFD

Requesting Data

Introduction

Request Contract for Difference (CFD) data in your algorithm to receive a feed of contract prices in the `on_data` method. QuantConnect supports CFD trading with OANDA and Interactive Brokers .

OANDA Subscriptions

To create a CFD subscription, in the `initialize` method, call the `add_cfd` method. The `add_cfd` method returns a `Cfd` Security object, which contains a `symbol` property. Save a reference to the `symbol` so you can use it in `on_data` to access the security data in the `Slice` .

```
self._symbol = self.add_cfd("XAUUSD").symbol
```

PY

To view the supported CFD contracts, see Supported Assets . For more information about the specific dataset we use for backtests, see the OANDA CFD dataset listing . To trade OANDA CFDs live, use our QuantConnect data provider .

Interactive Brokers Subscriptions

To create a CFD subscription for Interactive Brokers (IB) , in the `initialize` method, call the `add_cfd` method and set the `market` parameter to `Market.INTERACTIVE_BROKERS` . The `add_cfd` method returns a `Cfd` Security object, which contains a `symbol` property. Save a reference to the `symbol` so you can use it in `on_data` to access the security data in the `Slice` .

```
self._symbol = self.add_cfd("SPY", market=Market.INTERACTIVE_BROKERS).symbol
```

PY

Historical data for backtesting IB CFDs is unavailable.

In live trading, include the Interactive Brokers data provider when you deploy the algorithm to access IB CFD data. You can use this data provider for paper or real-money accounts. IB provides data for Indexes, Metals, Forex, and Global Stock CFDs. To view the Index and Forex CFD products that IB supports in live trading, see the Interactive Brokers Supported Contracts . To view the Equity CFD products, see the Products Search page on the IB website.

If you live in the EU and can't trade US ETFs due to regulation, you can trade their CFD equivalents in live mode.

```
security_type = SecurityType.CFD if self.live_mode else SecurityType.EQUITY
market=Market.INTERACTIVE_BROKERS if self.live_mode else Market.USA
self._symbol = Symbol.create("SPY", security_type, market)
self.add_security(self._symbol)
```

PY

Market hours for IB CFDs are not modeled. You cannot use them for scheduled events or to get market open/close times . To create a scheduled event, use a ticker of any US Equity that you haven't added as a IB CFD or create a US Equity `Symbol` .

```
def initialize(self):
    us_equity_symbol = Symbol.create("SPY", SecurityType.EQUITY, Market.USA)
    # Call the _before_market_open method 10 minutes before open every day US Equity stocks are trading.
    self.schedule.on(
        self.date_rules.every_day(us_equity_symbol),
        self.time_rules.before_market_open(us_equity_symbol, 10),
        self._before_market_open
    )
```

PY

Resolutions

The following table shows the available resolutions and data formats for CFD subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
TICK				✓
SECOND		✓		
MINUTE		✓		
HOUR		✓		
DAILY		✓		

The default resolution for CFD subscriptions is `Resolution.MINUTE` . To change the resolution, pass a `resolution` argument to the `add_cfd` method.

```
self._symbol = self.add_cfd("XAUUSD", Resolution.DAILY).symbol
```

PY

To create custom resolution periods, see Consolidating Data .

Supported Markets

The following `Market` enumeration members are available for CFDs:

To set the market for a security, pass a `market` argument to the `add_cfd` method.

```
self._symbol = self.add_cfd("XAUUSD", market=Market.OANDA).symbol
```

PY

The brokerage models have a default market for each asset class. If you set a brokerage model, you may not need to specify the market to use. In backtesting, set the market for CFDs to OANDA.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fill_forward` argument to false when you create the security subscription.

```
self._symbol = self.add_cfd("XAUUSD", fill_forward=False).symbol
```

PY

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. The specific margin available depends on your brokerage destination. To change the amount of leverage you can use for a CFD contract, pass a `leverage` argument to the `add_cfd` method.

```
self._symbol = self.add_cfd("XAUUSD", leverage=35).symbol
```

PY

Data Normalization

The data normalization mode doesn't affect the data that LEAN passes to `on_data` or the data from history request . If you change the data normalization mode, it won't change the outcome.

Interactive Brokers Stock CFDs apply corporate actions to the price of the asset, including paying dividends in cash to your account. This behavior is not modeled today and splits in live trading will result in price discontinuities. You should monitor the underlying Equity for events and use the underlying Equity for indicators.

Properties

The `add_cfd` method returns a `Cfd` object, which have the following properties:

Interactive Brokers Supported Contracts

The following table shows the CFD contracts that IB supports:

Examples

The following examples demonstrate some common practices for requesting CFD data.

Example 1: SMA Crossing

The following strategy purchases ETFs when their fast-moving average crosses over the slow-moving average. In live mode, the strategy purchases their CFD equivalents.

PY

```
class EtfCfdSwapMovingAverageCrossAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Request the data to feed into indicators and trade.
        # In live mode, request CFD data for trading.
        # CFD is more useful in non-trading hours to reduce slippage when market prices jump at market opening.
        tickers = ["SPY", "BND", "GLD", "QQQ"]
        security_type = SecurityType.CFD if self.live_mode else SecurityType.EQUITY
        for ticker in tickers:
            # Create fast and slow-moving average indicators to trade SAM cross trend-following strategy.
            equity = self.add_equity(ticker, Resolution.DAILY)
            equity.sma_fast = self.sma(equity.symbol, 50)
            equity.sma_slow = self.sma(equity.symbol, 200)
            equity.target_vehicle = self.add_cfd(ticker, Resolution.DAILY, market=Market.INTERACTIVE_BROKERS).symbol if self.live_mode
else equity.symbol

        # Create an schduled event to plot the prices.
        # We need to create a symbol representing the US Equity market
        # because market hours for IB CFDs are not modeled
        market = Symbol.create("SPY", SecurityType.EQUITY, Market.USA)
        self.schedule.on(self.date_rules.every_day(market), self.time_rules.midnight, self._plot_prices)

    def on_data(self, data: Slice) -> None:
        for security in self.securities.values():
            # Trade the SMA cross on the updated SMA indicator signals.
            # If fast MA is above slow MA, the price is in an uptrend, and we buy.
            if security.sma_fast > security.sma_slow:
                self.set_holdings(security.target_vehicle, 0.25)
            # Else, the price is in a downtrend, and we are short.
            else:
                self.set_holdings(security.target_vehicle, 0)

    def _plot_prices(self):
        for security in self.securities.values():
            self.plot(security.symbol.value, 'EOD', security.price)
```

CFD

Handling Data

Introduction

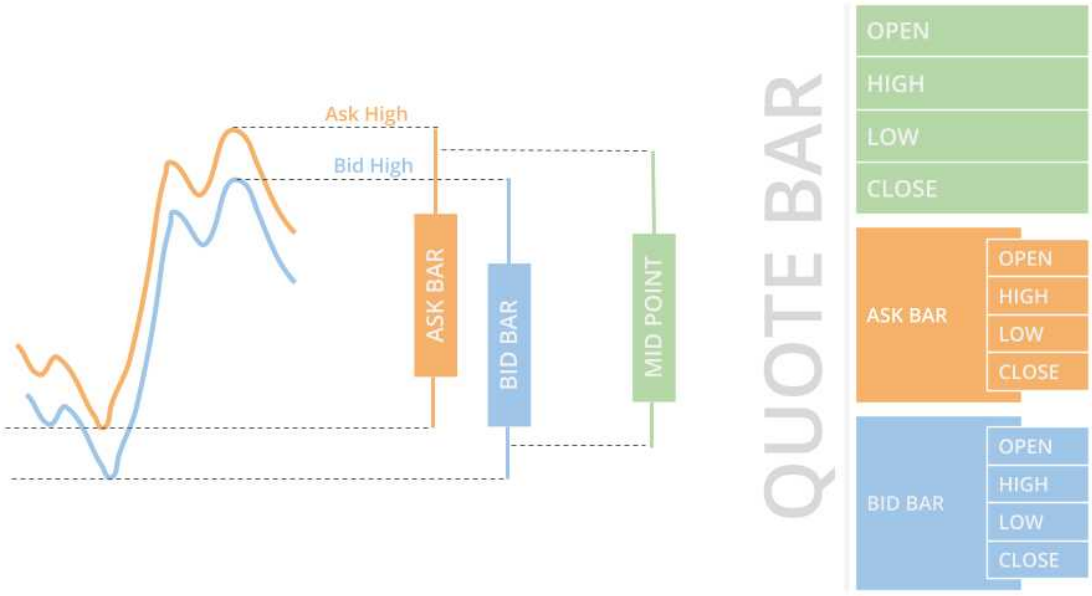
LEAN passes the data you request to the `on_data` method so you can make trading decisions. The `Slice` object that the `on_data` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `on_data` method, use the `current_slice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `QuoteBars` `DataDictionary` is made up of `QuoteBar` objects. To access individual data points in the dictionary, you can index the dictionary with the CFD ticker or `symbol` , but we recommend you use the `symbol` .

To view the resolutions that are available for CFD data, see Resolutions .

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `open` , `high` , `low` , and `close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `open` , `high` , `low` , and `close` properties of the `QuoteBar` copy the values of either the `bid` or `ask` instead of taking their mean.



To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the CFD `symbol` . If the CFD doesn't actively get quotes or you are in the same time step as when you added the CFD subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for your CFD before you index the `Slice` with the CFD `symbol` .

```
def on_data(self, slice: Slice) -> None:
    # Obtain the mapped QuoteBar of the symbol if any
    quote_bar = slice.quote_bars.get(self._symbol)   # None if not found
```

PY

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
def on_data(self, slice: Slice) -> None:
    # Iterate all received Symbol-QuoteBar key-value pairs
    for symbol, quote_bar in slice.quote_bars.items():
        ask_price = quote_bar.ask.close
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

`QuoteBar` objects have the following properties:

Ticks

`Tick` objects represent a single trade or quote at a moment in time. A trade tick is a record of a transaction for the CFD. A quote tick is an offer to buy or sell the CFD at a specific price.

Trade ticks have a non-zero value for the `quantity` and `price` properties, but they have a zero value for the `bid_price` , `bid_size` , `ask_price` , and `ask_size` properties. Quote ticks have non-zero values for `bid_price` and `bid_size` properties or have non-zero values for `ask_price` and `ask_size` properties. To check if a tick is a trade or a quote, use the `ticktype` property.

In backtests, LEAN groups ticks into one millisecond buckets. In live trading, LEAN groups ticks into ~70-millisecond buckets. To get the `Tick` objects in the `Slice` , index the `Ticks` property of the `Slice` with a `symbol` . If the CFD doesn't actively trade or you are in the same time step as when you added the CFD subscription, the `Slice` may not contain data for your `symbol` . To avoid issues, check if the `Slice` contains data for your CFD before you index the `Slice` with the CFD `symbol` .

```
def on_data(self, slice: Slice) -> None:
    ticks = slice.ticks.get(self._symbol, [])   # Empty if not found
    for tick in ticks:
        price = tick.price
```

You can also iterate through the `Ticks` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `list[Tick]` objects.

```
def on_data(self, slice: Slice) -> None:
    for symbol, ticks in slice.ticks.items():
        for tick in ticks:
            price = tick.price
```

Tick data is raw and unfiltered, so it can contain bad ticks that skew your trade results. For example, some ticks come from dark pools, which aren't tradable. We recommend you only use tick data if you understand the risks and are able to perform your own online tick filtering.

`Tick` objects have the following properties:

Examples

The following examples demonstrate common practices for handling CFD data.

Example 1: Buy And Hold

The following algorithm is a buy-and-hold strategy on the DE30EUR CFD contract. We only place orders when quote data is available to avoid stale fills. Also, we set the algorithm time zone to Berlin and the account currency to Euros for a more convenient comparison.

```py
class CfdExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Set the timezone as Berlin to conveniently compare the data.
        self.set_time_zone(TimeZones.BERLIN)
        # Set the account currency to EUR to trade the DAX CFD.
        self.set_account_currency("EUR", 10000)
        # Request the CFD data to trade.
        self._dax = self.add_cfd("DE30EUR").symbol

    def on_data(self, slice: Slice) -> None:
        # Trade based on updated data; CFDs only have quote data.
        bar = slice.quote_bars.get(self._dax)
        if bar:
            # Buy and hold DAX CFD.
            if not self.portfolio[self._dax].is_long:
                self.set_holdings(self._dax, 0.5)
```

Example 2: Global Indices

The following algorithm buys and holds various Index CFDs that trade in different market hours and currencies during their opening hours.

```py
class CfdExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Seed the price of each asset with its last known price to
        # avoid trading errors.
        self.settings.seed_initial_prices = True
        # Let's select CFD contracts that trade in different market
        # hours so the algorithm is always invested.
        for ticker in ['DE30EUR', 'SG30SGD', 'US30USD']:
            # Add the CFD.
            symbol = self.add_cfd(ticker).symbol
            # Set scheduled events to hold each CFD contract during
            # their regular trading hours.
            # Buy after market open.
            self.schedule.on(
                self.date_rules.every_day(symbol),
                self.time_rules.after_market_open(symbol, 1),
                lambda symbol=symbol: self.set_holdings(symbol, 0.3)
            )
            # Liquidate before market close.
            self.schedule.on(
                self.date_rules.every_day(symbol),
                self.time_rules.before_market_close(symbol, 1),
                lambda symbol=symbol: self.liquidate(symbol)
            )
```

Portfolio

Portfolio

Key Concepts

Introduction

The `portfolio` object provides information about the investment state and history of all of the securities that have been in the algorithm during its lifetime.

The `portfolio` property of the `QCAlgorithm` class is a dictionary where the keys are `Symbol` objects and the values are `SecurityHolding` objects. The `SecurityHolding` object provides information about the investment state and history of a security.

Investment Status

To get the investment status of your strategy, access the `invested` property of a `portfolio` object.

PY

```
# Get the investment status and return True if the portfolio is invested.
invested = self.portfolio.invested
```

Holdings Status

You can identify a position as long- or short-biased based on the sign of the holding quantity. Long positions have a positive quantity and short positions have a negative quantity. The `SecurityHolding` object has the following properties to describe the holding status.

PY

```
# Create a SecurityHolding object.
holdings = self.portfolio[self._symbol]
# Check the holding quantity of the security.
quantity = holdings.quantity
# Check the investing status of the security.
invested = holdings.invested
# Check if the strategy is long or short the security.
is_long = holdings.is_long
is_short = holdings.is_short
```

The quantity can be lower than the minimum order size. If the quantity is less than the lot size of the asset, the `invested` property is `False` .

Buying Power

To get the maximum buying power in your account currency you can use for a given `Symbol` and order direction, call the `get_buying_power` method.

PY

```
# Check the total amount of buying power available. Margin available varies by order direction and current holdings.
available_buying_power = self.portfolio.get_buying_power(self._symbol, OrderDirection.BUY)
```

For more information about buying power, see Buying Power .

Cost Averaging Accounting

LEAN uses the cost averaging accounting method, which determines the cost of your holdings by taking a weighted average of all your purchase prices. For example, say you place the following buy orders:

1. Buy 10 ABC @ $10
2. Buy 5 ABC @ $11
3. Buy 20 ABC @ $14
4. Buy 3 ABC @ $9

In the preceding example, the average cost of your ABC position is (10*10 + 5*11 + 20*14 + 3*9) / (10 + 5 + 20 + 3) = 12.1579/share. In contrast, if you use the first-in, first-out (FIFO) accounting method, the cost of the first 10 shares is 10/share, not 12.1579/share.

To get the cost of your security holdings, use the `holdings_cost` property of the SecurityHolding object . If you fill buy and sell orders, the holdings cost is the product of the holding quantity and the average price. For example, the following table shows how the average price and holdings cost changes with each buy and sell order order in a long position:

Order Quantity	Fill Price ($)	Holding Quantity	Average Price ($)	Holdings Cost ($)
2	10	2	(2 * 10) / 2 = 10	2 * 10 = 20
-1	11	1	(1 * 10) / 1 = 10	1 * 10 = 10
1	12	2	(1 * 10 + 1 * 12) / 2 = 11	2 * 11 = 22
-2	13	0	0	0 * 0 = 0

The following table shows how the average price and holdings cost changes with each buy and sell order order in a short position:

Order Quantity	Fill Price ($)	Holding Quantity	Average Price ($)	Holdings Cost ($)
-2	10	-2	(-2 * 10) / -2 = 10	-2 * 10 = -20
1	11	-1	(-1 * 10) / -1 = 10	-1 * 10 = -10
-1	12	-2	(-1 * 10 + (-1) * 12) / -2 = 11	-2 * 11 = -22
2	13	0	0	0 * 0 = 0

Note that when you decrease the position size without closing the trade, the average price doesn't change because the denominator and the coefficients in the numerator of its formula are scaled by the quotient of the current holding quantity and the previous holding quantity. For instance, if the last row in the preceding table had an order quantity 1, the holding quantity would be -1 and the average price would be

$$\frac{(-1 * q) * 10 + (-1 * q) * 12}{-2 * q} =\frac{(-1 * \frac{-1}{-2}) * 10 + (-1 * \frac{-1}{-2}) * 12}{-2 * \frac{-1}{-2}} =\frac{\frac{-1}{2} * 10 + \frac{-1}{2} * 12}{-1 } =\frac{-5 - 6}{-1} = 11$$

Performance Statistics

The `portfolio` object has a collection of properties that provide the combined state of holdings and the cashbook .

```py
# Access key statistics of the portfolio using the properties of the portfolio object.
value = self.portfolio.total_portfolio_value
total_margin_used = self.portfolio.total_margin_used
margin_remaining = self.portfolio.margin_remaining
total_net_profit = self.portfolio.total_net_profit
total_unrealised_profit = self.portfolio.total_unrealised_profit
total_fees = self.portfolio.total_fees
cash = self.portfolio.cash
```

Properties

The `portfolio` object has the following properties:

Examples

The following examples demonstrate common practices for handling the portfolio.

Example 1: Martingale

The following algorithm trades a Martingale strategy on AAPL. The trend indicated by an EMA indicator follows the trend with a $1 per share stop-loss and a $2 take-profit level. Yet, if the last trade is lost, it will double the next trading size to recover the last loss.

PY

```
class PortfolioExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Request AAPL's data to trade.
        self.aapl = self.add_equity("AAPL").symbol

        # Create an EMA indicator to generate trading data.
        self._ema = self.ema(self.aapl, 20, Resolution.DAILY)
        # Warm up the indicator to provide an immediate trade signal.
        self.warm_up_indicator(self.aapl, self._ema, Resolution.DAILY)

        self.next_quantity = 1

    def on_data(self, slice: Slice) -> None:
        # Ride on the AAPL trend indicated by the EMA indicator.
        if not self.portfolio.invested:
            if self.securities[self.aapl].price >= self._ema.current.value:
                self.market_order(self.aapl, self.next_quantity)
            else:
                self.market_order(self.aapl, -self.next_quantity)
        else:
            holding = self.portfolio[self.aapl]
            # Stop loss at $1 per share.
            if holding.unrealized_profit <= -1 * self.next_quantity:
                self.liquidate(self.aapl)
                # Double the next quantity to recover this loss.
                self.next_quantity *= 2
            # Take profit at $2 per share.
            elif holding.unrealized_profit >= 2:
                self.liquidate(self.aapl)
                self.next_quantity = 1
```

Portfolio

Holdings

Introduction

The `portfolio` is a dictionary where the key is a `Symbol` and the value is a `SecurityHolding` .

```
# Create shortcut helper to the SPY SecurityHolding object from the Portfolio collection.
security_holding = self.portfolio["SPY"]
```

Properties

`SecurityHolding` objects have the following properties:

```
#  Save shortcut to SecurityHolding object, and fetch quantity and invested status.
security_holding = self.portfolio["SPY"]
quantity = security_holding.quantity
invested = security_holding.invested
```

`FutureHolding` objects also have `settled_profit` and `unsettled_profit` properties.

Get Total Close Profit

To get the profit of a position holding if you closed the position, call the `total_close_profit` method. The value this method returns is denominated in your account currency and accounts for order fees.

```
profit = self.portfolio["SPY"].total_close_profit()
```

The `total_close_profit` method accepts the following optional arguments:

Argument	Data Type	Description	Default Value
`include_fees`	`bool`	Whether to reduce the profit based on the estimated fee from the fee model .	`True`
`exit_price`	`float/NoneType`	A hypothetical exit price to use for the profit calculation. If you don't provide a value, it uses the bid price for sell orders or the ask price for buy orders.	`None`
`entry_price`	`float/NoneType`	A hypothetical exit price to use for the profit calculation. If you don't provide a value, it uses the average price of the `SecurityHolding` .	`None`
`quantity`	`float/NoneType`	The quantity to liquidate. If you don't provide a value, it uses the quantity of the `SecurityHolding` .	`None`

LEAN uses this method to define the `unrealized_profit` property.

Get Quantity Value

To get the value of a security at any quantity, call the `get_quantity_value` method. The value this method returns is denominated in your account currency.

```py
# Get the quantity value at the current price
value_at_current_price = self.portfolio["SPY"].get_quantity_value(100)

# Get the quantity value at a specific price
value_at_specific_price = self.portfolio["SPY"].get_quantity_value(100, price=30)
```

Set Initial Holdings

When you deploy a backtest or a new paper trading algorithm, the default initial portfolio state contains $100,000 USD. However, in the initialize method, you can define the initial portfolio state to something else. To set the initial cash balances , call `set_cash` with the currency ticker and quantity. To set multiple currencies, call the method multiple times.

```py
self.set_cash(100000)       # Set the quantity of the account currency to 100,000
self.set_cash("BTC", 10)    # Set the Bitcoin quantity to 10
self.set_cash("EUR", 10000) # Set the EUR quantity to 10,000
```

To set the initial security holdings, subscribe to the security so that it enters your portfolio , then call the `SecurityHolding.set_holdings` method with the average purchase price and quantity.

```py
if not self.live_mode:
    self.portfolio["SPY"].set_holdings(average_price=500, quantity=100)
```

Examples

The following examples demonstrate common practices for setting the portfolio holdings.

Example 1: Initial Holdings

The following algorithm simulates an account with multiple initial positions and cash. Note that these initial holdings will affect the algorithm's performance.

```py
class PortfolioExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Simulate initial cash in multiple currencies.
        # Note that all currencies other than the account currency will affect the performance.
        self.set_account_currency("USD", 10000)
        self.set_cash("EUR", 1000)
        self.set_cash("JPY", 1000000)
        self.set_cash("HKD", 10000)

        # Add a security initializer that seeds the price of each asset with its
        # last known price. This ensures the holdings we add below will initialize
        # with a non-zero value.
        self.settings.seed_initial_prices = True

        # Request data for some securities in the account already.
        spy = self.add_equity("SPY").symbol
        aapl = self.add_equity("AAPL").symbol
        btcusd = self.add_crypto("BTCUSD").symbol
        xauusd = self.add_cfd("XAUUSD").symbol

        # Simulate that the account initially holds some assets.
        # Note that all initial holdings will affect the performance.
        self.portfolio[spy].set_holdings(average_price=420, quantity=102)
        self.portfolio[aapl].set_holdings(average_price=120, quantity=25)
        self.portfolio[btcusd].set_holdings(average_price=45000, quantity=0.125)
        self.portfolio[xauusd].set_holdings(average_price=1000, quantity=100)
```

Portfolio

Cashbook

Introduction

The `CashBook` is a dictionary where the keys are currency tickers and the values are `Cash` objects. The `Cash` objects track the amount of each currency in the portfolio. As you buy and sell securities, LEAN credits and debits the `Cash` objects to reflect your cash holdings.

Account Currency

The default account currency is USD, but you can change it. All of the properties of the Portfolio object that return a currency value denominate the currency value in your account currency. Depending on your account currency and security subscriptions, LEAN may add internal security subscriptions to calculate the `value_in_account_currency` . For example, if you only add BTCETH to your algorithm and set the account currency to USDT, LEAN adds BTCUSDT and ETHUSDT as internal feeds.

To get your account currency, use the `account_currency` property.

```
account_currency = self.account_currency
```

PY

To set your account currency, in the `initialize` method, call the `set_account_currency` method. You can only set the account currency once. LEAN ignores each additional call to `set_account_currency` .

```
self.set_account_currency("EUR")
```

PY

Settled vs Unsettled Cash

The `portfolio` has two independent cashbooks. The `cash_book` tracks settled cash and the `unsettled_cash_book` tracks unsettled cash, which you can't spend. If you trade with a margin account, trades settle immediately so LEAN credits and debits the `cash_book` at the time of the trade. In some cases, transactions can take time to settle. For example, Equity trades in a cash account settle in T+3. Therefore, if you sell shares of stock on Monday, the transaction settles on Thursday. In contrast, Option trades settle in T+1.

```
settled_cash_book = self.portfolio.cash_book
unsettled_cash_book = self.portfolio.unsettled_cash_book
```

PY

Track Cash Balances

To get the balance of a currency in the cash book, use the `amount` property.

```
# Return the cash book balance in US Dollar amount.
usd = self.portfolio.cash_book["USD"].amount
# Return the cash book balance in Bitcoin amount.
btc = self.portfolio.cash_book["BTC"].amount
```

PY

To get the value of a currency in the cash book, denominated in your account currency, use the `value_in_account_currency` property.

```
# Return the cash book value of Ethereum in account currency (US Dollar, Euro, etc.) amount.
eth_value = self.portfolio.cash_book["ETH"].value_in_account_currency
```

PY

Deposits and Withdrawals

In backtests, you can add and remove cash from the cash book. To add or remove cash, call the `add_amount` method.

```
# Adjust the backtesting cashbook balances to add 100 USD and subtract 1.5 BTC.
new_usd_balance = self.portfolio.cash_book["USD"].add_amount(100)
new_btc_balance = self.portfolio.cash_book["BTC"].add_amount(-1.5)
```

In live trading, add and withdraw cash through your brokerage account. If you adjust the cash balances in your algorithm with the `add_amount` method, the cash balance in your algorithm will be out of sync with the cash balance in your brokerage account.

Currency Symbols

A currency symbol is a graphic that represents the currency name. For example, $ is for dollars, € for euros, and ฿ for Bitcoin. To get the symbol of a currency in the cash book, use `currency_symbol` property.

```
usd_symbol = self.portfolio.cash_book["USD"].currency_symbol
```

Conversion Rates

To get the conversion rate for a currency in the cashbook to your account currency, use the `conversion_rate` property.

```
eur_conversion_rate = self.portfolio.cash_book["EUR"].conversion_rate
```

Examples

The following examples demonstrate common practices for controlling the portfolio cashbook.

Example 1: Dollar Cost Averaging

The following algorithm deposits USD 1000 on every month's start and buys SPY with the deposited cash. It results in a dollar cost averaging investment strategy on the overall market.

```
class PortfolioCashbookAlgorithm(QCAlgorithm):
    deposit = 1000

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000)

        # Request SPY data to trade the overall market representative.
        self.spy = self.add_equity("SPY").symbol

        # Deposit each month start and invest in SPY by dollar cost averaging.
        self.schedule.on(
            self.date_rules.month_start(self.spy),
            self.time_rules.after_market_open(self.spy, 0),
            self.deposit_and_rebalance
        )

        # To warm up the price data of SPY to calculate the quantity to be brought.
        self.set_warm_up(1)

    def deposit_and_rebalance(self) -> None:
        # Deposit the account currency's preset level ($1000) at the month's start.
        # Simulate the monthly salary deposit for dollar cost-averaging investment in the market.
        self.portfolio.cash_book[self.account_currency].add_amount(self.deposit)

        # Calculate the number of shares that can be invested using the deposited amount.
        quantity = self.deposit // self.securities[self.spy].price
        self.market_order(self.spy, quantity)
```

Example 2: Crypto Cashbook

This example trades an EMA cross strategy on the ETH-BTC crypto pair in a cash account. To obtain the maximum tradable order size, we need to use the cash book and check the amount of BTC in long ETHBTC trades and in short ETHBTC trades to avoid insufficient initial margin.

PY

```
class PortfolioCashbookAlgorithm(QCAlgorithm):

    buffer = 0.01

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Set the account currency as USDT and set the starting cash in a cash account.
        self.set_brokerage_model(BrokerageName.COINBASE, AccountType.CASH)
        self.set_account_currency("USDT", 100)
        self.set_cash("BTC", 100)
        self.set_cash("ETH", 2000)

        # We would like to trade the EMA cross between 2 popular cryptos BTC & ETH,
        # so we are requesting ETHBTC data to find trading opportunities.
        self.ethbtc = self.add_crypto("ETHBTC", Resolution.MINUTE, Market.COINBASE).symbol

        # Add automatic-updating EMA indicator for trend trade signal emission.
        self._ema = self.ema(self.ethbtc, 50, Resolution.DAILY)
        # Warm up the indicator for its readiness usage immediately.
        self.warm_up_indicator(self.ethbtc, self._ema, Resolution.DAILY)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self.ethbtc)
        if not (bar and self._ema.is_ready):
            return
        ema = self._ema.current.value
        # ETHBTC's current price is higher than EMA, suggesting an uptrend.
        if bar.close > ema and not self.portfolio[self.ethbtc].is_long:
            # Convert to the corresponding quantity of the quote currency.
            quantity = self.portfolio.cash_book["BTC"].amount * (1 - self.buffer) / bar.close
        # ETHBTC's current price is below the EMA, suggesting a downtrend.
        elif bar.close < ema and not self.portfolio[self.ethbtc].is_short:
            quantity = -self.portfolio.cash_book["ETH"].amount
        else:
            return
        # Round down to observe the lot size.
        lot_size = self.securities[self.ethbtc].symbol_properties.lot_size
        quantity = int(quantity / lot_size) * lot_size
        if quantity:
            self.market_order(self.ethbtc, quantity)
```

Universes

Universes

Key Concepts

Introduction

Universe selection is the process of selecting a basket of assets you may trade. Dynamic universe selection increase diversification and decrease selection bias in your algorithm.

How Universe Selection Works

When you add a universe to your algorithm, LEAN sends a large dataset into a filter function you define. Your filter function needs to return a list of `Symbol` objects. LEAN automatically subscribes to these new symbols and adds them to your algorithm. Your algorithm can do almost anything inside your filter functions, but the goal should be to narrow down the set of securities to the securities that are most applicable for your algorithm.

Selection Functions

The following example filter function selects the 100 most liquid US Equities:

```py
# Use a fundamental filter function to select the 100 most liquid Equities.
class MyFundamentalUniverseAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.universe_settings.asynchronous = True
        self.add_universe(self._fundamental_filter_function)

    def _fundamental_filter_function(self, fundamental: List[Fundamental]) -> List[Symbol]:
        sorted_by_dollar_volume = sorted(fundamental, key=lambda x: x.dollar_volume, reverse=True)
        return [c.symbol for c in sorted_by_dollar_volume[:100]]
```

To learn how to define filter functions for other asset classes, custom data universes , or alternative data universes , see the following pages in this Universes chapter.

Security Changed Events

When your universe adds and removes assets, LEAN notifies your algorithm through the `on_securities_changed` event handler. The event handler receives a `SecurityChanges` object, which contains references to the added and removed securities. To access the added securities, check the `changes.added_securities` method property. To access the removed securities, check the `changes.removed_securities` method property.

```py
# Use the on_securities_changed method to know when an asset is added or removed.
def on_securities_changed(self, changes: SecurityChanges) -> None:
    # Iterate through the added securities.
    for security in changes.added_securities:
        self.debug(f"{self.time}: Added {security.symbol}")

    # Iterate through the removed securities.
    for security in changes.removed_securities:
        self.debug(f"{self.time}: Removed {security.symbol}")

        if security.invested:
            self.liquidate(security.symbol, tag="Removed from Universe")
```

The preceding example liquidates securities that leave the universe. In this case, LEAN creates a market on open order and frees up buying power when the market opens.

Custom Security Properties

If you need to save data or create objects for each security in the universe, add custom members to the respective `Security` objects . This technique is useful if you want to track stop loss levels or add indicators for each asset in the universe.

```py
# Add custom properties to the security by duck-typing.
def on_securities_changed(self, changes: SecurityChanges) -> None:
    for security in changes.added_securities:
        # Create an SMA indicator with 10 periods for the asset.
        # Use duck typing to store it on the security object.
        security.indicator = self.sma(security.Symbol, 10)

        # Warm up the indicator with historical data.
        self.warm_up_indicator(security.symbol, security.indicator)

    # Remove the automatic indicator updates when the security leaves the universe.
    for security in changes.removed_securities:
        self.deregister_indicator(security.indicator)
```

Select Current Constituents

If you don't want to make any changes to the current universe, return `Universe.UNCHANGED` from your filter functions.

```py
class MyUniverseAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.universe_settings.asynchronous = True
        self.add_universe(self._my_fundamental_filter_function)

    # Use Universe.UNCHANGED to leave the universe unchanged.
    def _my_fundamental_filter_function(self, fundamental: List[Fundamental]) -> List[Symbol]:
        return Universe.UNCHANGED
```

Universe Manager

The universe manager tracks all the universes in your algorithm. If you add multiple universe, you can access the constituents of each individual universe. To access the constituents of a universe in a multi-universe algorithm, save references to each universe when you add them.

```py
# In the initialize method, add a new universe.
self.universe_settings.asynchronous = True
self._universe = self.add_universe(self._my_fundamental_filter_function)

# Use the universe_manager to get information about the assets in each universe.
universe_members = self.universe_manager[self._universe.configuration.symbol].members
for kvp in universe_members:
    symbol = kvp.key # The symbol of the asset.
    security = kvp.value # The security in the universe.
```

When you remove an asset from a universe, LEAN usually removes the security from the `Members` collection and removes the security subscription. However, it won't remove the security in any of the following situations:

- You own the security.
- You have an open order for the security.
- The security wasn't in the universe long enough to meet the `minimum_time_in_universe` setting.

To get only the assets that are currently in the universe, see Selected Securities .

Active Securities

The `QCAlgorithm.active_securities` is a collection of `Universe.members` of all universes. The `active_securities` property of the algorithm class contains all of the assets currently in your algorithm. It is a dictionary where the key is a `Symbol` and the value is a `Security` . When you remove an asset from a universe, LEAN usually removes the security from the `active_securities` collection and removes the security subscription. However, it won't remove the security in any of the following situations:

- You own the security.
- You have an open order for the security.
- The security wasn't in the universe long enough to meet the `minimum_time_in_universe` setting.

When LEAN removes the security, the `Security` object remains in the `securities` collection for record-keeping purposes, like tracking fees and trading volume.

To improve iteration speed, LEAN removes delisted securities from the `securities` primary collection. To access all the securities, iterate the `securities.total` property.

```
# Access all the securities.
for security in self.securities.total:
    pass

# Exclude delisted securities.
for security in self.securities.values():
    pass
```

To get only the assets that are currently in the universe, see Selected Securities .

Selected Securities

The `selected` property of your `Universe` contains references to all the assets that are currently in the universe. The `Universe.selected` property differs from the `Universe.members` property because the `Universe.members` property can contain more assets than `Universe.selected` when they have assets with open positions, open order orders, or assets that haven't met the minimum time requirement. To access the `Universe` object, save a reference to the result of the `add_universe` method. The following algorithm demonstrates how to use the `Universe.selected` property to create simple rebalancing strategies:

```
# Rebalance after market open to hold the 5 most liquid Equities.
class SimpleRebalancingAlgorithm(QCAlgorithm):

    def initialize(self):
        symbol = Symbol.create("SPY", SecurityType.EQUITY, Market.USA)
        # Schedule the universe selection to run at the start of each week.
        date_rule = self.date_rules.week_start(symbol)
        self.universe_settings.schedule.on(date_rule)
        # Add a universe of the top 5 most liquid Equities.
        universe = self.add_universe(self.universe.top(5))
        # 30 minutes after market open, rebalance the portfolio.
        self.schedule.on(
            date_rule,
            self.time_rules.after_market_open(symbol, 30),
            lambda: self.set_holdings(
                [PortfolioTarget(symbol, 1/len(universe.selected)) for symbol in universe.selected],
                liquidate_existing_holdings=True
            )
        )
```

Derivative Universes

In a regular universe, you select a basket of assets from the entire universe of securities. In a derivative universe, you select a basket of contracts for an underlying asset. The following derivative universes are available:

- Equity Options
- Futures
- Future Options
- Index Options

Historical Asset Prices

LEAN supports over 100 indicators you can use to generate your trading signals. However, in some cases, it's more efficient to maintain a matrix of historical prices for all the assets in your universe instead of using indicators. For example, say you want to calculate the correlation coefficients between all n asset in your universe using a 1-year lookback period. If you were to use the Correlation indicator, when a new asset enters the universe, you would usually need to make a 1-year history request for n assets to warm-up the n new correlation indicators. These large and frequent history requests can make your algorithm very slow.

The following algorithm demonstrates an alternative, more efficient approach. It defines a DataFrame in the initialize method . When a new asset enters the universe, it adds a column of historical prices for that asset to the DataFrame. Then, each day, it adds a single row of daily prices to the DataFrame, which covers all the assets in the universe. This approach reduces the size and frequency of history requests you need to make to get the data.

```py
class MaintainHistoricalDailyUniversePriceDataAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1_000_000)

        # Add a universe of daily data.
        self.universe_settings.resolution = Resolution.DAILY
        self._universe = self.add_universe(
            lambda fundamentals: [f.symbol for f in sorted(fundamentals, key=lambda f: f.market_cap)[-10:]]
        )

        # Create a DataFrame to store the historical data.
        self._all_history = pd.DataFrame()
        # Define the lookback period.
        self._lookback = 252  # Trading days.

        # Create a Scheduled Event to record new daily prices and
        # rebelance the portfolio.
        spy = Symbol.create('SPY', SecurityType.EQUITY, Market.USA)
        self.schedule.on(
            self.date_rules.every_day(spy),
            self.time_rules.at(0, 1), # One minute after `on_securities_changed` runs (in backtests)
            self._rebalance
        )

    def on_securities_changed(self, changes):
        # Remove the historical prices of assets that leave the universe.
        for security in changes.removed_securities:
            if security.symbol in self._all_history.columns:
                self._all_history.drop(security.symbol, axis=1, inplace=True)

        # Warm-up the historical data of assets that enter the universe.
        history = self.history(
            [security.symbol for security in changes.added_securities], self._lookback+1, Resolution.DAILY
        )
        if not history.empty:
            # If you trade at market open, it might make more sense to generate signals
            # based on daily opening prices. Drop the last row in `history` because
            # `_rebalance` will add it.
            self._all_history = self._all_history.join(history.open.unstack(0).iloc[:-1], how='outer')

    def _rebalance(self):
        # Add yesterday's open price to the DataFrame of historical prices.
        self._all_history = pd.concat([
            self._all_history,
            self.history(list(self._universe.selected), 1, Resolution.DAILY).open.unstack(0)
        ])
        # Trim the history to the lookback window size.
        self._all_history = self._all_history.iloc[-self._lookback:]

        # To avoid trading errors, select the assets that have a price.
        history = self._all_history[[symbol for symbol in self._all_history.columns if self.securities[symbol].price]]

        # Calculate asset signals for this rebalance.
        # For example, set the signal to give greater weight to uncorrelated assets.
        signal_by_symbol = 1/history.dropna(axis=1).corr().abs().sum()
        signal_by_symbol /= signal_by_symbol.sum()

        # Rebalance the portfolio based on the signals.
        self.set_holdings([PortfolioTarget(symbol, signal) for symbol, signal in signal_by_symbol.items()],
liquidate_existing_holdings=True)
```

Examples

You may refer to the following table for examples of various asset classes:

Any	Custom Universes	Example
Any	Dataless Scheduled Universes	Example

Universes

Settings

Introduction

Universe settings and security initializers enable you to configure some properties of the securities in a universe.

Resolution

The `resolution` setting defines the time period of the asset data. The `Resolution` enumeration has the following members:

To view which resolutions are available for the asset class of your universe, follow these steps:

1. Open the Asset Classes documentation page.
2. Click an asset class.
3. Click Requesting Data .
4. On the Requesting Data page, in the table of contents, click Resolutions .

The default value is `Resolution.MINUTE` . To change the resolution, in the Initialize method, pass a `resolution` argument to the universe creation method.

```
PY
# Add daily Equity Option data for the SPY.
self.add_option("SPY", resolution=Resolution.DAILY)
```

Leverage

The `leverage` setting is a `float` that defines the maximum amount of leverage you can use for a single asset in a non-derivative universe. The default value is `Security.NULL_LEVERAGE` (0). To change the leverage, in the Initialize method, adjust the algorithm's `universe_settings` before you add the universe.

```
PY
# Assign 2x leverage for all securities in the universe.
self.universe_settings.leverage = 2.0
# Add a universe of the 50 most liquid US Equities.
self.add_universe(self.universe.top(50))
```

Fill Forward

The `fill_forward` setting is a `bool` that defines whether or not too fill forward data. The default value is `True` . To disable fill forward in non-derivative universes, in the Initialize method, adjust the algorithm's `universe_settings` before you add the universe.

```
PY
# Disable fill-forward data before creating the universe (it's enabled by default).
self.universe_settings.fill_forward = False
# Add the 50 Equities to the universe that have the most dollar trading volume.
self.add_universe(self.universe.top(50))
```

To disable fill forward in derivative universes, pass a `fill_forward` argument to the universe creation method.

```
PY
# Disable fill-forward in the VIX Index Option universe.
self.add_index_option("VIX", fill_forward=False)
```

Extended Market Hours

The `extended_market_hours` setting is a `bool` that defines the trading schedule. If it's `True` , your algorithm receives price data for all trading hours. If it's `False` , your algorithm receives price data only for regular trading hours. The default value is `False` .

You only receive extended market hours data if you create the subscription with an intraday resolution. If you create the subscription with daily

resolution, the daily bars only reflect the regular trading hours.

To view the trading schedule of an asset, open Asset Classes , click an asset class, then click Market Hours .

To enable extended market hours in non-derivative universes, in the Initialize method, adjust the algorithm's `universe_settings` before you add the universe.

```
# Enable pre- and post-market hours data for assets in the universe.
self.universe_settings.extended_market_hours = True
# Add the 50 Equities to the universe that have the most dollar trading volume.
self.add_universe(self.universe.top(50))
```

To enable extended market hours in derivative universes, pass an `extended_market_hours` argument to the universe creation method.

```
# Request pre- and post-market hours data for a Futures universe.
self.add_future(Futures.Currencies.BTC, extended_market_hours=True)
```

Minimum Time in Universe

The `minimum_time_in_universe` setting is a `timedelta` object that defines the minimum amount of time an asset must be in the universe before the universe can remove it. The default value is `timedelta(1)` . To change the minimum time, in the Initialize method, adjust the algorithm's `universe_settings` before you add the universe.

```
# Keep each security in the universe for a minimum of 7 days.
self.universe_settings.minimum_time_in_universe = timedelta(7)
# Add the top 50 most liquid Equities to the universe.
self.add_universe(self.universe.top(50))
```

Data Normalization Mode

The `data_normalization_mode` setting is an enumeration that defines how historical data is adjusted. This setting is only applicable for US Equities and Futures.

US Equities

In the case of US Equities, the data normalization mode affects how historical data is adjusted for corporate actions . To view all the available options, see Data Normalization . The default value is `DataNormalizationMode.ADJUSTED` . To change the data normalization mode, in the Initialize method, adjust the algorithm's `universe_settings` before you add the universe.

```
# Pipe raw price data (unadjusted for splits and dividends) into the algorithm.
# Equity Options require raw data and it improves the accuracy of modeling historical periods.
self.universe_settings.data_normalization_mode = DataNormalizationMode.RAW
# Add a universe of the 50 most liquid US Equities.
self.add_universe(self.universe.top(50))
```

Futures

In the case of Futures, the data normalization mode affects how historical data of two contracts is stitched together to form the continuous contract . To view all the available options, see Data Normalization . The default value is `DataNormalizationMode.ADJUSTED` . To change the data normalization mode, in the Initialize method, pass a `data_normalization_mode` argument to the `add_future` method.

```
# Set a specific data normalization mode for the continuous contract
# with the data_normalization_mode parameter of the add_future method.
self.add_future(Futures.Currencies.BTC, data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO)
```

Contract Depth Offset

The `contract_depth_offset` setting is an `int` that defines which contract to use for the continuous Futures contract. 0 is the front month contract, 1 is the following back month contract, and 3 is the second back month contract. The default value is 0. To change the contract depth offset, in the

Initialize method, pass a `contract_depth_offset` argument to the `add_future` method.

```
# To adjust the contract depth offset to the second back month contract,
# pass the value 3 to the contract_depth_offset argument in the add_future method.
self.add_future(Futures.Currencies.BTC, contract_depth_offset=3)
```

Asynchronous Selection

The `asynchronous` setting is a `bool` that defines whether or not LEAN can run universe selection asynchronously, utilizing concurrent execution to increase the speed of your algorithm. The default value for this setting is `False` . If you enable this setting, abide by the following rules:

- Don't make any history requests in your filter function . History requests can only provide data up to the algorithm time , but if your filter function runs asynchronously, the algorithm time may not be what you expect.
- Don't use the portfolio, security, or orders state. The `portfolio` , `securities` , and `transactions` objects are also functions of the algorithm time.
- If your filter function updates a class variable, don't update the class variable anywhere else in your algorithm.

To enable asynchronous universe selection, in the Initialize method, adjust the algorithm's `universe_settings` before you add the universe.

```
# To speed up algorithm performance, enable asynchronous universe selection.
// Only use this when the code is self-contained and stateless.
self.universe_settings.asynchronous = True
self.add_universe(self.universe.top(50))
```

Schedule

The `schedule` setting defines the selection schedule of the universe. Most universes run on a daily schedule. To change the selection schedule, call the `universe_settings.schedule.on` method with an `IDateRule` object before you add the universe.

```
# Run universe selection on a monthly basis.
self.universe_settings.schedule.on(self.date_rules.month_start())
self.add_universe(self.universe.top(50))
```

The following table describes the supported `DateRules` :

Member	Description
`self.date_rules.set_default_time_zone(time_zone: DateTimeZone)`	Sets the time zone for the `DateRules` object used in all methods in this table. The default time zone is the algorithm time zone .
`self.date_rules.on(year: int, month: int, day: int)`	Trigger an event on a specific date.
`self.date_rules.on(dates: list[datetime])`	Trigger an event on specific dates.
`self.date_rules.every_day()`	Trigger an event all seven days of the week.
`self.date_rules.every_day(symbol: Symbol, extended_market_hours: bool = False)`	Trigger an event every day a specific symbol is trading.
`self.date_rules.every(days: list[DayOfWeek])`	Trigger an event on specific days throughout the week. To view the `DayOfWeek` enum members, see DayOfWeek Enum in the .NET documentation.
`self.date_rules.month_start(days_offset: int = 0)`	Trigger an event on the first day of each month plus an offset.
`self.date_rules.month_start(symbol: Symbol, daysOffset: int = 0)`	Trigger an event on the first tradable date of each month for a specific symbol plus an offset.
`self.date_rules.month_end(days_offset: int = 0)`	Trigger an event on the last day of each month minus an offset.
`self.date_rules.month_end(symbol: Symbol, daysOffset: int = 0)`	Trigger an event on the last tradable date of each month for a specific symbol minus an offset.
`self.date_rules.week_start(days_offset: int = 0)`	Trigger an event on the first day of each week plus an offset.
`self.date_rules.week_start(symbol: Symbol, days_offset: int = 0)`	Trigger an event on the first tradable date of each week for a specific symbol plus an offset.
`self.date_rules.week_end(days_offset: int = 0)`	Trigger an event on the last day of each week minus an offset.
`self.date_rules.week_end(symbol: Symbol, days_offset: int = 0)`	Trigger an event on the last tradable date of each week for a specific symbol minus an offset.
`self.date_rules.year_start(days_offset: int = 0)`	Trigger an event on the first day of each year plus an offset.
`self.date_rules.year_start(symbol: Symbol, days_offset: int = 0)`	Trigger an event on the first tradable date of each year for a specific symbol plus an offset.
`self.date_rules.year_end(days_offset: int = 0)`	Trigger an event on the last day of each year minus an offset.
`self.date_rules.year_end(symbol: Symbol, days_offset: int = 0)`	Trigger an event on the last tradable date of each year for a specific symbol minus an offset.
`self.date_rules.today`	Trigger an event once today.
`self.date_rules.tomorrow`	Trigger an event once tomorrow.

To define custom date rules, create a `FuncDateRule` object. The `FuncDateRule` constructor expects a `name` argument of type `str` and a `get_dates_function` argument of type `Callable[[datetime, datetime], list[datetime]]` . The `get_dates_function` function receives the start and end dates of the algorithm and returns a list of dates for the date rule. In live trading, the end date is 12/31/2025. The following example demonstrates how to define a date rule that represents the 10th day of each month:

```py
# Create a date rule that specifies the 10th day of each month.
date_rule = FuncDateRule(
    name="10th_day_of_the_month",
    get_dates_function=lambda start, end: [
        datetime(year, month, 10)
        for year in range(start.year, end.year) for month in range(1,12)
    ]
)
```

Some date rules require a Symbol. However, they accept a string representation of the Symbol as well. If your algorithm doesn't add the security , it assumes the string refers to a US Equity Symbol. For example, if you use the `self.date_rules.every_day('ES')` method, it assumes that 'ES' refers to a US Equity. To create a Symbol without adding a security to your algorithm, call the `Symbol.create` method.

```
symbol = Symbol.create('ES', SecurityType.FUTURE, Market.CME)
```

In live trading, scheduled universes run at roughly 8 AM Eastern Time to ensure there is enough time for the data to process.

Configure Universe Securities

Instead of configuring global universe settings, you can individually configure the settings of each security in the universe with a security initializer. Security initializers let you apply any security-level reality model or special data requests on a per-security basis. To set the security initializer, in the `initialize` method, call the `set_security_initializer` method and then define the security initializer.

```
# A custom security initializer can override default models such as
# setting new fee and fill models for the security.
self.set_security_initializer(self._custom_security_initializer)

def _custom_security_initializer(self, security: Security) -> None:
    security.set_fee_model(ConstantFeeModel(0, "USD"))
```

For simple requests, you can use the functional implementation of the security initializer. This style lets you configure the security object with one line of code.

```
# Disable the trading fees for each security by using lambda function
# for the set_security_initializer argument.
self.set_security_initializer(lambda security: security.set_fee_model(ConstantFeeModel(0, "USD")))
```

If you call the `set_security_initializer` method, it overwrites the default security initializer. The default security initializer uses the security-level reality models of the brokerage model to set the following reality models of each security:

- Fill
- Slippage
- Fee
- Buying Power
- Settlement
- Short availability
- Margin Interest Rate

The default security initializer also sets the leverage of each security and intializes each security with a seeder function. To extend upon the default security initializer instead of overwriting it, call `add_security_initializer` before you create the subscriptions.

```
class AddSecurityInitializerExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the security initializer to set models of assets.
        self.add_security_initializer(self._custom_security_initializer)

    def _custom_security_initializer(self, security: Security) -> None:
        # Overwrite some of the reality models
        security.set_fee_model(ConstantFeeModel(0, "USD"))
```

Examples

The following examples demonstrate some common practices for universe settings.

Example 1: Weekly-Updating Liquid Universe

The following algorithm demonstrates daily EMA cross, trading on the most liquid stocks. The universe is set to be updated weekly. Various universe settings have been set to simulate the brokerage environment best and for trading needs.

PY

```
class UniverseSettingsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # To avoid over-updating the universe, which causes insufficient time to earn the trend, update the universe weekly.
        self.universe_settings.schedule.on(self.date_rules.week_start())
        self.universe_settings.minimum_time_in_universe = timedelta(7)
        # Rebalancing frequency is daily, so we only need to subscribe to daily resolution.
        self.universe_settings.resolution = Resolution.DAILY
        # To best simulate IB's margin requirement, set the leverage to 50%.
        self.universe_settings.leverage = 2
        # Since we trade by market order, we cannot use extended market hours data to fill.
        self.universe_settings.extended_market_hours = False
        # We want to trade the EMA with raw price but not altered by splits.
        self.universe_settings.data_normalization_mode = DataNormalizationMode.SPLIT_ADJUSTED

                # Only trade on the top 10 most traded stocks since they have the most popularity to drive trends.
        self.add_universe(self.universe.top(10))

    def on_data(self, slice: Slice) -> None:
        for symbol, bar in slice.bars.items():
            # Trade the trend by EMA crossing.
            ema = self.securities[symbol].ema.current.value
            if bar.close > ema:
                self.set_holdings(symbol, 0.05)
            else:
                self.set_holdings(symbol, -0.05)

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for removed in changes.removed_securities:
            # Liquidate the ones leaving the universe since we will not trade their EMA anymore.
            self.liquidate(removed.symbol)
            # Deregister the EMA indicator to free resources
            self.deregister_indicator(removed.ema)

        for added in changes.added_securities:
            # Create EMA indicator for trend trading signals.
            added.ema = self.ema(added.symbol, 50, Resolution.DAILY)
            # Warm up the EMA indicator to ensure its readiness for immediate use.
            self.warm_up_indicator(added.symbol, added.ema, Resolution.DAILY)
```

Universes

Equity

You can create any of the following dynamic universes of equity. Click one to learn more.

Liquidity Universes

Fundamental Universes

ETF Constituents Universes

Chained Universes

Legacy Fundamental Universes

Alternative Data Universes

US Equity

Equity

Liquidity Universes

Introduction

A liquidity universe lets you select a set of stocks with the greatest dollar volume in the market.

Create Universes

To add a dollar volume universe, call the `universe.dollar_volume.top` helper method and pass the result to the `add_universe` method.

```py
# Add the 50 stocks with the highest dollar volume.
self.universe_settings.asynchronous = True
self.add_universe(self.universe.top(50))
```

Selection Frequency

Equity universes run on a daily basis by default. To adjust the selection schedule, see Schedule .

Examples

The following examples demonstrate some common liquidity universes for US Equities.

Example 1: Minute-Resolution Universe

The following algorithm asynchronously selects the 10 most liquid US Equities as the universe. It uses minute resolution data to provide the most realistic results.

```py
class MinuteLiquidUniverseAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Use asynchronous universe selection to speed up your algorithm.
        self.universe_settings.asynchronous = True
        # Use minute resolution data so orders fill at realistic prices.
        self.universe_settings.resolution = Resolution.MINUTE
        # Add a universe of the 10 most liquid US Equities.
        self.add_universe(self.universe.top(10))
```

Example 2: Trade Liquid Assets off Bollinger Bands

The following algorithm asynchronously selects the 500 most liquid US Equities as the universe. Each day, it forms a portfolio of the assets in the universe that are below their lower Bollinger Band .

```py
class AsynchronousLiquidUniverseAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.settings.automatic_indicator_warm_up = True
        # When a new asset enters the universe, seed its current price so you can trade it right away.
        self.settings.seed_initial_prices = True
        # Use asynchronous universe selection to speed up the algorithm.
        self.universe_settings.asynchronous = True
        # Use daily data. It doesn't affect accuracy since the trades fill at the daily market open.
        self.universe_settings.resolution = Resolution.DAILY
        # Add a universe of the 500 most liquid Equities.
        self._universe = self.add_universe(self.universe.top(500))

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        # Create Bollinger Band indicators for the universe constituents.
        for security in changes.added_securities:
            security.bb = self.bb(security.symbol, 60, 2)
        # Deregister the indicators when assets leave the universe.
        for security in changes.removed_securities:
            self.deregister_indicator(security.bb)

    def on_data(self, slice: Slice) -> None:
        # Ensure there are TradeBar objects in the current slice.
        if not slice.bars:
            return
        # Select the Equities that are below their lower Bollinger Band.
        securities = [self.securities[symbol] for symbol in self._universe.selected]
        selected = [
            security for security in securities
            if security.bb.is_ready and security.price and security.price < security.bb.lower_band.current.value
        ]
        # Form an equal-weighted portfolio with the selected assets.
        weight = 1 / len(selected)
        self.set_holdings([PortfolioTarget(security.symbol, weight) for security in selected], liquidate_existing_holdings=True)
```

Fundamental Universes

Introduction

A fundamental universe lets you select stocks based on corporate fundamental data. This data is powered by Morningstar® and includes approximately 8,100 tickers (including delisted companies and excluding ETFs, ADRs, and OTC) with 900 properties each.

Create Universes

To add a fundamental universe, in the `initialize` method, pass a filter function to the `add_universe` method. The filter function receives a list of `Fundamental` objects and must return a list of `Symbol` objects. The `Symbol` objects you return from the function are the constituents of the fundamental universe and LEAN automatically creates subscriptions for them. Don't call `add_equity` in the filter function.

```
class MyUniverseAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.universe_settings.asynchronous = True
        # Add a fundamental universe with a custom filter function.
        self._universe = self.add_universe(self._fundamental_function)

    def _fundamental_function(self, fundamental: List[Fundamental]) -> List[Symbol]:
        # Select US Equities that have fundamental data.
        return [c.symbol for c in fundamental if c.has_fundamental_data]
```

`Fundamental` objects have the following attributes:

Example

The simplest example of accessing the fundamental object would be harnessing the iconic PE ratio for a stock. This is a ratio of the price it commands to the earnings of a stock. The lower the PE ratio for a stock, the more affordable it appears.

```
# In the initialize method:
self.universe_settings.asynchronous = True
# Add a fundamental universe with a custom filter function.
self._universe = self.add_universe(self._fundamental_selection_function)

def _fundamental_selection_function(self, fundamental: List[Fundamental]) -> List[Symbol]:
    # Select assets that have a price > $10, fundamental data, and a price_to_earnings ratio.
    filtered = [f for f in fundamental if f.price > 10 and f.has_fundamental_data and not np.isnan(f.valuation_ratios.pe_ratio)]
    # Select the 100 most liquid assets.
    sorted_by_dollar_volume = sorted(filtered, key=lambda f: f.dollar_volume, reverse=True)[:100]
    # Select the 10 assets with the lowest P/E ratios.
    sorted_by_pe_ratio = sorted(sorted_by_dollar_volume, key=lambda f: f.valuation_ratios.pe_ratio)[:10]
    # Return the selected securities.
    return [f.symbol for f in sorted_by_pe_ratio]
```

Asset Categories

In addition to valuation ratios, the US Fundamental Data from Morningstar has many other data point attributes, including over 200 different categorization fields for each US stock. Morningstar groups these fields into sectors, industry groups, and industries.

Sectors are large super categories of data. To get the sector of a stock, use the `morningstar_sector_code` property.

```
# Select the US Equities in the technology sector.
tech = [x for x in fundamental if x.asset_classification.morningstar_sector_code == MorningstarSectorCode.TECHNOLOGY]
```

Industry groups are clusters of related industries that tie together. To get the industry group of a stock, use the `morningstar_industry_group_code` property.

```
# Select the US Equities in the agricluture industry group.
ag = [x for x in fundamental if x.asset_classification.morningstar_industry_group_code == MorningstarIndustryGroupCode.AGRICULTURE]
```

Industries are the finest level of classification available. They are the individual industries according to the Morningstar classification system. To get the industry of a stock, use the `morningstar_industry_code` property.

```
# Select the US Equities in the coal industry.
coal = [x for x in fundamental if x.asset_classification.morningstar_industry_code == MorningstarIndustryCode.COAL]
```

Practical Limitations

Fundamental universes allow you to select an unlimited universe of assets to analyze. Each asset in the universe consumes approximately 5MB of RAM, so you may quickly run out of memory if your universe filter selects many assets. If you backtest your algorithms in the Algorithm Lab, familiarize yourself with the RAM capacity of your backtesting and live trading nodes . To keep your algorithm fast and efficient, only subscribe to the assets you need.

Data Availability

`Fundamental` objects can have NaN values for some of their properties. Before you sort the `Fundamental` objects by one of the properties, filter out the objects that have a NaN value for the property.

```
def _fundamental_selection_function(self, fundamental: List[Fundamental]) -> List[Symbol]:
    # Select objects that have a value for the fundamental property.
    filtered = [f for f in fundamental if f.has_fundamental_data and not np.isnan(f.valuation_ratios.pe_ratio)]
    # Sort the objects by the fundamental property.
    sorted_by_pe_ratio = sorted(filtered, key=lambda f: f.valuation_ratios.pe_ratio)
    return [f.symbol for f in sortedByPeRatio[:10] ]
```

Direct Access

To get fundamental data for Equities in your algorithm, use the `fundamentals` property of the `Equity` objects. The fundamental data represent the company's fundamentals for the current algorithm time.

```
fundamentals = self.securities[self._symbol].fundamentals
```

To get fundamental data for Equities, regardless of whether or not you have subscribed to them in your algorithm, call the `fundamentals` method. If you pass one `Symbol` , the method returns a `Fundamental` object. If you pass a list of `Symbol` objects, the method returns a list of `Fundamental` objects. The fundamental data represents the corporate fundamentals for the current algorithm time.

```
# Single asset
ibm = Symbol.create("IBM", SecurityType.EQUITY, Market.USA)
ibm_fundamental = self.fundamentals(ibm)

# Multiple assets
nb = Symbol.create("NB", SecurityType.EQUITY, Market.USA)
fundamentals = self.fundamentals([ nb, ibm ])
```

Data Availability

Some assets don't have fundamentals (for example, ETFs) and the Morningstar dataset doesn't provide fundamentals for all US Equities. To check if fundamental data is available for an asset, use the `has_fundamental_data` property.

```
has_fundamental_data = self.securities[self._symbol].fundamentals.has_fundamental_data
```

Object References

If you save a reference to the `fundamentals` object or its properties, you can access the fundamental properties as they change over time.

```
self._fundamentals = self.securities[self._symbol].fundamentals
earning_ratios = self.fundamentals.earning_ratios
```

Historical Data

To get historical fundamental data, call the `history` method. The return type depends on how you call the method.

```
ibm = Symbol.create("IBM", SecurityType.EQUITY, Market.USA)

# DataFrame of fundamental data for a given asset
df_history = self.history(Fundamental, ibm, timedelta(30), flatten=True)

# Fundamental objects
fundamental_history = self.history[Fundamental](ibm, timedelta(30))

# Fundamentals objects for all US Equities (including delisted companies)
fundamentals_history = self.history[Fundamentals](timedelta(30))

# DataFrame of fundamental data for universe constituents
df_history = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series of fundamental data for universe constituents
series_history = self.history(self._universe, 30, Resolution.DAILY)
for (universe_symbol, time), fundamental in series_history.items():
    highest_market_cap = sorted(fundamental, key=lambda x: x.market_cap)[-5:]
```

For more information about historical fundamental data, see Equity Fundamental Data .

Selection Frequency

Equity universes run on a daily basis by default. To adjust the selection schedule, see Schedule .

Live Trading Considerations

The live data for fundamental universe selection arrives at 6/7 AM Eastern Time (ET), so fundamental universe selection runs for live algorithms between 7 and 8 AM ET. This timing allows you to place trades before the market opens. Don't schedule anything for midnight because the universe selection data isn't ready yet.

Examples

The following examples demonstrate some common practices for fundamental universes.

Example 1: 500 Stocks >10/Share and >10M in Daily Trading Volume

The following algorithm selects the 500 most liquid US Equities above 10/share and 10M in daily volume.

```
class LiquidNonPennyStocksUniverseAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Configure the universe to update at the start of each month. Most of the top 500 doesn't change very
        # frequently.
        self.universe_settings.schedule.on(self.date_rules.month_start())
        # Add a universe with custom selection rules for filtering.
        self.add_universe(
            lambda fundamental: [
                x.symbol for x in sorted(
                    [f for f in fundamental if f.price > 10 and f.dollar_volume > 10_000_000],
                    key=lambda f: f.dollar_volume
                )[-500:]
            ]
        )
```

Example 2: 10 Stocks Above Their 200-Day EMA With >$1B of Daily Trading Volume

Another common request is to filter the universe by a technical indicator, such as only picking stocks above their 200-day Exponential Moving Average (EMA). The `Fundamental` object has daily price and volume information, so you can do any price-related analysis. The following algorithm defines a separate class to contain the indicator of each asset.

```py
class UpTrendLiquidUniverseAlgorithm(QCAlgorithm):

    _selection_data_by_symbol = {}

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.settings.seed_initial_prices = True
        # Add the custom universe.
        self.universe_settings.data_normalization_mode = DataNormalizationMode.RAW
        self._universe = self.add_universe(self._select_assets)
        # Add a warm-up period to warm up the indicators.
        self.set_warm_up(timedelta(300))

    def _select_assets(self, fundamentals: List[Fundamental]) -> List[Symbol]:
        # Update the indicator of all stocks in the universe dataset and
        # get the subset of stocks that have their indicator ready.
        ready_stocks = [
            f for f in fundamentals
            if self._selection_data_by_symbol.setdefault(f.symbol, SelectionData(self, f, 200)).update(f)
        ]
        # As assests leave the Fundamental dataset, delete their SelectionData object.
        for symbol in self._selection_data_by_symbol.keys() - {f.symbol for f in fundamentals}:
            del self._selection_data_by_symbol[symbol]
        # During warm-up, keep the universe empty.
        if self.is_warming_up:
            return []
        # Select the Equities that are above their EMA and have a daily volume of $1B.
        # These assets are in an uptrend and are very liquid.
        selected = [self._selection_data_by_symbol[f.symbol] for f in ready_stocks]
        selected = [x for x in selected if x.is_above_ema and x.volume > 1_000_000_000]
        # Select the 10 most liquid Equities to avoid extra slippage.
        return [x.symbol for x in sorted(selected, key=lambda x: x.volume)[-10:]]

# Create a separate class to contain the EMA information of each asset.
class SelectionData:

    def __init__(self, algorithm, f, period):
        self._algorithm = algorithm
        self._price_scale_factor = f.price_scale_factor
        # Create an EMA indicator for trend estimation and filtering.
        self.symbol = f.symbol
        self._ema = ExponentialMovingAverage(period)
        self.is_above_ema = False
        self.volume = 0

    # Update your variables and indicators with the latest data.
    def update(self, f):
        # If there hasn't been a split or dividend since the last trading
        # day, just update the indicator like normal.
        if f.price_scale_factor == self._price_scale_factor:
            return self._update(f.end_time, f.volume, f.price)
        # Otherwise, reset the indicator and warm it up with the new
        # adjusted history.
        self._price_scale_factor = f.price_scale_factor
        self._ema.reset()
        history = self._algorithm.history[TradeBar](
            self.symbol,
            self._ema.warm_up_period,
            Resolution.DAILY,
            data_normalization_mode=DataNormalizationMode.SCALED_RAW
        )
        for bar in history:
            self._update(bar.end_time, bar.volume, bar.close)
        return self._ema.is_ready

    def _update(self, end_time, volume, price):
        self.volume = volume * price
        if self._ema.update(end_time, price):
            self.is_above_ema = price > self._ema.current.value
        return self._ema.is_ready
```

In this example, the `SelectionData` class group variables for the universe selection and updates the indicator of each asset. We highly recommend you follow this pattern to keep your algorithm tidy and bug free. The following snippet shows an example implementation of the `SelectionData` class, but you can make this whatever you need to store your custom universe filters. Note that the preceding `SelectionData` class uses a manual EMA indicator instead of the automatic version . For more information about universes that select assets based on indicators, see Indicator Universes . You need to use a `SelectionData` class instead of assigning the EMA to the `Fundamental` object because you can't create custom attributes on `Fundamental` objects like you can with `Security` objects.

Example 3: 10 Stocks Furthest Above their 10-day SMA of Volume

The process to get the 10-day Simple Moving Average (SMA) stock volume is the same process as in Example 2. First, define a `SelectionData` class

that performs the averaging. This class tracks the ratio of today's volume relative to historical volumes. You can use this ratio to select assets that are above their 10-day SMA and sort the results by the Equities that have had the biggest jump since yesterday.

```py
class HighRelativeVolumeUniverseAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.settings.seed_initial_prices = True
        # Add the custom universe.
        self._selection_data_by_symbol = {}
        self.universe_settings.data_normalization_mode = DataNormalizationMode.RAW
        self._universe = self.add_universe(self._select_assets)
        # Add a warm-up period to warm up the indicators.
        self.set_warm_up(timedelta(30))

    def _select_assets(self, fundamentals: List[Fundamental]) -> List[Symbol]:
        # Update the indicator of all stocks in the universe dataset and
        # get the subset of stocks that have their indicator ready.
        ready_stocks = [
            f for f in fundamentals
            if self._selection_data_by_symbol.setdefault(f.symbol, SelectionData(self, f, 10)).update(f)
        ]
        # As assests leave the Fundamental dataset, delete their SelectionData object.
        for symbol in self._selection_data_by_symbol.keys() - {f.symbol for f in fundamentals}:
            del self._selection_data_by_symbol[symbol]
        # During warm-up, keep the universe empty.
        if self.is_warming_up:
            return []
        # Select the Equities with higher trading volume than their SMA, indicating higher capital flow.
        selected = [self._selection_data_by_symbol[f.symbol] for f in ready_stocks]
        selected = [sd for sd in selected if sd.volume_ratio > 1]
        # Select the 10 Equities with the highest relative volume, since they have the highest capactity
        # for scalp-trading or intra-day movement.
        return [x.symbol for x in sorted(selected, key=lambda x: x.volume_ratio)[-10:]]

# Create a separate class to contain the SMA information of each asset.
class SelectionData:

    def __init__(self, algorithm, f, period):
        self._algorithm = algorithm
        self._price_scale_factor = f.price_scale_factor
        # Create an SMA of volume to track the popularity of the stock.
        self.symbol = f.symbol
        self._sma = SimpleMovingAverage(period)

    # Update your variables and indicators with the latest data.
    def update(self, f):
        # If there hasn't been a split or dividend since the last trading
        # day, just update the indicator like normal.
        if f.price_scale_factor == self._price_scale_factor:
            return self._update(f.end_time, f.volume)
        # Otherwise, reset the indicator and warm it up with the new
        # adjusted history.
        self._price_scale_factor = f.price_scale_factor
        self._sma.reset()
        history = self._algorithm.history[TradeBar](
            self.symbol,
            self._sma.warm_up_period,
            Resolution.DAILY,
            data_normalization_mode=DataNormalizationMode.SCALED_RAW
        )
        for bar in history:
            self._update(bar.end_time, bar.volume)
        return self._sma.is_ready

    def _update(self, end_time, volume):
        # Update the SMA with today's data and calculate the relative volume position for filtering.
        if self._sma.update(end_time, volume):
            self.volume_ratio = volume / self._sma.current.value if self._sma.current.value != 0 else -1
        return self._sma.is_ready
```

Example 4: 10 "Fastest Moving" Stocks With a 50-Day EMA > 200 Day EMA

You can construct complex universe filters with the `SelectionData` helper class pattern. To view a full example of this algorithm, see the EmaCrossUniverseSelectionAlgorithm in the LEAN GitHub repository or take the related Boot Camp lesson .

Example 5: Piotroski F-Score

To view this example, see the Piotroski F-Score Investing Research post.

Example 6: Stocks Far Above Their SMA

The following example shows how to select a universe of US Equities based on their price and SMA indicator. The `SelectionData` class keeps track of the SMA indicator for each stock in the universe dataset. When a split or dividend occurs for a stock, the data in its indicator becomes invalid because it doesn't account for the price adjustments that the split or dividend causes. The `SelectionData` class resets and warms up the indicator with the `SCALED_RAW` data normalization mode , which gives you accurate indicator values to use in your universe selection after each corporate action.

PY

```
class EquityIndicatorUniverseSelectionAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.settings.seed_initial_prices = True
        # Add a universe of US Equities based on an indicator.
        self._selection_data_by_symbol = {}
        self._universe = self.add_universe(self._select_assets)
        # Add a warm-up period to warm up the indicators in the universe selection.
        self.set_warm_up(timedelta(60))

    def _select_assets(self, fundamentals):
        # Update the indicator of all stocks in the universe dataset and
        # get the subset of stocks that have their indicator ready.
        ready_stocks = [
            f for f in fundamentals
            if self._selection_data_by_symbol.setdefault(f.symbol, SelectionData(self, f)).update(f)
        ]
        # As assests leave the Fundamental dataset, delete their SelectionData object.
        for symbol in self._selection_data_by_symbol.keys() - {f.symbol for f in fundamentals}:
            del self._selection_data_by_symbol[symbol]
        # During warm-up, keep the universe empty.
        if self.is_warming_up:
            return []
        # Select a subset of the stocks based on the indicator.
        # Example: 10 stocks furthest above their SMA.
        factor_by_symbol = {
            f.symbol: f.price / self._selection_data_by_symbol[f.symbol].indicator.current.value
            for f in ready_stocks
        }
        return sorted(
            {k: v for k, v in factor_by_symbol.items() if v > 0},
            key=lambda symbol: factor_by_symbol[symbol]
        )[-100:]

class SelectionData:

    def __init__(self, algorithm, f):
        self._algorithm = algorithm
        self._price_scale_factor = f.price_scale_factor
        self.indicator = SimpleMovingAverage(21)

    def update(self, f):
        # If there hasn't been a split or dividend since the last trading
        # day, just update the indicator like normal.
        if f.price_scale_factor == self._price_scale_factor:
            return self.indicator.update(f.end_time, f.price)
        # Otherwise, reset the indicator and warm it up with the new
        # adjusted history.
        self._price_scale_factor = f.price_scale_factor
        self.indicator.reset()
        history = self._algorithm.history[TradeBar](
            f.symbol,
            self.indicator.warm_up_period,
            Resolution.DAILY,
            data_normalization_mode=DataNormalizationMode.SCALED_RAW
        )
        for bar in history:
            self.indicator.update(bar)
        return self.indicator.is_ready
```

Equity

ETF Constituents Universes

Introduction

An ETF constituents universe lets you select a universe of securities in an exchange traded fund. The US ETF Constituents dataset includes 2,650 US ETFs you can use to create your universe.

Create Universes

To add an ETF Constituents universe, call the `universe.etf` method.

```
class ETFConstituentsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.universe_settings.asynchronous = True
        self.add_universe(self.universe.etf("SPY"))
```

The following table describes the `etf` method arguments:

Argument: `etf_ticker` The ETF ticker. To view the supported ETFs in the US ETF Constituents dataset, see Supported ETFs . Data Type: `str` | Default Value: `None`
Argument: `universe_settings` The universe settings . If you don't provide an argument, it uses the algorithm `universe_settings` . Data Type: `UniverseSettings` | Default Value: `None`
Argument: `universe_filter_func` A function to select some of the ETF constituents for the universe. If you don't provide an argument, it selects all of the constituents. Data Type: `Callable[[List[ETFConstituentUniverse]], List[Symbol]]` | Default Value: `None`

To select a subset of the ETF constituents, provide a `universe_filter_func` argument. The filter function receives `ETFConstituentUniverse` objects, which represent one of the ETF constituents. `ETFConstituentUniverse` objects have the following attributes:

```
class ETFConstituentsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.universe_settings.asynchronous = True
        self._universe = self.universe.etf("SPY", self.universe_settings, self._etf_constituents_filter)
        self.add_universe(self._universe)

    def _etf_constituents_filter(self, constituents: List[ETFConstituentUniverse]) -> List[Symbol]:
        # Get the 10 securities with the largest weight in the index
        selected = sorted(
            constituents, key=lambda c: c.weight or 0.0, reverse=True
        )[:10]
        return [c.symbol for c in selected]
```

Historical Data

To get historical ETF constituents data, call the `history` method with the `Universe` object and the lookback period.

```py
# DataFrame object:
df_history = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series object:
series_history = self.history(self._universe, 30, Resolution.DAILY)
for (universe_symbol, time), constituents in history.items():
    for constituent in constituents:
        self.log(f'{constituent.symbol} weight at {constituent.end_time}: {constituent.weight}')
```

For more information about ETF Constituents data, see US ETF Constituents .

Selection Frequency

Equity universes run on a daily basis by default. To adjust the selection schedule, see Schedule .

Examples

The following examples demonstrate some common practices for ETF constituent universes.

Example 1: Short the Smallest ETF Constituents

A subset of the SPY constituents outperform the SPY while many of the constituents underperform the overall index. In an attempt to exclude the ETF constituents that underperform the index, the following algorithm buys the SPY and shorts the 100 assets in the index with the smallest weight in the ETF.

```py
class ETFConstituentsUniverseAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(10_000_000)

        self.set_holdings(targets, liquidate_existing_holdings=True)
```

Example 2: SPY Constituents in an Uptrend

The following example chains an ETF constituents universe and a fundamental universe . It first selects all the constituents of the SPY ETF and then filters them down in the fundamental universe filter to select the assets that are trading above their average price over the last 200 days. The output of the fundamental universe selection method is the output of the chained universe. The `Fundamental` objects that the fundamental universe filter function recieves contains the prices of the ETF constituents. By chaining the ETF constituents universe into the fundamental universe, you can update the indicators with the price instead of making a history request .

```py
class ChainedUniverseAlgorithm(QCAlgorithm):

    _selection_data_by_symbol = {}

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Seed the price of each asset that enters the universe with its last known price so you can trade it
        # on the same morning it enters the universe without getting warnings.
        self.settings.seed_initial_prices = True
        # Add a chained universe that selects the SPY constituents trading above their 200-day SMA.
        spy = Symbol.create("SPY", SecurityType.EQUITY, Market.USA)
        self._universe = self.add_universe(self.universe.etf(spy), self._fundamental_selection)
        # Trade daily at market open since the trading signal is generated on a daily resolution.
        self.schedule.on(self.date_rules.every_day(spy), self.time_rules.after_market_open(spy, 1), self._rebalance)

    def _fundamental_selection(self, fundamental: List[Fundamental]) -> List[Symbol]:
        # Create/Update an SMA indicator for each asset that enters the ETF.

Equity

Chained Universes

Introduction

You can combine ("chain") universes together to fetch fundamental and alternative data on a specific subset of assets. Universes filter input data and return `Symbol` objects. The only requirement is that `Symbol` objects the filter returns are a subset of the input data. The source of the `Symbol` objects is unrestricted, so you can feed the output of one universe into another.

Filter Pattern

Universes filter a large set of Symbol objects by a coarse filter to quickly reduce the data processing requirement. This is often a first step before applying a second filter or requesting alternative data. For example, a strategy might only be interested in easily tradable liquid assets so quickly eliminates all stocks with less than $1M USD / day in trading volume.

The order of your filters can improve the speed of your research. By applying filters that narrow the universe the most, or are the lightest weight first, you can significantly reduce the amount of data your algorithm processes. Unless necessary, you can also not return any selections from earlier filters to further improve research speed, keeping only the universe data for later filters.

Universe Data Weights

To speed up your algorithm, request the lightest weight data first before chaining heavier filters or adding alternative data. The following table shows the size each dataset:

Name	**Data Size / Weight**
US Equities (Fundamental - Dollar Volume only)	Light (100 MB)
US Equities (Fundamental)	Heavy (up to 20 GB)
US Equity Options	Huge (200 TB)
US Index Options	Medium (500 GB)
US Futures	Medium (500 GB)
US Futures Options	Medium (500 GB)
Crypto	Light (1 GB)
Alternative / General	Light (100 MB - 2 GB)
Alternative / Tiingo News	Medium (200 GB)

Chain Fundamental and Alternative Data

The following example chains a fundamental universe and a QuiverCNBCsUniverse alternative universe . It first selects the 100 most liquid US Equities and then filters them down to those mentioned by CNBC commentator/trader Jim Cramer. The output of the alternative universe selection method is the output of the chained universe.

```py
from AlgorithmImports import *

class ChainedUniverseAlgorithm(QCAlgorithm):

    _fundamental = []

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.add_universe(self._fundamental_filter_function)
        self.add_universe(QuiverCNBCsUniverse, self._mad_money_selection)

    def _fundamental_filter_function(self, fundamental: List[Fundamental]) -> List[Symbol]:
        # Filter the top 100 liquid equities of the last trading day, and save the symbols for the next filtering.
        sorted_by_dollar_volume = sorted(fundamental, key=lambda x: x.dollar_volume, reverse=True)
        self._fundamental = [c.symbol for c in sorted_by_dollar_volume[:100]]
        return Universe.UNCHANGED

    def _mad_money_selection(self, alt_coarse: List[QuiverCNBCsUniverse]) -> List[Symbol]:
        # Filter the equities being commented on by CNBC analyst Cramer, then select the ones that intersect with the fundamental
universe.
        madmoney = [d.symbol for d in alt_coarse if 'Cramer' in d.traders]
        return list(set(self._fundamental) & set(madmoney))

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        # Request CNBC data for the selected stocks.
        for added in changes.added_securities:

        for canonical_symbol, chain in data.option_chains.items():
            equity_symbol = canonical_symbol.underlying
            for contract in chain:
                contract_symbol = contract.symbol
                price = contract.last_price
```

Equity

Legacy Fundamental Universes

Introduction

Warning: This API for Universe Selection was deprecated on November 2023. Please refer to the new Fundamental Universe API .

There are several ways to create an Equities universe. You can select a universe based on `CoarseFundamental` data or the constituents of an ETF, and then you can further filter your universe down with corporate fundamentals. The following sections explain each of these techniques in detail.

Coarse Universe Selection

A coarse universe enables you pick a set of stocks based on their trading volume, price, or whether they have fundamental data. To add a coarse universe, in the `initialize` method, pass a filter function to the `add_universe` method. The coarse filter function receives a list of `CoarseFundamental` objects and must return a list of `Symbol` objects. The `Symbol` objects you return from the function are the constituents of the universe and LEAN automatically creates subscriptions for them. Don't call `add_equity` in the filter function.

```py
class MyCoarseUniverseAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.universe_settings.asynchronous = True
        self.add_universe(self._coarse_filter_function)

    def _coarse_filter_function(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
        sorted_by_dollar_volume = sorted(coarse, key=lambda x: x.dollar_volume, reverse=True)
        return [c.symbol for c in sorted_by_dollar_volume[:100]]
```

`CoarseFundamental` objects have the following attributes:

The total number of stocks in the US Equity Security Master dataset is 30,000 but your coarse filter function won't receive all of these at one time because the US Equity Security Master dataset is free of survivorship bias and some of the securities have delisted over time. The number of securities that are passed into your coarse filter function depends on the date of your algorithm. Currently, there are about 10,000 securities that LEAN passes into your coarse filter function.

Fundamentals Selection

A fundamental universe lets you select stocks based on corporate fundamental data. This data is powered by Morningstar® and includes approximately 8,100 tickers with 900 properties each. This universe doesn't include ETFs, ADRs, or OTC equities. Due to the sheer volume of information, fundamental selection is performed on the output of another universe filter. Think of this process as a 2-stage filter. An initial filter function selects a set of stocks and then a fine fundamental filter function selects a subset of those stocks.

QuantConnect Coarse and Fine Universe Selection

To add a fundamental universe, in the `initialize` method, pass two filter functions to the `add_universe` method. The first filter function can be a coarse universe filter , dollar volume filter , or an ETF constituents filter . The second filter function receives a list of `FineFundamental` objects and must return a list of `Symbol` objects. The list of `FineFundamental` objects contains a subset of the `Symbol` objects that the first filter function returned. The `Symbol` objects you return from the second function are the constituents of the fundamental universe and LEAN automatically creates

subscriptions for them. Don't call `add_equity` in the filter function.

> **Tip:** Only 8,100 assets have fundamental data. If your first filter function receives `CoarseFundamental` data, you should only select assets that have a true value for their `has_fundamental_data` property.

```
class MyUniverseAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.universe_settings.asynchronous = True
        self.add_universe(self._coarse_filter_function, self._fine_fundamental_function)

    def _coarse_filter_function(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
        # In addition to further coarse universe selection, ensure the security has fundamental data
        return [c.symbol for c in coarse if c.has_fundamental_data]

    def _fine_fundamental_function(self, fine: List[FineFundamental]) -> List[Symbol]:
        # Return a list of Symbols
        return []
```

`FineFundamental` objects have the following attributes:

Example

The simplest example of accessing the fundamental object would be harnessing the iconic PE ratio for a stock. This is a ratio of the price it commands to the earnings of a stock. The lower the PE ratio for a stock, the more affordable it appears.

```
# In Initialize:
self.universe_settings.asynchronous = True
self.add_universe(self._coarse_selection_function, self._fine_selection_function)

def _coarse_selection_function(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
    sorted_by_dollar_volume = sorted(coarse, key=lambda x: x.dollar_volume, reverse=True)
    filtered = [x.symbol for x in sorted_by_dollar_volume if x.has_fundamental_data]
    return filtered[:50]

def _fine_selection_function(self, fine: List[FineFundamental]) -> List[Symbol]:
    sorted_by_pe_ratio = sorted(fine, key=lambda x: x.valuation_ratios.pe_ratio, reverse=False)
    return [x.symbol for x in sorted_by_pe_ratio[:10]]
```

Asset Categories

In addition to valuation ratios, the US Fundamental Data from Morningstar has many other data point attributes, including over 200 different categorization fields for each US stock. Morningstar groups these fields into sectors, industry groups, and industries.

Sectors are large super categories of data. To get the sector of a stock, use the `MorningstarSectorCode` property.

```
tech = [x for x in fine if x.asset_classification.morningstar_sector_code == MorningstarSectorCode.TECHNOLOGY]
```

Industry groups are clusters of related industries that tie together. To get the industry group of a stock, use the `MorningstarIndustryGroupCode` property.

```
ag = [x for x in fine if x.asset_classification.morningstar_industry_group_code == MorningstarIndustryGroupCode.AGRICULTURE]
```

Industries are the finest level of classification available. They are the individual industries according to the Morningstar classification system. To get the industry of a stock, use the `MorningstarIndustryCode` .

```
coal = [x for x in fine if x.asset_classification.morningstar_industry_code == MorningstarSectorCode.COAL]
```

Practical Limitations

Like coarse universes, fine universes allow you to select an unlimited universe of assets to analyze. Each asset in the universe consumes approximately 5MB of RAM, so you may quickly run out of memory if your universe filter selects many assets. If you backtest your algorithms in the

Algorithm Lab, familiarize yourself with the RAM capacity of your backtesting and live trading nodes . To keep your algorithm fast and efficient, only subscribe to the assets you need.

Live Trading Considerations

The live data for fundamental universe selection arrives at 6/7 AM Eastern Time (ET), so fundamental universe selection runs for live algorithms between 7 and 8 AM ET. This timing allows you to place trades before the market opens. Don't schedule anything for midnight because the universe selection data isn't ready yet.

Examples

The legacy fundamental universe is deprecated. For examples of the new fundamental universe API, see Examples .

Equity

Alternative Data Universes

Introduction

An alternative data universe lets you select a basket of Equities based on an alternative dataset that's linked to them. If you use an alternative data universe, you limit your universe to only the securities in the dataset, which avoids unnecessary subscriptions.

Supported Datasets

The following alternative datasets support universe selection:

- Brain Language Metrics on Company Filings
- Brain ML Stock Ranking
- Brain Sentiment Indicator
- Crypto Market Cap
- Upcoming Dividends
- Upcoming Earnings
- Upcoming IPOs
- Upcoming Splits

Examples

The following examples demonstrate some common alternative data universes.

Example 1: Brain Sentiment Universe

The following algorithm uses the Brain Sentiment Indicator dataset to create a universe of US Equities that have some article mentions and the most positive sentiment. It then forms a sentiment-weighted portfolio at the start of each month.

```py
class BrainSentimentUniverseAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add an Equity universe that updates at the start of each month.
        spy = Symbol.create('SPY', SecurityType.EQUITY, Market.USA)
        self.universe_settings.schedule.on(self.date_rules.month_start(spy))
        self.add_universe(BrainSentimentIndicatorUniverse, self._select_assets)
        # Create a Scheduled Event to rebalance the portfolio at the start of each month.
        self.schedule.on(self.date_rules.month_start(spy), self.time_rules.at(9, 45), self._rebalance)

    def _select_assets(self, alt_data: List[BrainSentimentIndicatorUniverse]) -> List[Symbol]:
        # Select the assets with recent mentions and a sentiment score.
        alt_data = [x for x in alt_data if x.total_article_mentions_30_days and x.sentiment_30_days]
        # Select the 10 assets with the greatest sentiment score.
        selected = sorted(alt_data, key=lambda x: x.sentiment_30_days)[-10:]
        # Save the sentiment scores for rebalancing later.
        self._sentiment_by_symbol = {x.symbol: x.sentiment_30_days for x in selected}
        # Return the Symbol objects of the selected assets.
        return list(self._sentiment_by_symbol.keys())

    def _rebalance(self) -> None:
        # To avoid trading errors, filter out the assets that don't have a price yet.
        self._sentiment_by_symbol = {
            symbol: sentiment for symbol, sentiment in self._sentiment_by_symbol.items()
            if self.securities[symbol].price
        }
        # Form a sentiment-weighted portfolio.
        sentiment_sum = sum(list(self._sentiment_by_symbol.values()))
        self.set_holdings(
            [PortfolioTarget(symbol, sentiment/sentiment_sum) for symbol, sentiment in self._sentiment_by_symbol.items()],
            liquidate_existing_holdings=True
        )
```

Example 2: Insiders Trading Universe

Insiders have more information to evaluate the overall prospect of the company, so following their trades can be useful. The following algorithm uses the Insider Trading to create a universe of US Equities that insiders have recently purchased. It then invests equally into the companies with positive insider trades, which may provide extra confidence in their expected return, and hold for 3 months.

```py
class InsiderTradingUniverseAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Seed the price of each asset with its last known price to
        # avoid trading errors.
        self.settings.seed_initial_prices = True
        # Keep each security in the universe for a minimum of 30 days to
        # digest the insiders purchase sentiment.
        self.universe_settings.minimum_time_in_universe = timedelta(30)
        # Add the QuiverInsiderTrading dataset for insider trade
        # detection and filtering.
        self._universe = self.add_universe(
            QuiverInsiderTradingUniverse, self._select_assets
        )
        # Add a Scheduled Event to rebalance the portfolio each day.
        spy = Symbol.create('SPY', SecurityType.EQUITY, Market.USA)
        self.schedule.on(
            self.date_rules.every_day(spy),
            self.time_rules.after_market_open(spy, 1),
            self._rebalance
        )

    def _select_assets(
            self, alt_data: List[QuiverInsiderTradingUniverse]) -> List[Symbol]:
        # Calculate the net dollar volume of insider trades for each
        # asset.
        dollar_volume_by_symbol = {}
        for data in alt_data:
            symbol = data.symbol
            if not data.price_per_share:
                continue
            if symbol not in dollar_volume_by_symbol:
                dollar_volume_by_symbol[symbol] = 0
            dollar_volume_by_symbol[symbol] += data.shares * data.price_per_share
        # Select the 10 assets with the largest dollar volume of insider
        # trades.
        return [
            symbol for symbol, _ in sorted(
                dollar_volume_by_symbol.items(), key=lambda kvp: kvp[1]
            )[-10:]
        ]

    def _rebalance(self):
        # Equally invest in insider buying companies to evenly
        # dissipate the capital risk.
        symbols = [s for s in self._universe.selected if self.securities[s].price]
        self.set_holdings(
            [PortfolioTarget(symbol, 1/len(symbols)) for symbol in symbols],
            True
        )
```

Example 3: Share Buyback Universe

The following algorithm uses the Corporate Buybacks dataset to create a universe of US Equities that have announced an upcoming share buyback program:

PY

```
class SmartInsiderIntentionUniverseAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Seed the price of each asset with its last known price to
        # avoid trading errors.
        self.settings.seed_initial_prices = True
        # Add a universe that selects assets at the start of each week.
        # The universe should select Equities that have announced a
        # material buyback plan, since they have confidence in their
        # future prospect and the reduction in supply can drive their
        # price up.
        self.universe_settings.schedule.on(self.date_rules.week_start())
        self.add_universe(SmartInsiderIntentionUniverse, self._select_assets)
        # Add a Scheduled Event to rebalance the portfolio at the start
        # of each week. The weekly schedule allows time to capitalize
        # the market swings from the positive sentiment.
        spy = Symbol.create('SPY', SecurityType.EQUITY, Market.USA)
        self.schedule.on(
            self.date_rules.week_start(spy),
            self.time_rules.after_market_open(spy, 1),
            self._rebalance
        )

    def _select_assets(
            self,
            alt_coarse: List[SmartInsiderIntentionUniverse]) -> List[Symbol]:
        self._buyback_size = {}
        selected = []
        for d in alt_coarse:
            # Select assets that have a material buyback size to have
            # strong confidence.
            if d.amount_value and d.amount_value > 10_000_000:
                # Record the buyback size in the dictionary.
                self._buyback_size[d.symbol] = d.amount_value
                selected.append(d.symbol)
        return selected

    def _rebalance(self) -> None:
        # Ignore illiquid assets that have no price yet.
        self._buyback_size = {
            symbol: amount
            for symbol, amount in self._buyback_size.items()
            if self.securities[symbol].price
        }
        # Get the sum of all buyback size so we can scale the portfolio
        # weights based on the buyback size.
        buyback_sum = sum(self._buyback_size.values())
        # Place the trades to rebalance the portfolio.
        self.set_holdings(
            [
                PortfolioTarget(symbol, size / buyback_sum)
                for symbol, size in self._buyback_size.items()
            ]
        )

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        # Liquidate assets when they leave the universe.
        for removed in changes.removed_securities:
            self.liquidate(removed.symbol)
            self._buyback_size.pop(removed.symbol, None)
```

Universes

Equity Options

Introduction

An Equity Options universe lets you select a basket of contracts for a single Option. LEAN models Option subscriptions as a universe of Option contracts.

Create Universes

To add a universe of Equity Option contracts, in the `initialize` method, call the `add_option` method. This method returns an `Option` object, which contains the canonical `symbol`. You can't trade with the canonical Option `symbol`, but save a reference to it so you can easily access the Option contracts in the OptionChain that LEAN passes to the `on_data` method.

```
class BasicOptionAlgorithm(QCAlgorithm):

    def initialize(self):
        self.universe_settings.asynchronous = True
        option = self.add_option("SPY")
        option.set_filter(self._filter)
        self._symbol = option.symbol

    def _filter(self, universe):
        return universe.expiration(0, 7).delta(0.35, 0.75)

    def on_data(self, data):
        chain = data.option_chains.get(self._symbol)
        if chain:
            contract = sorted(chain, key=lambda x: (x.expiry, x.greeks.delta))[0]
```

PY

The following table describes the `add_option` method arguments:

Argument	Data Type	Description
`ticker`	`str`	The underlying Equity ticker. To view the supported underlying Equity tickers, see Supported Assets .
`resolution`	`Resolution`	The resolution of the market data. To view the supported resolutions, see Resolutions . The Equity resolution must be less than or equal to the Equity Option resolution. For example, if you set the Equity resolution to minute, then you must set the Equity Option resolution to minute, hour, or daily.
`market`	`str`	The underlying Equity market.
`fill_forward`	`bool`	If true, the current slice contains the last available data even if there is no data at the current time.
`leverage`	`float`	The leverage for this Equity.
`extended_market_hours`	`bool`	A flag that signals if LEAN should send data during pre- and post-market trading hours.

If you don't set any of these parameters, LEAN uses the `self.universe_settings` values. See Set Universe Settings for more information.

If you add an Equity Option universe but don't have a subscription to the underlying Equity, LEAN automatically subscribes to the underlying Equity with the following settings:

Setting	Value
Fill forward	Same as the Option universe
Leverage	0
Extended Market Hours	Same as the Option universe
Data Normalization	`DataNormalizationMode.RAW`

If you already have a subscription to the underlying Equity but it's not `RAW` data normalization, LEAN automatically changes it to `RAW` .

Filter by Investment Strategy

Options trading strategies consist of simultaneously buying or selling one or more Option contracts of the same underlying Equity, but with different features.

```py
# Example 1: Select a Straddle
option.set_filter(lambda option_filter_universe: option_filter_universe.straddle(30))

# Example 2: Select the contracts (including weeklys) that expire in the next 30 days that form an Iron Condor
option.set_filter(lambda option_filter_universe: option_filter_universe.strikes(-20, 20).expiration(0, 30).iron_condor(30, 5, 10))

# Example 3: Select the 0DTE contracts that form an Strangle
option.set_filter(lambda option_filter_universe: option_filter_universe.expiration(0, 0).strangle(30, 5, -10))
```

The following table describes the filter methods of the `OptionFilterUniverse` class that select contracts for Option strategies:

`naked_call(min_days_till_expiry: int, strike_from_atm: float)` Selects a call contract to form Naked Call , Covered Call , or Protective Call Option strategies.
`naked_put(min_days_till_expiry: int, strike_from_atm: float)` Selects a put contract to form Naked Put , Covered Put , or Protective Put Option strategies.
`call_spread(min_days_till_expiry: int, higher_strike_from_atm: float, lower_strike_from_atm: float)` Selects two call contracts to form Bull Call Spread or Bear Call Spread Option strategies.
`put_spread(min_days_till_expiry: int, higher_strike_from_atm: float, lower_strike_from_atm: float)` Selects two put contracts to form Bull Put Spread or Bear Put Spread Option strategies.
`call_calendar_spread(strike_from_atm: int, min_near_days_till_expiry: int, min_far_days_till_expiry: int)` Selects two call contracts to form Long Call Calendar Spread or Short Call Calendar Spread Option strategies.
`put_calendar_spread(strike_from_atm: int, min_near_days_till_expiry: int, min_far_days_till_expiry: int)` Selects two put contracts to form Long Put Calendar Spread or Short Put Calendar Spread Option strategies.
`strangle(min_days_till_expiry: int, higher_strike_from_atm: float, lower_strike_from_atm: float)` Selects two contracts to form Long Strangle or Short Strangle Option strategies.
`straddle(min_days_till_expiry: int)` Selects two contracts to form Long Straddle or Short Straddle Option strategies.

`protective_collar(min_days_till_expiry: int, higher_strike_from_atm: float, lower_strike_from_atm: float)` Selects two contracts to form Protective Collar Option strategies.
`conversion(min_days_till_expiry: int, strike_from_atm: float)` Selects two contracts to form Conversion or Reverse Conversion Option strategies.
`call_butterfly(min_days_till_expiry: int, strike_spread: float)` Selects three contracts to form Long Call Butterfly or Short Call Butterfly Option strategies.
`put_butterfly(min_days_till_expiry: int, strike_spread: float)` Selects three contracts to form Long Put Butterfly or Short Put Butterfly Option strategies.
`iron_butterfly(min_days_till_expiry: int, strike_spread: float)` Selects four contracts to form Long Iron Butterfly or Short Iron Butterfly Option strategies.
`iron_condor(min_days_till_expiry: int, near_strike_spread: float, far_strike_spread: float)` Selects four contracts to form Long Iron Condor or Short Iron Condor Option strategies.
`box_spread(min_days_till_expiry: int, strike_spread: float)` Selects four contracts to form Box Spread or Short Box Spread Option strategies.
`jelly_roll(strike_from_atm: float, min_near_days_till_expiry: int, min_far_days_till_expiry: int)` Selects four contracts to form Jelly Roll or Short Jelly Roll Option strategies.
`call_ladder(min_days_till_expiry: int, higher_strike_from_atm: float, middle_strike_from_atm: float, lower_strike_from_atm: float)` Selects four contracts to form Bear Call Ladder or Bull Call Ladder Option strategies.
`put_ladder(min_days_till_expiry: int, higher_strike_from_atm: float, middle_strike_from_atm: float, lower_strike_from_atm: float)` Selects four contracts to form Bear Put Ladder or Bull Put Ladder Option strategies.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

Filter by Implied Volatility and Greeks

Option price models compute the theoretical price of Option contracts, their implied volatility, and their Greek values. Theoretical prices can help you detect undervalued and overvalued contracts, implied volatility can provide you insight into the upcoming volatility of the underlying security, and Greek values can help you hedge your portfolio.

```py
# Example 1: Select the contracts with delta between 0.25 and 0.75
option.set_filter(lambda option_filter_universe: option_filter_universe.delta(0.25, 0.75))

# Example 2: Select the contracts (including weeklys) that expire in the next 90 days with implied volatility below 20%
option.set_filter(lambda option_filter_universe: option_filter_universe.iv(0, 20).expiration(0, 90))

# Example 3: Select the contracts (including weeklys) that expire in the next 30 days with implied volatility below 20% that forms an
Iron Condor
option.set_filter(lambda option_filter_universe: option_filter_universe.iv(0, 20).expiration(0, 30).iron_condor(30, 5, 10))
```

The following table describes the filter methods of the `OptionFilterUniverse` class that select contract for a range of implied volatility, Greek values, and open interest:

`iv(min: float, max: float)`
`implied_volatility(min: float, max: float)`
 	
Selects a contract with implied volatility within the range you set.

`d(min: float, max: float)`
`delta(min: float, max: float)`
 	
Selects a contract with delta within the range you set.

`g(min: float, max: float)`
`gamma(min: float, max: float)`
 	
Selects a contract with gamma within the range you set.

`r(min: float, max: float)`
`rho(min: float, max: float)`
 	
Selects a contract with rho within the range you set.

`v(min: float, max: float)`
`vega(min: float, max: float)`
 	
Selects a contract with vega within the range you set.

`t(min: float, max: float)`
`theta(min: float, max: float)`
 	
Selects a contract with theta within the range you set.

`oi(min: int, max: int)`
`open_interest(min: float, max: float)`
 	
Selects a contract with open interest within the range you set.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

To perform thorough filtering on the `OptionFilterUniverse` , define an isolated filter method.

```
# Select the put contracts with the lowest strike price.
option.set_filter(self._contract_selector)

def _contract_selector(self, option_filter_universe: OptionFilterUniverse) -> OptionFilterUniverse:
    return option_filter_universe \
        .delta(0.5, 1.5) \
        .gamma(0.0001, 0.0006) \
        .vega(0.01, 1.5) \
        .theta(-2.0, -0.5) \
        .rho(0.5, 3.0) \
        .implied_volatility(1, 3) \
        .open_interest(100,500)
```

Filter by Other Contract Properties

To set a contract filter, in the `initialize` method, call the `set_filter` method of the `Option` object.

```py
# Select contracts that have a strike price within 1 strike level above and below the underlying price
option.set_filter(min_strike=-1, max_strike=1)

# Select contracts that expire within 30 days
option.set_filter(min_expiry=timedelta(days=0), maxExpiry=timedelta(days=30))

# Select contracts that have a strike price within 1 strike level and expire within 30 days
option.set_filter(min_strike=-1, max_strike=1, min_expiry=timedelta(days=0), maxExpiry=timedelta(days=30))

# Select call contracts
option.set_filter(lambda option_filter_universe: option_filter_universe.calls_only())
```

The following table describes the available filter techniques:

`set_filter(minStrike: int, maxStrike: int)` Selects the contracts that have a strike price within a minimum and maximum strike level relative to the underlying price. For example, say the underlying price is 302 and there are strikes at every 5. If you set `m_strike` to -1 and `max_strike` to 1, LEAN selects the contracts that have a strike of 300 or 305. This filter runs asynchronously by default.
`set_filter(minExpiry: timedelta, maxExpiry: timedelta)` Selects the contracts that expire within the range you set. This filter runs asynchronously by default.
`set_filter(minStrike: int, maxStrike: int, minExpiry: timedelta, maxExpiry: timedelta)` Selects the contracts that expire and have a strike within the range you set. This filter runs asynchronously by default.
`set_filter(universeFunc: Callable[[OptionFilterUniverse], OptionFilterUniverse])` Selects the contracts that a function selects.

The following table describes the filter methods of the `OptionFilterUniverse` class:

`strikes(min_strike: int, max_strike: int)` Selects contracts that are within `m_strike` strikes below the underlying price and `max_strike` strikes above the underlying price.
`calls_only()` Selects call contracts.
`puts_only()` Selects put contracts.
`standards_only()` Selects standard contracts.
`weeklys_only()` Selects weekly contracts.
`front_month()` Selects the front month contract.
`back_months()` Selects the non-front month contracts.
`back_month()` Selects the back month contracts.
`expiration(min_expiryDays: int, max_expiryDays: int)` Selects contracts that expire within a range of dates relative to the current day.
`contracts(contracts: list[Symbol])` Selects a list of contracts.
`contracts(contract_selector: Callable[[list[Symbol]], list[Symbol]])` Selects contracts that a selector function selects.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

```
# Example 1: Select the front month call contracts
option.set_filter(lambda option_filter_universe: option_filter_universe.calls_only().front_month())

# Example 2: Select the contracts (including weeklys) that expire in the next 90 days
option.set_filter(lambda option_filter_universe: option_filter_universe.strikes(-20, 20).expiration(0, 90))
```

Some of the preceding filter methods only set an internal enumeration in the `OptionFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `OptionFilterUniverse` .

Default Filter

By default, LEAN subscribes to the Option contracts that have the following characteristics:

- Standard and weeklys
- Within 1 strike price of the underlying asset price
- Expire within 35 days

To adjust the universe of contracts, set a filter. The filter usually runs at the first bar of every day. When the filter selects a contract that isn't currently in your universe, LEAN adds the new contract data to the next `Slice` that it passes to the `on_data` method.

Navigate Intraday Option Chains

`OptionChain` objects represent an entire chain of Option contracts for a single underlying security.

To get the `OptionChain` , index the `option_chains` property of the `Slice` with the canonical `symbol` . After you get the `OptionChain` , you can sort and filter the Option contracts in the chain.

```
PY
def on_data(self, slice: Slice) -> None:
    # Try to get the OptionChain using the canonical symbol
    chain = slice.option_chains.get(self._symbol)
    if chain:
        # Example: Find 5 put contracts that are closest to at-the-money (ATM) and have the farthest expiration
        contracts = [x for x in chain if x.right == OptionRight.PUT]
        contracts = sorted(sorted(contracts, \
            key = lambda x: abs(chain.underlying.price - x.strike)), \
            key = lambda x: x.expiry, reverse=True)[:5]

        # Select the contract with the delta closest to -0.5
        contract = sorted(contracts, key=lambda x: abs(-0.5 - x.greeks.delta))[0]
```

You can also loop through the `option_chains` property to get each `OptionChain` .

```
PY
def on_data(self, slice: Slice) -> None:
    # Iterate all received Canonical Symbol-OptionChain key-value pairs
    for canonical_symbol, chain in slice.option_chains.items():
        contracts = chain.contracts
```

`OptionChain` objects have the following properties:

Navigate Daily Option Chains

To get the daily, pre-calculated Greeks and implied volaility of all the currently tradable contracts, call the `option_chain` method. This method returns a `DataHistory[OptionUniverse]` object, which you can format into a DataFrame or iterate through. Each row in the DataFrame and each `OptionUniverse` object represents a single contract. The data this method returns contains information on all the currently tradable contracts, not just the contracts that pass your filter.

```
PY
# In the initialize method, create a Scheduled Event to get the Option
# chain and rebalance the portfolio.
self.schedule.on(
    self.date_rules.week_start(self._symbol),
    self.time_rules.after_market_open(self._symbol, 1),
    self._rebalance
  )

# Define the method.
def _rebalance(self):
    daily_option_chain = self.option_chain(self._symbol, flatten=True)

    # Get the DataFrame format.
    df = daily_option_chain.data_frame
    delta_by_symbol = df.delta

    # Get the OptionUniverse objects format.
    for option_universe in daily_option_chain:
        close = option_universe.close
        oi = option_universe.open_interest
        delta = option_universe.greeks.delta
```

The `option_chain` method was previously known as the `option_chain_provider.get_option_contract_list` method.

`OptionUniverse` objects have the following properties:

Greeks and Implied Volatility

There are several ways to get the implied volatility and Greeks of contracts.

The Greeks and IV values in the filter function are the daily, pre-calculated values based on the end of the previous trading day.

```
def initialize(self):
    option = self.add_option("SPY")
    option.set_filter(lambda universe: universe.delta(0.3, 0.7).expiration(0,7))
```

To calculate the values, we use our implementation of the forward tree pricing model, which accounts for the interest rate and dividend payments.

You can't customize the Greeks and IV values that the filter function receives. However, you can create indicators to customize how the Greeks and IV are calculated for the contracts already in your universe.

To override the default pricing model of the Option, set a pricing model . If you set a price model, it sets the price model of the individual contracts in the universe.

```
// Set price_model field to use the Binomial Cox-Ross-Rubinstein model to price the Options.
option.price_model = OptionPriceModels.binomial_cox_ross_rubinstein()
```

To override the initial guess of implied volatility , set and warm up the underlying volatility model .

Historical Data

To get historical chains for an Equity Option, call the `history[OptionUniverse]` method with the canonical Option `Symbol` . This method returns the entire Option chain for each trading day, not the subset of contracts that pass your universe filter.

```
class OptionHistoryAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        option = self.add_option('SPY')
        # DataFrame example:
        history_df = self.history(option.symbol, 5, flatten=True)
        # OptionUniverse objects example:
        history = self.history[OptionUniverse](option.symbol, 5)
        for chain in history:
            end_time = chain.end_time
            filtered_contracts = [c for c in chain if c.greeks.delta > 0.3]
            for contract in filtered_contracts:
                symbol = contract.symbol
                expiry = contract.id.date
                strike = contract.id.strike_price
                price = contract.close
                iv = contract.implied_volatility
```

The Greeks and IV values that you get from a history request of the Option universe are the daily, pre-calculated values based on the end of the previous trading day. To get the intraday values or to customize the Greeks and IV calculations, create some Option indicators .

The method represents each contract with an `OptionUniverse` object, which have the following properties:

Selection Frequency

By default, Equity Option universes run at the first time step of each day to select their contracts.

Examples

The following examples demonstrate some common Equity Option universes.

Example 1: 0DTE Contracts

0DTE Options are Option contracts that expire on the same day you trade them. The following algorithm selects 0DTE Option contracts for the SPY that fall within 3 strikes of the underlying price.

```py
class ZeroDTEOptionUniverseAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        option = self.add_option('SPY')
        option.set_filter(lambda u: u.expiration(0, 0).strikes(-3, 3))
```

For trading full examples of Equity Option Universe, please refer to the Securities > Equity Options > Requesting Data > Universes page.

Universes

Equity CFD

Introduction

An Equity CFD universe lets you select a set of Equity CFD assets. To select the underlying Equities, you can use a fundamental universe to select assets based on corporate fundamental data, an ETF constituents universe to select the CFD versions of stocks in an exchange-traded fund, or an alternative data universe to select assets based on alternative data. This feature is powerful for European clients seeking to trade US ETF products.

Only the Interactive Brokers CFD integration supports trading Stock-CFD products. QuantConnect doesn't have historical data for Interactive Brokers CFD products; however, you can use the `live_mode` flag to swap to the CFD equivalents for live trading. In live trading, you must include Interactive Brokers as a data provider to trade Equity-CFD products.

Create Universes Using Fundamentals

To add a fundamental universe, in the `initialize` method, pass a filter function to the `add_universe` method. The filter function receives a list of `Fundamental` objects and must return a list of `Symbol` objects. The `Symbol` objects you return from the function are the constituents of the fundamental universe and LEAN automatically creates subscriptions for them. In live mode, call the `Symbol.create` method to swap for a CFD version of the same `Symbol` . Don't call `add_cfd` in the filter function.

```
PY
# Create a universe for CFD securities based on fundamental data.
class MyUniverseAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.universe_settings.asynchronous = True
        # Pass the filter function as an argument to the AddUniverse method.
        self._universe = self.add_universe(self._fundamental_function)

    def _fundamental_function(self, fundamental: List[Fundamental]) -> List[Symbol]:
        symbols = [c.symbol for c in fundamental if c.has_fundamental_data]
        if self.live_mode:
            return [Symbol.create(x.value, SecurityType.CFD, Market.INTERACTIVE_BROKERS) for x in symbols]
        return symbols
```

Example

The simplest example of accessing the fundamental object would be harnessing the iconic PE ratio for a stock. This is a ratio of the price it commands to the earnings of a stock. The lower the PE ratio for a stock, the more affordable it appears.

```
PY
# Select the top 50 by dollar volume and then select the top 10 by their PE ratio.
self.universe_settings.asynchronous = True
self._universe = self.add_universe(self._fundamental_selection_function)

def _fundamental_selection_function(self, fundamental: List[Fundamental]) -> List[Symbol]:
    filtered = [f for f in fundamental if f.price > 10 and f.has_fundamental_data and not np.isnan(f.valuation_ratios.pe_ratio)]
    sorted_by_dollar_volume = sorted(filtered, key=lambda f: f.dollar_volume, reverse=True)[:100]
    sorted_by_pe_ratio = sorted(sorted_by_dollar_volume, key=lambda f: f.valuation_ratios.pe_ratio, reverse=False)[:10]
    symbols = [f.symbol for f in sorted_by_pe_ratio]
    if self.live_mode:
        return [Symbol.create(x.value, SecurityType.CFD, Market.INTERACTIVE_BROKERS) for x in symbols]
    return symbols
```

Practical Limitations

Fundamental universes allow you to select an unlimited universe of assets to analyze. Each asset in the universe consumes approximately 5MB of RAM, so you may quickly run out of memory if your universe filter selects many assets. If you backtest your algorithms in the Algorithm Lab, familiarize yourself with the RAM capacity of your backtesting and live trading nodes . To keep your algorithm fast and efficient, only subscribe to the assets you need.

Create Universes using ETF Constituents

To add an ETF Constituents universe, in the `initialize` method, call the `universe.etf` method with a filter function, and pass it to the `add_universe` method. The filter function receives a list of `ETFConstituentUniverse` objects and must return a list of `Symbol` objects. The `Symbol` objects you return

from the function are the constituents of the fundamental universe and LEAN automatically creates subscriptions for them. In live mode, call the `Symbol.create` method to swap for a CFD version of the same `Symbol` . Don't call `add_cfd` in the filter function.

```
class MyUniverseAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.universe_settings.asynchronous = True
        self._universe = self.universe.etf("SPY", self.universe_settings, self._etf_constituents_filter)
        self.add_universe(self._universe)

    def _etf_constituents_filter(self, constituents: List[ETFConstituentUniverse]) -> List[Symbol]:
        # Get the 10 securities with the largest weight in the index
        selected = sorted(constituents, key=lambda c: c.weight or 0.0, reverse=True)[:10]
        symbols = [c.symbol for c in selected]
        if self.live_mode:
            return [Symbol.create(x.value, SecurityType.CFD, Market.INTERACTIVE_BROKERS) for x in symbols]
        return symbols
```

PY

Selection Frequency

Equity universes run on a daily basis by default. To adjust the selection schedule, see Schedule .

Live Trading Considerations

The live data for fundamental universe selection arrives at 6/7 AM Eastern Time (ET), so fundamental universe selection runs for live algorithms between 7 and 8 AM ET. This timing allows you to place trades before the market opens. Don't schedule anything for midnight because the universe selection data isn't ready yet.

Examples

The following examples demonstrate common practices for implementing Equity CFD's universe.

Example 1: Short Bottom-Weighted SPY Constituents

A subset of the SPY constituents outperforms the SPY, while many underperform the overall index. To exclude the ETF constituents that underperform the index, the following algorithm buys the SPY CFD and shorts the CFD of the 100 constituents in the index with the smallest weight in the ETF.

PY

```
class EquityCfdUniverseAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(10_000_000)
        self.settings.minimum_order_margin_portfolio_percentage = 0
        # Request SPY to trade. In live mode, request the IB CFD
        self._spy = self.add_cfd("SPY", market= Market.InteractiveBrokers).symbol if self.live_mode else self.add_equity("SPY").symbol
        # The SPY ETF provides market hours for scheduled events.
        spy = Symbol.create("SPY", SecurityType.EQUITY, Market.USA)
        # Refilter and rebalance weekly to avoid over-trading and high transaction costs.
        self.universe_settings.schedule.on(self.date_rules.week_end(spy))
        # Add a universe to select the CFD contracts of the SPY constituents.
        self._universe = self.add_universe(self.universe.etf(spy, universe_filter_func=self._select_assets))

        # Create a scheduled event to rebalance the portfolio.
        self.schedule.on(
            self.date_rules.week_start(spy),
            self.time_rules.after_market_open(spy, 1),
            self._rebalance
        )

    def _select_assets(self, constituents: List[ETFConstituentUniverse]) -> List[Symbol]:
        # Cache the constituent weights in a dictionary for filtering and position sizing.
        self._etf_weight_by_symbol = {c.symbol: c.weight for c in constituents if c.weight}
        # Select the CFD contracts of the bottom-weighted 100 constituents.
        # They should have negative excess returns.
        def get_symbol(symbol):
            if self.live_mode:
                return Symbol.create(symbol.value, SecurityType.CFD, Market.INTERACTIVE_BROKERS)
            return symbol
        return [
            get_symbol(symbol) for symbol, _ in sorted(
                self._etf_weight_by_symbol.items(),
                key=lambda x: x[1]
            )[:100]
        ]

    def _rebalance(self) -> None:
        # Get the ETF weight of all the assets currently in the universe.
        weight_by_symbol = { symbol: self._etf_weight_by_symbol[symbol] for symbol in self._universe.selected }
        # Sell the CFD of the 100 ETF constituents with the lowest weight due to expected negative excess return.
        targets = [PortfolioTarget(symbol, -weight) for symbol, weight in weight_by_symbol.items()]
        # Buy the SPY CFD to eliminate systematic risk.
        targets.append(PortfolioTarget(self._spy, 1 - sum(weight_by_symbol.values())))
        # Place orders to rebalance the portfolio.
        self.set_holdings(targets, liquidate_existing_holdings=True)
```

Universes

Futures

Introduction

A Futures universe lets you select a basket of contracts for a single Future. LEAN models Future subscriptions as a universe of Future contracts. A Future universe is similar to an Option universe , except Future contracts don't have a strike price, so the universe filter primarily focuses on the contract expiration date.

Create Universes

To add a universe of Future contracts, in the `initialize` method, call the `add_future` method. This method returns an `Future` object, which contains the continuous contract `symbol` . The continuous contract `symbol` is the key to access the contracts in the FutureChain that LEAN passes to the `on_data` method. The continuous contract `mapped` property references the current contract in the continuous contract series. When you create the Future subscription, save a reference to the `Future` object so you can use it later in your algorithm.

```
class BasicFutureAlgorithm(QCAlgorithm):
    def initialize(self):
        self.universe_settings.asynchronous = True
        self._future = self.add_future(Futures.Currencies.BTC,
            extended_market_hours=True,
            data_mapping_mode=DataMappingMode.LAST_TRADING_DAY,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0)
        self._future.set_filter(0,62)

    def on_data(self, data):
        if self.portfolio.invested:
            return
        continuous_trade_bar = data.bars.get(self._future.symbol)
        mapped_trade_bar = data.bars.get(self._future.mapped)
        self.market_order(self._future.mapped, 1)

    # Track events when security changes its ticker allowing algorithm to adapt to these changes.
    def on_symbol_changed_events(self, symbol_changed_events):
        for symbol, changed_event in  symbol_changed_events.items():
            old_symbol = changed_event.old_symbol
            new_symbol = changed_event.new_symbol
            quantity = self.portfolio[old_symbol].quantity

            # Rolling over: to liquidate any position of the old mapped contract and switch to the newly mapped contract
            tag = f"Rollover - Symbol changed at {self.time}: {old_symbol} -> {new_symbol}"
            self.liquidate(old_symbol, tag=tag)
            if quantity: self.market_order(new_symbol, quantity, tag=tag)
```

The following table describes the `add_future` method arguments:

Argument: `ticker` The Future ticker. To view the supported assets in the US Futures dataset, see Supported Assets . Data Type: `str`
Argument: `resolution` The resolution of the market data. To view the supported resolutions, see Resolutions . If you don't provide a value, it uses `Resolution.MINUTE` by default. Data Type: `Resolution/NoneType`

Argument: `market` The Futures market. To view the supported markets in the US Futures dataset, see Supported Markets . If you don't provide a value, it uses the default Future market of your brokerage model . Data Type: `str`
Argument: `fill_forward` If true, the current slice contains the last available data even if there is no data at the current time. Data Type: `bool`
Argument: `leverage` The leverage for this Future. Data Type: `float`
Argument: `extended_market_hours` If true, use data from the pre and post market sessions Data Type: `bool`
Argument: `data_mapping_mode` The contract mapping mode to use for the continuous future contract Data Type: `DataMappingMode/NoneType`
Argument: `data_normalization_mode` The price scaling mode to use for the continuous future contract Data Type: `DataNormalizationMode/NoneType`
Argument: `contract_depth_offset` The continuous future contract desired offset from the current front month. For example, 0 is the front month, 1 is the back month contract. Data Type: `int`

If you don't set any of these parameters, LEAN uses the `self.universe_settings` values. See Set Universe Settings for more information.

Continous Contracts

By default, LEAN only subscribes to the continuous Future contract. A continuous Future contract represents a series of separate contracts stitched together to form a continuous price. If you need a lot of historical data to warm up an indicator, apply the indicator to the continuous contract price series. The `Future` object has a `symbol` property and a `mapped` property. The price of the `symbol` property is the adjusted price of the continuous contract. The price of the `mapped` property is the raw price of the currently selected contract in the continuous contract series.

```
# Get the adjusted price of the continuous contract.
adjusted_price = self.securities[self._future.symbol].price

# Get the raw price of the currently selected contract in the continuous contract series.
raw_price = self.securities[self._future.mapped].price
```

The continuous Futures contract isn't a tradable security . You must place orders for a specific Futures contract. To access the currently selected contract in the continuous contract series, use the `mapped` property of the `Future` object.

```
# Place a market order for the currently selected contract in the continuous contract series.
self.market_order(self._future.mapped, 1)
```

To configure how LEAN identifies the current Future contract in the continuous series and how it forms the adjusted price between each contract, provide `data_mapping_mode` , `data_normalization_mode` , and `contract_depth_offset` arguments to the `add_future` method. The `Future` object that the `add_future` method returns contains a `mapped` property that references the current contract in the continuous contract series. As the contracts roll over, the `mapped` property references the next contract in the series and you receive a `SymbolChangedEvent` object in the `on_data` method. The `SymbolChangedEvent` references the old contract `Symbol` and the new contract `Symbol` . You can use `SymbolChangedEvents` to roll over contracts.

```
class BasicFutureAlgorithm(QCAlgorithm):
    # Track when the continuous contract switches from one contract to the next.
    def on_symbol_changed_events(self, symbol_changed_events):
        for symbol, changed_event in  symbol_changed_events.items():
            old_symbol = changed_event.old_symbol
            new_symbol = changed_event.new_symbol
            quantity = self.portfolio[old_symbol].quantity

            # Rolling over: To liquidate the old mapped contract and switch to the new mapped contract.
            tag = f"Rollover - Symbol changed at {self.time}: {old_symbol} -> {new_symbol}"
            self.liquidate(old_symbol, tag=tag)
            if quantity: self.market_order(new_symbol, quantity, tag=tag)
```

In backtesting, the `SymbolChangedEvent` occurs at midnight Eastern Time (ET). In live trading, the live data for continuous contract mapping arrives at 6/7 AM ET, so that's when it occurs.

Data Normalization Modes

The `data_normalization_mode` argument defines how the price series of two contracts are stitched together when the contract rollovers occur. The following `DataNormalizatoinMode` enumeration members are available for continuous contracts:

We use the entire Futures history to adjust historical prices. This process ensures you get the same adjusted prices, regardless of the backtest end date.

Data Mapping Modes

The `data_mapping_mode` argument defines when contract rollovers occur. The `DataMappingMode` enumeration has the following members:

`Futures.Indices.VIX` (VX) doesn't support continous contract rolling with `DataMappingMode.OPEN_INTEREST` and `DataMappingMode.OPEN_INTEREST_ANNUAL` .

Contract Depth Offsets

The `contract_depth_offset` argument defines which contract to use. 0 is the front month contract, 1 is the following back month contract, and 2 is the second back month contract.

Filter Contracts

By default, LEAN doesn't add any contracts to the FuturesChain it passes to the `on_data` method.

To set a contract filter, in the `initialize` method, call the `set_filter` method of the `Future` object. The following table describes the available filter techniques:

`set_filter(minExpiry: int, maxExpiry: int)` Selects the contracts that expire within the range you set. This filter runs asynchronously by default.
`set_filter(universeFunc: Callable[[FutureFilterUniverse], FutureFilterUniverse])` Selects the contracts that a function selects.

```py
# Select the contracts that expire within 182 days.
self._future.set_filter(0, 182)

# Select the front month contract.
self._future.set_filter(lambda future_filter_universe: future_filter_universe.front_month())
```

The following table describes the filter methods of the `FutureFilterUniverse` class:

`standards_only()` Selects standard contracts
`front_month()` Selects the front month contract
`back_months()` Selects the non-front month contracts
`back_month()` Selects the back month contracts
`expiration(min_expiry: timedelta, max_expiry: timedelta)` Selects contracts that expire within a range of dates relative to the current day
`expiration(min_expiry_days: int, max_expiry_days: int)` Selects contracts that expire within a range of dates relative to the current day
`contracts(contracts: list[Symbol])` Selects a list of contracts
`contracts(contractSelector: Callable[[list[Symbol]], list[Symbol]])` Selects contracts that a selector function selects

The preceding methods return an `FutureFilterUniverse` , so you can chain the methods together.

```py
# Select the front month standard contracts
self._future.set_filter(lambda future_filter_universe: future_filter_universe.standards_only().front_month())
```

You can also define an isolated filter method.

```py
# In Initialize
self._future.set_filter(self._contract_selector)

def _contract_selector(self,
    future_filter_universe: Callable[[FutureFilterUniverse], FutureFilterUniverse]) -> FutureFilterUniverse:
    return future_filter_universe.standards_only().front_month()
```

Navigate Futures Chains

`FuturesChain` objects represent an entire chain of contracts for a single underlying Future. They have the following properties:

To get the `FuturesChain` , index the `futures_chains` property of the `Slice` with the continuous contract `Symbol` .

```py
def on_data(self, slice: Slice) -> None:
    chain = slice.futures_chains.get(self._symbol)
    if chain:
        # Example: Select the contract with the greatest open interest
        contract = sorted(chain, key=lambda contract: contract.open_interest, reverse=True)[0]
```

You can also loop through the `futures_chains` property to get each `FuturesChain` .

```py
def on_data(self, slice: Slice) -> None:
    for continuous_contract_symbol, chain in slice.futures_chains.items():
        pass
```

Historical Data

To get historical Future universe data, call the `history` method. This method returns the all the available contracts for each trading day, not the subset of contracts that pass your universe filter. The return type depends on how you call the method.

```py
class FutureHistoryAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        future = self.add_future(Futures.Indices.SP_500_E_MINI)
        # DataFrame example:
        history_df = self.history(FutureUniverse, future.symbol, 5, flatten=True)
        # Series example:
        history_series = self.history(FutureUniverse, future.symbol, 5, flatten=False)
        # FutureUniverse objects example:
        history = self.history[FutureUniverse](future.symbol, 5)
        for universe in history:
            end_time = universe.end_time
            for contract in universe:
                symbol = contract.symbol
                expiry = contract.id.date
                price = contract.close
                oi = contract.open_interest
```

The method represents each contract with a `FutureUniverse` object, which have the following properties:

Selection Frequency

By default, Futures universes run at the first time step of each day to select their contracts.

Examples

The following examples demonstrate some common Futures universes.

Example 1: Contracts Expiring On Quarter End

To reduce the need for rolling over, you can filter Future contracts that expire only on quarter ends to save transaction costs. The following example trades a simple EMA cross strategy on SP500 EMini Future contracts that expire on quarter ends.

```py
class QuarterlyFuturesAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(10000000)

        # Request ES Future data for trading.
        self.future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            extended_market_hours=True,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
        )
        # We only filter the ones expiring on quarter ends to reduce the transaction cost needed for rolling over contracts.
        self.future.set_filter(lambda future_filter_universe: future_filter_universe.expiration_cycle([3, 6, 9, 12]))

        # Create an EMA indicator to track trends for trade signal generation.
        self._ema = self.ema(self.future.symbol, 20, Resolution.DAILY)
        # Warm up the indicator for immediate readiness.
        self.warm_up_indicator(self.future.symbol, self._ema, Resolution.DAILY)

        # A variable to control the algorithm trading in daily frequency only, since the indicator signal is by daily.
        self._day = -1

    def on_data(self, slice: Slice) -> None:
        # Get the chain to trade from the filtered contracts.
        chain = slice.future_chains.get(self.future.symbol)
        if self._day != slice.time.day and chain:
            # Select the contract with the nearest expiry.
            contract = min(chain, key=lambda x: x.expiry)

            # Trade an EMA cross strategy to follow the trend.
            quantity = self.portfolio[self.future.symbol].quantity
            if contract.last_price > self._ema.current.value and quantity <= 0:
                self.market_order(contract.symbol, 1-quantity)
            elif contract.last_price < self._ema.current.value and quantity >= 0:
                self.market_order(contract.symbol, -1-quantity)

            self._day = slice.time.day
```

Example 2: Contracts Expiring Within One Week

The trading volume of Futures reaches its maximum during the last week of the trading period. The following algorithm selects contracts that expire within a week:

PY

```
class WeeklyFuturesAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add ES Futures for trading. The continuous contract data is
        # only used for indicator values.
        self._future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            extended_market_hours=True,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST
        )
        # Select the contract expiring within a week since they have
        # the highest liquidity.
        self._future.set_filter(lambda universe: universe.expiration(0, 7))
        # Create a Bollinger Band indicator to identify extreme prices
        # for trade signal generation.
        self._bb = self.bb(self._future.symbol, 60, 2)
        # Warm up the indicator for so we can trade right away.
        self.warm_up_indicator(self._future.symbol, self._bb)

    def on_data(self, slice: Slice) -> None:
        # Get the current Futures chain, if there is one.
        chain = slice.future_chains.get(self._future.symbol)
        if not chain:
            return
        # Select the contract with the nearest expiry.
        contract = min(chain, key=lambda x: x.expiry)
        # Trade a mean-reversal strategy based on Bollinger Band signal.
        holding = self.portfolio[contract.symbol]
        price = contract.last_price
        # Case 1: Short
        if not holding.is_short and price > self._bb.upper_band.current.value:
            target_quantity = -1
        # Case 2: Long
        elif not holding.is_long and price < self._bb.lower_band.current.value:
            target_quantity = 1
        # Case 3: Exit
        elif ((holding.is_short and price < self._bb.middle_band.current.value) or
            (holding.is_long and price > self._bb.middle_band.current.value)):
            target_quantity = 0
        # Case 4: Hold
        else:
            return
        self.market_order(contract.symbol, target_quantity - holding.quantity)
```

Universes

Future Options

Introduction

A Future Option universe lets you select a basket of Option contracts on the contracts in a Futures universe .

Create Universes

To add a universe of Future Option contracts, in the `initialize` method, define a Future universe and then pass the canonical `symbol` to the `add_future_option` method.

```
self.universe_settings.asynchronous = True
future = self.add_future(Futures.Metals.GOLD)
future.set_filter(0, 90)
self.add_future_option(future.symbol)
```

The following table describes the `add_future_option` method arguments:

Argument	Data Type	Description
`symbol`	`Symbol`	The continuous Future contract Symbol. To view the supported assets in the US Future Options dataset, see Supported Assets .
`option_filter`	`Callable[[OptionFilterUniverse], OptionFilterUniverse]`	A function that selects Future Option contracts

The subscription characteristics such as resolution, market, and fill forward behavior are inherited from the `self.universe_settings` values. See Set Universe Settings for more information.

To override the default pricing model of the Option, set a pricing model in a security initializer.

```
# In Initialize
seeder = SecuritySeeder.NULL
self.set_security_initializer(MySecurityInitializer(self.brokerage_model, seeder, self))

# Outside of the algorithm class
class MySecurityInitializer(BrokerageModelSecurityInitializer):

    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder, QCAlgorithm algorithm) -> None:
        super().__init__(brokerage_model, security_seeder)
        self._algorithm = algorithm;

    def initialize(self, security: Security) -> None:
        # First, call the superclass definition
        # This method sets the reality models of each security using the default reality models of the brokerage model
        super().initialize(security)

        # Next, set the price model
        if security.type == SecurityType.FUTURE_OPTION: # Option type
            security.price_model = OptionPriceModels.binomial_cox_ross_rubinstein()
```

To override the initial guess of implied volatility , set and warm up the underlying volatility model .

Filter Contracts

By default, LEAN subscribes to the Option contracts that have the following characteristics:

- Standard type (weeklies and non-standard contracts are not available)
- Within 1 strike price of the underlying asset price
- Expire within 35 days

To adjust the universe of contracts, set a filter. The filter usually runs at every time step in your algorithm. When the filter selects a contract that isn't

currently in your universe, LEAN adds the new contract data to the next `Slice` that it passes to the `on_data` method.

To set a contract filter, in the `initialize` method, pass a filter function to the `add_future_option` method. The following table describes the available filter techniques:

```
self.add_future_option(future.symbol, lambda option_filter_universe: option_filter_universe.strikes(-1, 1))
```

The following table describes the filter methods of the `OptionFilterUniverse` class:

`strikes(min_strike: int, max_strike: int)` Selects contracts that are within `m_strike` strikes below the underlying price and `max_strike` strikes above the underlying price.
`calls_only()` Selects call contracts.
`puts_only()` Selects put contracts.
`standards_only()` Selects standard contracts.
`weeklys_only()` Selects weekly contracts. This filter doesn't currently work. To add this functionality to our roadmap , react to this GitHub Issue with a thumbs up emoji.
`front_month()` Selects the front month contract.
`back_months()` Selects the non-front month contracts.
`back_month()` Selects the back month contracts.
`expiration(min_expiryDays: int, max_expiryDays: int)` Selects contracts that expire within a range of dates relative to the current day.
`contracts(contracts: list[Symbol])` Selects a list of contracts.
`contracts(contract_selector: Callable[[list[Symbol]], list[Symbol]])` Selects contracts that a selector function selects.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

```
self.add_future_option(future.symbol, lambda option_filter_universe: option_filter_universe.strikes(-1, 1).calls_only())
```

To perform thorough filtering on the `OptionFilterUniverse` , define an isolated filter method.

```
# In Initialize
self.add_future_option(future.Symbol, self._contract_selector)

def _contract_selector(self, option_filter_universe: OptionFilterUniverse) -> OptionFilterUniverse:
    symbols = option_filter_universe.PutsOnly()
    strike = min([symbol.id.strike_price for symbol in symbols])
    symbols = [symbol for symbol in symbols if symbol.id.strike_price == strike]
    return option_filter_universe.contracts(symbols)
```

Some of the preceding filter methods only set an internal enumeration in the `OptionFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `OptionFilterUniverse` .

Navigate Option Chains

`OptionChain` objects represent an entire chain of Option contracts for a single underlying security.

To get the `OptionChain` , loop through the `option_chains` property. After you get the `OptionChain` , you can sort and filter the Option contracts in the chain.

```
def on_data(self, slice: Slice) -> None:
    for _, option_chain in slice.option_chains.items():
        # Example: Find 5 put contracts that are closest to at-the-money (ATM) and have the farthest expiration
        contracts = [x for x in option_chain if x.right == OptionRight.PUT]
        contracts = sorted(sorted(contracts, \
            key=lambda x: abs(option_chain.underlying.price - x.strike)), \
            key=lambda x: x.expiry, reverse=True)[:5]

        # Select the contract with the delta closest to -0.5
        contract = sorted(contracts, key=lambda x: abs(-0.5 - x.greeks.delta))[0]
```

You can also iterate through the `futures_chains` first.

```
def on_data(self, slice: Slice) -> None:
    for continuous_future_symbol, futures_chain in slice.futures_chains.items():
        # Select a Future Contract and create its canonical FOP Symbol
        futures_contract = [contract for contract in futures_chain][0]
        canonical_fop_symbol = Symbol.create_canonical_option(futures_contract.symbol)
        fop_chain = slice.option_chains.get(canonical_fop_symbol)
        if fop_chain:
            for contract in fop_chain:
                pass
```

`OptionChain` objects have the following properties:

Historical Data

To get historical Future Option universe data, call the `history` method with the canoncial Option `Symbol` . This method returns the all the available contracts for each trading day, not the subset of contracts that pass your universe filter. The return type depends on how you call the method.

```py
class FutureOptionsHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Select a Futures contract.
        future = self.add_future(Futures.Indices.SP_500_E_MINI)
        futures_contract = list(self.futures_chain(future.symbol))[0]
        # Create the canoncial Option Symbol for this Futures contract.
        canonical = Symbol.create_canonical_option(futures_contract.symbol)
        # Get the historical Option universe data for this Futures contract.
        # DataFrame example:
        history_df = self.history(OptionUniverse, canonical, 3, flatten=True)
        # Series example:
        history_series = self.history(OptionUniverse, canonical, 3, flatten=False)
        # OptionUniverse example:
        history = self.history[OptionUniverse](canonical, 3)
        for universe in history:
            end_time = universe.end_time
            for contract in universe:
                symbol = contract.symbol
                expiry = contract.id.date
                price = contract.close
```

The method represents each contract with a `OptionUniverse` object, which have the following properties:

Selection Frequency

By default, Future Option universes run at the first time step of each day to select their contracts.

Examples

The following examples demonstrate some common Future Option universes.

Example 1: 0DTE Contracts

0DTE Options are Option contracts that expire on the same day you trade them. The following algorithm selects 0DTE Future Option contracts for the E-mini S&P 500 that fall within 3 strikes of the underlying price.

```py
class ZeroDTEFutureOptionUniverseAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        future = self.add_future(Futures.Indices.SP_500_E_MINI)
        future.set_filter(0, 90)
        self.add_future_option(
            future.symbol,
            lambda u: u.expiration(0, 0).strikes(-3, 3)
        )
```

For full trading examples of Future Options, see Examples .

Universes

Index Options

Introduction

An Index Option universe lets you select a basket of Option contracts on an Index.

Create Universes

To add a universe of Index Option contracts, in the `initialize` method, call the `add_index_option` method. This method returns an `Option` object, which contains the canonical `symbol`. You can't trade with the canonical Option `symbol`, but save a reference to it so you can easily access the Option contracts in the OptionChain that LEAN passes to the `on_data` method. The method to create the universe depends on if the Index Options you want require a target ticker.

Create Non-Standard Universes

Non-standard Option contracts are popular among Option traders. To create a universe of non-standard Index Options like weekly VIX contracts, pass the index Symbol and target Option ticker to the `add_index_option` method.

```
class WeeklyIndexOptionAlgorithm(QCAlgorithm):

    def initialize(self):
        underlying = self.add_index("VIX").symbol
        option = self.add_index_option(underlying, "VIXW")
        option.set_filter(lambda universe: universe.expiration(0, 7).delta(0.35, 0.75))
        self._symbol = option.symbol

    def on_data(self, data):
        chain = data.option_chains.get(self._symbol)
        if chain:
            contract = sorted(chain, key=lambda x: (x.expiry, x.greeks.delta))[0]
```

The following table describes the `add_index_option` method arguments for non-standard universes:

Argument	Data Type	Description
`underlying`	`Symbol`	The underlying Index `Symbol`. To view the supported indices, see Supported Assets.
`target_option`	`str`	The target Option ticker. To view the supported target Options, see Supported Assets.
`resolution`	`Resolution`	The resolution of the market data. To view the supported resolutions, see Resolutions. The Index resolution must be less than or equal to the Index Option resolution. For example, if you set the Index resolution to minute, then you must set the Index Option resolution to minute, hour, or daily.
`market`	`str`	The Index Option market.
`fill_forward`	`bool`	If true, the current slice contains the last available data even if there is no data at the current time.

If you don't set any of these parameters, LEAN uses the `self.universe_settings` values. See Set Universe Settings for more information.

If you add an Option universe for an underlying Index that you don't have a subscription for, LEAN automatically subscribes to the underlying Index.

Create Standard Universes

To create a universe of Index Options based on an index like VIX, SPX, or NDX, pass the index ticker to the `add_index_option` method.

```
option = self.add_index_option("SPX")
option.set_filter(lambda universe: universe.expiration(0, 60).delta(0.35, 0.75))
self._symbol = option.symbol
```

The following table describes the `add_index_option` method arguments for standard universes:

Argument	Data Type	Description
`ticker`	`str`	The underlying Index ticker. To view the supported indices, see Supported Assets .
`resolution`	`Resolution`	The resolution of the market data. To view the supported resolutions, see Resolutions .
`market`	`str`	The Index Option market.
`fill_forward`	`bool`	If true, the current slice contains the last available data even if there is no data at the current time.

If you don't set any of these parameters, LEAN uses the `self.universe_settings` values. See Set Universe Settings for more information.

If you add an Option universe for an underlying Index that you don't have a subscription for, LEAN automatically subscribes to the underlying Index and sets its fill forward property to match that of the Index Option universe.

Filter by Investment Strategy

Options trading strategies consist of simultaneously buying or selling one or more Option contracts on the same underlying Index, but with different features.

```
# Example 1: Select a Straddle
option.set_filter(lambda option_filter_universe: option_filter_universe.straddle(30))

# Example 2: Select the contracts (including weeklys) that expire in the next 30 days that form an Iron Condor
option.set_filter(lambda option_filter_universe: option_filter_universe.strikes(-20, 20).expiration(0, 30).iron_condor(30, 5, 10))

# Example 3: Select the 0DTE contracts that form an Strangle
option.set_filter(lambda option_filter_universe: option_filter_universe.expiration(0, 0).strangle(30, 5, -10))
```

The following table describes the filter methods of the `OptionFilterUniverse` class that select contracts for Option strategies:

`naked_call(min_days_till_expiry: int, strike_from_atm: float)` Selects a call contract to form Naked Call , Covered Call , or Protective Call Option strategies.
`naked_put(min_days_till_expiry: int, strike_from_atm: float)` Selects a put contract to form Naked Put , Covered Put , or Protective Put Option strategies.
`call_spread(min_days_till_expiry: int, higher_strike_from_atm: float, lower_strike_from_atm: float)` Selects two call contracts to form Bull Call Spread or Bear Call Spread Option strategies.
`put_spread(min_days_till_expiry: int, higher_strike_from_atm: float, lower_strike_from_atm: float)` Selects two put contracts to form Bull Put Spread or Bear Put Spread Option strategies.
`call_calendar_spread(strike_from_atm: int, min_near_days_till_expiry: int, min_far_days_till_expiry: int)` Selects two call contracts to form Long Call Calendar Spread or Short Call Calendar Spread Option strategies.

`put_calendar_spread(strike_from_atm: int, min_near_days_till_expiry: int, min_far_days_till_expiry: int)` Selects two put contracts to form Long Put Calendar Spread or Short Put Calendar Spread Option strategies.
`strangle(min_days_till_expiry: int, higher_strike_from_atm: float, lower_strike_from_atm: float)` Selects two contracts to form Long Strangle or Short Strangle Option strategies.
`straddle(min_days_till_expiry: int)` Selects two contracts to form Long Straddle or Short Straddle Option strategies.
`protective_collar(min_days_till_expiry: int, higher_strike_from_atm: float, lower_strike_from_atm: float)` Selects two contracts to form Protective Collar Option strategies.
`conversion(min_days_till_expiry: int, strike_from_atm: float)` Selects two contracts to form Conversion or Reverse Conversion Option strategies.
`call_butterfly(min_days_till_expiry: int, strike_spread: float)` Selects three contracts to form Long Call Butterfly or Short Call Butterfly Option strategies.
`put_butterfly(min_days_till_expiry: int, strike_spread: float)` Selects three contracts to form Long Put Butterfly or Short Put Butterfly Option strategies.
`iron_butterfly(min_days_till_expiry: int, strike_spread: float)` Selects four contracts to form Long Iron Butterfly or Short Iron Butterfly Option strategies.
`iron_condor(min_days_till_expiry: int, near_strike_spread: float, far_strike_spread: float)` Selects four contracts to form Long Iron Condor or Short Iron Condor Option strategies.
`box_spread(min_days_till_expiry: int, strike_spread: float)` Selects four contracts to form Box Spread or Short Box Spread Option strategies.
`jelly_roll(strike_from_atm: float, min_near_days_till_expiry: int, min_far_days_till_expiry: int)` Selects four contracts to form Jelly Roll or Short Jelly Roll Option strategies.
`call_ladder(min_days_till_expiry: int, higher_strike_from_atm: float, middle_strike_from_atm: float, lower_strike_from_atm: float)` Selects four contracts to form Bear Call Ladder or Bull Call Ladder Option strategies.
`put_ladder(min_days_till_expiry: int, higher_strike_from_atm: float, middle_strike_from_atm: float, lower_strike_from_atm: float)` Selects four contracts to form Bear Put Ladder or Bull Put Ladder Option strategies.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

Filter by Implied Volatility and Greeks

Option price models compute the theoretical price of Option contracts, their implied volatility, and their Greek values. Theoretical prices can help you

detect undervalued and overvalued contracts, implied volatility can provide you insight into the upcoming volatility of the underlying security, and Greek values can help you hedge your portfolio.

```py
# Example 1: Select the contracts with delta between 0.25 and 0.75
option.set_filter(lambda option_filter_universe: option_filter_universe.delta(0.25, 0.75))

# Example 2: Select the contracts (including weeklys) that expire in the next 90 days with implied volatility below 20%
option.set_filter(lambda option_filter_universe: option_filter_universe.iv(0, 20).expiration(0, 90))

# Example 3: Select the contracts (including weeklys) that expire in the next 30 days with implied volatility below 20% that forms an
Iron Condor
option.set_filter(lambda option_filter_universe: option_filter_universe.iv(0, 20).expiration(0, 30).iron_condor(30, 5, 10))
```

The following table describes the filter methods of the `OptionFilterUniverse` class that select contract for a range of implied volatility, Greek values, and open interest:

`iv(min: float, max: float)`
`implied_volatility(min: float, max: float)`
 	
Selects a contract with implied volatility within the range you set.

`d(min: float, max: float)`
`delta(min: float, max: float)`
 	
Selects a contract with delta within the range you set.

`g(min: float, max: float)`
`gamma(min: float, max: float)`
 	
Selects a contract with gamma within the range you set.

`r(min: float, max: float)`
`rho(min: float, max: float)`
 	
Selects a contract with rho within the range you set.

`v(min: float, max: float)`
`vega(min: float, max: float)`
 	
Selects a contract with vega within the range you set.

`t(min: float, max: float)`
`theta(min: float, max: float)`
 	
Selects a contract with theta within the range you set.

`oi(min: int, max: int)`
`open_interest(min: float, max: float)`
 	
Selects a contract with open interest within the range you set.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

To perform thorough filtering on the `OptionFilterUniverse` , define an isolated filter method.

```py
# Select the put contracts with the lowest strike price.
option.set_filter(self._contract_selector)

def _contract_selector(self, option_filter_universe: OptionFilterUniverse) -> OptionFilterUniverse:
    return option_filter_universe \
        .delta(0.5, 1.5) \
        .gamma(0.0001, 0.0006) \
        .vega(0.01, 1.5) \
        .theta(-2.0, -0.5) \
        .rho(0.5, 3.0) \
        .implied_volatility(1, 3) \
        .open_interest(100,500)
```

Filter by Other Contract Properties

To set a contract filter, in the `initialize` method, call the `set_filter` method of the `Option` object.

```py
# Select contracts that have a strike price within 1 strike level above and below the underlying price
option.set_filter(min_strike=-1, max_strike=1)

# Select contracts that expire within 30 days
option.set_filter(min_expiry=timedelta(days=0), maxExpiry=timedelta(days=30))

# Select contracts that have a strike price within 1 strike level and expire within 30 days
option.set_filter(min_strike=-1, max_strike=1, min_expiry=timedelta(days=0), maxExpiry=timedelta(days=30))

# Select call contracts
option.set_filter(lambda option_filter_universe: option_filter_universe.calls_only())
```

The following table describes the available filter techniques:

`set_filter(minStrike: int, maxStrike: int)` Selects the contracts that have a strike price within a minimum and maximum strike level relative to the underlying price. For example, say the underlying price is 302 and there are strikes at every 5. If you set `m_strike` to -1 and `max_strike` to 1, LEAN selects the contracts that have a strike of 300 or 305. This filter runs asynchronously by default.
`set_filter(minExpiry: timedelta, maxExpiry: timedelta)` Selects the contracts that expire within the range you set. This filter runs asynchronously by default.
`set_filter(minStrike: int, maxStrike: int, minExpiry: timedelta, maxExpiry: timedelta)` Selects the contracts that expire and have a strike within the range you set. This filter runs asynchronously by default.
`set_filter(universeFunc: Callable[[OptionFilterUniverse], OptionFilterUniverse])` Selects the contracts that a function selects.

The following table describes the filter methods of the `OptionFilterUniverse` class:

`strikes(min_strike: int, max_strike: int)` Selects contracts that are within `m_strike` strikes below the underlying price and `max_strike` strikes above the underlying price.
`calls_only()` Selects call contracts.
`puts_only()` Selects put contracts.
`standards_only()` Selects standard contracts.
`weeklys_only()` Selects weekly contracts.
`front_month()` Selects the front month contract.
`back_months()` Selects the non-front month contracts.
`back_month()` Selects the back month contracts.
`expiration(min_expiryDays: int, max_expiryDays: int)` Selects contracts that expire within a range of dates relative to the current day.
`contracts(contracts: list[Symbol])` Selects a list of contracts.
`contracts(contract_selector: Callable[[list[Symbol]], list[Symbol]])` Selects contracts that a selector function selects.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

```
# Example 1: Select the front month call contracts
option.set_filter(lambda option_filter_universe: option_filter_universe.calls_only().front_month())

# Example 2: Select the contracts (including weeklys) that expire in the next 90 days
option.set_filter(lambda option_filter_universe: option_filter_universe.strikes(-20, 20).expiration(0, 90))
```

Some of the preceding filter methods only set an internal enumeration in the `OptionFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `OptionFilterUniverse` .

Default Filter

By default, LEAN subscribes to the Option contracts that have the following characteristics:

- Standard and weeklys
- Within 1 strike price of the underlying asset price
- Expire within 35 days

To adjust the universe of contracts, set a filter. The filter usually runs at the first bar of every day. When the filter selects a contract that isn't currently in your universe, LEAN adds the new contract data to the next `Slice` that it passes to the `on_data` method.

Navigate Intraday Option Chains

`OptionChain` objects represent an entire chain of Option contracts for a single underlying security.

To get the `OptionChain` , index the `option_chains` property of the `Slice` with the canonical `symbol` . After you get the `OptionChain` , you can sort and filter the Option contracts in the chain.

```
PY
def on_data(self, slice: Slice) -> None:
    # Try to get the OptionChain using the canonical symbol
    chain = slice.option_chains.get(self._symbol)
    if chain:
        # Example: Find 5 put contracts that are closest to at-the-money (ATM) and have the farthest expiration
        contracts = [x for x in chain if x.right == OptionRight.PUT]
        contracts = sorted(sorted(contracts, \
            key = lambda x: abs(chain.underlying.price - x.strike)), \
            key = lambda x: x.expiry, reverse=True)[:5]

        # Select the contract with the delta closest to -0.5
        contract = sorted(contracts, key=lambda x: abs(-0.5 - x.greeks.delta))[0]
```

You can also loop through the `option_chains` property to get each `OptionChain` .

```
PY
def on_data(self, slice: Slice) -> None:
    # Iterate all received Canonical Symbol-OptionChain key-value pairs
    for canonical_symbol, chain in slice.option_chains.items():
        contracts = chain.contracts
```

`OptionChain` objects have the following properties:

Navigate Daily Option Chains

To get the daily, pre-calculated Greeks and implied volaility of all the currently tradable contracts, call the `option_chain` method. This method returns a `DataHistory[OptionUniverse]` object, which you can format into a DataFrame or iterate through. Each row in the DataFrame and each `OptionUniverse` object represents a single contract. The data this method returns contains information on all the currently tradable contracts, not just the contracts that pass your filter.

```
PY
# In the initialize method, create a Scheduled Event to get the Option
# chain and rebalance the portfolio.
self.schedule.on(
    self.date_rules.week_start(self._symbol),
    self.time_rules.after_market_open(self._symbol, 1),
    self._rebalance
  )

# Define the method.
def _rebalance(self):
    daily_option_chain = self.option_chain(self._symbol, flatten=True)

    # Get the DataFrame format.
    df = daily_option_chain.data_frame
    delta_by_symbol = df.delta

    # Get the OptionUniverse objects format.
    for option_universe in daily_option_chain:
        close = option_universe.close
        oi = option_universe.open_interest
        delta = option_universe.greeks.delta
```

The `option_chain` method was previously known as the `option_chain_provider.get_option_contract_list` method.

`OptionUniverse` objects have the following properties:

Greeks and Implied Volatility

There are several ways to get the implied volatility and Greeks of contracts.

The Greeks and IV values in the filter function are the daily, pre-calculated values based on the end of the previous trading day.

```
PY
def initialize(self):
    option = self.add_index_option("SPX")
    option.set_filter(lambda universe: universe.delta(0.3, 0.7).expiration(0,7))
```

To calculate the values, we use our implementation of the Black-Scholes pricing model, which accounts for the interest rate and dividend payments when applicable. For example, VIX doesn't have dividends. We use SPY for SPX and QQQ for NDX.

You can't customize the Greeks and IV values that the filter function receives. However, you can create indicators to customize how the Greeks and IV are calculated for the contracts already in your universe.

To override the default pricing model of the Option, set a pricing model . If you set a price model, it sets the price model of the individual contracts in the universe.

```
PY
// Set price_model field to use the Binomial Cox-Ross-Rubinstein model to price the Options.
option.price_model = OptionPriceModels.binomial_cox_ross_rubinstein()
```

To override the initial guess of implied volatility , set and warm up the underlying volatility model .

Historical Data

To get historical chains for an Index Option, call the `history[OptionUniverse]` method with the canonical Option `Symbol` . This method returns the entire Option chain for each trading day, not the subset of contracts that pass your universe filter.

```
PY
class OptionHistoryAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        option = self.add_index_option('SPX');
        # DataFrame example:
        history_df = self.history(option.symbol, 5, flatten=True)
        # OptionUniverse objects example:
        history = self.history[OptionUniverse](option.symbol, 5)
        for chain in history:
            end_time = chain.end_time
            filtered_contracts = [c for c in chain if c.greeks.delta > 0.3]
            for contract in filtered_contracts:
                symbol = contract.symbol
                expiry = contract.id.date
                strike = contract.id.strike_price
                price = contract.close
                iv = contract.implied_volatility
```

The Greeks and IV values that you get from a history request of the Option universe are the daily, pre-calculated values based on the end of the previous trading day. To get the intraday values or to customize the Greeks and IV calculations, create some Option indicators .

The method represents each contract with an `OptionUniverse` object, which have the following properties:

Selection Frequency

By default, Index Option universes run at the first time step of each day to select their contracts.

Examples

The following examples demonstrate some common Index Option universes.

Example 1: 0DTE Contracts

0DTE Options are Option contracts that expire on the same day you trade them. The following algorithm selects 0DTE Option contracts for the SPX Index that fall within 3 strikes of the underlying price.

```py
class ZeroDTEIndexOptionUniverseAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        index = self.add_index('SPX')
        index_option = self.add_index_option(index.symbol, 'SPXW')
        index_option.set_filter(lambda u: u.expiration(0, 0).strikes(-3, 3))
```

For trading full examples of Index Option Universe, please refer to the Securities > Index Options > Requesting Data > Universes page.

Universes

Crypto

Introduction

A Crypto universe lets you select a basket of Cryptocurrencies based on `CryptoUniverse` data.

Crypto Universes

To add a universe of Cryptocurrencies, in the `initialize` method, pass a `CryptoUniverse` to the `add_universe` method.

```py
def initialize(self) -> None:
    self.universe_settings.asynchronous = True
    self.universe_settings.resolution = Resolution.DAILY
    self.set_brokerage_model(BrokerageName.COINBASE, AccountType.CASH)

    # Add crypto universe selection
    self._universe = self.add_universe(CryptoUniverse.coinbase(lambda universe_day: [c.symbol for c in universe_day]))
```

The following table shows the helper methods to create Crypto universes for the supported exchanges:

Brokerage Name	Helper Method	Example
`BrokerageName.BINANCE`	`CryptoUniverse.binance`	Example
`BrokerageName.BINANCE_US`	`CryptoUniverse.binance_us`	Example
`BrokerageName.BITFINEX`	`CryptoUniverse.bitfinex`	Example
`BrokerageName.BYBIT`	`CryptoUniverse.bybit`	Example
`BrokerageName.COINBASE`	`CryptoUniverse.coinbase`	Example
`BrokerageName.KRAKEN`	`CryptoUniverse.kraken`	Example

The following table describes the `CryptoUniverse` method arguments:

Argument	Data Type	Description	Default Value
`selector`	`Callable[[List[CryptoUniverse]], List[Symbol]]`	A function to select some of the Cryptocurrencies for the universe.	
`universe_settings`	`UniverseSettings`	The universe settings .	`None`

The filter function receives `CryptoUniverse` objects, which represent one of the Cryptocurrencies in the market. The `Symbol` objects that the filter function returns represent the universe constituents. `CryptoUniverse` objects have the following attributes:

To perform thorough filtering on the `CryptoUniverse` objects, define an isolated filter method.

```py
def initialize(self) -> None:
    self.universe_settings.asynchronous = True
    self.universe_settings.resolution = Resolution.DAILY
    self.set_brokerage_model(BrokerageName.COINBASE, AccountType.CASH)

    # Add crypto universe selection
    self._universe = self.add_universe(CryptoUniverse.coinbase(self._universe_filter))

def _universe_filter(self, universe_day):
    # Define the universe selection function
    return [cf.symbol for cf in universe_day if cf.volume >= 100 and cf.volume_in_usd > 10000]
```

Historical Data

To get historical Cryptocurrency universe data, call the `history` method with the `Universe` object and the lookback period. The return type is a multi-index `pandas.Series` or `pandas.DataFrame` containing `CryptoUniverse` data.

```
PY
# Get 30 days of history for the Crypto universe.
# DataFrame object:
df_history = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series object:
series_history = self.history(self._universe, 30, Resolution.DAILY)
for (univere_symbol, time), universe_day in history.items():
    for universe_item in universe_day:
        self.log(f"{universe_item.symbol} price at {universe_item.end_time}: {universe_item.close}")
```

For more information about Cryptocurrency data, see Crypto .

Alternative Data Universes

An alternative data universe lets you select a basket of Cryptocurrencies based on an alternative dataset that's linked to them. If you use an alternative data universe, you limit your universe to only the securities in the dataset, which avoids unnecessary subscriptions. Currently, only the Crypto Market Cap alternative dataset supports universe selection for Crypto.

Selection Frequency

Crypto universes run on a daily basis by default. To adjust the selection schedule, see Schedule .

Live Trading Considerations

In live mode, the pipeline has a 16-hour delay. Your algorithm receives the `CryptoUniverse` objects at around 16:00-16:30 Coordinated Universal Time (UTC) each day, depending on the data processing task.

Examples

The following examples demonstrate some common Crypto universes.

Example 1: Highly Liquid Crypto Universe

To fairly compare the liquidity between Crypto pairs, use the `volume_in_usd` property of the `CryptoUniverse` objects during universe selection. The following algorithm selects the 10 Crypto pairs with the greatest USD volume on Bitfinex:

```
PY
class HighlyLiquidCryptoUniverseAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.add_universe(CryptoUniverse.bitfinex(self._select_assets))

    def _select_assets(self, data):
        selected = sorted(
            [x for x in data if x.volume_in_usd],
            key=lambda x: x.volume_in_usd
        )[-10:]
        return [x.symbol for x in selected]
```

Example 2: Highly Volatile Crypto Universe

The following algorithm creates a universe of volatile Crypto pairs on Binance by selecting the pairs with the largest trading range in the previous day:

```
class HighlyVolatileCryptoUniverseAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.add_universe(CryptoUniverse.binance(self._select_assets))

    def _select_assets(self, data):
        selected = sorted(data, key=lambda x: (x.high - x.low) / x.low)[-10:]
        return [x.symbol for x in selected]
```

Example 3: Large Cap Crypto Universe

The following algorithm uses the CoinGecko Crypto Market Cap dataset to create a universe of the largest Crypto pairs on Coinbase. To avoid trading errors, it only selects pairs that have a quote currency that matches your account currency . At noon each day, it rebalances the portfolio to give equal weight to each coin in the universe.

```
class LargeCapCryptoUniverseAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Set the account currency. USD is already the default value. Change it here if you want.
        self.set_account_currency("USD")
        # Get the pairs that our brokerage supports and have a quote currency that
        # matches your account currency. We need this list in the universe selection function.
        self._market = Market.COINBASE
        self._market_pairs = [
            x.key.symbol
            for x in self.symbol_properties_database.get_symbol_properties_list(self._market)
            if x.value.quote_currency == self.account_currency
        ]
        # Add a universe of Cryptocurrencies.
        self._universe = self.add_universe(CoinGeckoUniverse, 'CoinGeckoUniverse', Resolution.HOUR, self._select_assets)
        # Add a Sheduled Event to rebalance the portfolio.
        self.schedule.on(self.date_rules.every_day(), self.time_rules.at(12, 0), self._rebalance)

    def _select_assets(self, data: List[CoinGecko]) -> List[Symbol]:
        # Select the coins that our brokerage supports and have a quote currency that matches
        # our account currency.
        tradable_coins = [d for d in data if d.coin + self.account_currency in self._market_pairs]
        # Select the largest coins and create their Symbol objects.
        return [
            c.create_symbol(self._market, self.account_currency)
            for c in sorted(tradable_coins, key=lambda x: x.market_cap)[-10:]
        ]

    def _rebalance(self):
        if not self._universe.selected:
            return
        symbols = [symbol for symbol in self._universe.selected if self.securities[symbol].price]
        # Liquidate coins that are no longer in the universe.
        targets = [PortfolioTarget(symbol, 0) for symbol, holding in self.portfolio.items() if holding.invested and symbol not in
symbols]
        # Form an equal weighted portfolio of the coins in the universe.
        targets += [PortfolioTarget(symbol, 0.5/len(symbols)) for symbol in symbols]
        # Place orders to rebalance the portfolio.
        self.set_holdings(targets)
```

Example 4: Indicator Universe

The following example shows how to select a universe of Crypto pairs based on indicators.

PY

```
class CryptoIndicatorUniverseSelectionAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add a universe of Crypto pairs based on indicators.
        self._selection_data_by_symbol = {}
        self._universe = self.add_universe(CryptoUniverse.coinbase(self._select_assets))
        # Add a warm-up period to warm up the indicators in the universe selection.
        self.set_warm_up(timedelta(60))

    def _select_assets(self, data):
        # Update the indicator of all Crypto pairs in the universe dataset and
        # get the subset of them that have their indicator ready.
        ready_pairs = [
            c for c in data
            if self._selection_data_by_symbol.setdefault(c.symbol, SelectionData()).update(c)
        ]
        # As Crypto pairs leave the universe dataset, delete their SelectionData objects.
        for symbol in self._selection_data_by_symbol.keys() - {c.symbol for c in data}:
            del self._selection_data_by_symbol[symbol]
        # During warm-up, keep the universe empty.
        if self.is_warming_up:
            return []
        # Select a subset of the Crypto pairs based on their indicators.
        # Example: Pairs trading above their bollinger band with high volume.
        filtered = []
        for c in ready_pairs:
            selection_data = self._selection_data_by_symbol[c.symbol]
            if c.close > selection_data.bb.upper_band.current.value:
                filtered.append(c)
        filtered = sorted(filtered, key=lambda c: self._selection_data_by_symbol[c.symbol].mean_daily_usd_volume)[-10:]
        return [c.symbol for c in filtered]

class SelectionData:

    def __init__(self):
        self.mean_daily_usd_volume = SimpleMovingAverage(30)
        self.bb = BollingerBands(30, 2)

    def update(self, c):
        # Update all the indicators and return true if they are all ready.
        return (
            self.mean_daily_usd_volume.update(c.end_time, c.volume_in_usd) &
            self.bb.update(TradeBar(c.end_time, c.symbol, c.open, c.high, c.low, c.close, c.volume_in_usd))
        )
```

Universes

Custom Universes

Introduction

A custom universe lets you select a basket of assets from a custom dataset.

Data Sources

You can gather your custom data from any of the following sources:

The data source should serve data in chronological order and each data point should have a unique timestamp. Each request has a 1 second overhead, so bundle samples together for fast execution.

Define Custom Universe Types

Custom universes should extend the `PythonData` class. Extensions of the `PythonData` class must implement a `get_source` and `reader` method.

The `get_source` method in your custom data class instructs LEAN where to find the data. This method must return a `SubscriptionDataSource` object, which contains the data location and format (`SubscriptionTransportMedium`). You can even change source locations for backtesting and live modes. We support many different data sources.

The `reader` method of your custom data class takes one line of data from the source location and parses it into one of your custom objects. You can add as many properties to your custom data objects as you need, but must set `symbol` and `end_time` properties. When there is no useable data in a line, the method should return `None` . LEAN repeatedly calls the `reader` method until the date/time advances or it reaches the end of the file.

```py
# Example custom universe data; it is virtually identical to other custom data types.
class MyCustomUniverseDataClass(PythonData):

    def get_source(self, config: SubscriptionDataConfig, date: datetime, is_live_mode: bool) -> SubscriptionDataSource:
        return SubscriptionDataSource(@"your-remote-universe-data", SubscriptionTransportMedium.REMOTE_FILE)

    def reader(self, config: SubscriptionDataConfig, line: str, date: datetime, is_live_mode: bool) -> BaseData:
        items = line.split(",")

        # Generate required data, then return an instance of your class.
        data = MyCustomUniverseDataClass()
        data.end_time = datetime.strptime(items[0], "%Y-%m-%d")
        # define Time as exactly 1 day earlier Time
        data.time = data.end_time - timedelta(1)
        data.symbol = Symbol.create(items[1], SecurityType.CRYPTO, Market.BITFINEX)
        data["CustomAttribute1"] = int(items[2])
        data["CustomAttribute2"] = float(items[3])
        return data
```

Your `reader` method should return objects in chronological order. If an object has a timestamp that is the same or earlier than the timestamp of the previous object, LEAN ignores it.

If you need to create multiple objects in your `reader` method from a single `line` , follow these steps:

1. In the `get_source` method, pass `FileFormat.UNFOLDING_COLLECTION` as the third argument to the `SubscriptionDataSource` constructor.
2. In the `reader` method, order the objects by their timestamp and then return a `BaseDataCollection(end_time, config.symbol, objects)` where `objects` is a list of your custom data objects.

```py
class MyCustomUniverseDataClass(PythonData):

    def get_source(self, config, date, isLive):
        return SubscriptionDataSource("your-data-source-url", SubscriptionTransportMedium.REMOTE_FILE, FileFormat.UNFOLDING_COLLECTION)

    def reader(self, config, line, date, isLive):
        json_response = json.loads(line)

        end_time = datetime.strptime(json_response[-1]["date"], '%Y-%m-%d') + timedelta(1)

        data = list()

        for json_datum in json_response:
            datum = MyCustomUniverseDataClass()
            datum.symbol = Symbol.create(json_datum["Ticker"], SecurityType.EQUITY, Market.USA)
            datum.time = datetime.strptime(json_datum["date"], '%Y-%m-%d')
            datum.end_time = datum.time + timedelta(1)
            datum['CustomAttribute1'] = int(json_datum['Attr1'])
            datum.value = float(json_datum['Attr1'])
            data.append(datum)

        return BaseDataCollection(end_time, config.symbol, data)
```

Initialize Custom Universes

To add a custom universe to your algorithm, in the `initialize` method, pass your universe type and a selector function to the `add_universe` method. The selector function receives a list of your custom objects and must return a list of `Symbol` objects. In the selector function definition, you can use any of the properties of your custom data type. The `Symbol` objects that you return from the selector function set the constituents of the universe.

```py
# In Initialize
self._universe = self.add_universe(MyCustomUniverseDataClass, "myCustomUniverse", Resolution.DAILY, self.selector_function)

# Define the selector function
def selector_function(self, data: list[MyCustomUniverseDataClass]) -> list[Symbol]:
    sorted_data = sorted([ x for x in data if x["CustomAttribute1"] > 0 ],
                         key=lambda x: x["CustomAttribute2"],
                         reverse=True)
    return [x.symbol for x in sorted_data[:5]]
```

Historical Data

To get historical custom universe data, call the `history` method with the `Universe` object and the lookback period. The return type is a `pandas.DataFrame` where the columns contain the custom type attributes.

```py
# DataFrame where teh columns are the universe attributes:
history_df = self.history(self._universe, 30, flatten=True)

# Series where the values are lists of universe objects:
history_series = self.history(self._universe, 30)
for time, data in history_series.iterrows():
    for single_stock_data in data:
        self.log(f"{single_stock_data.symbol} CustomAttribute1 at {single_stock_data.end_time}: {single_stock_data['CustomAttribute1']}")
```

Selection Frequency

Custom universes run on a schedule based on the `end_time` of your custom data objects. To adjust the selection schedule, see Schedule .

Examples

The following examples demonstrate some common practices for Custom Universe.

Example 1: Sourcing from the Object Store

This project demonstrates how to read custom data from the Object Store , and then use it to define a universe and place trades. The following research environment file generates the demo universe data, which contains a daily set of assets and their respective signals:

```
# Set a random seed to ensure reproducibility.
import random
np.random.seed(0)
# Select the asset weights for each trading day.
indices = [[x] * 3 for x in pd.bdate_range('2015-01-01', '2024-12-31')]
weights = list(np.random.dirichlet((10, 5, 3), size=(len(indices),)).flatten())
# Select the universe for each trading day.
equities = []
for i in range(len(indices)):
    random.seed(i)
    equities.extend(list(random.sample(["SPY", "TLT", "GLD", "USO", "IWM"], 3)))
# Organize the data into a DataFrame.
df = pd.DataFrame({"Date": [x for y in indices for x in y], "Symbol": equities, "Weight": weights})
# Save the DataFrame as a CSV in the Object Store.
df.to_csv(QuantBook().object_store.get_file_path("portfolio-targets.csv"), index=False)
```

The following algorithm file reads the preceding CSV file from the Object Store and uses its contents to form the daily universe and place trades:

```
class CustomUniverseExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add a universe that reads from the Object Store.
        self._universe = self.add_universe(
            CustomUniverseData, "CustomUniverse", Resolution.DAILY, self._selector_function
        )
        # Add a Scheduled Event to rebalance the portfolio.
        spy = Symbol.create('SPY', SecurityType.EQUITY, Market.USA)
        self.schedule.on(
            self.date_rules.every_day(spy),
            self.time_rules.after_market_open(spy, 1),
            lambda: self.set_holdings(
                [PortfolioTarget(symbol, self._weight_by_symbol[symbol]) for symbol in self._universe.selected],
                liquidate_existing_holdings=True
            )
        )

    def _selector_function(self, alt_coarse: List[PythonData]) -> List[Symbol]:
        # Select the symbols that have a significant weight in the custom universe data to avoid
        # small-size trades that erode returns. Save the weight to use during the rebalance.
        self._weight_by_symbol = {d.symbol: d.weight for d in alt_coarse if d["weight"] > 0.05}
        return list(self._weight_by_symbol.keys())

class CustomUniverseData(PythonData):

    def get_source(self, config: SubscriptionDataConfig, date: datetime, is_live_mode: bool) -> SubscriptionDataSource:
        # Define the location and format of the data file.
        return SubscriptionDataSource(
            "portfolio-targets.csv", SubscriptionTransportMedium.OBJECT_STORE, FileFormat.CSV
        )

    def reader(self, config: SubscriptionDataConfig, line: str, date: datetime, is_live_mode: bool) -> BaseData:
        # Skip the header row.
        if not line[0].isnumeric():
            return None
        # Split the line by each comma.
        items = line.split(",")
        # Parse the data from the CSV file.
        data = CustomUniverseData()
        data.end_time = datetime.strptime(items[0], "%Y-%m-%d")
        data.time = data.end_time - timedelta(1)
        data.symbol = Symbol.create(items[1], SecurityType.EQUITY, Market.USA)
        data["weight"] = float(items[2])
        return data
```

Universes

Dataless Scheduled Universes

Introduction

A dataless scheduled universe let's you select a set of assets on a specific schedule. You can control which days the other types of universe run by adjusting the Schedule universe setting . However, the `schedule` universe setting doesn't accept a `TimeRule` argument, so you can't control the time of the day they run. In contrast, a dataless scheduled universe accepts a `TimeRule` argument, but its selection function only receives the algorithm time.

Create Universes

To add a dataless scheduled universe, in the `initialize` method, call the `add_universe` method with a `ScheduledUniverse` object.

```
PY
class MyUniverseAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.universe_settings.asynchronous = True
        self._universe = self.add_universe(
            ScheduledUniverse(
                self.date_rules.month_start(),
                self.time_rules.at(8, 0),
                self._select_symbols
            )
        )

    def _select_symbols(self, dt):
        return [Symbol.create("SPY", SecurityType.EQUITY, Market.USA)]
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`date_rule`	`IDateRule`	Date rule that defines what days the universe selection function runs	
`time_rule`	`ITimeRule`	Time rule that defines what times on each day selected by date rule the universe selection function runs	
`Callable[[datetime], List[Symbol]]`	`selector`	Selector function that accepts the current date time and returns the universe's `Symbol` objects	
`settings`	`UniverseSettings`	The universe settings . If you don't provide an argument, the model uses the `algorithm.universe_settings` by default.	`None`

Date Rules

The following table describes the supported `DateRules` :

Member	Description
`self.date_rules.set_default_time_zone(time_zone: DateTimeZone)`	Sets the time zone for the `DateRules` object used in all methods in this table. The default time zone is the algorithm time zone .
`self.date_rules.on(year: int, month: int, day: int)`	Trigger an event on a specific date.
`self.date_rules.on(dates: list[datetime])`	Trigger an event on specific dates.
`self.date_rules.every_day()`	Trigger an event all seven days of the week.
`self.date_rules.every_day(symbol: Symbol, extended_market_hours: bool = False)`	Trigger an event every day a specific symbol is trading.
`self.date_rules.every(days: list[DayOfWeek])`	Trigger an event on specific days throughout the week. To view the `DayOfWeek` enum members, see DayOfWeek Enum in the .NET documentation.
`self.date_rules.month_start(days_offset: int = 0)`	Trigger an event on the first day of each month plus an offset.
`self.date_rules.month_start(symbol: Symbol, daysOffset: int = 0)`	Trigger an event on the first tradable date of each month for a specific symbol plus an offset.
`self.date_rules.month_end(days_offset: int = 0)`	Trigger an event on the last day of each month minus an offset.
`self.date_rules.month_end(symbol: Symbol, daysOffset: int = 0)`	Trigger an event on the last tradable date of each month for a specific symbol minus an offset.
`self.date_rules.week_start(days_offset: int = 0)`	Trigger an event on the first day of each week plus an offset.
`self.date_rules.week_start(symbol: Symbol, days_offset: int = 0)`	Trigger an event on the first tradable date of each week for a specific symbol plus an offset.
`self.date_rules.week_end(days_offset: int = 0)`	Trigger an event on the last day of each week minus an offset.
`self.date_rules.week_end(symbol: Symbol, days_offset: int = 0)`	Trigger an event on the last tradable date of each week for a specific symbol minus an offset.
`self.date_rules.year_start(days_offset: int = 0)`	Trigger an event on the first day of each year plus an offset.
`self.date_rules.year_start(symbol: Symbol, days_offset: int = 0)`	Trigger an event on the first tradable date of each year for a specific symbol plus an offset.
`self.date_rules.year_end(days_offset: int = 0)`	Trigger an event on the last day of each year minus an offset.
`self.date_rules.year_end(symbol: Symbol, days_offset: int = 0)`	Trigger an event on the last tradable date of each year for a specific symbol minus an offset.
`self.date_rules.today`	Trigger an event once today.
`self.date_rules.tomorrow`	Trigger an event once tomorrow.

To define custom date rules, create a `FuncDateRule` object. The `FuncDateRule` constructor expects a `name` argument of type `str` and a `get_dates_function` argument of type `Callable[[datetime, datetime], list[datetime]]` . The `get_dates_function` function receives the start and end dates of the algorithm and returns a list of dates for the date rule. In live trading, the end date is 12/31/2025. The following example demonstrates how to define a date rule that represents the 10th day of each month:

```py
# Create a date rule that specifies the 10th day of each month.
date_rule = FuncDateRule(
    name="10th_day_of_the_month",
    get_dates_function=lambda start, end: [
        datetime(year, month, 10)
        for year in range(start.year, end.year) for month in range(1,12)
    ]
)
```

Some date rules require a Symbol. However, they accept a string representation of the Symbol as well. If your algorithm doesn't add the security , it assumes the string refers to a US Equity Symbol. For example, if you use the `self.date_rules.every_day('ES')` method, it assumes that 'ES' refers to a US Equity. To create a Symbol without adding a security to your algorithm, call the `Symbol.create` method.

```
symbol = Symbol.create('ES', SecurityType.FUTURE, Market.CME)
```

Time Rules

The following table describes the supported `TimeRules` :

Member	Description
`self.time_rules.set_default_time_zone(time_zone: DateTimeZone)`	Sets the time zone for the `TimeRules` object used in all methods in this table, except when a different time zone is given. The default time zone is the algorithm time zone .
`self.time_rules.before_market_open(symbol: Symbol, minutes_before_open: float = 0, extended_market_open: bool = False)`	Trigger an event a few minutes before market open for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`self.time_rules.after_market_open(symbol: Symbol, minutes_after_open: float = 0, extended_market_open: bool = False)`	Trigger an event a few minutes after market open for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`self.time_rules.before_market_close(symbol: Symbol, minutes_before_close: float = 0, extended_market_open: bool = False)`	Trigger an event a few minutes before market close for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`self.time_rules.after_market_close(symbol: Symbol, minutes_after_close: float = 0, extended_market_open: bool = False)`	Trigger an event a few minutes after market close for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`self.time_rules.every(interval: timedelta)`	Trigger an event every period interval starting at midnight. This time rule triggers every period, regardless of whether or not the market is open.
`self.time_rules.now`	Trigger an event at the current time of day.
`self.time_rules.midnight`	Trigger an event at midnight.
`self.time_rules.noon`	Trigger an event at noon.
`self.time_rules.at(hour: int, minute: int, second: int = 0)`	Trigger an event at a specific time of day (e.g. 13:10).
`self.time_rules.at(hour: int, minute: int, second: int, time_zone: DateTimeZone)`	Trigger an event at a specific time of day in the given time zone (e.g. 13:10 UTC).

To define custom time rules, create a `FuncTimeRule` object. The `FuncTimeRule` constructor expects a `name` argument of type `str` and a `create_utc_event_times_function` argument of type `Callable[[list[datetime]], list[datetime]]` . The function receives the list of dates from the date rule and then returns a list of `datetime` that define the time rule.

```
time_rule = FuncTimeRule(
    name="CustomTimeRule",
    create_utc_event_times_function=lambda dates: [d + timedelta(hours=10) for d in dates]
)
```

Some time rules require a Symbol. However, they accept a string representation of the Symbol as well. If your algorithm doesn't add the security , it assumes the string refers to a US Equity Symbol. For example, if you use the `self.time_rules.before_market_open('ES', 15)` method, it assumes that 'ES' refers to a US Equity. To create a Symbol without adding a security to your algorithm, call the `Symbol.create` method.

```
symbol = Symbol.create('ES', SecurityType.FUTURE, Market.CME)
```

Selection Frequency

Dataless scheduled universes run at whatever selection schedule you define by the `date_rule` and `time_rule` arguments.

Examples

The following examples demonstrate some common practices for dataless scheduled universes.

Example 1: Download External Universe Files

The following algorithm downloads a CSV file from Dropbox. The first column in the file contains the universe date. The second column in the file contains a list of Equity tickers that represents the universe for the day. The dataless scheduled universe parses the file contents each trading day and adds the universe constituents.

```py
from io import StringIO

class DatalessScheduledUniverseExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Download the initial universe file.
        self._download_universe_file()
        # Add the custom universe.
        self.universe_settings.extended_market_hours = True
        spy = Symbol.create('SPY', SecurityType.EQUITY, Market.USA)
        date_rule = self.date_rules.every_day(spy)
        self._universe = self.add_universe(
            ScheduledUniverse(date_rule, self.time_rules.at(8, 0), self._select_assets)
        )
        # Schedule rebalances for market open.
        self.schedule.on(date_rule, self.time_rules.after_market_open(spy, 0), self._rebalance)

    def _download_universe_file(self):
        # Download the universe CSV file. Dropbox links require the "dl=1" URL parameter.
        file = self.download(
            "https://www.dropbox.com/scl/fi/fbrxitk4ec3w91nse1raa/df.csv?rlkey=7r042rukzkthp7y1srloyhkov&st=5r4sdfwd&dl=1"
        )
        # Convert the CSV file data into a dictionary where the key is the date and
        # the value is a comma-separated string of stock tickers.
        df = pd.read_csv(StringIO(file), index_col=0).iloc[:, 0]
        df.index = pd.to_datetime(df.index).date
        self._tickers_by_date = df.to_dict()

    def _select_assets(self, dt: datetime) -> List[Symbol]:
        # When live trading, re-download the CSV file each day to get the new rows.
        if self.live_mode:
            self._download_universe_file()
        # Get the current day's data from the CSV file.
        data = self._tickers_by_date.get(dt.date(), '')
        # If there isn't an entry for the current date, return an empty universe.
        if not data:
            return []
        # Convert the stock tickers in the CSV file to Symbol objects.
        return [Symbol.create(x, SecurityType.EQUITY, Market.USA) for x in data.split(",")]

    def _rebalance(self) -> None:
        # Form an equal-weighted portfolio of all the universe constituents.
        symbols = list(self._universe.selected)
        weight = 1 / len(symbols)
        self.set_holdings([PortfolioTarget(symbol, weight) for symbol in symbols], liquidate_existing_holdings=True)
```

Example 2: Quarter End Selection

The following algorithm selects SPY on the last month of each quarter. For the remaining months, it selects no assets.

```
class DatalessScheduledUniverseDemoAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.add_universe(
            ScheduledUniverse(
                self.date_rules.month_start(),
                self.time_rules.at(8, 0),
                self._select_assets
            )
        )

    def _select_assets(self, dt: datetime) -> List[Symbol]:
        if dt.month % 3 == 0:
            return [Symbol.create("SPY", SecurityType.EQUITY, Market.USA)]
        return []
```

Example 3: Third Week VIX

Standard Options expire at end of the third week of each month. The following algorithm selects VIX-related products on the third week to trade the foreseeable increase in volatility.

```
class DatalessScheduledUniverseDemoAlgorithm(QCAlgorithm):

    def initialize(self):
        self._month = -1
        self._week = -1
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.add_universe(
            ScheduledUniverse(
                self.date_rules.week_start(),
                self.time_rules.at(8, 0),
                self._select_assets
            )
        )

    def _select_assets(self, dt: datetime) -> List[Symbol]:
        if dt.month == self._month:
            self._week += 1
            if self._week == 3:
                return [Symbol.create("VXZ", SecurityType.EQUITY, Market.USA)]
            return []

        self._month = dt.month
        self._week = 0
        return []
```

Datasets

Datasets

Overview

Introduction

It's common to use price and fundamental data points to inform trading decisions. Alternative datasets are datasets that aren't classified as market or fundamental data. Alternative data research began gaining popularity in 2007 after the financial crisis and its usage has continued to grow over the years. As usage has grown, so has the number of unique alternative datasets that are available for investors. The benefit of alternative datasets is that it's easier to find alpha in these datasets because they receive less attention from investment researchers and these datasets contain information not found in market and fundamental datasets. Most traders research with market and fundamental datasets, so it's difficult to find alpha in them.

Methodology

The journey of raw data from its source to its integration with a trading platform can be complex. Alternative data is generally created through individuals, business processes, and sensors. Individuals create content on social media platforms, write reviews on e-commerce sites, and visit corporate Wikipedia pages. Businesses process transactions, file SEC reports, and issue company announcements. Sensors collect location data, gather satellite images, and monitor customer behavior.

Data providers can capture these forms of data for traders to inform trading decisions in ways that supplement traditional market and fundamental datasets. With over a million terabytes of data on the internet, there is virtually a limitless amount of information that can be informative for investors when analyzing a security's performance in the marketplace.

Examples

A common example of alternative data in a trading system is using sentiment analysis on news sources to predict the future price movements of Equities. A second example is using announcements regarding corporate share buyback programs to trading Equities. A third example is using global supply and demand information for US Crude Products to inform Futures trades. To view all of the datasets we have available, see the left navigation menu.

Challenges

A challenge of working with datasets is that it can be difficult to find a reliable, high-quality, and inexpensive data source to use in live algorithms. If a data source has survivorship bias, insufficient history, or hasn't been cleaned and processed properly, the data can cause poor trading performance. We thoroughly vet the datasets we add to the Dataset Market to ensure they are free of survivorship bias and have a reliable live feed. All of the available datasets have already been cleaned and processed, so you can just focus on the strategy research and development.

Future Outlook

The Dataset Market is still in the early phases of development. Over time, we will add more markets and alternative datasets. Alternative datasets are an ever-expanding data source, so it's expected to continue to grow into the future. In today's digital world, more data is created each year than in the previous year. To take advantage of the trend, we have implemented a new onboarding process to integrate many new alternative data sources into the QuantConnect platform. With the Dataset Market, you can import a new alternative dataset into your trading algorithm with just a single line of code. The Dataset Market gives everyone the ability to access high-quality alternative datasets that were previously only accessible to major hedge funds.

Live Trading Considerations

We receive most daily alternative data at 7 AM Eastern Time (ET) and start processing it. In live trading, your algorithm receives this data within 30 minutes of 7 AM ET. In backtesting, this data has a timestamp of midnight, so your algorithm receives it about seven hours earlier than it does in live mode.

In backtests, your algorithm receives data at perfect timing. If you request minute resolution data, your algorithm receives the bars at the top of each minute. In live trading, bars have a slight delay, so you may receive them milliseconds after the top of each minute.

Note that there will be delay for data available to be backtested. Live feed data is available for backtesting after 24-48 hours normally. Consider using Paper live trading if close monitoring is needed.

Datasets

QuantConnect

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Binance Crypto Future Margin Rate Data

Introduction

The Binance Crypto Future Margin Rate Data by QuantConnect is for crypto-currency futures margin interest data points. The data covers 718 Cryptocurrency pairs, starts in August 2020, and is delivered on a daily update frequency. This dataset is created by downloading data using Binance API.

This dataset is an important companion to the Binance Crypto Future Price Data dataset because it contains information on margin interest data to model margin costs.

For more information about the Binance Crypto Future Margin Rate Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the Binance Crypto Future Margin Rate dataset:

```
def initialize(self) -> None:
    self.set_brokerage_model(BrokerageName.BINANCE_FUTURES, AccountType.MARGIN)
    #self.set_brokerage_model(BrokerageName.BINANCE_COIN_FUTURES, AccountType.MARGIN)

    self.crypto_future_symbol = self.add_crypto_future("BTCBUSD", Resolution.MINUTE).symbol
```

The Binance Crypto Future Margin Rate data is added to your algorithm along with the market data when you add a crypto future subscription.

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	August 2020
Asset Coverage	718 Crypto Futures Pairs
Data Density	Regular
Resolution	Daily
Timezone	UTC
Market Hours	Always Open

Requesting Data

To add Binance Crypto Future Margin Rate data to your algorithm, call the `add_crypto_future` method. Save a reference to the Crypto Future `Symbol` so you can access the data later in your algorithm.

```py
class CoinAPIDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2020, 6, 1)
        self.set_end_date(2021, 6, 1)

        # Set Account Currency to Binance Stable Coin for USD
        self.set_account_currency("BUSD")
        self.set_cash(100000)

        self.set_brokerage_model(BrokerageName.BINANCE_FUTURES, AccountType.MARGIN)
        self.set_brokerage_model(BrokerageName.BINANCE_COIN_FUTURES, AccountType.MARGIN)

        crypto_future = self.add_crypto_future("BTCBUSD", Resolution.MINUTE)
        # perpetual futures does not have a filter function
        self.btcbusd = crypto_future.symbol
```

For more information about creating Crypto Future subscriptions, see Requesting Data .

Accessing Data

To get the current Binance Crypto Margin Rate data, index the `margin_interest_rates` property of the current `Slice` with the Crypto Future `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```py
def on_data(self, slice: Slice) -> None:
    if self.btcbusd in slice.margin_interest_rates:
        interest_rate = slice.margin_interest_rates[self.btcbusd].interest_rate
        self.log(f"{self.btcbusd} close at {slice.time}: {interest_rate}")
```

You can also iterate through all of the data objects in the current `Slice` .

```py
def on_data(self, slice: Slice) -> None:
    for symbol, margin_interest_rate in slice.margin_interest_rates.items():
        interest_rate = margin_interest_rate.interest_rate
        self.log(f"{symbol} close at {slice.time}: {interest_rate}")
```

For more information about accessing Crypto Future data, see Handling Data .

Historical Data

To get historical Binance Crypto Future Margin Rate data, call the `history` method with `MarginInterestRate` data type and the Crypto Future `Symbol` . If there is no data in the period you request, the history result is empty.

```py
# DataFrame
history_df = self.history(MarginInterestRate, self.btcbusd, 100, Resolution.DAILY)

# MarginInterestRate objects
history = self.history[MarginInterestRate](self.btcbusd, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To unsubscribe from a Crypto pair that you added with the `add_crypto` method, call the `remove_security` method.

```py
self.remove_security(self.btcbusd)
```

The `remove_security` method cancels your open orders for the security and liquidates your holdings in the virtual pair .

Supported Assets

The following table shows the available Crypto Future pairs:

Pairs Available (718)					
0GUSDT	1000000BOBUSDT	1000000MOGUSDT	1000BONKUSDC	1000BONKUSDT	1000CATUSDT

Example Applications

The Binance Crypto Future Margin Rate dataset enables correct margin cost so you can accurately design strategies for Cryptocurrencies with term structure. Examples include the following strategies:

- Horizontal/Diagonal arbitrage with the underlying cryptocurrencies
- Trade Contango/Backwardation predictions
- Hedge for illiquid cryptocurrencies

Classic Algorithm Example

The following example algorithm holds a long position in the BTCUSDT perpetual Future contract on the Binance exchange. When the margin interest rate is relatively low, it flips to a short position.

```py
from AlgorithmImports import *

class BinanceCryptoFutureDataAlgorithm(QCAlgorithm):

    # Add an indicator to track the low of trailing margin interest rates.
    _low_interest_rate = Minimum(10)

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Set Account Currency to USDT, since USD cannot be used to trade.
        self.set_cash("USDT", 100_000)
        # Binance Futures Exchange accepts both Cash and Margin account types, select the one you need for the best reality modeling.
        self.set_brokerage_model(BrokerageName.BINANCE_FUTURES, AccountType.MARGIN)
        # Requesting data, we only trade on BTCUSDT Future in Binance Future exchange
        # Perpetual futures does not have a filter function.
        self._future = self.add_crypto_future("BTCUSDT", Resolution.DAILY)
        # Historical data
        history = self.history[MarginInterestRate](self._future.symbol, 10, Resolution.DAILY)
        for data_point in history:
            self._low_interest_rate.update(data_point.end_time, data_point.interest_rate)

    def on_data(self, slice: Slice) -> None:
        # Note that you may want to access the margin interest of the crypto future to calculate if it would impact a trade's PnL
        # Or you can calculate the trade size on keeping the quote currency constant
        if self._future.symbol not in slice.margin_interest_rates:
            return
        interest_rate = slice.margin_interest_rates[self._future.symbol].interest_rate
        self.plot('Margin Interest Rate', str(self._future.symbol), interest_rate)
        # Short when margin interest rates are relatively low. Otherwise, long.
        if interest_rate <= self._low_interest_rate.current.value:
            if not self._future.holdings.is_short:
                self.set_holdings(self._future.symbol, -0.5)
        elif not self._future.holdings.is_long:
            self.set_holdings(self._future.symbol, 1)
        # Update the indicator.
        self._low_interest_rate.update(self.time, interest_rate)
```

Framework Algorithm Example

The following example algorithm holds a long position in the BTCUSDT perpetual Future contract on the Binance exchange. When the margin interest rate is relatively low, it flips to a short position.

```py
from AlgorithmImports import *

class BinanceCryptoFutureDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.settings.free_portfolio_value_percentage = 0.1
        # Set Account Currency to USDT, since USD cannot be used to trade.
        self.set_cash("USDT", 100000)
        # Binance Futures Exchange accepts both Cash and Margin account types, select the one you need for the best reality modeling.
        self.set_brokerage_model(BrokerageName.BINANCE_FUTURES, AccountType.MARGIN)

        self.universe_settings.resolution = Resolution.DAILY
        self.universe_settings.leverage = 2
        # We only trade on BTCUSDT Future in Binance Future exchange
        symbols = Symbol.create("BTCUSDT", SecurityType.CRYPTO_FUTURE, Market.BINANCE)
        self.add_universe_selection(ManualUniverseSelectionModel(symbols))
        # Custom alpha model to emit insights based on the Crypto Future price data
        self.add_alpha(CryptoFutureAlphaModel())
        # Equally invest to evenly dissipate the capital concentration risk of inidividual crypto pair
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())
        self.set_execution(ImmediateExecutionModel())

class CryptoFutureAlphaModel(AlphaModel):

    _min_by_symbol = {}

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        insights = []
        for symbol, low_interest_rate in self._min_by_symbol.items():
            # Note that you may want to access the margin interest of the crypto future to calculate if it would impact a trade's PnL
            # Or you can calculate the trade size on keeping the quote currency constant
            if symbol not in slice.margin_interest_rates:
                continue
            interest_rate = slice.margin_interest_rates[symbol].interest_rate
            algorithm.plot('Margin Interest Rate', str(symbol), interest_rate)
            # Short when margin interest rates are relatively low. Otherwise, long.
            if interest_rate <= low_interest_rate.current.value:
                direction = InsightDirection.DOWN
            else:
                direction = InsightDirection.UP
            insights.append(Insight.price(symbol, timedelta(1), direction))
            # Update the indicator.
            low_interest_rate.update(slice.time, interest_rate)
        return insights

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            symbol = security.symbol
            # Add an indicator to track the low of trailing margin interest rates.
            self._min_by_symbol[symbol] = Minimum(10)
            # Historical data
            history = algorithm.history[MarginInterestRate](symbol, 10, Resolution.DAILY)
            for data_point in history:
                self._min_by_symbol[symbol].update(data_point.end_time, data_point.interest_rate)
        for security in changes.removed_securities:
            self._min_by_symbol.pop(security.symbol, None)
```

Data Point Attributes

The Binance Crypto Future Margin Rate dataset provides `MarginInterestRates` objects with the following attributes:

QuantConnect

Bybit Crypto Future Margin Rate Data

Introduction

The Bybit Crypto Future Margin Rate Data by QuantConnect is for Cryptocurrency Futures margin interest data points. The data covers 631 Cryptocurrency pairs, starts in August 2020, and is delivered on a daily update frequency. This dataset is created by downloading data using Bybit API.

This dataset is an important companion to the Bybit Crypto Future Price Data dataset because it contains information on margin interest data to model margin costs.

For more information about the Bybit Crypto Future Margin Rate Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the Bybit Crypto Future Margin Rate dataset:

```
def Initialize(self) -> None:
    self.SetBrokerageModel(BrokerageName.Bybit, AccountType.Margin)

    self.crypto_future_symbol = self.AddCryptoFuture("BTCBUSD", Resolution.Minute).Symbol
```

The Bybit Crypto Future Margin Rate data is added to your algorithm along with the market data when you add a crypto future subscription.

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	August 2020
Asset Coverage	631 Crypto Futures Pairs
Data Density	Regular
Resolution	Daily
Timezone	UTC
Market Hours	Always Open

Requesting Data

To add Bybit Crypto Future Margin Rate data to your algorithm, call the `add_crypto_future` method. Save a reference to the Crypto Future `Symbol` so you can access the data later in your algorithm.

```
from AlgorithmImports import *
from QuantConnect.DataSource import *

class CoinAPIDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2020, 6, 1)
        self.set_end_date(2021, 6, 1)

        # Set Account Currency to Tether
        self.set_account_currency("USDT", 100000)

        self.set_brokerage_model(BrokerageName.BYBIT, AccountType.MARGIN)

        crypto_future = self.add_crypto_future("BTCUSDT", Resolution.MINUTE)
        # perpetual futures does not have a filter function
        self.btcusdt = crypto_future.symbol
```

For more information about creating Crypto Future subscriptions, see Requesting Data .

Accessing Data

To get the current Bybit Crypto Margin Rate data, index the `margin_interest_rates` property of the current `Slice` with the Crypto Future `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
        if self.btcusdt in slice.margin_interest_rates:
            interest_rate = slice.margin_interest_rates[self.btcusdt].interest_rate
            self.log(f"{self.btcusdt} close at {slice.time}: {interest_rate}")
```

You can also iterate through all of the data objects in the current `Slice` .

```
def on_data(self, slice: Slice) -> None:
    for symbol, margin_interest_rate in slice.margin_interest_rates.items():
        interest_rate = margin_interest_rate.interest_rate
        self.log(f"{symbol} close at {slice.time}: {interest_rate}")
```

For more information about accessing Crypto Future data, see Handling Data .

Historical Data

To get historical Bybit Crypto Future Margin Rate data, call the `history` method with `MarginInterestRate` data type and the Crypto Future `Symbol` . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.history(MarginInterestRate, self.btcusdt, 100, Resolution.DAILY)

# MarginInterestRate objects
history = self.history[MarginInterestRate](self.btcusdt, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To unsubscribe from a Crypto pair that you added with the `add_crypto` method, call the `remove_security` method.

```
self.remove_security(self.btcusdt)
```

The `remove_security` method cancels your open orders for the security and liquidates your holdings in the virtual pair .

Supported Assets

Example Applications

The Binance Crypto Future Margin Rate dataset enables correct margin cost so you can accurately design strategies for Cryptocurrencies with term structure. Examples include the following strategies:

- Horizontal/Diagonal arbitrage with the underlying Cryptocurrencies
- Trade Contango/Backwardation predictions
- Hedge for illiquid Cryptocurrencies

Classic Algorithm Example

The following example algorithm holds a long position in the BTCUSDT perpetual Future contract on the Bybit exchange. When the margin interest rate is relatively low, it flips to a short position.

```py
from AlgorithmImports import *

class BybitCryptoFutureDataAlgorithm(QCAlgorithm):

    # Add an indicator to track the low of trailing margin interest rates.
    _low_interest_rate = Minimum(10)

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Set Account Currency to USDT, since USD cannot be used to trade.
        self.set_cash("USDT", 100_000)
        # Bybit  accepts both Cash and Margin account types, select the one you need for the best reality modeling.
        self.set_brokerage_model(BrokerageName.BYBIT, AccountType.MARGIN)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Requesting data, we only trade on BTCUSDT Future in Bybit  exchange
        # Perpetual futures does not have a filter function.
        self._future = self.add_crypto_future("BTCUSDT", Resolution.DAILY)
        # Historical data
        history = self.history[MarginInterestRate](self._future.symbol, 10, Resolution.DAILY)
        for data_point in history:
            self._low_interest_rate.update(data_point.end_time, data_point.interest_rate)

    def on_data(self, slice: Slice) -> None:
        # Note that you may want to access the margin interest of the crypto future to calculate if it would impact a trade's PnL
        # Or you can calculate the trade size on keeping the quote currency constant
        if self._future.symbol not in slice.margin_interest_rates:
            return
        interest_rate = slice.margin_interest_rates[self._future.symbol].interest_rate
        self.plot('Margin Interest Rate', str(self._future.symbol), interest_rate)
        # Short when margin interest rates are relatively low. Otherwise, long.
        if interest_rate <= self._low_interest_rate.current.value:
            if not self._future.holdings.is_short:
                self.set_holdings(self._future.symbol, -0.5)
        elif not self._future.holdings.is_long:
            self.set_holdings(self._future.symbol, 1)
        # Update the indicator.
        self._low_interest_rate.update(self.time, interest_rate)
```

Framework Algorithm Example

The following example algorithm holds a long position in the BTCUSDT perpetual Future contract on the Bybit exchange. When the margin interest rate is relatively low, it flips to a short position.

```py
from AlgorithmImports import *

class BybitCryptoFutureDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.settings.free_portfolio_value_percentage = 0.1
        # Set Account Currency to USDT, since USD cannot be used to trade.
        self.set_cash("USDT", 100000)
        # Bybit accepts both Cash and Margin account types, select the one you need for the best reality modeling.
        self.set_brokerage_model(BrokerageName.BYBIT, AccountType.MARGIN)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        self.universe_settings.resolution = Resolution.DAILY
        self.universe_settings.leverage = 2
        # We only trade on BTCUSDT Future in Bybit exchange
        symbols = Symbol.create("BTCUSDT", SecurityType.CRYPTO_FUTURE, Market.BYBIT)
        self.add_universe_selection(ManualUniverseSelectionModel(symbols))
        # Custom alpha model to emit insights based on the Crypto Future price data
        self.add_alpha(CryptoFutureAlphaModel())
        # Equally invest to evenly dissipate the capital concentration risk of inidividual crypto pair
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())
        self.set_execution(ImmediateExecutionModel())

class CryptoFutureAlphaModel(AlphaModel):

    _min_by_symbol = {}

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        insights = []
        for symbol, low_interest_rate in self._min_by_symbol.items():
            # Note that you may want to access the margin interest of the crypto future to calculate if it would impact a trade's PnL
            # Or you can calculate the trade size on keeping the quote currency constant
            if symbol not in slice.margin_interest_rates:
                continue
            interest_rate = slice.margin_interest_rates[symbol].interest_rate
            algorithm.plot('Margin Interest Rate', str(symbol), interest_rate)
            # Short when margin interest rates are relatively low. Otherwise, long.
            if interest_rate <= low_interest_rate.current.value:
                direction = InsightDirection.DOWN
            else:
                direction = InsightDirection.UP
            insights.append(Insight.price(symbol, timedelta(1), direction))
            # Update the indicator.
            low_interest_rate.update(slice.time, interest_rate)
        return insights

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            symbol = security.symbol
            # Add an indicator to track the low of trailing margin interest rates.
            self._min_by_symbol[symbol] = Minimum(10)
            # Historical data
            history = algorithm.history[MarginInterestRate](symbol, 10, Resolution.DAILY)
            for data_point in history:
                self._min_by_symbol[symbol].update(data_point.end_time, data_point.interest_rate)
        for security in changes.removed_securities:
            self._min_by_symbol.pop(security.symbol, None)
```

Data Point Attributes

The Binance Crypto Future Margin Rate dataset provides `MarginInterestRate` objects, which have the following attributes:

QuantConnect

CFD Data

Introduction

The CFD Data by QuantConnect serves 51 contracts for differences (CFD). The data starts as early as May 2002 and is delivered on any frequency from tick to daily. This dataset is created by QuantConnect processing raw tick data from OANDA.

CFD data does not include ask and bid sizes.

For more information about the CFD Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the CFD dataset:

```py
self.xauusd = self.add_cfd("XAUUSD", Resolution.DAILY).symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	Mixed, earliest starts May 2002
Asset Coverage	51 Contracts
Data Density	Dense
Resolution	Tick, Second, Minute, Hour, & Daily
Timezone	Mixed, in which the contract is listed*
Market Hours	Always Open , except from Friday 5 PM EST to Sunday 5 PM EST. Index CFDs depends on the underlying market hour*

* E.g.: DE30EUR tracks DAX30 Index, which is listed in Europe/Berlin timezone.

Requesting Data

To add CFD data to your algorithm, call the `add_cfd` method. Save a reference to the CFD `Symbol` so you can access the data later in your algorithm.

```py
class CfdAlgorithm (QCAlgorithm):
    def initialize(self) -> None:
        self.set_account_currency('EUR');

        self.set_start_date(2019, 2, 20)
        self.set_end_date(2019, 2, 21)
        self.set_cash('EUR', 100000)

        self.de30eur = self.add_cfd('DE30EUR').symbol

        self.set_benchmark(self.de30eur)
```

For more information about creating CFD subscriptions, see Requesting Data .

Accessing Data

To get the current CFD data, index the `quote_bars` , or `ticks` properties of the current `Slice` with the CFD `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    if self.de30eur in slice.quote_bars:
        quote_bar = slice.quote_bars[self.de30eur]
        self.log(f"{self.de30eur} bid at {slice.time}: {quote_bar.bid.close}")

    if self.de30eur in slice.ticks:
        ticks = slice.ticks[self.de30eur]
        for tick in ticks:
            self.log(f"{self.de30eur} price at {slice.time}: {tick.price}")
```

You can also iterate through all of the data objects in the current `Slice` .

```
PY
def on_data(self, slice: Slice) -> None:
    for symbol, quote_bar in slice.quote_bars.items():
        self.log(f"{symbol} bid at {slice.time}: {quote_bar.bid.close}")

    for symbol, ticks in slice.ticks.items():
        for tick in ticks:
            self.log(f"{symbol} price at {slice.time}: {tick.price}")
```

For more information about accessing CFD data, see Handling Data .

Historical Data

To get historical CFD data, call the `history` method with the CFD `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.history(self.de30eur, 100, Resolution.MINUTE)

# QuoteBar objects
history_quote_bars = self.history[QuoteBar](self.de30eur, 100, Resolution.MINUTE)

# Tick objects
history_ticks = self.history[Tick](self.de30eur, timedelta(seconds=10), Resolution.TICK)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a CFD subscription, call the `remove_security` method.

```
PY
self.remove_security(self.de30eur)
```

The `remove_security` method cancels your open orders for the security and liquidates your holdings.

Supported Assets

The following table shows the available contracts:

Contract Available (51)					
AU200AUD	BCOUSD	CH20CHF	CORNUSD	DE10YBEUR	DE30EUR
EU50EUR	FR40EUR	HK33HKD	JP225USD	NAS100USD	NATGASUSD
NL25EUR	SG30SGD	SOYBNUSD	SPX500USD	SUGARUSD	UK100GBP
UK10YBGBP	US2000USD	US30USD	USB02YUSD	USB05YUSD	USB10YUSD
USB30YUSD	WHEATUSD	WTICOUSD	XAGAUD	XAGCAD	XAGCHF
XAGEUR	XAGGBP	XAGHKD	XAGJPY	XAGNZD	XAGSGD
XAGUSD	XAUAUD	XAUCAD	XAUCHF	XAUEUR	XAUGBP
XAUHKD	XAUJPY	XAUNZD	XAUSGD	XAUUSD	XAUXAG
XCUUSD	XPDUSD	XPTUSD			

Example Applications

The CFD price data enables you to trade CFD assets in your algorithm. Examples include the following strategies:

- Exploring the daily worldwide news cycles with CFDs that track international indices.
- Trading price movements of commodities with no delivery of physical goods. For example, pairs trading between gold and silver, corn and wheat, brent and crude oil, etc.

Classic Algorithm Example

The following example algorithm implements a pairs trading strategy using Gold and Silver CFDs, XAUUSD and XAGUSD, respectively. When the spread is higher than one standard deviation above its mean, the algorithm buys the spread (buy XAUUSD and sell XAGUSD). When the spread is lower than one standard deviation below its mean, it sells the spread (buy XAGUSD and sell XAUUSD).

```py
from AlgorithmImports import *

class SMAPairsTrading(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Request gold and sliver spot CFDs for trading their spread difference, assuming their spread series is cointegrated
        self.add_cfd('XAUUSD', Resolution.HOUR)
        self.add_cfd('XAGUSD', Resolution.HOUR)

        # Use 500-step mean and SD indicator on determine the spread relative difference for trading signal generation
        self.pair = [ ]
        self.spread_mean = SimpleMovingAverage(500)
        self.spread_std = StandardDeviation(500)

    def on_data(self, slice: Slice) -> None:
        # Update the indicator with updated spread difference, such that the an updated cointegration threshold is calculated for trade
inception
        spread = self.pair[1].price - self.pair[0].price
        self.spread_mean.update(self.time, spread)
        self.spread_std.update(self.time, spread)

        spread_mean = self.spread_mean.current.value
        upperthreshold = spread_mean  + self.spread_std.current.value
        lowerthreshold = spread_mean  - self.spread_std.current.value

        # If the spread is higher than upper threshold, bet their spread series will revert to mean
        if spread > upperthreshold:
            self.set_holdings(self.pair[0].symbol, 1)
            self.set_holdings(self.pair[1].symbol, -1)
        elif spread < lowerthreshold:
            self.set_holdings(self.pair[0].symbol, -1)
            self.set_holdings(self.pair[1].symbol, 1)
        # Close positions if mean reverted
        elif (self.portfolio[self.pair[0].symbol].quantity > 0 and spread < spread_mean)\
        or (self.portfolio[self.pair[0].symbol].quantity < 0 and spread > spread_mean):
            self.liquidate()

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        self.pair = [x for x in changes.added_securities]

        #1. Call for 500 bars of history data for each symbol in the pair and save to the variable history
        history = self.history([x.symbol for x in self.pair], 500)
        #2. Unstack the Pandas data frame to reduce it to the history close price
        history = history.close.unstack(level=0)
        #3. Iterate through the history tuple and update the mean and standard deviation with historical data
        for tuple in history.itertuples():
            self.spread_mean.update(tuple[0], tuple[2]-tuple[1])
            self.spread_std.update(tuple[0], tuple[2]-tuple[1])
```

Framework Algorithm Example

The following example algorithm implements a pairs trading strategy using Gold and Silver CFDs, XAUUSD and XAGUSD, respectively. When the spread is higher than one standard deviation above its mean, the algorithm buys the spread (buy XAUUSD and sell XAGUSD). When the spread is lower than one standard deviation below its mean, it sells the spread (buy XAGUSD and sell XAUUSD).

```py
from AlgorithmImports import *

class GoldSilverPairsTradingAlgorithm (QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        self.universe_settings.resolution = Resolution.HOUR
        # Custom universe contains only gold and sliver spot CFDs for trading their spread difference, assuming their spread series is
cointegrated
        self.set_universe_selection(ManualUniverseSelectionModel
        (
            [ Symbol.create(x, SecurityType.CFD, Market.OANDA) for x in ["XAUUSD", "XAGUSD"] ]
        ))
        # Custom alpha model to emit trade insights based on the gold-sliver price spread
        self.add_alpha(PairsTradingAlphaModel())
        # Equal weighting trades assuming the spread is cointegrated by 1:1 ratio
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

class PairsTradingAlphaModel(AlphaModel):

    def __init__(self) -> None:
        # Use 500-step mean and SD indicator on determine the spread relative difference for trading signal generation

```

Data Point Attributes

The CFD dataset provides `QuoteBar` and `Tick` objects.

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

Tick Attributes

`Tick` objects have the following attributes:

QuantConnect

Cash Indices

Introduction

The Cash Indices dataset by QuantConnect covers 125 US Indices and 3 International indices. The data starts on various dates from January 1998 and is delivered on any frequency from minute to daily.

For more information about the Cash Indices dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Live Data

The Cash Indices dataset does not provide a live data feed. To receive Cash Indices' data in your live algorithm, you must add a brokerage or a third-party data provider (see Cloud Platform > Datasets).

Getting Started

The following snippet demonstrates how to request data from the Cash Indices dataset:

```
self.vix = self.add_index("VIX", Resolution.DAILY).symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1998
Coverage	125 US Indices and 3 International indices (HSI, SX5E and N225)
Data Density	Dense
Resolution	Minute, Hour, & Daily
Timezone	New York for US Indices, refer to `Supported Assets` below for International indices
Market Hours	Regular Only

Requesting Data

To add Cash Indices data to your algorithm, call the `add_index` method. Save a reference to the Index `Symbol` so you can access the data later in your algorithm.

```
class CashIndexAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2020, 6, 1)
        self.set_end_date(2021, 6, 1)
        self.set_cash(100000)

        self.vix = self.add_index("VIX").symbol
```

For more information about creating Index subscriptions, see Requesting Data .

Accessing Data

To get the current Cash Indices data, index the `bars` property of the current `Slice` with the Index `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    if self.vix in slice.bars:
        trade_bar = slice.bars[self.vix]
        self.log(f"{self.vix} close at {slice.time}: {trade_bar.close}")
```

You can also iterate through all of the data objects in the current `Slice` .

```
PY
def on_data(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.bars.items():
        self.log(f"{symbol} close at {slice.time}: {trade_bar.close}")
```

For more information about accessing Index data, see Handling Data .

Historical Data

To get historical Cash Indices data, call the `history` method with the Index `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.history(self.vix, 100, Resolution.DAILY)

# TradeBar objects
history_bars = self.history[TradeBar](self.vix, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove an Index subscription, call the `remove_security` method.

```
PY
self.remove_security(self.vix)
```

Supported Indices

US Cash Indices

The following table shows the US Cash indices with Index Option support:

Ticker	Index	Expiry	Start Date
VIX	S&P500	30 Days	Jul 2003
SPX	S&P500	-	Jan 1998
NDX	NASDAQ-100	-	Jan 1998
RUT	Russell 2000	-	Jan 2008

VIX - CBOE Volatility Index

The Cboe Volatility Index (VIX) is a real-time index that represents the market's expectations for the relative strength of near-term price changes of the S&P 500 Index (SPX). Because it's derived from the prices of SPX index Options with near-term expiration dates, it generates a 30-day forward projection of volatility. Volatility, or how fast prices change, is often seen as a way to gauge market sentiment, and in particular, the degree of fear

among market participants.

SPX - S&P 500 Index

The S&P 500 Index, or the Standard & Poor's 500 Index, is a market-capitalization-weighted index of the 500 largest publicly-traded companies in the U.S. It is not an exact list of the top 500 U.S. companies by market capitalization because there are other criteria included in the index. The index is widely regarded as the best gauge of large-cap U.S. Equities.

NDX - Nasdaq 100 Index

The Nasdaq-100 Index is a modified market-capitalization-weighted index composed of securities issued by 100 of the largest non-financial companies listed on the Nasdaq Stock Market (Nasdaq). The index includes companies from various industries except for the financial industry, like commercial and investment banks. These non-financial sectors include retail, biotechnology, industrial, technology, health care, and others.

RUT - Russell 2000 Index

The Russell 2000 Index is a small-cap U.S. stock market index that makes up the smallest 2,000 stocks in the Russell Index. It was started by the Frank Russell Company in 1984. The index is maintained by FTSE Russell, a subsidiary of the London Stock Exchange Group (LSEG).

All US Cash Indices

The following table shows all US Cash indices:

Indices Available (125). Note: QuantConnect is working on its modeling: market hours and symbol properties.					
AEX	ASX	BKX	BRR	BRTI	BXD

International Cash Indices

The following table shows the International Cash indices:

Ticker	Index	Start Date	Time Zone	Currency
HSI	Hang Seng Index	Dec 2006	Asia/Hong Kong	HKD
SX5E	EUREX EU STOXX	Jul 2003	Europe/Berlin	EUR
N225	Nikkei 225	Jul 2003	Asia/Tokyo	JPY

Example Applications

The Cash Indices enable you to incorporate popular indices into your trading algorithms. Examples include the following use cases:

- Exploring the difference between the Index and the ETF that tracks it
- Using these indices as the underlying asset fo Index Options strategies
- Understanding the stock market's level of expected forward-looking volatility, also known as the "fear index". When the VIX starts moving higher, it tells you that traders are getting nervous. When the VIX starts moving lower, it tells you that traders are gaining confidence.

Classic Algorithm Example

The following example algorithm tracks the 80-day EMA and 200-day EMA of SPX. When the short EMA crosses above the long EMA, the algorithm buys SPY. Otherwise, it holds cash.

```py
from AlgorithmImports import *

class IndexDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Request SPY data as a trading vehicle for SPX
        self.spy = self.add_equity("SPY").symbol

        # Request SPX data for trade signal generation
        spx = self.add_index("SPX").symbol

        # Create short and long-term EMA indicators for trend estimation to trade
        self.ema_fast = self.EMA(spx, 80, Resolution.DAILY)
        self.ema_slow = self.EMA(spx, 200, Resolution.DAILY)
        self.set_warm_up(200, Resolution.DAILY)

        # Historical data
        history = self.history(spx, 60, Resolution.DAILY)
        self.debug(f'We got {len(history.index)} items from our history request')

    def on_data(self, slice: Slice) -> None:
        # Trade signals required indicators to be ready
        if self.is_warming_up or not self.ema_slow.is_ready:
            return

        # If short-term EMA is above long-term, it indicates an up trend, so we buy SPY
        if not self.portfolio.invested and self.ema_fast > self.ema_slow:
            self.set_holdings(self.spy, 1)
        # If it is the reverse, it indicates a downtrend, and we liquidate any position
        elif self.ema_fast < self.ema_slow:
            self.liquidate()
```

Framework Algorithm Example

The following example algorithm tracks the 80-day EMA and 200-day EMA of SPX. When the short EMA crosses above the long EMA, the algorithm buys SPY. Otherwise, it holds cash.

```
PY
```

```
from AlgorithmImports import *

        return []
```

Data Point Attributes

The Cash Indices dataset provides `TradeBar` object.

TradeBar Attributes

`TradeBar` objects have the following attributes:

QuantConnect

FOREX Data

Introduction

The FOREX Data by QuantConnect serves 71 foreign exchange (FOREX) pairs, starts on various dates from January 2007, and is delivered on any frequency from tick to daily. This dataset is created by QuantConnect processing raw tick data from OANDA.

FOREX data does not include ask and bid sizes.

For more information about the FOREX Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the FOREX dataset:

```
self.eurusd = self.add_forex("EURUSD", Resolution.DAILY).symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2007
Asset Coverage	71 Currency pairs
Data Density	Dense
Resolution	Tick, Second, Minute, Hour, & Daily
Timezone	UTC
Market Hours	Always Open , except from Friday 5 PM EST to Sunday 5 PM EST

Requesting Data

To add FOREX data to your algorithm, call the `add_forex` method. Save a reference to the Forex `Symbol` so you can access the data later in your algorithm.

```
class ForexAlgorithm (QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 2, 20)
        self.set_end_date(2019, 2, 21)
        self.set_cash(100000)

        self.eurusd = self.add_forex('EURUSD', Resolution.MINUTE).symbol

        self.set_benchmark(self.eurusd)
```

For more information about creating Forex subscriptions, see Requesting Data .

Accessing Data

To get the current Forex data, index the `quote_bars` , or `ticks` properties of the current `Slice` with the Forex `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    if self.eurusd in slice.quote_bars:
        quote_bar = slice.quote_bars[self.eurusd]
        self.log(f"{self.eurusd} bid at {slice.time}: {quote_bar.bid.close}")

    if self.eurusd in slice.ticks:
        ticks = slice.ticks[self.eurusd]
        for tick in ticks:
            self.log(f"{self.eurusd} price at {slice.time}: {tick.price}")
```

PY

You can also iterate through all of the data objects in the current `Slice` .

```
def on_data(self, slice: Slice) -> None:
    for symbol, quote_bar in slice.quote_bars.items():
        self.log(f"{symbol} bid at {slice.time}: {quote_bar.bid.close}")

    for symbol, ticks in slice.ticks.items():
        for tick in ticks:
            self.log(f"{symbol} price at {slice.time}: {tick.price}")
```

PY

For more information about accessing Forex data, see Handling Data .

Historical Data

To get historical Forex data, call the `history` method with the Forex `Symbol` . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.history(self.eurusd, 100, Resolution.MINUTE)

# QuoteBar objects
history_quote_bars = self.history[QuoteBar](self.eurusd, 100, Resolution.MINUTE)

# Tick objects
history_ticks = self.history[Tick](self.eurusd, timedelta(seconds=10), Resolution.TICK)
```

PY

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a Forex pair subscription, call the `remove_security` method.

```
self.remove_security(self.eurusd)
```

PY

The `remove_security` method cancels your open orders for the security and liquidates your holdings.

Supported Assets

The following table shows the available Forex pairs:

Pairs Available (71)					
AUDCAD	AUDCHF	AUDHKD	AUDJPY	AUDNZD	AUDSGD
AUDUSD	CADCHF	CADHKD	CADJPY	CADSGD	CHFHKD
CHFJPY	CHFZAR	EURAUD	EURCAD	EURCHF	EURCZK

USDJPY	USDMXN	USDNOK	USDPLN	USDSAR	USDSEK
USDSGD	USDTHB	USDTRY	USDZAR	ZARJPY	

Example Applications

The FOREX price data enables you to trade currency pairs in the global market. Examples include the following strategies:

- Exploring the impact that daily worldwide news cycles have on international currencies
- Carry Trade: borrow from a lower interest currency pair to fund the purchase of a currency pair with a higher interest rate

Classic Algorithm Example

The following example algorithm implements a FOREX carry trade. It buys the FOREX pair of the country with the lowest interest rate and sells the FOREX pair of the country with the highest interest rate.

```py
from AlgorithmImports import *

class ForexCarryTradeAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(25000)

        # We will use hard-coded interest rates for each base currency
        self.rates = {
            "USDAUD": 1.5,    # Australia
            "USDCAD": 0.5,    # Canada
            "USDCNY": 4.35,   # China
            "USDEUR": 0.0,    # Euro Area
            "USDINR": 6.5,    # India
            "USDJPY": -0.1,   # Japan
            "USDMXN": 4.25,   # Mexico
            "USDTRY": 7.5,    # Turkey
            "USDZAR": 7.0     # South Africa
        }

        # Subscribe to forex data for trading
        for ticker in self.rates:
            self.add_forex(ticker, Resolution.DAILY)

        # Use a month counter as variable to control rebalancing
        self.month = -1

    def on_data(self, slice: Slice) -> None:
        # Monthly rebalance checker
        if self.month == self.time.month:
            return
        self.month = self.time.month

        # Long the pair with highest interest rate and sell the pair with the lowest to earn the max monetary inflation difference
between the two
        sorted_rates = sorted(self.rates.items(), key = lambda x: x[1])
        self.set_holdings(sorted_rates[0][0], -0.5)
        self.set_holdings(sorted_rates[-1][0], 0.5)
```

Framework Algorithm Example

The following example algorithm implements a FOREX carry trade. It buys the FOREX pair of the country with the lowest interest rate and sells the FOREX pair of the country with the highest interest rate.

```py
from AlgorithmImports import *

class ForexCarryTradeAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(25000)

        def to_symbol(ticker: str) -> Symbol:
            return Symbol.create(ticker, SecurityType.FOREX, Market.OANDA)

        # We will use hard-coded interest rates for each base currency
        rates = {
            to_symbol("USDAUD"): 1.5,    # Australia
            to_symbol("USDCAD"): 0.5,    # Canada
            to_symbol("USDCNY"): 4.35,   # China
            to_symbol("USDEUR"): 0.0,    # Euro Area
            to_symbol("USDINR"): 6.5,    # India
            to_symbol("USDJPY"): -0.1,   # Japan
            to_symbol("USDMXN"): 4.25,   # Mexico
            to_symbol("USDTRY"): 7.5,    # Turkey
            to_symbol("USDZAR"): 7.0     # South Africa
        }

        self.set_universe_selection(ManualUniverseSelectionModel(list(rates.keys())))
        # A custom alpha model to emit insight according to interest rate
        self.set_alpha(IntestRatesAlphaModel(rates))
        # Equal size to capitalize the monetary value of quote currency only based on interest rate difference
        # For dollar-neutral to save margin cost
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel(Expiry.END_OF_MONTH))

class IntestRatesAlphaModel(AlphaModel):
    def __init__(self, rates: float) -> None:
        self.rates = rates
        # Variable to control the rebalancing time
        self.month = -1

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        # Monthly rebalance
        if self.month == algorithm.time.month:
            return []
        self.month = algorithm.time.month

        # # Long the pair with highest interest rate and sell the pair with the lowest to earn the max monetary inflation difference
between the two
        sorted_rates = sorted(self.rates.items(), key = lambda x: x[1])
        return Insight.group(
            Insight.price(sorted_rates[0][0], Expiry.END_OF_MONTH, InsightDirection.UP),
            Insight.price(sorted_rates[-1][0], Expiry.END_OF_MONTH, InsightDirection.DOWN)
        )
```

QuantConnect

Fear and Greed

Introduction

The Fear and Greed dataset by QuantConnect provides data points to quantify the degree of fear and greed in the US Equity market. The data starts in 2014 and is delivered on a daily frequency, delayed by two days. This dataset is created by aggregating seven indicators, including market volatility, stock market breadth, and put-call ratios.

For more information about the Fear and Greed dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the Fear and Greed dataset:

```
PY
self._dataset_symbol = self.add_data(FearGreedIndex, 'FG').symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	July 2014
Data Density	Dense
Resolution	Daily
Timezone	New York

The latest daily data points are about two days since the VIX and SPX prices are inputs into the index and their latest daily prices are also two days old. New data is available at 9 AM EST.

Requesting Data

To add Fear and Greed data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
PY
class FearAndGreedDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._dataset_symbol = self.add_data(FearGreedIndex, "FG").symbol
```

Accessing Data

To get the current Fear and Greed data, index the current `Slice` with the dataset `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self._dataset_symbol):
        data_point = slice[self._dataset_symbol]
        self.log(f"{self._dataset_symbol} value at {slice.time}: {data_point.value}")
```

Historical Data

To get historical Fear and Greed data, call the `history` method with the dataset `Symbol`. If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.history(self._dataset_symbol, 100, Resolution.DAILY)

# Dataset objects
history = self.history[FearGreedIndex](self._dataset_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests.

Remove Subscription

To remove a subscription to the Fear and Greed dataset, call the `remove_security` method.

```
self.remove_security(self._dataset_symbol)
```

Example Applications

The Fear and Greed dataset quantifies the degree of fear and greed in the US Equity market. Example use cases include the following strategies:

- Accumulate long-term positions when the market is fearful (the index is low).
- Short risky assets when the market is greedy.
- Trade butterfly Option strategies based on the market volatility indicator.

Classic Algorithm Example

The following example algorithm buys SPY when the Fear and Greed index is less than 25 (extreme fear) and sells when it's above 75 (extreme greed).

```
from AlgorithmImports import *

class FearAndGreedExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Add the market index to trade.
        self._equity = self.add_equity('SPY', Resolution.DAILY)
        # Add the Fear and Greed dataset.
        self._dataset_symbol = self.add_data(FearGreedIndex, 'FG').symbol

    def on_data(self, data: Slice) -> None:
        # Wait until the Fear and Greed dataset has new data.
        if self._dataset_symbol not in data:
            return
        value = data[self._dataset_symbol].value
        # Buy when the market is fearful.
        if not self._equity.invested and value < 25:
            self.set_holdings(self._equity.symbol, 1)
        # Sell when the market is greedy.
        elif self._equity.invested and value > 75:
            self.liquidate()
```

Framework Example

The following example algorithm buys SPY when the Fear and Greed index is less than 25 (extreme fear) and sells when it's above 75 (extreme greed).

```py
from AlgorithmImports import *

class FearAndGreedExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Trade SPY on a daily basis.
        self.universe_settings.resolution = Resolution.DAILY
        symbols = [Symbol.create('SPY', SecurityType.EQUITY, Market.USA)]
        self.add_universe_selection(ManualUniverseSelectionModel(symbols))
        # Add a custom Alpha model that emits insights based on the Fear and Greed dataset.
        self.add_alpha(FearAndGreedAlphaModel(self))
        # Set the equal weighted PCM so the algorithm places trades.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

# Define the custom alpha model.
class FearAndGreedAlphaModel(AlphaModel):

    def __init__(self, algorithm):
        # Create a list to track the current universe.
        self._securities = []
        # Add the Fear and Greed dataset.
        self._dataset_symbol = algorithm.add_data(FearGreedIndex, 'FG').symbol

    def update(self, algorithm: QCAlgorithm, data: Slice) -> List[Insight]:
        # Wait until the Fear and Greed dataset has new data.
        if self._dataset_symbol not in data:
            return []
        # Wait until the Fear and Greed index is extreme.
        value = data[self._dataset_symbol].value
        if 25 <= value <= 75:
            return []
        insights = []
        for security in self._securities:
            # Buy when the market is fearful.
            if not security.invested and value < 25:
                direction = InsightDirection.UP
            # Sell when the market is greedy.
            elif security.invested and value > 75:
                direction = InsightDirection.FLAT
            else:
                continue
            insights.append(Insight.price(security.symbol, timedelta(2*365), direction))
        return insights

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        # When assets enter the universe, save them.
        for security in changes.added_securities:
            self._securities.append(security)
        # When assets leave the universe, remove them.
        for security in changes.removed_securities:
            if security in self._securities:
                self._securities.remove(security)
```

Data Point Attributes

The Fear and Greed dataset provides `FearGreedIndex` objects, which have the following attributes:

QuantConnect

International Future Universe

Introduction

The International Future Universe dataset by QuantConnect lists the available International Future contracts, their daily trading volume, and Open Interest. The data covers 4 contracts (DAX, FESX, HSI, and NKD), starts in July 1998, and is delivered on daily frequency. This dataset is created by monitoring the trading activity on the EUREX, HKFE, and CME.

This dataset depends on the US Futures Security Master dataset because the US Futures Security Master dataset contains information on symbol changes of the contracts.

This dataset `does not` contain market data. For market data, see International Futures by TickData and US Futures by AlgoSeek for NKD.

For more information about the International Future Universe dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The International Futures Universe dataset provides data for contract filtering/selection:

```py
hsi = self.add_future(Futures.Indices.HANG_SENG, Resolution.MINUTE)          # "HSI"
hsi.set_filter(0, 90)
dax = self.add_future(Futures.Indices.DAX, Resolution.MINUTE)                # "DAX"
dax.set_filter(0, 90)
fesx = self.add_future(Futures.Indices.EURO_STOXX_50, Resolution.MINUTE)     # "FESX"
fesx.set_filter(0, 90)
nkd = self.add_future(Futures.Indices.NIKKEI_225_DOLLAR, Resolution.MINUTE)  # "NKD"
nkd.set_filter(0, 90)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	July 1998 (for details, see `Supported Assets`)
Coverage	4 Contracts
Data Density	Dense
Resolution	Daily
Timezone	Various (for details, see `Supported Assets`)
Market Hours	Regular and Extended

Requesting Data

To add International Future Universe data to your algorithm, call the `add_future` method. Save a reference to the Future object so you can access the data later in your algorithm. To define which contracts should be in your universe, specify the filter when requesting the Future data.

The `add_future` method provides a daily stream of Future chain data. To get the most recent daily chain, call the `futures_chain` method with the underlying Future Symbol. The `futures_chain` method returns data on all the tradable contracts, not just the contracts that pass your universe filter.

```py
class InternationalFuturesDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2013, 12, 20)
        self.set_end_date(2014, 2, 20)
        self.set_cash(1000000)
        self.universe_settings.asynchronous = True
        self._future = self.add_future(Futures.Indices.HANG_SENG)
        # Set our contract filter for this Future chain.
        self._future.set_filter(lambda universe: universe.standards_only().front_month())
        # Get the entire Futures chain for the current day.
        chain = self.futures_chain(self._future.symbol, flatten=True).data_frame
```

For more information about creating Future Universes, see Futures .

Accessing Data

For information about accessing International Future Universe data, see Futures .

Historical Data

You can get historical International Future Universe data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical International Future Universe data in an algorithm, call the `history` method with continuous Future `Symbol` and a lookback period. This method returns the all the available contracts for each trading day, not the subset of contracts that pass your universe filter. If there is no data for the period you requested, the history result is empty.

```py
# Add the Future and save a reference to it.
future = self.add_future(Futures.Indices.HANG_SENG)

# DataFrame example where the columns are the FutureUniverse attributes:
history_df = self.history(FutureUniverse, future.symbol, 5, flatten=True)

# Series example where the values are lists of FutureUniverse objects:
history_series = self.history(FutureUniverse, future.symbol, 5, flatten=False)

# FutureUniverse objects example:
history = self.history[FutureUniverse](future.symbol, 5)
```

For more information about historical International Future Universe data in algorithms, see Contracts .

Historical Data In Research

To get historical International Future Universe data in the Research Environment, call the `history` method with continuous Future `Symbol` and a time period. This method returns the all the available contracts for each trading day, not the subset of contracts that pass your universe filter. If there is no data for the period you requested, the history result is empty.

```py
# Add the Future and save a reference to it.
future = qb.add_future(Futures.Indices.HANG_SENG)

# DataFrame example where the columns are the FutureUniverse attributes:
history_df = qb.history(FutureUniverse, future.symbol, datetime(2025, 1, 1), datetime(2025, 4, 1), flatten=True)

# Series example where the values are lists of FutureUniverse objects:
history_series = qb.history(FutureUniverse, future.symbol, 5, flatten=False)

# FutureUniverse objects example:
history = qb.history[FutureUniverse](future.symbol, datetime(2025, 1, 1), datetime(2025, 4, 1))
```

For more information about historical International Future Universe data in the Research Environment, see Daily Prices History .

Supported Assets

The following table shows the available Futures:

Ticker	Future	Start Date	Time Zone	Currency
HSI	Hang Seng Index Futures	Jan 2010	Asia/Hong Kong	HKD
DAX	German Index Futures	Jan 2010	Europe/Berlin	EUR
FESX	EURO STOXX 50 Index Futures	Jul 1998	Europe/Berlin	EUR
NKD	Nikkei 225 Index Futures	Jan 2007	America/Chicago	USD

Example Applications

The International Futures Universe dataset enables you to design Futures strategies accurately. Examples include the following strategies:

- Buying the Futures contract with the most open interest to reduce slippage and market impact
- Trade speculation on an International Index
- Trading bull calendar spreads to reduce volatility and margin requirements

Classic Algorithm Example

The following example algorithm uses the ZigZag indicator to determine the trend of Hang Seng Index. It then trades the Index with HSI Futures.

```py
from AlgorithmImports import *

class InternationalFuturesDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Set the time zone to HKT to make it more comparable with the exchange.
        self.set_time_zone(TimeZones.HONG_KONG)
        # Set the account currency as HKD to trade HSI Futures.
        self.set_account_currency("HKD", 1000000)
        # Seed the last price of the contracts for filling.
        self.settings.seed_initial_prices = True

        # Request HSI Futures to trade.
        # Note that we will trade the contract with the highest open interest for liquidity.
        self.hsi_future = self.add_future(
            Futures.Indices.HANG_SENG,
            extended_market_hours=True,
            data_mapping_mode=DataMappingMode.LAST_TRADING_DAY,
            contract_depth_offset=0
        )
        # Adds contracts that expiry within 90 days. We will trade the farthest contract
        self.hsi_future.set_filter(0,90)
        # Request the corresponding underlying Index for feeding indicator for trade signal generation.
        hsi_index = self.add_index("HSI").symbol

        # Create a ZigZag indicator to trade Hang Seng Index price pivot points.
        self._zz = self.zz(hsi_index, 0.15, 5, Resolution.DAILY)
        # Warm up indicator for immediate readiness to trade.
        self.warm_up_indicator(hsi_index, self._zz, Resolution.DAILY)

    def on_data(self, slice: Slice) -> None:
        # Only place trade if the Future contracts is in market opening hours to avoid stale fills.
        if self.is_market_open(self.hsi_future.symbol) and self._zz.is_ready:
            pivot = self._zz.pivot_type
            # If the last pivot point is a low point, the current trend is increasing after this low point.
            if pivot == PivotPointType.LOW:
                contracts = sorted([x.symbol for x in slice.future_chains.get(self.hsi_future.symbol)],
                    key=lambda x: x.id.date)
                self.set_holdings(contracts[-1], 0.2)
            # If the last pivot point is a high point, the current trend is decreasing after this high point.
            if pivot == PivotPointType.HIGH:
                contracts = sorted([x.symbol for x in slice.future_chains.get(self.hsi_future.symbol)],
                    key=lambda x: x.id.date)
                self.set_holdings(contracts[-1], -0.2)
```

Data Point Attributes

The International Future Universe dataset provides `FutureFilterUniverse` and `FutureUniverse` objects.

FutureFilterUniverse Attributes

`FutureFilterUniverse` objects have the following attributes:

FutureUniverse Attributes

`FutureUniverse` objects have the following attributes:

QuantConnect

US ETF Constituents

Introduction

The US ETF Constituents dataset by QuantConnect tracks the constituents and weighting of US Equities in 2,650 ETF listings. The data starts in June 2009 and is delivered on a daily basis (monthly basis before January 2015). This dataset is created by tracking the host ETF websites and can be delayed by up to 1 week.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the US ETF Constituents dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 160,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the US ETF Constituents dataset:

```
def initialize(self) -> None:
    self.universe_settings.asynchronous = True
    # Use the following method for a Classic Algorithm
    self._universe = self.add_universe(self.universe.etf("SPY", Market.USA, self.universe_settings, self.etf_constituents_filter))

    symbol = Symbol.create("SPY", SecurityType.EQUITY, Market.USA)
    # Use the following method for a Framework Algorithm
    self.add_universe_selection(ETFConstituentsUniverseSelectionModel(symbol, self.universe_settings, self.etf_constituents_filter))

    def etf_constituents_filter(self, constituents: List[ETFConstituentUniverse]) -> List[Symbol]:
        # Add all Symbols of the ETFConstituentUniverse
       return [x.symbol for x in constituents]
```

PY

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	June 2009
Asset Coverage	2,650 US ETF Listings
Data Density	Dense
Resolution	Daily (Monthly before Jan 2015)
Timezone	New York

Requesting Data

To add US ETF Constituents data to your algorithm, call the `add_universe` and `universe.etf` methods. To select which constituents occupy the universe, provide the ETF `Symbol` and a selection function.

```
class ETFConstituentUniverseAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2018, 1, 1)
        self.set_end_date(2020, 8, 25)
        self.set_cash(100000)
        self.universe_settings.asynchronous = True
        self._universe = self.add_universe(self.universe.etf("SPY", self.universe_settings, self.etf_constituents_filter))
```

For more information about universe settings, see Settings .

Accessing Data

To access the US ETF Constituent data, use the `ETFConstituentUniverse` objects in your selection function. The data is available in daily resolution. The `Symbol` objects you return from your selection function defines the universe constituents.

```
def etf_constituents_filter(self, constituents: List[ETFConstituentUniverse]) -> List[Symbol]:
    for c in constituents:
        self.debug(f'{c.end_time} :: {c.last_update} :: {c.weight} :: {c.shares_held} :: {c.market_value}')
    return [x.symbol for x in constituents]
```

Historical Data

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `history` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```
# DataFrame example where the columns are the ETFConstituentUniverse attributes:
df_history = self.history(self.universe, 30, Resolution.DAILY, flatten=True)

# Series example where the values are lists of ETFConstituentUniverse objects:
series_history = self.history(self.universe, 30, Resolution.DAILY)
for (universe_symbol, time), constituents in series_history.items():
    for constituent in constituents:
        self.log(f'{constituent.symbol} weight at {constituent.end_time}: {constituent.weight}')
```

Historical Universe Data in Research

To get historical universe data in research, call the `universe_history` method with the `Universe` object and the lookback period. The `universe_history` returns the filtered universe. If there is no data in the period you request, the history result is empty.

```
# DataFrame example where the columns are the ETFConstituentUniverse attributes:
df_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time, flatten=True)

# Series example where the values are lists of ETFConstituentUniverse objects:
series_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (universe_symbol, time), constituents in series_history.items():
    for constituent in constituents:
       print(f"{constituent.symbol} weight at {constituent.end_time}: {constituent.weight}")
```

You can call the `history` method in Research.

Example Applications

The ETF Constituents dataset provides an excellent source of tradable universes for strategies without selection bias. When you use an ETF universe, the original ETF can serve as an excellent benchmark for your strategy performance. Other use cases include the following:

- Creating an index-tracking algorithm for customized passive portfolio management
- Performing statistical arbitrage with the base ETF

Classic Algorithm Example

The following example algorithm creates a dynamic universe of the 10 largest US Equities in the SPY ETF. Each day, the algorithm forms a dollar-neutral and market-neutral portfolio by buying the 10 ETF constituents and shorting the SPY ETF.

```py
from AlgorithmImports import *

class ETFConstituentUniverseAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Add the SPY to trade.
        self._spy = self.add_equity("SPY").symbol
        # Add an ETF constituents universe that selects the large caps
        # in SPY. Save the universe object so you can get history
        # for the universe.
        universe = self.add_universe(
            self.universe.etf(
                self._spy,
                universe_filter_func=self._select_assets
            )
        )
        # Get historical universe data.
        history = self.history(universe, 30, Resolution.DAILY, flatten=True)
        # Show an example of wrangling the historical data.
        etf_weights = history.weight.unstack(1)
        # Create a dictionary to store the ETF weights each day.
        self._weight_by_symbol = {}
        # Add a Scheduled Event to rebalance the portfolio each day.
        self.schedule.on(
            self.date_rules.every_day(self._spy),
            self.time_rules.after_market_open(self._spy, 1),
            self._rebalance
        )

    def _select_assets(
            self, constituents: List[ETFConstituentUniverse]) -> List[Symbol]:
        # Select the 10 largest stocks in the SPY.
        selected = sorted(
            [c for c in constituents if c.weight],
            key=lambda c: c.weight
        )[-10:]
        # Save the weights for position sizing.
        self._weight_by_symbol = {c.symbol: c.weight for c in selected}
        # Return the selected assets.
        return list(self._weight_by_symbol.keys())

    def _rebalance(self) -> None:
        # Create a long-short portfolio to earn the excess return of the
        # top 10 weighted stocks from SPY.
        spy_weight = sum(self._weight_by_symbol.values())
        targets = [PortfolioTarget(self._spy, -0.5)]
        for symbol, weight in self._weight_by_symbol.items():
            targets.append(PortfolioTarget(symbol, 0.5*weight/spy_weight))
        # Liquidate the stocks that aren't in top 10.
        self.set_holdings(targets, True)
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of the 10 largest US Equities in the SPY ETF. Each day, the algorithm forms a dollar-neutral and market-neutral portfolio by buying the 10 ETF constituents and shorting the SPY ETF.

```py
class ETFConstituentUniverseFrameworkAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.universe_settings.asynchronous = False
        self.universe_settings.resolution = Resolution.MINUTE
        self.weight_by_symbol = {}

        # Add universe selection on SPY's constituents to select only from large cap stocks
        # Save the universe to access its members for historical data call
        spy = self.add_equity("SPY").symbol
        self.add_universe_selection(ETFConstituentsUniverseSelectionModel(spy, self.universe_settings, self.etf_constituents_filter))

        # Add alpha model that set normalized weight as investment insight
        self.add_alpha(ETFConstituentsAlphaModel(self, spy))

        # Set up portfolio construction model that invest by the insight weights
        pcm = InsightWeightingPortfolioConstructionModel()
        # Avoid excessive rebalance on insight changes
        pcm.rebalance_on_insight_changes = False
        self.set_portfolio_construction(pcm)

        self.add_risk_management(NullRiskManagementModel())

        self.set_execution(ImmediateExecutionModel())

    def etf_constituents_filter(self, constituents: List[ETFConstituentUniverse]) -> List[Symbol]:
        # The top 10 weighted securities are considered better active selections
        # Save the weights for position sizing
        selected = sorted([c for c in constituents if c.weight],
            key=lambda c: c.weight, reverse=True)[:10]
        self.weight_by_symbol = {c.symbol: c.weight for c in selected}

        return list(self.weight_by_symbol.keys())

class ETFConstituentsAlphaModel(AlphaModel):

    def __init__(self, algorithm: QCAlgorithm, etf: Symbol) -> None:
        self.algorithm = algorithm
        self.etf = etf
        self.day = -1

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        # Rebalance daily since selection is on daily basis
        if self.day == algorithm.time.day:
            return []

        self.day = algorithm.time.day

        insights = []

        # Create a long-short portfolio to earn excess return of the top 10 weighted stocks from SPY
        etf_weight = sum(self.algorithm.weight_by_symbol.values())
        if etf_weight> 0:
            # Invest half the portfolio by normalized weights of the top 10 constituents
            for symbol, weight in self.algorithm.weight_by_symbol.items():
                if algorithm.securities.contains_key(symbol):
                    insights.append(Insight.price(symbol, Expiry.END_OF_DAY, InsightDirection.UP, weight=0.5*weight/etf_weight))

            # Short the other half with SPY, looking to profit from the active selection
            insights.append(Insight.price(self.etf, Expiry.END_OF_DAY, InsightDirection.DOWN, weight=0.5))

        return insights

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        # Liquidate the ones not in top 10 weights
        symbols = [x.symbol for x in changes.removed_securities if x.invested]
        algorithm.liquidate(symbols, tag='Removed From Universe')
```

Research Example

The following example lists ETF constituents with the greatest weight in the SPY:

```py
qb = QuantBook()

# Add the ETF
qb.spy = qb.add_equity("SPY").symbol

# Add ETF Universe Selection
def etf_constituents_filter(constituents):
    # Take the top 10 weighted constituents
    selected = sorted([c for c in constituents if c.weight],
        key=lambda c: c.weight, reverse=True)[:10]
    return [c.symbol for c in selected]

universe = qb.add_universe(qb.universe.etf(qb.spy, qb.universe_settings, etf_constituents_filter))

# Historical Universe data
universe_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (universe_symbol, time), constituents in universe_history.items():
    for constituent in constituents:
        print(f"{constituent.symbol} weight at {constituent.end_time}: {constituent.weight}")
```

Data Point Attributes

The ETF Constituents dataset provides `ETFConstituentUniverse` objects, which have the following attributes:

QuantConnect

US Equities Short Availability

Introduction

The US Equity Short Availability dataset provides the available shares for open short positions and their borrowing cost in the US Equity market. The data covers 10,500 US Equities, starts in January 2018, and is delivered on a daily frequency. This dataset is created using information from the exchanges.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the US Equities Short Availability dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippets demonstrate how to request data from the US Equities Short Availability dataset.

Interactive Brokers Data

```
security.set_shortable_provider(InteractiveBrokersShortableProvider())
```

Axos Clearing Data

```
security.set_shortable_provider(LocalDiskShortableProvider("axos"))
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2018
Asset Coverage	10,500 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	New York

Requesting Data

To add US Equities Short Availability data to your algorithm, set the shortable provider of each US Equity in your algorithm.

```
class ShortAvailabilityDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        security = self.add_equity("AAPL")
        # Set shortable provider as IB
        security.set_shortable_provider(InteractiveBrokersShortableProvider())
        self._symbol = security.symbol
```

Accessing Data

To check how many shares are available for a security to short, call the `shortable_quantity` method of the `shortable_provider`

```
shortable_provider = self.securities[self._symbol].shortable_provider
# Get the shortable quantity of the selected symbol at the selected time
shortable_quantity = shortable_provider.shortable_quantity(self._symbol, self.time)

# Check if there are a certain quantity of shares available
quantity = 100;
is_shortable_quantity = self.shortable(self._symbol, quantity)
```

To check borrowing cost, call the `fee_rate` or `rebate_rate` method of the `shortable_provider`

```
fee_rate = shortable_provider.fee_rate(self._symbol, self.time);
rebate_rate = shortable_provider.rebate_rate(self._symbol, self.time);
```

To get valid borrowing rates, use the InteractiveBrokersShortableProvider .

Example Applications

The US Equities Short Availability dataset enables you to accurately design strategies harnessing information about short availability. Examples include the following use cases:

- Avoiding short orders that the brokerage will reject
- Selecting securities based on how many shares are available to short

Classic Algorithm Example

The following example algorithm shorts GameStop every day there are shares available to short. If the algorithm receives a margin call, it liquidates the position and start again on the next day.

```py
from AlgorithmImports import *

class ShortAvailabilityDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000)
        # Seed the security price as the last known price, such that the price data is immediately available at initial rebalance
        self.settings.seed_initial_prices = True
        self.add_security_initializer(self._custom_security_initializer)

        self.equity = self.add_equity("GME")

        # Set up daily rebalance scheduled event, since shortable quantity is updated daily
        self.schedule.on(
            self.date_rules.every_day(self.equity.symbol),
            self.time_rules.after_market_open(self.equity.symbol, 10),
            self.rebalance)

    def rebalance(self) -> None:
        symbol = self.equity.symbol

        # You can obtain the shortable quantity to decide the submission of a short order
        shortable_quantity = self.equity.shortable_provider.shortable_quantity(symbol, self.time)
        if not shortable_quantity:
            shortable_quantity = 0
        # Fee and rebate rate is also available, such that you can calculate the expected return and decide if the margin is worthwhile
        self.plot('Total Shortable Quantity', symbol, shortable_quantity)
        self.plot('Borrowing Cost', "Fee Rate", self.equity.shortable_provider.fee_rate(symbol, self.time))
        self.plot('Borrowing Cost', "Rebate Rate", self.equity.shortable_provider.rebate_rate(symbol, self.time))

        # Test whether we can short the desired quantity
        quantity = self.calculate_order_quantity(symbol, -1)
        if quantity and self.shortable(symbol, quantity):
            self.market_order(symbol, quantity)

    def on_margin_call_warning(self) -> None:
        self.liquidate()

    def _custom_security_initializer(self, security: Security) -> None:
        # Set the shortable provider as your broker for accurate short reality modeling
        security.set_shortable_provider(InteractiveBrokersShortableProvider())
```

Framework Algorithm Example

The following example algorithm shorts GameStop every day there are shares available to short. If the algorithm receives a margin call, it liquidates the position and start again on the next day.

```py
from AlgorithmImports import *

class ShortAvailabilityDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:

        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000)
        # Seed the security price as the last known price, such that the price data is immediately available at initial rebalance
        self.settings.seed_initial_prices = True
        self.add_security_initializer(self._custom_security_initializer)

        self.set_universe_selection(ManualUniverseSelectionModel(
            [Symbol.create("GME", SecurityType.EQUITY, Market.USA)]))

        # Emit down-direction insights to short all securities in the universe
        self.set_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.DOWN, timedelta(1)))
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())
        self.set_execution(ShortableExecutionModel())

    # On Margin Call, emit flat-direction insights to liquidate the positions
    def on_margin_call_warning(self) -> None:
        self.emit_insights([Insight.price(kvp.Key, timedelta(1), InsightDirection.FLAT)
            for kvp in self.securities if kvp.Value.invested])

    def _custom_security_initializer(self, security: Security) -> None:
        # Set the shortable provider as IB
        security.set_shortable_provider(InteractiveBrokersShortableProvider())

class ShortableExecutionModel(ExecutionModel):
    def __init__(self) -> None:
        self.targets_collection = PortfolioTargetCollection()

    def execute(self, algorithm: QCAlgorithm, targets: List[PortfolioTarget]) -> None:
        '''Immediately submits orders for the specified portfolio targets.
        Args:
            algorithm: The algorithm instance
            targets: The portfolio targets to be ordered'''

        # for performance we check count value, OrderByMarginImpact and ClearFulfilled are expensive to call
        self.targets_collection.add_range(targets)
        if self.targets_collection.count > 0:
            for target in self.targets_collection.order_by_margin_impact(algorithm):
                # calculate remaining quantity to be ordered
                quantity = OrderSizing.get_unordered_quantity(algorithm, target)
                # If the quantity is negative, ensure that the security is shortable
                if quantity > 0 or algorithm.shortable(target.symbol, quantity):
                    algorithm.market_order(target.symbol, quantity)

            self.targets_collection.clear_fulfilled(algorithm)
```

Data Point Attributes

The US Equities Short Availability data is a `Symbol` /decimal pair for `ShortQuantity` , `FeeRate` , and `RebateRate` .

QuantConnect

US Equity Coarse Universe

Introduction

The US Equity Coarse Universe dataset by QuantConnect is a daily universe of all trading stocks in the US for a given day with the end of day price and volume. The data covers 30,000 US Equities in total, with approximately 8,000 Equities per day. The data starts in January 1998 and is delivered each trading day. This dataset is created by taking the closing auction price tick from the daily L1 trade and quote exchange dumps.

This dataset depends on the US Equities by AlgoSeek dataset because universe selection adds and removes market data subscriptions and on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

QuantConnect/LEAN combines the data of this dataset with MorningStar Fundamental data in runtime. You can use this dataset in local development without the Morningstar counterpart.

For more information about the US Equity Coarse Universe dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the US Equity Coarse Universe dataset:

- Direct Access using the Security object

```
equity = self.add_equity("IBM")
ibm_fundamental = equity.fundamentals
```

- Direct Access using the Symbol object

```
ibm = Symbol.create("IBM", SecurityType.EQUITY, Market.USA)
ibm_fundamental = self.fundamentals
```

- Universe Selection

```
def initialize(self) -> None:
    # Universe selection
    self._universe = self.add_universe(self.fundamental_filter_function)

def fundamental_filter_function(self, fundamental: List[Fundamental]):
    # Sort all equities with price above $10 by dollar volume
    sorted_by_dollar_volume = sorted([f for f in fundamental if f.price > 10],
                                     key=lambda f: f.dollar_volume, reverse=True)
    # Take the top 10
    return [f.symbol for f in sorted_by_dollar_volume[:10]]
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1998
Asset Coverage	30,000 US Equities
Data Density	Dense
Resolution	Daily
Timezone	New York

This dataset doesn't include Over-the-Counter (OTC) stocks.

Requesting Data

You don't need any special code to request US Coarse Fundamental Data. You can access the current and historical fundamental data for any of the US Equities that this dataset includes.

```
PY
class CoarseFundamentalDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2021, 1, 1)
        self.set_end_date(2021, 7, 1)
        self.set_cash(100000)
        self.universe_settings.asynchronous = True

        # Option 1: Subscribe to individual US Equity assets
        self.add_equity("IBM")

        # Option 2A: Create a fundamental universe (classic version)
        self._universe = self.add_universe(self.fundamental_function)

        # Option 2B: Create a fundamental universe (framework version)
        self.add_universe_selection(FundamentalUniverseSelectionModel(self.fundamental_function))
```

For more information about universe settings, see Settings .

Accessing Data

If you add a fundamental universe to your algorithm, you can access fundamental data in the universe selection function.

```
PY
def fundamental_function(self, fundamental: List[Fundamental]) -> List[Symbol]:
    sorted_by_dollar_volume = sorted(fundamental, key=lambda x: x.dollar_volume, reverse=True)[:3]
    for cf in sorted_by_dollar_volume:
        self.debug(f"{cf.end_time} :: {cf.symbol} : {cf.adjusted_price} :: {cf.dollar_volume}")

    return [ x.symbol for x in sorted_by_dollar_volume]
```

To get fundamental data for Equities in your algorithm, use the `fundamentals` property of the `Equity` objects. The fundamental data represent the corporate fundamentals for the current algorithm time.

```
PY
fundamentals = self.securities[symbol].fundamentals
```

To get fundamental data for Equities, regardless of whether or not you have subscribed to them in your algorithm, call the `fundamentals` method. If you pass one `Symbol` , the method returns a `Fundamental` object. If you pass a list of `Symbol` objects, the method returns a list of `Fundamental` objects.

```
PY
# Single asset
ibm = Symbol.create("IBM", SecurityType.EQUITY, Market.USA)
ibm_fundamental = self.fundamentals(ibm)

# Multiple assets
nb = Symbol.create("NB", SecurityType.EQUITY, Market.USA)
fundamentals = self.fundamentals([ nb, ibm ])
```

Historical Data

You can get historical fundamental data in an algorithm and in the Research Environment.

Historical Data in Algorithms

To get historical fundamental data in an algorithm, call the `history` method with `Fundamental` type and the Equity `Symbol` . If there is no data in the period you request, the history result is empty.

```py
ibm = Symbol.create("IBM", SecurityType.EQUITY, Market.USA)

# DataFrame of fundamental data for a given asset
df_history = self.history(Fundamental, ibm, timedelta(30), flatten=True)

# Fundamental objects
fundamental_history = self.history[Fundamental](ibm, timedelta(30))

# Fundamentals objects for all US Equities (including delisted companies)
fundamentals_history = self.history[Fundamentals](timedelta(30))

# DataFrame of fundamental data for universe constituents
df_history = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series of fundamental data for universe constituents
series_history = self.history(self._universe, 30, Resolution.DAILY)
for (universe_symbol, time), fundamental in series_history.items():
    most_liquid = sorted(fundamental, key=lambda x: x.dollar_volume)[-5:]
```

Historical Universe Data in Research

To get historical universe data in the Research Environment, call the `universe_history` method with the `Universe` object and the lookback period. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```py
# DataFrame of fundamental data for universe constituents
df_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time, flatten=True)

# Series of fundamental data for universe constituents
series_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (universe_symbol, time), fundamentals in series_history.items():
    for fundamental in fundamentals:
        print(f"{fundamental.symbol} dollar volume at {fundamental.end_time}: {fundamental.dollar_volume}")
```

For more information about historical US Equity fundamental data, see Equity Fundamental Data .

Example Applications

The US Equity Coarse Universe dataset enables you to accurately design a universe of US Equities. Examples include the following strategies:

- Selecting securities with the largest dollar volume
- Selecting securities within a specific price range
- Selecting securities that have fundamental data available (together with MorningStar Fundamental data in `Fundamental` objects)

Classic Algorithm Example

The following example algorithm creates a dynamic universe of the three most liquid US Equities. Each time the universe changes, the algorithm forms an equal-weighted portfolio of the three companies.

```py
from AlgorithmImports import *

class USEquityCoarseUniverseConstituentsDataAlgorithm(QCAlgorithm):

    _number_of_symbols = 3
    _changes = None

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Set Asynchronous to True to improve speed performance.
        self.universe_settings.asynchronous = True
        # Add a universe of US Equities.
        universe = self.add_universe(self._select_assets)
        # Get historical data for the universe.
        history = self.history(universe, 30, Resolution.DAILY, flatten=True)

    def _select_assets(self, fundamental: List[Fundamental]) -> List[Symbol]:
        # Select the top traded stocks, since they are the most popular
        # with high capital flow.
        return [
            x.symbol for x in sorted(
                fundamental, key=lambda x: x.dollar_volume
            )[-self._number_of_symbols:]
        ]

    def on_data(self, slice: Slice) -> None:
        # If we have no changes, do nothing.
        if not slice.bars or self._changes is None:
            return
        # Liquidate removed securities, since they are not the most
        # popular stocks.
        for security in self._changes.removed_securities:
            if security.invested:
                self.liquidate(security.symbol)
        # We want 1/N allocation for each security in our universe to
        # evenly dissipate risk.
        for security in self._changes.added_securities:
            self.set_holdings(security.symbol, 1 / self._number_of_symbols)
        self._changes = None

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        self._changes = changes
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of the three most liquid US Equities and forms an equal-weighted portfolio with them.

```py
from AlgorithmImports import *

class USEquityCoarseUniverseConstituentsDataAlgorithm(QCAlgorithm):

    _number_of_symbols = 3

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Set Asynchronous to True to improve speed performance
        self.universe_settings.asynchronous = True

        # Requesting data
        self.set_universe_selection(
            FundamentalUniverseSelectionModel(self.fundamental_selection_function))

        # we want 1/N allocation in each security in our universe to evenly dissipate risk
        self.set_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(1)))
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

        self.add_risk_management(NullRiskManagementModel())

        self.set_execution(ImmediateExecutionModel())

    def fundamental_selection_function(self, fundamental: List[Fundamental]) -> List[Symbol]:
        # Select the top traded stocks, since they are the most popular with high capital flow
        sorted_by_dollar_volume = sorted(fundamental, key=lambda x: x.dollar_volume, reverse=True)
        return [ x.symbol for x in sorted_by_dollar_volume[:self._number_of_symbols] ]
```

Research Example

The following example lists the three most liquid US Equities:

```py
qb = QuantBook()

# Add Fundamental Universe Selection
def fundamental_selection_function(fundamentals):
    selected = sorted(fundamentals, key=lambda x: x.dollar_volume, reverse=True)[:10]
    return [x.symbol for x in selected]

universe = qb.add_universe(fundamental_selection_function)

# Historical Universe data
universe_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (universe_symbol, time), fundamentals in universe_history.items():
    for fundamental in fundamentals:
        print(f"{fundamental.symbol} dollar volume at {fundamental.end_time}: {fundamental.dollar_volume}")
```

Data Point Attributes

The US Equity Coarse Universe dataset provides its data within `Fundamental` objects, which have the following . The attributes from `market_cap` to `asset_classification` listed in the following widget are NaN until this dataset is combined with the MorningStar Fundamental dataset.

QuantConnect

US Equity Option Universe

Introduction

The US Equity Option Universe dataset by QuantConnect lists the available US Equity Options contracts and the current Implied Volatility and Greeks. The data covers 4,000 Symbols, starts in January 2012, and is delivered on a daily update frequency. To create this dataset, we use our implementation of the forward tree pricing model, which accounts for the interest rate, dividend payments, and daily closing prices. The values in this dataset are the same values you can get from daily indicators with mirror Options.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes of the underlying security.

This dataset `does not` contain market data. For market data, see US Equity Options by AlgoSeek .

For more information about the US Equity Option Universe dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the US Equity Options Universe dataset:

```
option = self.add_option("GOOG")
self.option_symbol = option.symbol
option.set_filter(lambda universe: universe.delta(0.4, 0.6))
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2012
Asset Coverage	4,000 Symbols
Data Density	Dense
Resolution	Daily
Timezone	New York

Requesting Data

To add US Equity Options Universe data to your algorithm, call the `add_option` method. Save a reference to the Equity Option `Symbol` so you can access the data later in your algorithm. To define which contracts should be in your universe, call the `set_filter` method of the Option object.

The `add_option` method provides a daily stream of Option chain data. To get the most recent daily chain, call the `option_chain` method with the underlying Equity Symbol. The `option_chain` method returns data on all the tradable contracts, not just the contracts that pass your universe filter.

```
class USEquityOptionsDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2020, 6, 1)
        self.set_end_date(2021, 6, 1)
        self.set_cash(100000)
        self.universe_settings.asynchronous = True
        option = self.add_option("GOOG")
        self.option_symbol = option.symbol
        # Set our strike/expiry filter for this option chain
        option.set_filter(self._option_filter)
        # Get the entire Option chain for the current day.
        chain = self.option_chain(option.symbol.underlying, flatten=True).data_frame

    def _option_filter(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
        # Contracts can be filtered by greeks, implied volatility, open interest:
        return universe \
            .delta(0.5, 1.5) \
            .gamma(0.0001, 0.0006) \
            .vega(0.01, 1.5) \
            .theta(-2.0, -0.5) \
            .rho(0.5, 3.0) \
            .implied_volatility(1, 3) \
            .open_interest(100,500)
```

The Equity resolution must be less than or equal to the Equity Option resolution. For example, if you set the Equity resolution to minute, then you must set the Equity Option resolution to minute, hour, or daily.

For more information about creating US Equity Option Universes, see Equity Options .

Accessing Data

For information about accessing US Equity Options Universe data, see Equity Options .

Historical Data

You can get historical US Equity Options Universe data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Equity Options Universe data in an algorithm, call the `history` method with the canonical Equity Option `Symbol` . This method returns data on all of the tradable contracts, not just the contracts that pass your universe filter. If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.history(self.option_symbol, timedelta(3), flatten=True)

# OptionUniverse objects
history = self.history[OptionUniverse](self.option_symbol, timedelta(3))
```

For more information about historical Equity Options Universe data in algorithms, see Historical Data .

Historical Data In Research

To get historical US Equity Options Universe data in the Research Environment, call the `history` method with the canonical Option `Symbol` . This method returns data on all of the tradable contracts, not just the contracts that pass your universe filter.

```
qb = QuantBook()
option = qb.add_option("GOOG")
history = qb.history(option.symbol, datetime(2020, 6, 1), datetime(2020, 6, 5), flatten=True)
```

For more information about historical Equity Options Universe data in the Research Environment, see Universes .

Supported Assets

To view the supported assets in the US Equity Options Universe dataset, see the Data Explorer .

Example Applications

The US Equity Options Universe dataset enables you to accurately design Option strategies. Examples include the following strategies:

- Buying put Options to hedge against downward price movement in positive Equity positions
- Exploiting arbitrage opportunities that arise when the price of Option contracts deviate from their theoretical value

Classic Algorithm Example

The following example algorithm subscribes to Google put options that fall within delta range between -1 and -0.95, open interest range between 10 and 1000, and expire within seven days. Within this Option chain, the algorithm holds the put Option contract that has the minimum delta (closest to -1) during market hour to hedge the underlying intra-day movement completely. It avoid volatility from sentiment and only earns from inter-day movement from longer-term factors. When the contract expires, the algorithm rolls over to the next contract that meets this criteria.

```py
from AlgorithmImports import *

class USEquityOptionsUniverseAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(10000000)

        # Asynchronous can use computational resources efficiently
        self.universe_settings.asynchronous = True
        # Subscribe to the underlying for the underlying position
        # Set the data normalization mode to raw for strike price comparability
        self.equity = self.add_equity("GOOG", data_normalization_mode=DataNormalizationMode.RAW).symbol
        # Requesting option data and filter for the hedge candidates
        option = self.add_option(self.equity)
        option.set_filter(self.option_filter)
        self.option_symbol = option.symbol

        # Set scheduled event to buy a hedge option contract at market open to eliminate the intra-day movement
        self.schedule.on(
            self.date_rules.every_day(self.equity),
            self.time_rules.after_market_open(self.equity, 1),
            self.buy_hedge_contract
        )

        # Set a scheduled event to sell the hedge contract before market close, since we want to earn from inter-day movement
        # Leave 2 minutes contingency to fill
        self.schedule.on(
            self.date_rules.every_day(self.equity),
            self.time_rules.before_market_close(self.equity, 2),

        # Check if any hedge contract position, if so, liquidate before market close to expose to underlying overnight movement
        if self.hedge:
            self.liquidate(self.hedge)
            self.hedge = None
```

Framework Algorithm Example

The following example algorithm demonstrating a Gamma Scalping strategy through framework algorithm. It filters NVDA options with expiration between 30 to 90 days and open interest between 50 and 1000, due to liquidity concern and lower Gamma fluctuation. Assuming a significant upward trend is expecting, it orders a long straddle strategy from the strike price with Delta-neutral and the highest Gamma to earn the highest profit from upward underlying movement.

PY

```
from AlgorithmImports import *

class USEquityOptionsUniverseFrameworkAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Asynchronous can use computational resources efficiently
        self.universe_settings.asynchronous = True

        # Universe selection that select based on liquidity of the option contracts (by open interest)
        self.add_universe_selection(EquityOptionsUniverseSelectionModel())
        # Custom alpha model that use Delta and Gamma to signal insights
        self.add_alpha(OptionDeltaGammaAlphaModel())
        # To maintain long-short size equal, use a PCM that order a single contract
        self.set_portfolio_construction(SingleSharePortfolioConstructionModel())

class EquityOptionsUniverseSelectionModel(OptionUniverseSelectionModel):
    def __init__(self) -> None:
        # Daily update with the select_option_chain_symbols function

QuantConnect

US Equity Security Master

Introduction

The US Equity Security Master dataset by QuantConnect tracks US Equity corporate actions, including splits, dividends, delistings, mergers, and ticker changes through history. The data covers approximately 27,500 US Equities, starts in January 1998, and is delivered on a daily update frequency. You can easily download and install the dataset with the LEAN CLI so it's ready to use by LEAN. LEAN automatically handles all corporate actions and passes them into your algorithm as events .

This is `NOT` the underlying Equity data (US Equities dataset), which you need to purchase separately with a license from AlgoSeek. This security master dataset is required to purchase the US Equities or US Equities Options datasets.

For more information about the US Equity Security Master dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Data Summary

Data is delivered as a daily updated zip archive of map and factor files. The data is designed to be used in the LEAN Engine and cannot be consumed another way. The following table shows the dataset properties:

Property	Value
Start Date	January 1998
Data Points	Splits, Dividends, Mergers, IPO, & Delistings
Asset Coverage	27,500 US Equities
Resolution	Daily
Timezone	New York

This is `not` the underlying Equity data (US Equities dataset), which you need to purchase separately with a license from AlgoSeek. This security master dataset is required to purchase the US Equities or US Equities Options datasets.

Getting Started

You don't need any special code to utilize the US Equity Security Master. It automatically loads when you request US Equities data .

Accessing Splits

To get the current split data, index the `splits` property of the current `Slice` with the Equity `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```py
def on_data(self, slice: Slice) -> None:
    # Check if any splits for the symbol
    if slice.splits.contains_key(self._symbol):
        # If so, get the mapped split object
        split = slice.splits[self._symbol]
        split_type = {0: "Warning", 1: "SplitOccurred"}.get(split.type)
        self.log(f"Split: {split.symbol}\t{split.split_factor}\t{split.reference_price}\t{split_type}")
```

For more information about accessing splits, see Splits .

Accessing Dividends

To get the current dividend data, index the `dividends` property of the current `Slice` with the Equity `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    # Check if any dividend for the symbol
    if slice.dividends.contains_key(self._symbol):
        # If so, get the mapped dividend object
        dividend = slice.dividends[self._symbol]
        self.log(f'Dividend: {dividend.symbol}\t{dividend.distribution}\t{dividend.reference_price}')
```

For more information about accessing dividends, see Dividends .

Accessing Delistings

To get the current Delistings data, index the `delistings` property of the current `Slice` with the Equity `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    # Check if any delisting for the symbol
    if slice.delistings.contains_key(self._symbol):
        # If so, get the mapped delisting object
        delisting = slice.delistings[self._symbol]
        delisting_type = {0: "Warning", 1: "Delisted"}.get(delisting.type)
        self.log(f'Delistings: {delisting_type}')
```

For more information about accessing delistings, see Delistings .

Accessing Symbol Change Events

To get the current Symbol change events, index the `symbol_changed_events` property of the current `Slice` with the Equity `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    # Check if any symbol change event for the symbol
    if slice.symbol_changed_events.contains_key(self._symbol):
        # If so, get the mapped SymbolChangeEvent object
        symbol_changed_event = slice.symbol_changed_events[self._symbol]
        self.log(f"Symbol changed: {symbol_changed_event.old_symbol} -> {symbol_changed_event.new_symbol}")
```

For more information about accessing Symbol change events, see Symbol Changes .

Historical Data

To get historical US Equity Security Master data, call the `history` method with the data type and the Equity `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY
# Splits
split_history_df = self.history(Split, self._symbol, timedelta(5*365))
split_history = self.history[Split](self._symbol, timedelta(5*365))

# Dividends
dividend_history_df = self.history(Dividend, self._symbol, timedelta(5*365))
dividend_history = self.history[Dividend](self._symbol, timedelta(5*365))

# Symbol Changes
symbol_change_history_df = self.history(SymbolChangedEvent, self._symbol, timedelta(5*365))
symbol_change_history = self.history[SymbolChangedEvent](self._symbol, timedelta(5*365))

# Delistings
delisting_history_df = self.history(Delisting, self._symbol, timedelta(5*365))
delisting_history = self.history[Delisting](self._symbol, timedelta(5*365))
```

For more information about historical data, see History Requests .

Live Trading Considerations

In backtesting, corporate actions occurs at midnight (ET). In live trading, the live data for corporate actions arrives at 6/7 AM ET, so that's when they occur.

Supported Assets

To view the supported assets in the US Equity Security Master dataset, see the Data Explorer . This dataset doesn't include Over-the-Counter (OTC) stocks.

Example Applications

The US Security Master enables you to accurately design strategies harnessing any core corporate actions. Examples include the following strategies:

- Post-dividend announcement trading strategies.
- Trading on new Equities by monitoring for IPOs.
- Harnessing split announcements for reverse-split announcement momentum.

Classic Algorithm Example

The following example algorithm logs the `Split` , `Dividend` , `Delisting` , and `SymbolChangedEvent` objects of Apple:

```py
from AlgorithmImports import *

class USEquitySecurityMasterAlgorithm (QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000000)

        self.equity = self.add_equity("AAPL", Resolution.DAILY).symbol

    def on_data(self, slice: Slice) -> None:
        # Accessing Data - Splits
        split = slice.splits.get(self.equity)
        if split:
            self.debug(f"{self.time} >> SPLIT >> {split.symbol} - {split.split_factor} - {self.portfolio.cash} -
{self.portfolio[self.equity].price}")

        # Accessing Data - Dividends
        dividend = slice.dividends.get(self.equity)
        if dividend:
            self.debug(f"{self.time} >> DIVIDEND >> {dividend.symbol} - {dividend.distribution} - {self.portfolio.cash} -
{self.portfolio[self.equity].price}")

        # Accessing Data - Delisting
        delisting = slice.delistings.get(self.equity)
        if delisting:
            delistingType = {0: "Warning", 1: "Delisted"}.get(delisting.type)
            self.debug(f"{self.time} >> DELISTING >> {delisting.symbol} - {delistingType}")

        # Accessing Data - Symbol Changed Event
        symbolChangedEvent = slice.symbol_changed_events.get(self.equity)
        if symbolChangedEvent:
            self.debug(f"{self.time} >> SYMBOL CHANGED >> {symbolChangedEvent.old_symbol} -> {symbolChangedEvent.new_symbol}")
```

Framework Algorithm Example

The following algorithm demonstrates the payments for cash dividends in backtesting. When the data normalization mode is `Raw` , your portfolio receives cash dividends.

```py
from AlgorithmImports import *

class PaymentAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # this will use the Tradier Brokerage open order split behavior
        # forward split will modify open order to maintain order value
        # reverse split open orders will be canceled
        self.set_brokerage_model(BrokerageName.TRADIER_BROKERAGE)

        self.universe_settings.resolution = Resolution.DAILY
        self.universe_settings.data_normalization_mode = DataNormalizationMode.RAW

        # MSFT: Splits and Dividends
        # GOOG: Symbol Changed Event
        # AAA.1: Delisting

        self.set_universe_selection(ManualUniverseSelectionModel(
            Symbol.create("MSFT", SecurityType.EQUITY, Market.USA)))

        self.set_alpha(PaymentAlphaModel())
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())
        self.set_execution(BracketExecutionModel())

class PaymentAlphaModel(AlphaModel):

    symbol = Symbol.EMPTY

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        # Accessing Data - Splits
        split = slice.splits.get(self.symbol)
        if split:
            algorithm.debug(f"{algorithm.time} >> SPLIT >> {split.symbol} - {split.split_factor} - {algorithm.portfolio.cash} -
{algorithm.portfolio[self.symbol].price}")

        # Accessing Data - Dividends
        dividend = slice.dividends.get(self.symbol)
        if dividend:
            algorithm.debug(f"{algorithm.time} >> DIVIDEND >> {dividend.symbol} - {dividend.distribution} - {algorithm.portfolio.cash} -
{algorithm.portfolio[self.symbol].price}")

        # Accessing Data - Delistings
        delisting = slice.delistings.get(self.symbol)
        if delisting:
            delistingType = {0: "Warning", 1: "Delisted"}.get(delisting.type)
            algorithm.debug(f"{algorithm.time} >> DELISTING >> {delisting.symbol} - {delistingType}")

        # Accessing Data - Symbol Changed Events
        symbolChangedEvent = slice.symbol_changed_events.get(self.symbol)
        if symbolChangedEvent:
            algorithm.debug(f"{algorithm.time} >> SYMBOL CHANGED >> {symbolChangedEvent.old_symbol} -> {symbolChangedEvent.new_symbol}")

        bar = slice.bars.get(self.symbol)
        return [Insight.price(self.symbol, timedelta(1), InsightDirection.UP)] if bar else []

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        self.symbol = list(changes.added_securities)[0].symbol

class BracketExecutionModel(ExecutionModel):

    def __init__(self) -> None:
        '''Initializes a new instance of the ImmediateExecutionModel class'''
        self.targets_collection = PortfolioTargetCollection()

    def execute(self, algorithm: QCAlgorithm, targets: List[PortfolioTarget]) -> None:

        # for performance we check count value, OrderByMarginImpact and ClearFulfilled are expensive to call
        self.targets_collection.add_range(targets)
        if self.targets_collection.count > 0:
            for target in self.targets_collection.order_by_margin_impact(algorithm):
                # calculate remaining quantity to be ordered
                quantity = OrderSizing.get_unordered_quantity(algorithm, target)
                if quantity != 0 and algorithm.transactions.orders_count == 0:
                    bar = algorithm.securities[target.symbol].get_last_data()
                    algorithm.market_order(target.symbol, quantity)
                    # place some orders that won't fill, when the split comes in they'll get modified to reflect the split
                    algorithm.stop_market_order(target.symbol, -quantity, bar.low/2)
                    algorithm.limit_order(target.symbol, -quantity, bar.high*2)

            self.targets_collection.clear_fulfilled(algorithm)
```

Data Point Attributes

The US Equity Security Master dataset provides `Split`, `Dividend`, `Delisting`, and `SymbolChangedEvent` objects.

Split Attributes

When a split or merger occurs, we pass the previous `Symbol` data into your algorithm. `Split` objects have the following attributes:

Dividend Attributes

Dividend events are triggered on the payment date. `Dividend` objects have the following attributes:

Delisting Attributes

When a security is delisted, we notify your algorithm. `Delisting` objects have the following attributes:

SymbolChangedEvent Attributes

When a security changes their ticker, we notify your algorithm. `SymbolChangedEvent` objects have the following attributes:

QuantConnect

US Future Option Universe

Introduction

The US Future Option Universe dataset by QuantConnect lists the available US Future Options contracts and the current open interest. The data covers 15 Monthly Future contracts, starts in January 2012, and is delivered on a daily update frequency. This dataset is created by monitoring the trading activity on the CME, CBOT, NYMEX, and COMEX markets.

The US Future Option Universe dataset depends on the US Future Universe dataset because the US Future Universe dataset contains the universe of underlying Futures contracts. This dataset also depends on the US Futures Security Master dataset because the US Futures Security Master dataset contains information on symbol changes of the contracts.

This dataset `does not` contain market data. For market data, see US Future Options by AlgoSeek .

For more information about the US Future Option Universe dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the US Future Options Universe dataset:

```
future = self.add_future(Futures.Metals.GOLD, Resolution.MINUTE)
future.set_filter(0, 90)
self.add_future_option(future.symbol, lambda universe: universe.strikes(-1, 1))
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2012
Asset Coverage	15 Monthly Future Contracts. Standard expires only. No weeklies or 0DTE contracts.
Data Density	Dense
Resolution	Daily
Timezone	New York
Market Hours	Regular and Extended

Requesting Data

To add US Future Options Universe data to your algorithm, call the `add_future_option` method. To define which contracts should be in your universe, specify the filter when requesting the Future Option data.

The `add_future_option` method provides a daily stream of Option chain data. To get the most recent daily chain, call the `option_chain` method with the underlying Future Symbol. The `option_chain` method returns data on all the tradable contracts, not just the contracts that pass your universe filter.

```
class USFutureOptionsDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2020, 6, 1)
        self.set_end_date(2021, 6, 1)
        self.set_cash(100000)
        self.universe_settings.asynchronous = True

        self.future = self.add_future(Futures.Metals.GOLD, Resolution.MINUTE)
        self.future.set_filter(0, 90)
        # Set our strike/expiry filter for this option chain
        self.add_future_option(self.future.symbol, self._option_filter)

    def on_data(self, slice: Slice) -> None:
        # Get the entire Option chain for the current day.
        symbol = Symbol.create_canonical_option(self.future.mapped)
        chain = self.option_chain(symbol, flatten=True).data_frame

    def _option_filter(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
        # Contracts can be filtered by strike, and expiration
        return universe.strikes(-1, 1)
```

The Future resolution must be less than or equal to the Future Option resolution. For example, if you set the Future resolution to minute, then you must set the Future Option resolution to minute, hour, or daily.

For more information about creating US Future Option universes, see Future Options .

Accessing Data

For information about accessing US Future Options Universe data, see Future Options .

Historical Data

You can get historical US Future Options Universe data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Future Options Universe data in an algorithm, call the `history` method with the canonical mapped Future Option `Symbol` . This method returns data on all of the tradable contracts, not just the contracts that pass your universe filter. If there is no data in the period you request, the history result is empty.

```
future_option_symbol = Symbol.create_canonical_option(self.future.mapped)
# DataFrame
history_df = self.history(future_option_symbol, timedelta(10), flatten=True)
# OptionUniverse objects
history = self.history[OptionUniverse](future_option_symbol, timedelta(10))
```

For more information about historical US Future Options Universe data in algorithms, see Historical Data .

Historical Data In Research

To get historical US Future Options Universe data in the Research Environment, call the `history` method with the canonical Option `Symbol` . This method returns data on all of the tradable contracts, not just the contracts that pass your universe filter.

```
qb = QuantBook()
future = qb.add_future(Futures.Metals.GOLD, Resolution.MINUTE)
future.set_filter(0, 90)
symbol = Symbol.create_canonical_option(future.mapped)
history = qb.history(symbol, datetime(2020, 6, 1), datetime(2020, 6, 5), flatten=True)
```

For more information about historical Future Options Universe data in the Research Environment, see Universes .

Supported Assets

The following list shows the available (15) Futures Options:

- `Futures.Energy.CRUDE_OIL_WTI` : Crude Oil WTI Futures (NYMEX: LO | Underlying: CL)
- `Futures.Energy.GASOLINE` : Gasoline RBOB Futures (NYMEX: OB | Underlying: RB)
- `Futures.Energy.HEATING_OIL` : Heating Oil Futures (NYMEX: OH | Underlying: HO)

- `Futures.Energy.NATURAL_GAS` : Natural Gas Futures (NYMEX: ON | Underlying: NG)
- `Futures.Financials.Y_10_TREASURY_NOTE` : 10Y U.S. Treasury Note Futures (CBOT: OZN | Underlying: ZN)
- `Futures.Financials.Y_2_TREASURY_NOTE` : 2Y U.S. Treasury Note Futures (CBOT: OZT | Underlying: ZT)
- `Futures.Financials.Y_30_TREASURY_BOND` : 30Y U.S. Treasury Bond Futures (CBOT: OZB | Underlying: ZB)
- `Futures.Grains.CORN` : Corn Futures (CBOT: OZC | Underlying: ZC)
- `Futures.Grains.SOYBEANS` : Soybeans Futures (CBOT: OZS | Underlying: ZS)
- `Futures.Grains.WHEAT` : Default wheat contract is SRWWheat (CBOT: OZW | Underlying: ZW)
- `Futures.Indices.NASDAQ_100_E_MINI` : E-mini NASDAQ 100 Futures (CME: NQ)
- `Futures.Indices.SP_500_E_MINI` : E-mini S&P 500 Futures (CME: ES)
- `Futures.Metals.COPPER` : Copper Futures (COMEX: HXE | Underlying: HG)
- `Futures.Metals.GOLD` : Gold Futures (COMEX: OG | Underlying: GC)
- `Futures.Metals.SILVER` : Silver Futures (COMEX: SO | Underlying: SI)

Example Applications

The US Future Options dataset enables you to accurately design Future Option strategies. Examples include the following strategies:

- Selling out of the money Future Option contracts to collect the premium that the Option buyer pays
- Buying put Options to hedge against downward price movement in Future contracts you bought
- Exploiting arbitrage opportunities that arise when the price of Option contracts deviate from their theoretical value

Classic Algorithm Example

The following example demonstrates a bull call spread Option strategy using universe filtering.

```
PY
from AlgorithmImports import *

class FutureOptionAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Filter the underlying continuous Futures to narrow the FOP spectrum.
        self.underlying = self.add_future(Futures.Indices.SP_500_E_MINI,
            extended_market_hours=True,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0)
        self.underlying.set_filter(0, 182)
        # Use CallSpread filter to obtain the 2 best-matched contracts that forms a call spread.
        # It simplifies from further filtering and reduce computation on redundant subscription.
        self.add_future_option(self.underlying.symbol, lambda u: u.call_spread(5, 5, -5))

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested:
            return
        # Create canonical symbol for the mapped future contract, since we need that to access the option chain.
        symbol = Symbol.create_canonical_option(self.underlying.mapped)

        # Get option chain data for the mapped future only.
        # It requires 2 contracts with different strikes to form a call spread, so we make sure at least 2 contracts are present.
        chain = slice.option_chains.get(symbol)
        if not chain or len(list(chain)) < 2:
            return

        # Separate the contracts by strike, as we need to access their strike.
        expiry = min([x.expiry for x in chain])
        sorted_by_strike = sorted([x.strike for x in chain])
        itm_strike = sorted_by_strike[0]
        otm_strike = sorted_by_strike[-1]

        # Use abstraction method to order a bull call spread to avoid manual error.
        option_strategy = OptionStrategies.bull_call_spread(symbol, itm_strike, otm_strike, expiry)
        self.buy(option_strategy, 1)
```

Data Point Attributes

The US Future Options Universe dataset provides `OptionFilterUniverse` and `OptionUniverse` objects.

OptionFilterUniverse Attributes

`OptionFilterUniverse` objects have the following attributes:

OptionUniverse Attributes

`OptionUniverse` objects have the following attributes:

QuantConnect

US Future Universe

Introduction

The US Future Universe dataset by QuantConnect lists the available US Future contracts, their daily trading volume, and Open Interest. The data covers the 157 most liquid contracts, starts in May 2009, and is delivered on daily frequency. This dataset is created by monitoring the trading activity on the CFE, CBOT, CME, COMEX, NYMEX, and ICE *.

This dataset depends on the US Futures Security Master dataset because the US Futures Security Master dataset contains information on symbol changes of the contracts.

This dataset `does not` contain market data. For market data, see US Futures by AlgoSeek .

For more information about the US Future Universe dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the US Future Universe dataset:

```py
future = self.add_future(Futures.Metals.GOLD)
future.set_filter(0, 90)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	May 2009
Asset Coverage	157 Futures
Data Density	Dense
Resolution	Daily
Timezone	• Chicago (CFE, CME or CBOT) • New York (ICE, NYMEX or COMEX)
Market Hours	Regular and Extended

Requesting Data

To add US Future Universe data to your algorithm, call the `add_future` method. Save a reference to the Future object so you can access the data later in your algorithm. To define which contracts should be in your universe, specify the filter when requesting the Future data.

The `add_future` method provides a daily stream of Future chain data. To get the most recent daily chain, call the `futures_chain` method with the underlying Future Symbol. The `futures_chain` method returns data on all the tradable contracts, not just the contracts that pass your universe filter.

```
class USFutureDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2020, 6, 1)
        self.set_end_date(2021, 6, 1)
        self.set_cash(100000)
        self.universe_settings.asynchronous = True
        self._future = self.add_future(Futures.Metals.GOLD)
        # Set our contract filter for this Future chain.
        self._future.set_filter(lambda universe: universe.standards_only().front_month())
        # Get the entire Futures chain for the current day.
        chain = self.futures_chain(self._future.symbol, flatten=True).data_frame
```

For more information about creating US Future universes, see Futures .

Accessing Data

For information about accessing US Future Universe data, see Futures .

Historical Data

You can get historical US Future Universe data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Future Universe data in an algorithm, call the `history` method with continuous Future `Symbol` and a lookback period. This method returns the all the available contracts for each trading day, not the subset of contracts that pass your universe filter. If there is no data for the period you requested, the history result is empty.

```
# Add the Future and save a reference to it.
future = self.add_future(Futures.Metals.GOLD)

# DataFrame example where the columns are the FutureUniverse attributes:
history_df = self.history(FutureUniverse, future.symbol, 5, flatten=True)

# Series example where the values are lists of FutureUniverse objects:
history_series = self.history(FutureUniverse, future.symbol, 5, flatten=False)

# FutureUniverse objects example:
history = self.history[FutureUniverse](future.symbol, 5)
```

For more information about historical US Future Universe data in algorithms, see Contracts .

Historical Data In Research

To get historical US Future Universe data in the Research Environment, call the `history` method with continuous Future `Symbol` and a time period. This method returns the all the available contracts for each trading day, not the subset of contracts that pass your universe filter. If there is no data for the period you requested, the history result is empty.

```
# Add the Future and save a reference to it.
future = qb.add_future(Futures.Metals.GOLD)

# DataFrame example where the columns are the FutureUniverse attributes:
history_df = qb.history(FutureUniverse, future.symbol, datetime(2025, 1, 1), datetime(2025, 4, 1), flatten=True)

# Series example where the values are lists of FutureUniverse objects:
history_series = qb.history(FutureUniverse, future.symbol, 5, flatten=False)

# FutureUniverse objects example:
history = qb.history[FutureUniverse](future.symbol, datetime(2025, 1, 1), datetime(2025, 4, 1))
```

For more information about historical US Future Universe data in the Research Environment, see Daily Prices History .

Supported Assets

The following list shows the available (157) Futures:

- `Futures.Currencies.AUD` : Australian Dollar Futures (CME: 6A)
- `Futures.Currencies.AUDCAD` : Australian Dollar/Canadian Dollar Futures (CME: ACD)

- `Futures.Currencies.AUDJPY` : Australian Dollar/Japanese Yen Futures (CME: AJY)
- `Futures.Currencies.AUDNZD` : Australian Dollar/New Zealand Dollar Futures (CME: ANE)
- `Futures.Currencies.BRL` : Brazillian Real Futures (CME: 6L)
- `Futures.Currencies.BTC` : Bitcoin Futures (CME: BTC)
- `Futures.Currencies.BTIC_MICRO_BTC` : BTIC on Micro Bitcoin Futures (CME: MIB)
- `Futures.Currencies.BTIC_MICRO_ETHER` : BTIC on Micro Ether Futures (CME: MRB)
- `Futures.Currencies.CAD` : Canadian Dollar Futures (CME: 6C)
- `Futures.Currencies.CADJPY` : Canadian Dollar/Japanese Yen Futures (CME: CJY)
- `Futures.Currencies.CHF` : Swiss Franc Futures (CME: 6S)
- `Futures.Currencies.ETH` : Ether Futures (CME: ETH)
- `Futures.Currencies.EUR` : Euro FX Futures (CME: 6E)
- `Futures.Currencies.EURAUD` : Euro/Australian Dollar Futures (CME: EAD)
- `Futures.Currencies.EURCAD` : Euro/Canadian Dollar Futures (CME: ECD)
- `Futures.Currencies.EURO_FX_EMINI` : E-mini Euro FX Futures (CME: E7)
- `Futures.Currencies.EURSEK` : Euro/Swedish Krona Futures (CME: ESK)
- `Futures.Currencies.GBP` : British Pound Futures (CME: 6B)
- `Futures.Currencies.JAPANESE_YEN_EMINI` : E-mini Japanese Yen Futures (CME: J7)
- `Futures.Currencies.JPY` : Japanese Yen Futures (CME: 6J)
- `Futures.Currencies.MICRO_AUD` : Micro AUD/USD Futures (CME: M6A)
- `Futures.Currencies.MICRO_BTC` : Micro Bitcoin Futures (CME: MBT)
- `Futures.Currencies.MICRO_CAD` : Micro USD/CAD Futures (CME: M6C)
- `Futures.Currencies.MICRO_CADUSD` : Micro CAD/USD Futures (CME: MCD)
- `Futures.Currencies.MICRO_CHF` : Micro CHF/USD Futures (CME: MSF)
- `Futures.Currencies.MICRO_ETHER` : Micro Ether Futures (CME: MET)
- `Futures.Currencies.MICRO_EUR` : Micro EUR/USD Futures (CME: M6E)
- `Futures.Currencies.MICRO_GBP` : Micro GBP/USD Futures (CME: M6B)
- `Futures.Currencies.MICRO_INRUSD` : Micro INR/USD Futures (CME: MIR)
- `Futures.Currencies.MICRO_JPY` : Micro JPY/USD Futures (CME: MJY)
- `Futures.Currencies.MICRO_USDCHF` : Micro USD/CHF Futures (CME: M6S)
- `Futures.Currencies.MICRO_USDCNH` : Micro USD/CNH Futures (CME: MNH)
- `Futures.Currencies.MICRO_USDJPY` : Micro USD/JPY Futures (CME: M6J)
- `Futures.Currencies.MXN` : Mexican Peso Futures (CME: 6M)
- `Futures.Currencies.NZD` : New Zealand Dollar Futures (CME: 6N)
- `Futures.Currencies.RUB` : Russian Ruble Futures (CME: 6R)
- `Futures.Currencies.STANDARD_SIZE_USD_OFFSHORE_RMBCNH` : Standard-Size USD/Offshore RMB (CNH) Futures (CME: CNH)
- `Futures.Currencies.ZAR` : South African Rand Futures (CME: 6Z)
- `Futures.Energy.ARGUS_LL_SVS_WTI_ARGUS_TRADE_MONTH` : Argus LLS vs. WTI (Argus) Trade Month Futures (NYMEX: AE5)
- `Futures.Energy.ARGUS_PROPANE_FAR_EAST_INDEX` : Argus Propane Far East Index Futures (NYMEX: A7E)
- `Futures.Energy.ARGUS_PROPANE_SAUDI_ARAMCO` : Argus Propane (Saudi Aramco) Futures (NYMEX: A9N)
- `Futures.Energy.BRENT_CRUDE_OIL_VS_DUBAI_CRUDE_OIL_PLATTS` : Brent Crude Oil vs. Dubai Crude Oil (Platts) Futures (NYMEX: ADB)
- `Futures.Energy.BRENT_LAST_DAY_FINANCIAL` : Brent Last Day Financial Futures (NYMEX: BZ)
- `Futures.Energy.CHICAGO_ETHANOL_PLATTS` : Chicago Ethaanol (Platts) Futures (NYMEX: CU)
- `Futures.Energy.CONWAY_PROPANE_OPIS` : Conway Propane (OPIS) Futures (NYMEX: A8K)
- `Futures.Energy.CRUDE_OIL_WTI` : Crude Oil WTI Futures (NYMEX: CL)
- `Futures.Energy.DUBAI_CRUDE_OIL_PLATTS_FINANCIAL` : Dubai Crude Oil (Platts) Financial Futures (NYMEX: DCB)
- `Futures.Energy.EAST_WEST_GASOLINE_SPREAD_PLATTS_ARGUS` : East-West Gasoline Spread (Platts-Argus) Futures (NYMEX: EWG)
- `Futures.Energy.EAST_WEST_NAPHTHA_JAPAN_C_FVS_CARGOES_CIFNWE_SPREAD_PLATTS` : East-West Naphtha: Japan C&F vs. Cargoes CIF NWE Spread (Platts) Futures (NYMEX: EWN)
- `Futures.Energy.ETHANOL` : Ethanol Futures (CBOT: EH)
- `Futures.Energy.ETHANOL_T_2_FOB_RDAM_INCLUDING_DUTY_PLATTS` : Ethanol T2 FOB Rdam Including Duty (Platts) Futures (NYMEX: AZ1)
- `Futures.Energy.EUROPEAN_NAPHTHA_PLATTS_CRACK_SPREAD` : European Naphtha (Platts) Crack Spread Futures (NYMEX: EN)
- `Futures.Energy.EUROPEAN_PROPANE_CIFARA_ARGUS` : European Propane CIF ARA (Argus) Futures (NYMEX: APS)

- `Futures.Energy.EUROPEAN_PROPANE_CIFARA_ARGUS_VS_NAPHTHA_CARGOES_CIFNWE_PLATTS` : European Propane CIF ARA (Argus) vs. Naphtha Cargoes CIF NWE (Platts) Futures (NYMEX: EPN)
- `Futures.Energy.FREIGHT_ROUTE_TC_14_BALTIC` : Freight Route TC14 (Baltic) Futures (NYMEX: FRC)
- `Futures.Energy.GASOLINE` : Gasoline RBOB Futures (NYMEX: RB)
- `Futures.Energy.GASOLINE_EUROBOB_OXY_NWE_BARGES_ARGUS` : Gasoline Euro-bob Oxy NWE Barges (Argus) Futures (NYMEX: B7H)
- `Futures.Energy.GROUP_THREE_SUBOCTANE_GASOLINE_PLATTS_VS_RBOB` : Group Three Sub-octane Gasoliine (Platts) vs. RBOB Futures (NYMEX: AA8)
- `Futures.Energy.GROUP_THREE_ULSD_PLATTS_VS_NY_HARBOR_ULSD` : Group Three ULSD (Platts) vs. NY Harbor ULSD Futures (NYMEX: AA6)
- `Futures.Energy.GULF_COAST_CBOB_GASOLINE_A_2_PLATTS_VS_RBOB_GASOLINE` : Gulf Coast CBOB Gasoline A2 (Platts) vs. RBOB Gasoline Futures (NYMEX: CRB)
- `Futures.Energy.GULF_COAST_HSFO_PLATTS_VS_EUROPEAN_THREE_POINT_FIVE_PERCENT_FUEL_OIL_BARGES_FOB_RDAM_PLATTS` : Gulf Coast HSFO (Platts) vs. European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: GCU)
- `Futures.Energy.HEATING_OIL` : Heating Oil Futures (NYMEX: HO)
- `Futures.Energy.LOS_ANGELES_CARBOB_GASOLINE_OPI_SVS_RBOB_GASOLINE` : Los Angeles CARBOB Gasoline (OPIS) vs. RBOB Gasoline Futures (NYMEX: AJL)
- `Futures.Energy.LOS_ANGELES_CARB_DIESEL_OPI_SVS_NY_HARBOR_ULSD` : Los Angeles CARB Diesel (OPIS) vs. NY Harbor ULSD Futures (NYMEX: AKL)
- `Futures.Energy.LOS_ANGELES_JET_OPI_SVS_NY_HARBOR_ULSD` : Los Angeles Jet (OPIS) vs. NY Harbor ULSD Futures (NYMEX: AJS)
- `Futures.Energy.MARS_ARGUS_VS_WTI_FINANCIAL` : Mars (Argus) vs. WTI Financial Futures (NYMEX: AYX)
- `Futures.Energy.MARS_ARGUS_VS_WTI_TRADE_MONTH` : Mars (Argus) vs. WTI Trade Month Futures (NYMEX: AYV)
- `Futures.Energy.MICRO_CRUDE_OIL_WTI` : Micro WTI Crude Oil Futures (NYMEX: MCL)
- `Futures.Energy.MICRO_EUROPEAN_FOB_RDAM_MARINE_FUEL_ZERO_POINT_FIVE_PERCENT_BARGES_PLATTS` : Micro European FOB Rdam Marine Fuel 0.5% Barges (Platts) Futures (NYMEX: R5O)
- `Futures.Energy.MICRO_EUROPEAN_THREE_POINT_FIVE_PERCENT_OIL_BARGES_FOB_RDAM_PLATTS` : Micro European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: MEF)
- `Futures.Energy.MICRO_GASOIL_ZERO_POINT_ONE_PERCENT_BARGES_FOBARA_PLATTS` : Micro Gasoil 0.1% Barges FOB ARA (Platts) Futures (NYMEX: M1B)
- `Futures.Energy.MICRO_SINGAPORE_FOB_MARINE_FUEL_ZERO_POINT_FIVE_PERCET_PLATTS` : Micro Singapore FOB Marine Fuel 0.5% (Platts) Futures (NYMEX: S5O)
- `Futures.Energy.MICRO_SINGAPORE_FUEL_OIL_380_CST_PLATTS` : Micro Singapore Fuel Oil 380CST (Platts) Futures (NYMEX: MAF)
- `Futures.Energy.MINI_EUROPEAN_THREE_POINT_PERCENT_FIVE_FUEL_OIL_BARGES_PLATTS` : Mini European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: A0D)
- `Futures.Energy.MINI_SINGAPORE_FUEL_OIL_180_CST_PLATTS` : Mini Singapore Fuel Oil 180 cst (Platts) Futures (NYMEX: A0F)
- `Futures.Energy.MONT_BELVIEU_ETHANE_OPIS` : Mont Belvieu Ethane (OPIS) Futures (NYMEX: AC0)
- `Futures.Energy.MONT_BELVIEU_LDH_PROPANE_OPIS` : Mont Belvieu LDH Propane (OPIS) Futures (NYMEX: B0)
- `Futures.Energy.MONT_BELVIEU_NATURAL_GASOLINE_OPIS` : Mont Belvieu Natural Gasoline (OPIS) Futures (NYMEX: A7Q)
- `Futures.Energy.MONT_BELVIEU_NORMAL_BUTANE_OPIS` : Mont Belvieu Normal Butane (OPIS) Futures (NYMEX: AD0)
- `Futures.Energy.NATURAL_GAS` : Natural Gas Futures (NYMEX: NG)
- `Futures.Energy.NATURAL_GAS_HENRY_HUB_LAST_DAY_FINANCIAL` : Natural Gas (Henry Hub) Last-day Financial Futures (NYMEX: HH)
- `Futures.Energy.NATURAL_GAS_HENRY_HUB_PENULTIMATE_FINANCIAL` : Natural Gas (Henry Hub) Penultimate Financial Futures (NYMEX: HP)
- `Futures.Energy.ONE_PERCENT_FUEL_OIL_CARGOES_FOBNWE_PLATTS_VS_THREE_POINT_FIVE_PERCENT_FUEL_OIL_BARGES_FOB_RDAM_PLATTS` : 1% Fuel Oil Cargoes FOB NWE (Platts) vs. 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: FSS)
- `Futures.Energy.PREMIUM_UNLEADED_GASOLINE_10_PPM_FOBMED_PLATTS` : Premium Unleaded Gasoline 10 ppm FOB MED (Platts) Futures (NYMEX: A3G)
- `Futures.Energy.PROPANE_NON_LDH_MONT_BELVIEU_OPIS` : Propane Non-LDH Mont Belvieu (OPIS) Futures (NYMEX: A1R)
- `Futures.Energy.RBOB_GASOLINE_CRACK_SPREAD` : RBOB Gasoline Crack Spread Futures (NYMEX: ARE)
- `Futures.Energy.RBOB_GASOLINE_VS_EUROBOB_OXY_NWE_BARGES_ARGUS_THREE_HUNDRED_FIFTY_THOUSAND_GALLONS` : RBOB Gasoline vs. Euro-bob Oxy NWE Barges (Argus) (350,000 gallons) Futures (NYMEX: EXR)
- `Futures.Energy.SINGAPORE_FUEL_OIL_380_CST_PLATTS_VS_EUROPEAN_THREE_POINT_FIVE_PERCENT_FUEL_OIL_BARGES_FOB_RDAM_PLATTS` : Singapore Fuel Oil 380 cst (Platts) vs. European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: EVC)
- `Futures.Energy.SINGAPORE_GASOIL_PLATTS_VS_LOW_SULPHUR_GASOIL_FUTURES` : Singapore Gasoil (Platts) vs. Low Sulphur Gasoil Futures (NYMEX: AGA)

- `Futures.Energy.SINGAPORE_MOGAS_92_UNLEADED_PLATTS_BRENT_CRACK_SPREAD` : Singapore Mogas 92 Unleaded (Platts) Brent Crack Spread Futures (NYMEX: D1N)
- `Futures.Energy.THREE_POINT_FIVE_PERCENT_FUEL_OIL_BARGES_FOB_RDAM_PLATTS_CRACK_SPREAD` : 3.5% Fuel Oil Barges FOB Rdam (Platts) Crack Spread Futures (NYMEX: FO)
- `Futures.Energy.THREE_POINT_FIVE_PERCENT_FUEL_OIL_BARGES_FOB_RDAM_PLATTS_CRACK_SPREAD_1000_MT` : 3.5% Fuel Oil Barges FOB Rdam (Platts) Crack Spread (1000mt) Futures (NYMEX: BOO)
- `Futures.Energy.WTI_BRENT_FINANCIAL` : WTI-Brent Financial Futures (NYMEX: BK)
- `Futures.Energy.WTI_FINANCIAL` : WTI Financial Futures (NYMEX: CSX)
- `Futures.Energy.WTI_HOUSTON_ARGUS_VS_WTI_TRADE_MONTH` : WTI Houston (Argus) vs. WTI Trade Month Futures (NYMEX: HTT)
- `Futures.Energy.WTI_HOUSTON_CRUDE_OIL` : WTI Houston Crude Oil Futures (NYMEX: HCL)
- `Futures.Financials.EURO_DOLLAR` : EuroDollar Futures (CME: GE)
- `Futures.Financials.FIVE_YEAR_USDMAC_SWAP` : 5-Year USD MAC Swap Futures (CBOT: F1U)
- `Futures.Financials.MICRO_Y_10_TREASURY_NOTE` : Micro 10-Year Yield Futures (CBOT: 10Y)
- `Futures.Financials.MICRO_Y_2_TREASURY_BOND` : Micro 2-Year Yield Futures (CBOT: 2YY)
- `Futures.Financials.MICRO_Y_30_TREASURY_BOND` : Micro 30-Year Yield Futures (CBOT: 30Y)
- `Futures.Financials.MICRO_Y_5_TREASURY_BOND` : Micro 5-Year Yield Futures (CBOT: 5YY)
- `Futures.Financials.ULTRA_TEN_YEAR_US_TREASURY_NOTE` : Ultra 10-Year U.S. Treasury Note Futures (CBOT: TN)
- `Futures.Financials.ULTRA_US_TREASURY_BOND` : Ultra U.S. Treasury Bond Futures (CBOT: UB)
- `Futures.Financials.Y_10_TREASURY_NOTE` : 10Y U.S. Treasury Note Futures (CBOT: ZN)
- `Futures.Financials.Y_2_TREASURY_NOTE` : 2Y U.S. Treasury Note Futures (CBOT: ZT)
- `Futures.Financials.Y_30_TREASURY_BOND` : 30Y U.S. Treasury Bond Futures (CBOT: ZB)
- `Futures.Financials.Y_5_TREASURY_NOTE` : 5Y U.S. Treasury Note Futures (CBOT: ZF)
- `Futures.Forestry.LUMBER` : Lumber Futures (CME: LBR)
- `Futures.Forestry.RANDOM_LENGTH_LUMBER` : Random Length Lumber Futures (CME: LBS)
- `Futures.Grains.BLACK_SEA_CORN_FINANCIALLY_SETTLED_PLATTS` : Black Sea Corn Financially Settled (Platts) Futures (CBOT: BCF)
- `Futures.Grains.BLACK_SEA_WHEAT_FINANCIALLY_SETTLED_PLATTS` : Black Sea Wheat Financially Settled (Platts) Futures (CBOT: BWF)
- `Futures.Grains.CORN` : Corn Futures (CBOT: ZC)
- `Futures.Grains.HRW_WHEAT` : KC HRW Wheat Futures (CBOT: KE)
- `Futures.Grains.OATS` : Oats Futures (CBOT: ZO)
- `Futures.Grains.SOYBEANS` : Soybeans Futures (CBOT: ZS)
- `Futures.Grains.SOYBEAN_MEAL` : Soybean Meal Futures (CBOT: ZM)
- `Futures.Grains.SOYBEAN_OIL` : Soybean Oil Futures (CBOT: ZL)
- `Futures.Grains.WHEAT` : Default wheat contract is SRWWheat (CBOT: ZW)
- `Futures.Indices.BLOOMBERG_COMMODITY_INDEX` : Bloomberg Commodity Index Futures (CBOT: AW)
- `Futures.Indices.DOW_30_E_MINI` : E-mini Dow Indu 30 Futures (CBOT: YM)
- `Futures.Indices.DOW_JONES_REAL_ESTATE` : Dow Jones Real Estate futures on CME (CME: RX)
- `Futures.Indices.FTSE_EMERGING_EMINI` : E-mini FTSE Emerging Index Futures (CME: EI)
- `Futures.Indices.MICRO_DOW_30_E_MINI` : Micro E-mini Dow Jones Industrial Average Index Futures (CBOT: MYM)
- `Futures.Indices.MICRO_NASDAQ_100_E_MINI` : Micro E-mini Nasdaq-100 Index Futures (CME: MNQ)
- `Futures.Indices.MICRO_RUSSELL_2000_E_MINI` : Micro E-mini Russell 2000 Index Futures (CME: M2K)
- `Futures.Indices.MICRO_SP_500_E_MINI` : Micro E-mini S&P 500 Index Futures (CME: MES)
- `Futures.Indices.NASDAQ_100_BIOTECHNOLOGY_E_MINI` : E-mini Nasdaq-100 Biotechnology Index Futures (CME: BIO)
- `Futures.Indices.NASDAQ_100_E_MINI` : E-mini NASDAQ 100 Futures (CME: NQ)
- `Futures.Indices.NIKKEI_225_DOLLAR` : Nikkei-225 Dollar Futures (CME: NKD)
- `Futures.Indices.NIKKEI_225_YEN_CME` : Nikkei-225 Yen denominated Futures on CME (CME: NIY)
- `Futures.Indices.RUSSELL_1000_E_MINI` : E-mini Russell 1000 futures on CME (CME: RS1)
- `Futures.Indices.RUSSELL_2000_E_MINI` : E-mini Russell 2000 Futures (CME: RTY)

Example Applications

The US Future Universe dataset enables you to accurately design Futures strategies. Examples include the following strategies:

- Buying the Futures contract with the most open interest to reduce slippage and market impact
- Trading bull calendar spreads to reduce volatility and margin requirements
- Trading bull calendar spreads to speculate contango

Classic Algorithm Example

The following example algorithm selects and buys the front-month Mini Gold Futures contract and sells the front-month Micro Gold Futures contract. When the front-month contract changes, the algorithm rebalances the portfolio.

```py
from AlgorithmImports import *

class USFuturesDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000000)
        self.universe_settings.asynchronous = True
        # Requesting data on gold and micro-gold contracts.
        # Filter the universe to trade only the contracts expiring within 90 days to ensure liquidity.
        self.mini_gold = self.add_future(Futures.Metals.GOLD)
        self.mini_gold.set_filter(0, 90)

        self.micro_gold = self.add_future(Futures.Metals.MICRO_GOLD)
        self.micro_gold.set_filter(0, 90)

        # Save a cache of the mapped symbol to trade.
        self.contract = {self.mini_gold.symbol: None, self.micro_gold.symbol: None}

    def on_data(self, slice: Slice) -> None:
        for symbol, chain in slice.future_chains.items():
            if symbol in self.contract:
                # Select the contract with the greatest open interest to trade with the most efficiency.
                most_liquid_contract = sorted(chain, key=lambda contract: contract.open_interest, reverse=True)[0]

                if self.contract[symbol] is None or most_liquid_contract.symbol != self.contract[symbol].symbol:
                    # Liquidate any unmapped contracts.
                    if self.contract[symbol] is not None:
                        self.liquidate(self.contract[symbol].symbol)
                    self.contract[symbol] = most_liquid_contract

                    # Buy mini-gold and short micro-gold contracts as planned.
                    if symbol == self.mini_gold.symbol:
                        self.market_order(self.contract[symbol].symbol, 1)
                    elif symbol == self.micro_gold.symbol:
                        self.market_order(self.contract[symbol].symbol, -1)
```

Framework Algorithm Example

The following example algorithm selects and buys the front-month Mini Gold Futures contract and sells the front-month Micro Gold Futures contract. When the front-month contract changes, the algorithm rebalances the portfolio.

```py
from AlgorithmImports import *

class USFuturesDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.universe_settings.asynchronous = True
        # Set up an universe selection model that selects the front month contract
        self.set_universe_selection(FrontMonthFutureUniverseSelectionModel())
        self.add_alpha(ConstantFuturesAlphaModel())
        # A portfolio construction model that only order a single share per insight signal
        self.set_portfolio_construction(SingleSharePortfolioConstructionModel())

class FrontMonthFutureUniverseSelectionModel(FutureUniverseSelectionModel):
    def __init__(self,) -> None:
        # Daily updating with select_future_chain_symbols function
        super().__init__(timedelta(1), self.select_future_chain_symbols)

    def select_future_chain_symbols(self, utcTime: datetime) -> List[Symbol]:
        # Select gold and micro gold contracts for the strategy need
        future_pairs = [
            (Futures.Metals.GOLD, Market.COMEX),
            (Futures.Metals.MICRO_GOLD, Market.COMEX)
        ]
        return [Symbol.create(pair[0], SecurityType.FUTURE, pair[1]) for pair in future_pairs]

    def filter(self, filter: FutureFilterUniverse) -> FutureFilterUniverse:
        # Filter only front month contract for liquidity and most informed information
        return filter.front_month().only_apply_filter_at_market_open()

class ConstantFuturesAlphaModel(AlphaModel):
    # Long gold and short micro gold in this strategy
    long_symbol = Symbol.create(Futures.Metals.GOLD, SecurityType.FUTURE, Market.COMEX)
    short_symbol = Symbol.create(Futures.Metals.MICRO_GOLD, SecurityType.FUTURE, Market.COMEX)

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        if algorithm.portfolio.invested:
            return []

        insights = []

        for kvp in slice.future_chains:
            chain = [contract for contract in kvp.Value]
            contract = chain[0]

            # Long gold and short micro gold as planned
            if kvp.Key == self.long_symbol:
                insights.append(Insight.price(contract.symbol, contract.expiry + timedelta(days=1), InsightDirection.UP))
            elif kvp.Key == self.short_symbol:
                insights.append(Insight.price(contract.symbol, contract.expiry + timedelta(days=1), InsightDirection.DOWN))

        return insights

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            # Historical data
            history = algorithm.history(security.symbol, 10, Resolution.MINUTE)
            algorithm.debug(f"We got {len(history)} from our history request for {security.symbol}")

class SingleSharePortfolioConstructionModel(PortfolioConstructionModel):
    def create_targets(self, algorithm: QCAlgorithm, insights: List[Insight]) -> List[PortfolioTarget]:
        targets = []
        for insight in insights:
            if algorithm.securities[insight.symbol].is_tradable:
                # Single share only using integer portfolio target
                targets.append(PortfolioTarget(insight.symbol, insight.direction))
        return targets
```

Data Point Attributes

The US Future Universe dataset provides `FutureFilterUniverse` and `FutureUniverse` objects.

FutureFilterUniverse Attributes

`FutureFilterUniverse` objects have the following attributes:

FutureUniverse Attributes

`FutureUniverse` objects have the following attributes:

QuantConnect

US Futures Security Master

Introduction

The US Futures Security Master dataset by QuantConnect provides mapping reference data for the most liquid contracts of the CME Group exchanges, calculated with popular rolling techniques. The data covers 157 root Future contracts, starts in May 2009, and is delivered on a daily frequency with a zip file with all the contract mappings. This dataset is created by daily processing of the US historical Future chains.

This dataset, paired with the US Futures dataset, supports the following rolling techniques: forward panama canal, backwards panama canal, and backwards ratio. You can set the specific rolling date to occur on the last trading day, first day month, or the day when the contract with the greatest open interest changes.

VIX Futures don't support continous contract rolling with open interest.

This is `NOT` the underlying Futures data (US Futures dataset), which you need to purchase separately with a license from AlgoSeek. This security master dataset is required to purchase the US Futures or US Future Options datasets.

For more information about the US Futures Security Master dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

You don't need any special code to utilize the US Futures Security Master. It automatically loads when you request US Futures data .

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	May 2009
Asset Coverage	157 Liquid Futures
Data Density	Regular
Resolution	Daily

VIX Futures don't support continous contract rolling with open interest.

Key Concept

The US Futures Security Master lets you to construct continuous Futures, allowing the access of normalized historical data of the underlying assets, as well as trading the “lead” Future contracts for those assets.

Continuous Futures refer to sets of rolling lead Future contracts during their actively trading periods. Since Future contracts expire at their maturities, to analyze the historical price of a Future and to apply technical indicators, you need the continuous Future price series.

To access the continuous Future, use the Future's `symbol` property.

```
# Set the data normalization mode and data mapping mode to select the contract as the continuous contract with price adjustment for
smooth price series
future = self.add_future(Futures.Energy.CRUDE_OIL_WTI,
    data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
    data_mapping_mode=DataMappingMode.OPEN_INTEREST,
    contract_depth_offset=0)
self.continuous_contract_symbol = future.symbol
```

The `dataNormalizationMode` and `dataMappingMode` arguments makes the transition of the underlying contracts seemless. However, the Future `Symbol` doesn't map to an underlying Future contract. It works fine to trade within backtests, but could be subjected to friction costs during live trading since the order price could be a normalized price. For more information about this topic, see the `Live Trading Considerations` section.

Data Normalization Modes

The data normalization mode defines how the price series of two contracts are stitched together when the contract rollovers occur. The `DataNormalizatoinMode` enumeration has the following members available for continuous contracts:

If you use a data normalization mode that's not in the preceding list, LEAN automatically converts it to `DataNormalizationMode.BackwardsRatio` .

Data Mapping Modes

The data mapping mode defines when contract rollovers occur. The `DataMappingMode` enumeration has the following members:

VIX Futures don't support continous contract rolling with `DataMappingMode.OPEN_INTEREST` and `DataMappingMode.OPEN_INTEREST_ANNUAL` .

Tracking Contract Changes

As the contracts roll over, the `mapped` property of the `Future` object references the next contract in the series and you receive a `SymbolChangedEvent` . To get the current `Symbol` change events, index the `symbol_changed_events` property of the current `Slice` with the continuous Futures `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your Future at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    # Get Symbol Change Event of the Continuous Future (change in mapped contract)
    changed_event = slice.symbol_changed_events.get(self.continuous_future_symbol)
    if changed_event:
        old_symbol = changed_event.old_symbol
        new_symbol = self.add_future_contract(changed_event.new_symbol).symbol
        tag = f"Rollover - Symbol changed at {self.time}: {old_symbol} -> {new_symbol}"
        quantity = self.portfolio[old_symbol].quantity

        # Rolling over: to liquidate any position of the old mapped contract and switch to the newly mapped contract
        self.liquidate(old_symbol, tag = tag)
        if quantity != 0: self.market_order(new_symbol, quantity, tag = tag)
        self.log(tag)
```

`SymbolChangedEvent` objects have the following attributes:

Live Trading Considerations

You can trade continuous Futures, but the continuous Future `Symbol` doesn't map to a single underlying Future contract. Instead, it represents a set of rolling contracts. Thus, the prices could be frictional during a contract rollover, which could be catastrophic in live trading! For live trading, you should place your orders directly on the underlying contracts. To get the current underlying contract in the continuous Future series, use the `mapped` property.

```
# Get the mapped symbol
current_contract = self.continuous_contract.mapped
self.buy(current_contract, 1)
```

Data Format

If you download the files in the US Futures Security Master, you get a factor file and a map file for each of the exchanges with supported continuous Futures. To view the files, see the */data/future/<exchange_name>* directory under your LEAN CLI base directory.

For the factor file, it is a `.zip` collection of REST API styled `.csv` files for each Future `Symbol` , including the date, scaling factors for each type of data

normalization and the data mapping mode that indicates the Symbol changing event is on that day for that mapping mode. The following line is an example line in the `.csv` file:

```
{"Date":"2009-10-31T00:00:00","BackwardsRatioScale":[0.99141630901287553648068669 53,1.0,1.0],"BackwardsPanamaCanalScale":[-2.0,0.0,0.0],"ForwardPanamaCanalScale":[0.0,0.0,0.0],"DataMappingMode":1}
```

For the map file, it is a `.zip` collection of `.csv` files for each Future `Symbol` , including the date, new underlying contract Symbol, the exchange code, and the data mapping mode that indicates the Symbol changing event is on that day for that mapping mode. The following line is an example line in the `.csv` file:

```
20091130,aw uii3j0m6zbj9,CBOT,1
```

Historical Data

You can get historical US Future Security Master data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Future Security Master data in an algorithm, call the `history` method with continuous Future `Symbol` and a lookback period. This method returns the old and new contract of each rollover. If there is no data for the period you requested, the history result is empty.

```py
# Add the Future and define its rollover settings.
future = self.add_future(
    Futures.Indices.SP_500_E_MINI,
    data_mapping_mode=DataMappingMode.OPEN_INTEREST,
    data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
    contract_depth_offset=0
)

# DataFrame example where the columns are the SymbolChangedEvent attributes:
history_df = self.history(SymbolChangedEvent, future.symbol, timedelta(365))

# SymbolChangedEvent objects example:
history = self.history[SymbolChangedEvent](future.symbol, timedelta(365))
```

For more information about historical US Future Security Master data in algorithms, see Symbol Changes .

Historical Data In Research

To get historical US Future Security Master data in the Research Environment, call the `history` method with continuous Future `Symbol` and a time period. This method returns the old and new contract of each rollover. If there is no data for the period you requested, the history result is empty.

```py
# Add the Future and define its rollover settings.
future = qb.add_future(
    Futures.Indices.SP_500_E_MINI,
    data_mapping_mode=DataMappingMode.OPEN_INTEREST,
    data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
    contract_depth_offset=0
)

# DataFrame example where the columns are the SymbolChangedEvent attributes:
history_df = qb.history(SymbolChangedEvent, future.symbol, datetime(2023, 1, 1), datetime(2025, 1, 1))

# SymbolChangedEvent objects example:
history = qb.history[SymbolChangedEvent](future.symbol, datetime(2023, 1, 1), datetime(2025, 1, 1))
```

For more information about historical US Future Security Master data in the Research Environment, see Symbol Changes History .

Supported Assets

The following list shows the available (157) Futures:

- `Futures.Currencies.AUD` : Australian Dollar Futures (CME: 6A)
- `Futures.Currencies.AUDCAD` : Australian Dollar/Canadian Dollar Futures (CME: ACD)
- `Futures.Currencies.AUDJPY` : Australian Dollar/Japanese Yen Futures (CME: AJY)
- `Futures.Currencies.AUDNZD` : Australian Dollar/New Zealand Dollar Futures (CME: ANE)
- `Futures.Currencies.BRL` : Brazillian Real Futures (CME: 6L)
- `Futures.Currencies.BTC` : Bitcoin Futures (CME: BTC)
- `Futures.Currencies.BTIC_MICRO_BTC` : BTIC on Micro Bitcoin Futures (CME: MIB)

- `Futures.Currencies.BTIC_MICRO_ETHER` : BTIC on Micro Ether Futures (CME: MRB)
- `Futures.Currencies.CAD` : Canadian Dollar Futures (CME: 6C)
- `Futures.Currencies.CADJPY` : Canadian Dollar/Japanese Yen Futures (CME: CJY)
- `Futures.Currencies.CHF` : Swiss Franc Futures (CME: 6S)
- `Futures.Currencies.ETH` : Ether Futures (CME: ETH)
- `Futures.Currencies.EUR` : Euro FX Futures (CME: 6E)
- `Futures.Currencies.EURAUD` : Euro/Australian Dollar Futures (CME: EAD)
- `Futures.Currencies.EURCAD` : Euro/Canadian Dollar Futures (CME: ECD)
- `Futures.Currencies.EURO_FX_EMINI` : E-mini Euro FX Futures (CME: E7)
- `Futures.Currencies.EURSEK` : Euro/Swedish Krona Futures (CME: ESK)
- `Futures.Currencies.GBP` : British Pound Futures (CME: 6B)
- `Futures.Currencies.JAPANESE_YEN_EMINI` : E-mini Japanese Yen Futures (CME: J7)
- `Futures.Currencies.JPY` : Japanese Yen Futures (CME: 6J)
- `Futures.Currencies.MICRO_AUD` : Micro AUD/USD Futures (CME: M6A)
- `Futures.Currencies.MICRO_BTC` : Micro Bitcoin Futures (CME: MBT)
- `Futures.Currencies.MICRO_CAD` : Micro USD/CAD Futures (CME: M6C)
- `Futures.Currencies.MICRO_CADUSD` : Micro CAD/USD Futures (CME: MCD)
- `Futures.Currencies.MICRO_CHF` : Micro CHF/USD Futures (CME: MSF)
- `Futures.Currencies.MICRO_ETHER` : Micro Ether Futures (CME: MET)
- `Futures.Currencies.MICRO_EUR` : Micro EUR/USD Futures (CME: M6E)
- `Futures.Currencies.MICRO_GBP` : Micro GBP/USD Futures (CME: M6B)
- `Futures.Currencies.MICRO_INRUSD` : Micro INR/USD Futures (CME: MIR)
- `Futures.Currencies.MICRO_JPY` : Micro JPY/USD Futures (CME: MJY)
- `Futures.Currencies.MICRO_USDCHF` : Micro USD/CHF Futures (CME: M6S)
- `Futures.Currencies.MICRO_USDCNH` : Micro USD/CNH Futures (CME: MNH)
- `Futures.Currencies.MICRO_USDJPY` : Micro USD/JPY Futures (CME: M6J)
- `Futures.Currencies.MXN` : Mexican Peso Futures (CME: 6M)
- `Futures.Currencies.NZD` : New Zealand Dollar Futures (CME: 6N)
- `Futures.Currencies.RUB` : Russian Ruble Futures (CME: 6R)
- `Futures.Currencies.STANDARD_SIZE_USD_OFFSHORE_RMBCNH` : Standard-Size USD/Offshore RMB (CNH) Futures (CME: CNH)
- `Futures.Currencies.ZAR` : South African Rand Futures (CME: 6Z)
- `Futures.Energy.ARGUS_LL_SVS_WTI_ARGUS_TRADE_MONTH` : Argus LLS vs. WTI (Argus) Trade Month Futures (NYMEX: AE5)
- `Futures.Energy.ARGUS_PROPANE_FAR_EAST_INDEX` : Argus Propane Far East Index Futures (NYMEX: A7E)
- `Futures.Energy.ARGUS_PROPANE_SAUDI_ARAMCO` : Argus Propane (Saudi Aramco) Futures (NYMEX: A9N)
- `Futures.Energy.BRENT_CRUDE_OIL_VS_DUBAI_CRUDE_OIL_PLATTS` : Brent Crude Oil vs. Dubai Crude Oil (Platts) Futures (NYMEX: ADB)
- `Futures.Energy.BRENT_LAST_DAY_FINANCIAL` : Brent Last Day Financial Futures (NYMEX: BZ)
- `Futures.Energy.CHICAGO_ETHANOL_PLATTS` : Chicago Ethaanol (Platts) Futures (NYMEX: CU)
- `Futures.Energy.CONWAY_PROPANE_OPIS` : Conway Propane (OPIS) Futures (NYMEX: A8K)
- `Futures.Energy.CRUDE_OIL_WTI` : Crude Oil WTI Futures (NYMEX: CL)
- `Futures.Energy.DUBAI_CRUDE_OIL_PLATTS_FINANCIAL` : Dubai Crude Oil (Platts) Financial Futures (NYMEX: DCB)
- `Futures.Energy.EAST_WEST_GASOLINE_SPREAD_PLATTS_ARGUS` : East-West Gasoline Spread (Platts-Argus) Futures (NYMEX: EWG)
- `Futures.Energy.EAST_WEST_NAPHTHA_JAPAN_C_FVS_CARGOES_CIFNWE_SPREAD_PLATTS` : East-West Naphtha: Japan C&F vs. Cargoes CIF NWE Spread (Platts) Futures (NYMEX: EWN)
- `Futures.Energy.ETHANOL` : Ethanol Futures (CBOT: EH)
- `Futures.Energy.ETHANOL_T_2_FOB_RDAM_INCLUDING_DUTY_PLATTS` : Ethanol T2 FOB Rdam Including Duty (Platts) Futures (NYMEX: AZ1)
- `Futures.Energy.EUROPEAN_NAPHTHA_PLATTS_CRACK_SPREAD` : European Naphtha (Platts) Crack Spread Futures (NYMEX: EN)
- `Futures.Energy.EUROPEAN_PROPANE_CIFARA_ARGUS` : European Propane CIF ARA (Argus) Futures (NYMEX: APS)
- `Futures.Energy.EUROPEAN_PROPANE_CIFARA_ARGUS_VS_NAPHTHA_CARGOES_CIFNWE_PLATTS` : European Propane CIF ARA (Argus) vs. Naphtha Cargoes CIF NWE (Platts) Futures (NYMEX: EPN)
- `Futures.Energy.FREIGHT_ROUTE_TC_14_BALTIC` : Freight Route TC14 (Baltic) Futures (NYMEX: FRC)
- `Futures.Energy.GASOLINE` : Gasoline RBOB Futures (NYMEX: RB)
- `Futures.Energy.GASOLINE_EUROBOB_OXY_NWE_BARGES_ARGUS` : Gasoline Euro-bob Oxy NWE Barges (Argus) Futures (NYMEX: B7H)

- `Futures.Energy.GROUP_THREE_SUBOCTANE_GASOLINE_PLATTS_VS_RBOB` : Group Three Sub-octane Gasoliine (Platts) vs. RBOB Futures (NYMEX: AA8)
- `Futures.Energy.GROUP_THREE_ULSD_PLATTS_VS_NY_HARBOR_ULSD` : Group Three ULSD (Platts) vs. NY Harbor ULSD Futures (NYMEX: AA6)
- `Futures.Energy.GULF_COAST_CBOB_GASOLINE_A_2_PLATTS_VS_RBOB_GASOLINE` : Gulf Coast CBOB Gasoline A2 (Platts) vs. RBOB Gasoline Futures (NYMEX: CRB)
- `Futures.Energy.GULF_COAST_HSFO_PLATTS_VS_EUROPEAN_THREE_POINT_FIVE_PERCENT_FUEL_OIL_BARGES_FOB_RDAM_PLATTS` : Gulf Coast HSFO (Platts) vs. European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: GCU)
- `Futures.Energy.HEATING_OIL` : Heating Oil Futures (NYMEX: HO)
- `Futures.Energy.LOS_ANGELES_CARBOB_GASOLINE_OPI_SVS_RBOB_GASOLINE` : Los Angeles CARBOB Gasoline (OPIS) vs. RBOB Gasoline Futures (NYMEX: AJL)
- `Futures.Energy.LOS_ANGELES_CARB_DIESEL_OPI_SVS_NY_HARBOR_ULSD` : Los Angeles CARB Diesel (OPIS) vs. NY Harbor ULSD Futures (NYMEX: AKL)
- `Futures.Energy.LOS_ANGELES_JET_OPI_SVS_NY_HARBOR_ULSD` : Los Angeles Jet (OPIS) vs. NY Harbor ULSD Futures (NYMEX: AJS)
- `Futures.Energy.MARS_ARGUS_VS_WTI_FINANCIAL` : Mars (Argus) vs. WTI Financial Futures (NYMEX: AYX)
- `Futures.Energy.MARS_ARGUS_VS_WTI_TRADE_MONTH` : Mars (Argus) vs. WTI Trade Month Futures (NYMEX: AYV)
- `Futures.Energy.MICRO_CRUDE_OIL_WTI` : Micro WTI Crude Oil Futures (NYMEX: MCL)
- `Futures.Energy.MICRO_EUROPEAN_FOB_RDAM_MARINE_FUEL_ZERO_POINT_FIVE_PERCENT_BARGES_PLATTS` : Micro European FOB Rdam Marine Fuel 0.5% Barges (Platts) Futures (NYMEX: R5O)
- `Futures.Energy.MICRO_EUROPEAN_THREE_POINT_FIVE_PERCENT_OIL_BARGES_FOB_RDAM_PLATTS` : Micro European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: MEF)
- `Futures.Energy.MICRO_GASOIL_ZERO_POINT_ONE_PERCENT_BARGES_FOBARA_PLATTS` : Micro Gasoil 0.1% Barges FOB ARA (Platts) Futures (NYMEX: M1B)
- `Futures.Energy.MICRO_SINGAPORE_FOB_MARINE_FUEL_ZERO_POINT_FIVE_PERCET_PLATTS` : Micro Singapore FOB Marine Fuel 0.5% (Platts) Futures (NYMEX: S5O)
- `Futures.Energy.MICRO_SINGAPORE_FUEL_OIL_380_CST_PLATTS` : Micro Singapore Fuel Oil 380CST (Platts) Futures (NYMEX: MAF)

- `Futures.Softs.SUGAR_11` : Sugar #11 Futures ICE (ICE: SB)
- `Futures.Softs.SUGAR_11_CME` : Sugar #11 Futures CME (NYMEX: YO)

Example Applications

The US Futures Security Master enables you to design strategies harnessing continuous Futures contracts. Examples include the following strategies:

- Trading cyclical patterns in commodity Futures.
- Buying gold Futures as an inflation hedge with automatic contract roll-overs.
- Detecting arbitrage opportunities between index Futures and Equities.

Classic Algorithm Example

The following example algorithm buys the continuous Future contract for Crude Oil when its price rises above its simple moving average. When its price drops below its simple moving average, the algorithm sells the continuous contract. Each time the continuous Future contract rolls over, the algorithm logs the event.

```py
from AlgorithmImports import *

class USFuturesSecurityMasterDataClassicAlgorithm(QCAlgorithm):
    # Define a threshold for the SMA cross.
    _threshold = 0.01

    def initialize(self) -> None:
        self.set_cash(1000000)
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Seed the price of each asset with its last known price to
        # avoid trading errors.
        self.settings.seed_initial_prices = True
        # Add a Future. Set the continuous contract mapping criteria to
        # the contract with highest open interest to provide the best
        # price information for trend estimation.
        self._future = self.add_future(
            Futures.Energy.CRUDE_OIL_WTI,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            contract_depth_offset=0
        )
        # Historical data: Get the contract rollovers for the trailing
        # year.
        history = self.history(
            SymbolChangedEvent, self._future.symbol, timedelta(365)
        )
        # Set up an SMA indicator for to estimate the trend direction.
        self._sma = self.sma(self._future.symbol, 10, Resolution.DAILY)
        # Warm up the SMA indicator so we can trade right away.
        self.warm_up_indicator(self._future.symbol, self._sma)

    def on_data(self, slice: Slice) -> None:
        # Wait until we have the latest TradeBar and the indicator is
        # ready.
        if not (self._future.symbol in slice.bars and self._sma.is_ready):
            return
        contract = self.portfolio[self._future.mapped]
        # Long during an uptrend.
        if (not contract.is_long and
            self._future.price > self._sma.current.value * (1+self._threshold)):
            quantity = 1
        # Short during an downtrend.
        elif (not contract.is_short and
            self._future.price < self._sma.current.value * (1-self._threshold)):
            quantity = -1
        else:
            return
        self.market_order(self._future.mapped, quantity - contract.quantity)

    def on_symbol_changed_events(self, symbol_changed_events):
        for symbol, changed_event in symbol_changed_events.items():
            old_symbol = changed_event.old_symbol
            new_symbol = changed_event.new_symbol
            # The quantity to roll over should be consistent.
            quantity = self.portfolio[old_symbol].quantity
            if not quantity:
                continue
            # Rolling over: Liquidate the old mapped contract and switch
            # to the new mapped contract.
            tag = f"Rollover: {old_symbol} -> {new_symbol}"
            self.liquidate(old_symbol, tag=tag)
            self.market_order(new_symbol, quantity, tag=tag)
```

Framework Algorithm Example

The following example algorithm buys the continuous Future contract for Crude Oil when its price rises above its simple moving average. When its price drops below its simple moving average, the algorithm sells the continuous contract. Each time the contract rolls over, the algorithm logs the event.

PY

```
from AlgorithmImports import *

class USFuturesSecurityMasterDataFrameworkAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_cash(1000000)
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Setting the continuous contract mapping criteria, the contract with highest open interest provide the best price information
for trend estimation
        self.add_future(Futures.Energies.CRUDE_OIL_WTI,
                        data_normalization_mode = DataNormalizationMode.BACKWARDS_RATIO,
                        data_mapping_mode = DataMappingMode.OPEN_INTEREST,
                        contract_depth_offset = 0)
        self.add_alpha(ContinuousFuturesAlphaModel())
        self.set_portfolio_construction(SingleSharePortfolioConstructionModel())

class ContinuousFuturesAlphaModel(AlphaModel):
    # 1% margin to reassure trend direction
    threshold = 0.01
    symbol = None
    continuous_contract = None

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        insights = []
        # Check if contract data available, since all trades are based on that only
        if self.continuous_contract_symbol is None or self.continuous_contract is None:
            return insights

        # Up-to-date handling of switching the mapped contract for trade liquidity
        for symbol, changed_event in slice.symbol_changed_events.items():
            old_symbol = changed_event.old_symbol
            if algorithm.insights.has_active_insights(old_symbol, algorithm.utc_time):
                new_symbol = changed_event.new_symbol
                tag = f"Rollover - Symbol changed at {algorithm.time}: {old_symbol} -> {new_symbol}"
                last_insight = sorted(algorithm.insights[old_symbol], key=lambda x: x.close_time_utc)[-1]

```

Data Point Attributes

The US Futures Security Master dataset provides `SymbolChangedEvent` objects, which have the following attributes:

QuantConnect

US Index Option Universe

Introduction

The US Index Option Universe dataset by QuantConnect lists the available US Index Options contracts and the current Implied Volatility and Greeks. The data covers European Option contracts for 3 US Indices: SPX, VIX, and NDX. It starts in January 2012 and is delivered on a daily update frequency. To create this dataset, we use our implementation of the forward tree pricing model, which accounts for the interest rate, dividend payments, and daily closing prices. The values in this dataset are the same values you can get from daily indicators with mirror Options.

This dataset `does not` contain market data. For market data, see US Index Options by AlgoSeek .

For more information about the US Index Option Universe dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the US Index Options Universe dataset:

```
option = self.add_index_option('VIX')
option.set_filter(lambda universe: universe.delta(0.4, 0.6))
self.option_symbol = option.symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2012
Asset Coverage	7 Index Options
Data Density	Dense
Resolution	Daily
Timezone	New York

Specification Over Time

According to the SPX Options contract specification , some SPX contracts expire every month and SPXW contracts expires every day. Before 2021, you could only trade SPX contracts with the following expiration dates:

- Expires within the next 4 months
- Expires in September within the next 14 months
- Expires in January, March, or June within the next 2 years
- Expires in December within the next 3 years

During this time, SPXW didn't have 0DTE every day.

`Sources` :

- Cboe Options Exchange to List Three Long-Dated SPX Options Expirations, Beginning November 1, 2021

- S&P 500 Weekly Options Now Expire Five Days a Week

Requesting Data

To add US Index Options Universe data to your algorithm, call the `add_index_option` method. Save a reference to the Index Option `Symbol` so you can access the data later in your algorithm. To define which contracts should be in your universe, call the `set_filter` method of the `IndexOption` object.

The `add_index_option` method provides a daily stream of Option chain data. To get the most recent daily chain, call the `option_chain` method with the canonical Index Option Symbol. The `option_chain` method returns data on all the tradable contracts, not just the contracts that pass your universe filter.

```
PY
class IndexOptionsDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2021, 1, 1)
        self.set_end_date(2021, 6, 1)
        self.set_cash(1_000_000)
        self.universe_settings.asynchronous = True
        self.index_symbol = self.add_index('VIX').symbol

        standard_option = self.add_index_option(self.index_symbol)
        standard_option.set_filter(self._option_filter)
        self.standard_option_symbol = standard_option.symbol
        standard_chain = self.option_chain(standard_option.symbol, flatten=True).data_frame

        weekly_option = self.add_index_option(self.index_symbol, "VIXW")
        weekly_option.set_filter(self._option_filter)
        self.weekly_option_symbol = weekly_option.symbol
        weekly_chain = self.option_chain(weekly_option.symbol, flatten=True).data_frame
        weekly_chain = weekly_chain[
            weekly_chain.index.map(lambda symbol: not IndexOptionSymbol.is_standard(symbol))
        ]

    def _option_filter(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
        # Contracts can be filtered by greeks, implied volatility, open interest:
        return universe \
            .delta(0.5, 1.5) \
            .gamma(0.0001, 0.0006) \
            .vega(0.01, 1.5) \
            .theta(-2.0, -0.5) \
            .rho(0.5, 3.0) \
            .implied_volatility(1, 3) \
            .open_interest(100,500)
```

The Index resolution must be less than or equal to the Index Option resolution. For example, if you set the Index resolution to minute, then you must set the Index Option resolution to minute, hour, or daily.

For more information about creating US Index Option subscriptions, see Index Options .

Accessing Data

For information about accessing US Equity Options data, see Handling Data .

Historical Data

You can get historical US Index Options data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Index Options Universe data in an algorithm, call the `history` method with the canonical Index Option `Symbol` . This method returns data on all of the tradable contracts, not just the contracts that pass your universe filter. If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.history(self.standard_option_symbol, timedelta(3))

# OptionUniverse objects
history = self.history[OptionUniverse](self.standard_option_symbol, timedelta(3))
```

For more information about Index Options Universe data in algorithms, see Historical Data .

Historical Data In Research

To get historical US Index Options Universe data in the Research Environment, call the `history` method with the canonical Option `Symbol` . This method returns data on all of the tradable contracts, not just the contracts that pass your universe filter.

```py
qb = QuantBook()
index_symbol = qb.add_index('VIX').symbol
option = qb.add_index_option(index_symbol) # or qb.add_index_option(index_symbol, "VIXW")
history = qb.history(option.symbol, datetime(2020, 6, 1), datetime(2020, 6, 5))
```

For more information about historical Index Options Universe data in the Research Environment, see Universes .

Supported Assets

The following table shows the available Index Options:

Underlying Index	Underlying Ticker	Target Ticker	Standard Contracts	Weekly Contracts	Tradable on Expiry Day
NASDAQ-100	NDX		✓		
NASDAQ-100	NDX	NDXP	✓		✓
NASDAQ-100	NDX	NQX	✓	✓	✓
Russell 2000	RUT		✓		
Russell 2000	RUT	RUTW		✓	✓
S&P500	SPX		✓		
S&P500	SPX	SPXW		✓	✓
S&P500	VIX		✓		
S&P500	VIX	VIXW		✓	

For more information about each underlying Index, see Supported Indices .

Example Applications

The US Index Options Universe dataset enables you to accurately design strategies for Index Options. Examples include the following strategies:

- Buying VIX call Options to hedge against upcoming volatility
- Buying VIX put Options to capture the natural downward price movement in the VIX index
- Buying SPX put Options to protect against downward price movement in the S&P 500

Classic Algorithm Example

The following example algorithm subscribes to SPX put options that fall within delta range between -1 and -0.95, open interest range between 10 and 1000, and expire within seven days. Within this Option chain, the algorithm holds the put Option contract that has the minimum delta (closest to -1) during market hour to hedge the underlying intra-day movement completely. It avoid volatility from sentiment and only earns from inter-day movement from longer-term factors. When the contract expires, the algorithm rolls over to the next contract that meets this criteria.

```
from AlgorithmImports import * class IndexOptionsUniverseAlgorithm(QCAlgorithm): def initialize(self) -> None: self.set
_start_date(2024, 9, 1) self.set_end_date(2024, 12, 31) self.set_cash(10000000) # Asynchronous can use computational re
sources efficiently self.universe_settings.asynchronous = True # Subscribe to the underlying for the underlying positio
n # Set the data normalization mode to raw for strike price comparability self.index = self.add_index("SPX").symbol # R
equesting option data and filter for the hedge candidates option = self.add_index_option(self.index) option.set_filter(
self.option_filter) self.option_symbol = option.symbol # Set scheduled event to buy a hedge option contract at market o
pen to eliminate the intra-day movement self.schedule.on( self.date_rules.every_day(self.index), self.time_rules.after_
market_open(self.index, 1), self.buy_hedge_contract ) # Set a scheduled event to sell the hedge contract before market
close, since we want to earn from inter-day movement # Leave 2 minutes contingency to fill self.schedule.on( self.date_
rules.every_day(self.index), self.time_rules.before_market_close(self.index, 2), self.sell_hedge_contract ) self.hedge
= None def option_filter(self, universe: OptionFilterUniverse) -> OptionFilterUniverse: # Select the contracts with del
ta very close to -1 and high open interest # This can effectively hedge most of the price change of the underlying and
ensure the liquidity # Make sure the contract is expiring close for its tradbility return universe.puts_only().expirati
on(2, 7).delta(-1, -0.95).open_interest(10, 1000) def buy_hedge_contract(self) -> None: chain = self.current_slice.opti
on_chains.get(self.option_symbol) if chain: # Order the underlying if not hold, the order size should match the option
contract # Order only if option chain data ready for hedging if not self.portfolio[self.index].invested: self.market_or
der(self.index, self.securities[self.option_symbol].symbol_properties.contract_multiplier) # Get the contract with delt
a closest to -1 (lowest possible delta) contract = sorted(chain, key=lambda x: x.greeks.delta)[0] self.hedge = contract
.symbol # Buy 1 deep ITM put with delta close to -1 to eliminate the intraday movement self.market_order(self.hedge, 1)
def sell_hedge_contract(self) -> None: # Check if any hedge contract position, if so, liquidate before market close to
expose to underlying overnight movement if self.hedge: self.liquidate(self.hedge) self.hedge = None
```

Framework Algorithm Example

The following example algorithm demonstrating a Gamma Scalping strategy through framework algorithm. It filters SPX options with expiration between 30 to 90 days and open interest between 50 and 1000, due to liquidity concern and lower Gamma fluctuation. Assuming a significant upward trend is expecting, it orders a long straddle strategy from the strike price with Delta-neutral and the highest Gamma to earn the highest profit from upward underlying movement.

PY

```
from AlgorithmImports import *

class IndexOptionsUniverseFrameworkAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 12, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000000)
        # Asynchronous can use computational resources efficiently
        self.universe_settings.asynchronous = True

        # Universe selection that select based on liquidity of the option contracts (by open interest)
        self.add_universe_selection(IndexOptionsUniverseSelectionModel())
        # Custom alpha model that use Delta and Gamma to signal insights
        self.add_alpha(OptionDeltaGammaAlphaModel())
        # To maintain long-short size equal, use a PCM that order a single contract
        self.set_portfolio_construction(SingleSharePortfolioConstructionModel())

class IndexOptionsUniverseSelectionModel(OptionUniverseSelectionModel):
    def __init__(self) -> None:
        # Daily update with the select_option_chain_symbols function
        super().__init__(timedelta(1), self.select_option_chain_symbols)

    def select_option_chain_symbols(self, dt: datetime) -> List[Symbol]:
        # Select only SPX options as our focus, which is a highly traded volatile index with great upward momentum
        return [Symbol.create("SPX", SecurityType.INDEX_OPTION, Market.USA)]

    def filter(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
        # To ensure the liquidity and tradability, make sure the option is not 0-DTE and have a fair open interest
        # A longer TTM will have lower Gamma thus more stable in the local delta-neutral position
        return universe.expiration(30, 90).open_interest(50, 1000)

class OptionDeltaGammaAlphaModel(AlphaModel):
    def __init__(self) -> None:
        # A day count variable to control the alpha model only trade once a day
        self._day = -1

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        insights = []

        if self._day != slice.time.day:
            # We open position for each option underlying as separate bet
            for _, chain in slice.option_chains.items():
                # For theta-neutral, select the same expiry for both call and put
                expiry = min(x.expiry for x in chain)
                contracts = [x for x in chain if x.expiry == expiry]

                # Calculate delta and gamma per strike price group for later filtering, ensure both call and put available for option
strategy
                delta_gamma_symbols = []
                strikes = set(x.strike for x in contracts if len([y for y in contracts if y.strike == x.strike]) == 2)
                for strike in strikes:
                    # Get both call and put for their aggregated delta and gamma
                    call = next(filter(lambda x: x.right == OptionRight.CALL and x.strike == strike, contracts))
                    put = next(filter(lambda x: x.right == OptionRight.PUT and x.strike == strike, contracts))
                    delta_gamma_symbols.append((call.greeks.delta + put.greeks.delta, call.greeks.gamma + put.greeks.gamma, call.symbol,
put.symbol))

                if len(delta_gamma_symbols) == 0:
                    continue

                # We want a delta-neutral position, so it is likely to be ATM (like a long straddle)
                # Less than 2d.p. difference is non-significant, which we can risk for better reward
                # Assuming the market direction is up in most scenario, we try to get the strike providing max overall Gamma
                # Make sure the aggregated gamma to be positive to bet on large uptrend
                # So it will earn more when the price really go up higher and higher, but locally immune for small noise
                filtered = [item for item in delta_gamma_symbols if round(item[0], 2) <= 0.01 and item[1] > 0]
                if len(filtered) == 0:
                    continue
                selected = sorted(filtered, key=lambda x: x[1])[0]

US Equities

Introduction

The US Equities dataset by AlgoSeek is survivorship bias-free daily coverage of every stock traded in the US Securities Information Processors (SIP) CTA/UTP feed since 1998. The dataset covers approximately 27,500 securities, starts in January 1998, and is delivered in any resolution from tick to daily. The Data is collected from the full SIP feed via our Equinix co-located servers, including all trades and quotes published to every exchange as well as FINRA. Over-the-Counter (OTC) trades are not included.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the US Equities dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

AlgoSeek is a leading historical intraday US market data provider offering the most comprehensive and detailed market data and analytics products in the financial industry covering Equities, Futures, Options, cash FOREX, and Cryptocurrencies. AlgoSeek data is built for quantitative trading and machine learning. For more information about AlgoSeek, visit algoseek.com .

Getting Started

AlgoSeek is the default US Equities dataset on QuantConnect. The following snippet demonstrates how to request data from the US Equities dataset:

```py
self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1998
Asset Coverage	27,500 US Equities
Data Density	Dense
Resolution	Tick, Second, Minute, Hourly, & Daily
Timezone	New York
Market Hours	Regular and Extended

Requesting Data

To add US Equities data to your algorithm, call the `add_equity` method. Save a reference to the Equity `Symbol` so you can access the data later in your algorithm.

```py
class USEquityDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2018, 1, 1)
        self.set_end_date(2021, 6, 1)
        self.set_cash(100000)
        # Subscribe to AAPL data
        self.aapl = self.add_equity("AAPL", Resolution.MINUTE).symbol
```

For more information about creating US Equity subscriptions, see Requesting Data or US Equity Universes .

Accessing Data

To get the current US Equities data, index the `bars` , `quote_bars` , or `ticks` properties of the current `Slice` with the Equity `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    # Access data: TradeBar data
    if self.aapl in slice.bars:
        trade_bar = slice.bars[self.aapl]
        self.log(f"{self.aapl} close at {slice.time}: {trade_bar.close}")

    # Access data: QuoteBar data
    if self.aapl in slice.quote_bars:
        quote_bar = slice.quote_bars[self.aapl]
        self.log(f"{self.aapl} bid at {slice.time}: {quote_bar.bid.close}")

    # Access data: Ticks data
    if self.aapl in slice.ticks:
        ticks = slice.ticks[self.aapl]
        for tick in ticks:
            self.log(f"{self.aapl} price at {slice.time}: {tick.price}")
```

You can also iterate through all of the data objects in the current `Slice` .

```
PY
def on_data(self, slice: Slice) -> None:
    # Iterate all TradeBar received
    for symbol, trade_bar in slice.bars.items():
        self.log(f"{symbol} close at {slice.time}: {trade_bar.close}")

    # Iterate all QuoteBar received
    for symbol, quote_bar in slice.quote_bars.items():
        self.log(f"{symbol} bid at {slice.time}: {quote_bar.bid.close}")

    # Iterate all Ticks received
    for symbol, ticks in slice.ticks.items():
        for tick in ticks:
            self.log(f"{symbol} price at {slice.time}: {tick.price}")
```

For more information about accessing US Equities data, see Handling Data .

Historical Data

To get historical US Equity data, call the `history` method with the Equity `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.history(self.aapl, 100, Resolution.DAILY)

# TradeBar objects
history_trade_bars = self.history[TradeBar](self.aapl, 100, Resolution.DAILY)

# QuoteBar objects
history_quote_bars = self.history[QuoteBar](self.aapl, 100, Resolution.MINUTE)

# Tick objects
history_ticks = self.history[Tick](self.aapl, timedelta(seconds=10), Resolution.TICK)
```

For more information about historical data, see History Requests .

Universe Selection

To select a universe of US Equities, see Equity Universes .

Remove Subscriptions

To unsubscribe from a US Equity that you added with the `add_equity` method, call the `remove_security` method.

```
self.remove_security(self.aapl)
```

The `remove_security` method cancels your open orders for the security and liquidates your holdings.

Supported Assets

To view the supported assets in the US Equities dataset, see the Data Explorer . This dataset doesn't include Over-the-Counter (OTC) stocks.

Example Applications

The US Equities dataset enables you to accurately design Equity trading strategies. Examples include the following strategies:

- Momentum strategies using historical returns on the premise that the momentum will continue
- Value strategies using fundamental factors on the premise that the price of undervalued securities will rise
- Factor investing with periodic rebalancing

Classic Algorithm Example

The following example algorithm buys and holds Apple stock:

```
from AlgorithmImports import *

class USEquityDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Requesting single equity data, since we only trade AAPL
        self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol

        # Historical data
        history = self.history(self.aapl, 60, Resolution.DAILY)
        self.debug(f"We got {len(history)} items from our history request")

    def on_data(self, slice: Slice) -> None:
        # Check if the current slice containing AAPL and if we hold any position
        # As we make use of the most updated price data to decide the order size
        if slice.contains_key(self.aapl) and slice[self.aapl] is not None and not self.portfolio.invested:
            self.set_holdings(self.aapl, 1)
```

Framework Algorithm Example

The following example algorithm buys and holds Apple stock:

```
from AlgorithmImports import *

class USEquityDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        self.universe_settings.resolution = Resolution.DAILY
        # To select only AAPL, use a manual selection universe
        symbols = [Symbol.create("AAPL", SecurityType.EQUITY, Market.USA)]
        self.add_universe_selection(ManualUniverseSelectionModel(symbols))

        # Constant investment signal
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(days=7), 0.025, None))

        # Invest in all members equally
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())
```

Data Point Attributes

The US Equities dataset provides `TradeBar` , `QuoteBar` , and `Tick` objects.

TradeBar Attributes

`TradeBar` objects have the following attributes:

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

Tick Attributes

`Tick` objects have the following attributes:

AlgoSeek

US Equity Options

Introduction

The US Equity Options data by AlgoSeek provides Option data, including prices, strikes, expires, and open interest. The data covers 4,000 Symbols, starts in January 2012, and is delivered on a minute frequency. This dataset is created by monitoring Options Price Reporting Authority (OPRA) data feed, which consolidates last sale and quotation information originating from the national securities exchanges that have been approved by the Securities and Exchange Commission.

This dataset depends on the following datasets:

- US Equity Security Master - data on splits, dividends, and symbol changes for the underlying Equities.
- US Equity Option Universe - data on the available contracts and their daily Greeks and implied volatility values.
- US Equities - trade and quote data on the underlying Equities.

For more information about the US Equity Options dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

AlgoSeek was in 2014 with the goal of providing the highest quality, most accurate, ready-to-use data in the financial data industry. AlgoSeek provides access to Equities, ETFs, ETNs, Equity Indices, Equity Options, Futures, and Future Options for quantitative firms and traders.

Getting Started

The following snippet demonstrates how to request data from the US Equity Options dataset:

```py
option = self.add_option("GOOG")
self.option_symbol = option.symbol
option.set_filter(-2, +2, 0, 180)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2012*
Asset Coverage	4,000 Symbols
Data Density	Dense
Resolution	Minute, Hourly, & Daily
Timezone	New York
Market Hours	Regular Only

* Some data is available before this date. In 2012, AlgoSeek started to fetch data from 48 OPRA channels instead of 24, increasing the quality of the data.

Requesting Data

To add US Equity Options data to your algorithm, call the `add_option` method. Save a reference to the Equity Option `Symbol` so you can access the data later in your algorithm.

```
class USEquityOptionsDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2020, 6, 1)
        self.set_end_date(2021, 6, 1)
        self.set_cash(100000)
        self.universe_settings.asynchronous = True
        # Request GOOG option data
        option = self.add_option("GOOG")
        self.option_symbol = option.symbol
        # Set our strike/expiry filter for this option chain
        option.set_filter(-2, +2, 0, 180)
```

The Equity resolution must be less than or equal to the Equity Option resolution. For example, if you set the Equity resolution to minute, then you must set the Equity Option resolution to minute, hour, or daily.

For more information about creating US Equity Option subscriptions, see Requesting Data or Equity Options Universes .

Accessing Data

To get the current US Equity Options data, index the `option_chains` property of the current `Slice` with the canonical Equity Option `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your Index Option at every time step. To avoid issues, call the `get` method.

```
def on_data(self, slice: Slice) -> None:
    # Get the wanted option chain with the canonical symbol
    chain = slice.option_chains.get(self.option_symbol)
    if chain:
        # Iterate the option contracts in chain
        for contract in chain:
            self.log(f"{contract.symbol} price at {slice.time}: {contract.last_price}")
```

You can also iterate through all of the `OptionChain` objects in the current `Slice` .

```
def on_data(self, slice: Slice) -> None:
    # Iterate all option chains of all symbols
    for canonical_symbol, chain in slice.option_chains.items():
        # Iterate the option contracts in chain
        for contract in chain:
            self.log(f"{contract.symbol} price at {slice.time}: {contract.last_price}")
```

For more information about accessing US Equity Options data, see Handling Data .

Historical Data

You can get historical US Equity Options data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Equity Options data in an algorithm, call the `history` method with the Equity Option contract `Symbol` . If there is no data in the period you request, the history result is empty.

```
# DataFrame of trade and quote data
history_df = self.history(contract.symbol, 100, Resolution.MINUTE)

# DataFrame of open interest data
history_oi_df = self.history(OpenInterest, contract.symbol, 100, Resolution.MINUTE)

# TradeBar objects
history_trade_bars = self.history[TradeBar](contract.symbol, 100, Resolution.MINUTE)

# QuoteBar objects
history_quote_bars = self.history[QuoteBar](contract.symbol, 100, Resolution.MINUTE)

# OpenInterest objects
history_oi = self.history[OpenInterest](contract.symbol, 100, Resolution.MINUTE)
```

For more information about historical data in algorithms, see History Requests .

Historical Data In Research

To get historical US Equity Options data in the Research Environment, call the `history` or `option_history` method. The `history` method returns the price, volume, and open interest history for some given Option contract(s). The `option_history` method returns the price and volume history for the contracts that pass your daily universe filter.

```py
qb = QuantBook()
option = qb.add_option("GOOG")
option.set_filter(-2, 2, 0, 90)
history = qb.option_history(option.symbol.underlying, datetime(2020, 6, 1), datetime(2020, 6, 5))
history_df = history.data_frame
expiries = history.get_expiry_dates()
strikes = history.get_strikes()
```

To get historical data for arbitrary US Equity Option contracts instead of just the that pass your universe filter, call the `history` method like you would in an algorithm, but on the `QuantBook` object. For more information about historical data in the Research Environment, see Key Concepts .

Historical Greeks and IV Data

To get historical data for the Greeks and implied volatility of Equity Options, see the US Equity Option Universe dataset.

Supported Assets

To view the supported assets in the US Equity Options dataset, see the Data Explorer .

Example Applications

The US Equity Options dataset enables you to accurately design Option strategies. Examples include the following strategies:

- Buying put Options to hedge against downward price movement in positive Equity positions
- Exploiting arbitrage opportunities that arise when the price of Option contracts deviates from their theoretical value

Classic Algorithm Example

The following example algorithm subscribes to Google Options that fall within two strikes of the underlying stock price and expire within seven days. Within this Option chain, the algorithm buys the call Option contract that has the furthest expiry and has its strike price closest to the underlying stock price. When the contract expires, the algorithm rolls over to the next contract that meets this criteria.

```py
from AlgorithmImports import *

class USEquityOptionsDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.universe_settings.asynchronous = True
        # Requesting data
        self.underlying = self.add_equity("GOOG").symbol
        option = self.add_option("GOOG")
        self.option_symbol = option.symbol
        # To speculate trade the underlying with a low cost, filter for the ATM calls that expiring in the current week
        # -2/+2 strike buffer is given for small price change
        option.set_filter(lambda u: u.calls_only().strikes(-2, +2).expiration(0, 6))

        self.contract = None

    def on_data(self, slice: Slice) -> None:
        # If the Option contract is exercised, close the underlying position.
        if self.portfolio[self.underlying].invested:
            self.liquidate(self.underlying)
        # If the Option contract expires, rollover to the next contract.
        if self.contract and not self.portfolio[self.contract.symbol].invested:
            self.contract = None
        # Select with the lastest option chain data only
        chain = slice.option_chains.get(self.option_symbol)
        if not self.contract and chain:
            # Select the call contracts with the furthest expiration (week end)
            furthest_expiry = max([c.expiry for c in chain])
            furthest_expiry_calls = [contract for contract in chain if contract.expiry == furthest_expiry]
            # Get the ATM call for speculate trade with low cost and limited loss
            self.contract = sorted(furthest_expiry_calls, key = lambda x: abs(chain.underlying.price - x.strike))[0]
            self.market_order(self.contract.symbol, 1)

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for security in changes.added_securities:

            history = self.history(security.symbol, 10, Resolution.MINUTE)
            self.debug(f"We got {len(history)} from our history request for {security.symbol}")
```

Framework Algorithm Example

The following example algorithm buys a call Option contract for Google that falls within one strike of the underlying stock price and expires within seven days. When the contract expires, the algorithm rolls over to the next contract that meets this criteria.

```py
from AlgorithmImports import *

class USEquityOptionsDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.universe_settings.asynchronous = True
        # Requesting data
        self.set_universe_selection(EarliestExpiringWeeklyAtTheMoneyCallOptionUniverseSelectionModel())

        self.set_alpha(ConstantOptionsAlphaModel())

        self.set_portfolio_construction(SingleSharePortfolioConstructionModel())

class EarliestExpiringWeeklyAtTheMoneyCallOptionUniverseSelectionModel(OptionUniverseSelectionModel):

    def __init__(self) -> None:
        # Daily update with the select_option_chain_symbols function
        super().__init__(timedelta(1), self.select_option_chain_symbols)

    def select_option_chain_symbols(self, utcTime: datetime) -> List[Symbol]:
        # Always select only GOOG options as our focus
        return [ Symbol.create("GOOG", SecurityType.OPTION, Market.USA) ]

    def filter(self, filter: OptionFilterUniverse) -> OptionFilterUniverse:
        # To speculate trade the underlying with a low cost, filter for the ATM calls that expiring in the current week
        # -1/+1 strike buffer is given for small price change
        return (filter.calls_only()
                      .strikes(-1, -1)
                      .expiration(0, 7))

class ConstantOptionsAlphaModel(AlphaModel):

    underlying = None
    contract = None

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:

        insights = []

        # Liquidate the underlying if the option is being exercised/assigned
        if algorithm.portfolio[self.underlying].invested:
            insights.append(Insight.price(self.underlying, timedelta(days=7), InsightDirection.FLAT))

        if self.contract is not None and algorithm.portfolio[self.contract.symbol].invested:
            return insights

        # Get the ATM call for speculate trade with low cost and limited loss that expires at week end
        for kvp in slice.option_chains:

AlgoSeek

US Future Options

Introduction

The US Future Options dataset by AlgoSeek provides Option data on US Future contracts, including prices, strikes, and expires. The data covers 15 Monthly Future contracts, starts in January 2012, and is delivered on a minute frequency. This dataset is created by monitoring the trading activity on the CME, CBOT, NYMEX, and COMEX markets.

This dataset depends on the following datasets:

- US Future Option Universe - data on the available US Future Options contracts and their current Open Interest.
- US Futures Security Master - data to construct continuous Futures.
- US Future Universe - data on the available US Future contracts, their daily trading volume, and Open Interest.
- US Futures - data on the underlying Futures contracts, including price, volume, Open Interest, and expiry.

For more information about the US Future Options dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

AlgoSeek is a leading historical intraday US market data provider offering the most comprehensive and detailed market data and analytics products in the financial industry covering equities, futures, options, cash forex, and cryptocurrencies. AlgoSeek data is built for quantitative trading and machine learning. For more information about AlgoSeek, visit algoseek.com .

Getting Started

The following snippet demonstrates how to request data from the US Future Options dataset:

```
PY
future = self.add_future(Futures.Metals.GOLD, Resolution.MINUTE)
future.set_filter(0, 90)
self.add_future_option(future.symbol, lambda universe: universe.strikes(-5, +5))
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2012
Asset Coverage	15 Monthly Future Contracts. Standard expires only*.
Data Density	Dense
Resolution	Minute, Hourly, & Daily
Timezone	New York
Market Hours	Regular and Extended

* No weeklies or 0DTE contracts.

Requesting Data

To add US Future Options data to your algorithm, call the `add_future_option` method.

```
class FutureOptionDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2020, 1, 28)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)
        self.universe_settings.asynchronous = True
        future = self.add_future(Futures.Metals.GOLD, Resolution.MINUTE)
        future.set_filter(0, 90)
        self.add_future_option(future.symbol, lambda universe: universe.strikes(-5, +5))
```

The Future resolution must be less than or equal to the Future Option resolution. For example, if you set the Future resolution to minute, then the Future Option resolution must be minute, hour, or daily.

For more information about creating Future Options subscriptions, see Requesting Data or Future Options Universes .

Accessing Data

To get the current Future Options data, iterate through the `option_chains` property of the current `Slice` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your Future Options at every time step.

```
def on_data(self, slice: Slice) -> None:
    for canonical_fop_symbol, chain in slice.option_chains.items():
        for contract in chain:
            self.log(f"{contract.symbol} price at {slice.time}: {contract.last_price}")
```

You can also iterate through the `futures_chains` in the current `Slice` first.

```
def on_data(self, slice: Slice) -> None:
    for continuous_future_symbol, futures_chain in slice.futures_chains.items():
        # Select a Future Contract and create its canonical FOP Symbol
        futures_contract = [contract for contract in futures_chain][0]
        canonical_fop_symbol = Symbol.create_canonical_option(futures_contract.symbol)
        option_chain = slice.option_chains.get(canonical_fop_symbol)
        if option_chain:
            for fop_contract in option_chain:
                 self.log(f"{fop_contract.symbol} price at {slice.time}: {fop_contract.last_price}")
```

For more information about accessing Future Options data, see Handling Data .

Historical Data

You can get historical US Future Options data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Future Options data in an algorithm, call the `history` method with the Future Option contract `Symbol` . If there is no data in the period you request, the history result is empty.

```
# DataFrame of trade and quote data
history_df = self.history(contract.symbol, 100, Resolution.MINUTE)

# DataFrame of open interest data
history_oi_df = self.history(OpenInterest, contract.symbol, 100, Resolution.MINUTE)

# TradeBar objects
history_trade_bars = self.history[TradeBar](contract.symbol, 100, Resolution.MINUTE)

# QuoteBar objects
history_quote_bars = self.history[QuoteBar](contract.symbol, 100, Resolution.MINUTE)

# OpenInterest objects
history_oi = self.history[OpenInterest](contract.symbol, 100, Resolution.MINUTE)
```

For more information about historical data in algorithms, see History Requests .

Historical Data In Research

To get historical US Future Options data in the Research Environment, call the `history` or `option_history` method. The `history` method returns the

price, volume, and open interest history for some given Future Option contract(s). The `option_history` method returns the price and volume history for the contracts that pass your daily universe filter.

```py
qb = QuantBook()
future = qb.add_future(Futures.Indices.SP_500_E_MINI)
start_date = datetime(2024, 1, 2)
future_contract_symbol = sorted(
    qb.future_chain_provider.get_future_contract_list(future.symbol, start_date),
    key=lambda s: s.id.date
)[0]
history = qb.option_history(
    future_contract_symbol, start_date, future_contract_symbol.id.date, Resolution.HOUR
)
history_df = history.data_frame
expiries = history.get_expiry_dates()
strikes = history.get_strikes()
```

To get historical data for arbitrary US Equity Option contracts instead of just the that pass your universe filter, call the `history` method like you would in an algorithm, but on the `QuantBook` object. For more information about historical data in the Research Environment, see Key Concepts .

Supported Assets

The following list shows the available (15) Futures Options:

- `Futures.Energy.CRUDE_OIL_WTI` : Crude Oil WTI Futures (NYMEX: LO | Underlying: CL)
- `Futures.Energy.GASOLINE` : Gasoline RBOB Futures (NYMEX: OB | Underlying: RB)
- `Futures.Energy.HEATING_OIL` : Heating Oil Futures (NYMEX: OH | Underlying: HO)
- `Futures.Energy.NATURAL_GAS` : Natural Gas Futures (NYMEX: ON | Underlying: NG)
- `Futures.Financials.Y_10_TREASURY_NOTE` : 10Y U.S. Treasury Note Futures (CBOT: OZN | Underlying: ZN)
- `Futures.Financials.Y_2_TREASURY_NOTE` : 2Y U.S. Treasury Note Futures (CBOT: OZT | Underlying: ZT)
- `Futures.Financials.Y_30_TREASURY_BOND` : 30Y U.S. Treasury Bond Futures (CBOT: OZB | Underlying: ZB)
- `Futures.Grains.CORN` : Corn Futures (CBOT: OZC | Underlying: ZC)
- `Futures.Grains.SOYBEANS` : Soybeans Futures (CBOT: OZS | Underlying: ZS)
- `Futures.Grains.WHEAT` : Default wheat contract is SRWWheat (CBOT: OZW | Underlying: ZW)
- `Futures.Indices.NASDAQ_100_E_MINI` : E-mini NASDAQ 100 Futures (CME: NQ)
- `Futures.Indices.SP_500_E_MINI` : E-mini S&P 500 Futures (CME: ES)
- `Futures.Metals.COPPER` : Copper Futures (COMEX: HXE | Underlying: HG)
- `Futures.Metals.GOLD` : Gold Futures (COMEX: OG | Underlying: GC)
- `Futures.Metals.SILVER` : Silver Futures (COMEX: SO | Underlying: SI)

Example Applications

The US Future Options dataset enables you to accurately design Future Option strategies. Examples include the following strategies:

- Selling out of the money Future Option contracts to collect the premium that the Option buyer pays
- Buying put Options to hedge against downward price movement in Future contracts you bought
- Exploiting arbitrage opportunities that arise when the price of Option contracts deviates from their theoretical value

Classic Algorithm Example

The following example demonstrates a weekly-renewing covered call strategy to collect credit of selling the option. It filters the ATM call contract that expires within the current week at week start using `SetFilter` filtering function.

```py
from AlgorithmImports import *

class FutureOptionExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(5_000_000)
        # Subscribe the underlying since the updated price is needed for filtering
        self.underlying = self.add_future(Futures.Indices.SP_500_E_MINI,
            extended_market_hours=True,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0)
        # Filter the underlying continuous Futures to narrow the FOP spectrum
        self.underlying.set_filter(0, 182)
        # Filter for the current-week-expiring calls to formulate a covered call that expires at the end of week
        self.add_future_option(self.underlying.symbol, lambda u: u.calls_only().expiration(0, 5))

    def on_data(self, slice: Slice) -> None:
        # Create canonical symbol for the mapped future contract, since option chains are mapped by canonical symbol
        symbol = Symbol.create_canonical_option(self.underlying.mapped)

        # Get option chain data for the mapped future, as both the underlying and FOP have the highest liquidity among all other
contracts
        chain = slice.option_chains.get(symbol)
        if not self.portfolio.invested and chain:
            # Obtain the ATM call that expires at the end of week, such that both underlying and the FOP expires the same time
            expiry = max(x.expiry for x in chain)
            atm_call = sorted([x for x in chain if x.expiry == expiry],
                key=lambda x: abs(x.strike - x.underlying_last_price))[0]

            # Use abstraction method to order a covered call to avoid manual error
            option_strategy = OptionStrategies.covered_call(symbol, atm_call.strike,expiry)
            self.buy(option_strategy, 1)

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            if security.type == SecurityType.FUTURE_OPTION:
                # Historical data
                history = self.history(security.symbol, 10, Resolution.MINUTE)
```

Framework Algorithm Example

The following example demonstrates a daily renewing speculation trade on upward movement of Gold with FOP using algorithm framework. Using FOP, traders can achieve lower cost to get similar absolute profit, given the FOP is selected to be deep ITM with high Delta value.

```py
from AlgorithmImports import *

class USFuturesDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Override an option universe selection model to select the FOPs
        self.set_universe_selection(GoldFOPUniverseSelectionModel(self))
        # Handle the FOP trading logic in an alpha model
        self.add_alpha(ConstantFutureOptionsAlphaModel())
        # To order a single contract per insight, use a custom portfolio construction model
        self.set_portfolio_construction(SingleSharePortfolioConstructionModel())

class GoldFOPUniverseSelectionModel(OptionUniverseSelectionModel):

    # Daily renewed universe since option contract list is updated on a daily basis
    def __init__(self, algorithm) -> None:
        self._algorithm = algorithm
        super().__init__(timedelta(1), self.select_fop_symbols)

    def select_fop_symbols(self, utc_time: datetime) -> List[Symbol]:
        #  Create the underlying symbol to get the FOP contracts later
        future_symbol = Symbol.create(Futures.Metals.GOLD, SecurityType.FUTURE, Market.COMEX)
        # Get all gold FOP contracts of the front month gold contract expiring within 3 months, since their liquidity is the highest
        future_contract_list = self._algorithm.future_chain_provider.get_future_contract_list(future_symbol, self._algorithm.time)
        return [Symbol.create_canonical_option(x) for x in future_contract_list
                    if x.id.date <= self._algorithm.time + timedelta(90)]

    def filter(self, option_filter_universe: OptionFilterUniverse) -> OptionFilterUniverse:
        # Filter for the ATM calls that expires latest (same expiry as the underlying)
        # +/-5 strike range buffer for price movement
        return option_filter_universe.back_month().strikes(-5, +5).calls_only()

class ConstantFutureOptionsAlphaModel(AlphaModel):

    # A dictionary to cache the mapped FOP of the underlying Future for filtering wanted option chain data and check if invested
    option_contract_by_future_underlying_contract = {}

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        insights = []

AlgoSeek

US Futures

Introduction

The US Futures dataset by AlgoSeek provides Futures data, including price, volume, open interest, and expiry. The data covers the 157 most liquid contracts, starts in May 2009, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on the CFE *, CBOT, CME, COMEX, NYMEX, and ICE *.

This dataset also depends on the US Futures Security Master because the US Futures Security Master dataset contains information to construct continuous Futures.

For more information about the US Futures dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

AlgoSeek is a leading historical intraday US market data provider offering the most comprehensive and detailed market data and analytics products in the financial industry covering equities, futures, options, cash forex, and cryptocurrencies. AlgoSeek data is built for quantitative trading and machine learning. For more information about AlgoSeek, visit algoseek.com .

Getting Started

The following snippet demonstrates how to request data from the US Futures dataset:

```
future = self.add_future(Futures.Metals.GOLD)
future.set_filter(0, 90)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	May 2009
Asset Coverage	157 Futures
Data Density	Dense
Resolution	Tick, Second, Minute, Hour, & Daily
Timezone	• Chicago (CFE, CME or CBOT) • New York (ICE, NYMEX or COMEX)
Market Hours	Regular and Extended

This dataset only includes Sugar (SB) from the ICE exchange.

This data provider doesn't include a live data feed for the CFE market (VIX).

LBS (Random Length Lumber) was deprecated for LBR (Lumber).

Volume Discrepancies

The volume of the daily trade bars from this dataset is different from the daily volume that CME and other platforms like Yahoo Finance report because the CME includes pit trades in their daily volume calculation. In contrast, the volume of the daily trade bars in this dataset (from AlgoSeek) doesn't include pit trades because pit trades are over-the-counter, which algorithms can't trade.

Another discrepancy occurs from the start and end times of the daily bars. Daily bars from the CME and Yahoo Finance span from 5 PM Central Time (CT) to 4 PM CT on the following day. In contrast, QuantConnect consolidates daily bars from from 12 AM Eastern Time (ET) to 12 AM ET the following day. Therefore, to calculate the daily volume in the same way that CME does (excluding the pit trades), sum the volume of intraday bars that span 5 PM CT to 4 PM CT on the following day. For an example implementation, see Examples .

Requesting Data

To add US Futures data to your algorithm, call the `add_future` method. Save a reference to the Future so you can access the data later in your algorithm.

```
class USFuturesDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2013, 12, 20)
        self.set_end_date(2014, 2, 20)
        self.set_cash(1000000)
        self.universe_settings.asynchronous = True
        # Request Gold Future data
        future = self.add_future(Futures.Metals.GOLD)
        # Set filter to obtain the contracts expire within 90 days
        future.set_filter(0, 90)
        self.future_symbol = future.symbol
```

PY

For more information about creating Future subscriptions, see Requesting Data or Futures Universes .

Accessing Data

To get the current US Futures data, index the `bars` , `quote_bars` , or `ticks` properties of the current `Slice` with the Future `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    # Access data: TradeBar data
    if self.future_symbol in slice.bars:
        trade_bar = slice.bars[self.future_symbol]
        self.log(f"{self.future_symbol} close at {slice.time}: {trade_bar.close}")

    # Access data: QuoteBar data
    if self.future_symbol in slice.quote_bars:
        quote_bar = slice.quote_bars[self.future_symbol]
        self.log(f"{self.future_symbol} bid at {slice.time}: {quote_bar.bid.close}")

    # Access data: Ticks data
    if self.future_symbol in slice.ticks:
        ticks = slice.ticks[self.future_symbol]
        for tick in ticks:
            self.log(f"{self.future_symbol} price at {slice.time}: {tick.price}")
```

PY

You can also iterate through all of the data objects in the current `Slice` .

```
def on_data(self, slice: Slice) -> None:
    # Iterate all TradeBar received
    for symbol, trade_bar in slice.bars.items():
        self.log(f"{symbol} close at {slice.time}: {trade_bar.close}")

    # Iterate all QuoteBar received
    for symbol, quote_bar in slice.quote_bars.items():
        self.log(f"{symbol} bid at {slice.time}: {quote_bar.bid.close}")

    # Iterate all Ticks received
    for symbol, ticks in slice.ticks.items():
        for tick in ticks:
            self.log(f"{symbol} price at {slice.time}: {tick.price}")
```

PY

For more information about accessing US Futures data, see Handling Data .

Historical Data

You can get historical US Futures data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Futures data in an algorithm, call the `history` method with the canonical Futures `Symbol` or a Futures contract `Symbol` . If there is no data in the period you request, the history result is empty.

```py
# DataFrame objects
contract_history_df = self.history(contract.symbol, 100, Resolution.MINUTE)
continuous_history_df = self.history(self.future_symbol,
    start=self.time - timedelta(days=15),
    end=self.time,
    resolution=Resolution.MINUTE,
    fill_forward=False,
    extended_market_hours=False,
    data_mapping_mode=DataMappingMode.OPEN_INTEREST,
    data_normalization_mode=DataNormalizationMode.RAW,
    contract_depth_offset=0)

# TradeBar objects
contract_history_trade_bars = self.history[TradeBar](contract.symbol, 100, Resolution.MINUTE)
continous_history_trade_bars = self.history[TradeBar](self.future_symbol, 100, Resolution.MINUTE)

# QuoteBar objects
contract_history_quote_bars = self.history[QuoteBar](contract.symbol, 100, Resolution.MINUTE)
continous_history_quote_bars = self.history[QuoteBar](self.future_symbol, 100, Resolution.MINUTE)

# Tick objects
contract_history_ticks = self.history[Tick](contract.symbol, timedelta(seconds=10), Resolution.TICK)
continous_history_ticks = self.history[Tick](self.future_symbol, timedelta(seconds=10), Resolution.TICK)
```

For more information about historical data in algorithms, see History Requests . For more information about the price adjustments for continuous contracts, see Continous Contracts .

Historical Data In Research

To get historical US Futures data in the Research Environment for an entire Futures chain, call the `future_history` method with the canonical Future `Symbol` .

```py
qb = QuantBook()
future = qb.add_future(Futures.Metals.GOLD)
future.set_filter(0, 90)
history = qb.future_history(future.symbol, datetime(2020, 6, 1), datetime(2020, 6, 5))
history_df = history.data_frame
all_history = history.get_all_data()
expiries = history.get_expiry_dates()
```

To get historical data for a single US Futures contract or the continuous Futures contract, call the `history` method like you would in an algorithm but on the `QuantBook` object. For more information about historical data in the Research Environment, see Futures .

Supported Assets

The following list shows the available (157) Futures:

- `Futures.Currencies.AUD` : Australian Dollar Futures (CME: 6A)
- `Futures.Currencies.AUDCAD` : Australian Dollar/Canadian Dollar Futures (CME: ACD)
- `Futures.Currencies.AUDJPY` : Australian Dollar/Japanese Yen Futures (CME: AJY)
- `Futures.Currencies.AUDNZD` : Australian Dollar/New Zealand Dollar Futures (CME: ANE)
- `Futures.Currencies.BRL` : Brazillian Real Futures (CME: 6L)
- `Futures.Currencies.BTC` : Bitcoin Futures (CME: BTC)
- `Futures.Currencies.BTIC_MICRO_BTC` : BTIC on Micro Bitcoin Futures (CME: MIB)
- `Futures.Currencies.BTIC_MICRO_ETHER` : BTIC on Micro Ether Futures (CME: MRB)
- `Futures.Currencies.CAD` : Canadian Dollar Futures (CME: 6C)
- `Futures.Currencies.CADJPY` : Canadian Dollar/Japanese Yen Futures (CME: CJY)
- `Futures.Currencies.CHF` : Swiss Franc Futures (CME: 6S)
- `Futures.Currencies.ETH` : Ether Futures (CME: ETH)
- `Futures.Currencies.EUR` : Euro FX Futures (CME: 6E)
- `Futures.Currencies.EURAUD` : Euro/Australian Dollar Futures (CME: EAD)
- `Futures.Currencies.EURCAD` : Euro/Canadian Dollar Futures (CME: ECD)
- `Futures.Currencies.EURO_FX_EMINI` : E-mini Euro FX Futures (CME: E7)

- `Futures.Currencies.EURSEK` : Euro/Swedish Krona Futures (CME: ESK)
- `Futures.Currencies.GBP` : British Pound Futures (CME: 6B)
- `Futures.Currencies.JAPANESE_YEN_EMINI` : E-mini Japanese Yen Futures (CME: J7)
- `Futures.Currencies.JPY` : Japanese Yen Futures (CME: 6J)
- `Futures.Currencies.MICRO_AUD` : Micro AUD/USD Futures (CME: M6A)
- `Futures.Currencies.MICRO_BTC` : Micro Bitcoin Futures (CME: MBT)
- `Futures.Currencies.MICRO_CAD` : Micro USD/CAD Futures (CME: M6C)
- `Futures.Currencies.MICRO_CADUSD` : Micro CAD/USD Futures (CME: MCD)
- `Futures.Currencies.MICRO_CHF` : Micro CHF/USD Futures (CME: MSF)
- `Futures.Currencies.MICRO_ETHER` : Micro Ether Futures (CME: MET)
- `Futures.Currencies.MICRO_EUR` : Micro EUR/USD Futures (CME: M6E)
- `Futures.Currencies.MICRO_GBP` : Micro GBP/USD Futures (CME: M6B)
- `Futures.Currencies.MICRO_INRUSD` : Micro INR/USD Futures (CME: MIR)
- `Futures.Currencies.MICRO_JPY` : Micro JPY/USD Futures (CME: MJY)
- `Futures.Currencies.MICRO_USDCHF` : Micro USD/CHF Futures (CME: M6S)
- `Futures.Currencies.MICRO_USDCNH` : Micro USD/CNH Futures (CME: MNH)
- `Futures.Currencies.MICRO_USDJPY` : Micro USD/JPY Futures (CME: M6J)
- `Futures.Currencies.MXN` : Mexican Peso Futures (CME: 6M)
- `Futures.Currencies.NZD` : New Zealand Dollar Futures (CME: 6N)
- `Futures.Currencies.RUB` : Russian Ruble Futures (CME: 6R)
- `Futures.Currencies.STANDARD_SIZE_USD_OFFSHORE_RMBCNH` : Standard-Size USD/Offshore RMB (CNH) Futures (CME: CNH)
- `Futures.Currencies.ZAR` : South African Rand Futures (CME: 6Z)
- `Futures.Energy.ARGUS_LL_SVS_WTI_ARGUS_TRADE_MONTH` : Argus LLS vs. WTI (Argus) Trade Month Futures (NYMEX: AE5)
- `Futures.Energy.ARGUS_PROPANE_FAR_EAST_INDEX` : Argus Propane Far East Index Futures (NYMEX: A7E)
- `Futures.Energy.ARGUS_PROPANE_SAUDI_ARAMCO` : Argus Propane (Saudi Aramco) Futures (NYMEX: A9N)
- `Futures.Energy.BRENT_CRUDE_OIL_VS_DUBAI_CRUDE_OIL_PLATTS` : Brent Crude Oil vs. Dubai Crude Oil (Platts) Futures (NYMEX: ADB)
- `Futures.Energy.BRENT_LAST_DAY_FINANCIAL` : Brent Last Day Financial Futures (NYMEX: BZ)
- `Futures.Energy.CHICAGO_ETHANOL_PLATTS` : Chicago Ethaanol (Platts) Futures (NYMEX: CU)
- `Futures.Energy.CONWAY_PROPANE_OPIS` : Conway Propane (OPIS) Futures (NYMEX: A8K)
- `Futures.Energy.CRUDE_OIL_WTI` : Crude Oil WTI Futures (NYMEX: CL)
- `Futures.Energy.DUBAI_CRUDE_OIL_PLATTS_FINANCIAL` : Dubai Crude Oil (Platts) Financial Futures (NYMEX: DCB)
- `Futures.Energy.EAST_WEST_GASOLINE_SPREAD_PLATTS_ARGUS` : East-West Gasoline Spread (Platts-Argus) Futures (NYMEX: EWG)
- `Futures.Energy.EAST_WEST_NAPHTHA_JAPAN_C_FVS_CARGOES_CIFNWE_SPREAD_PLATTS` : East-West Naphtha: Japan C&F vs. Cargoes CIF NWE Spread (Platts) Futures (NYMEX: EWN)
- `Futures.Energy.ETHANOL` : Ethanol Futures (CBOT: EH)
- `Futures.Energy.ETHANOL_T_2_FOB_RDAM_INCLUDING_DUTY_PLATTS` : Ethanol T2 FOB Rdam Including Duty (Platts) Futures (NYMEX: AZ1)
- `Futures.Energy.EUROPEAN_NAPHTHA_PLATTS_CRACK_SPREAD` : European Naphtha (Platts) Crack Spread Futures (NYMEX: EN)
- `Futures.Energy.EUROPEAN_PROPANE_CIFARA_ARGUS` : European Propane CIF ARA (Argus) Futures (NYMEX: APS)
- `Futures.Energy.EUROPEAN_PROPANE_CIFARA_ARGUS_VS_NAPHTHA_CARGOES_CIFNWE_PLATTS` : European Propane CIF ARA (Argus) vs. Naphtha Cargoes CIF NWE (Platts) Futures (NYMEX: EPN)
- `Futures.Energy.FREIGHT_ROUTE_TC_14_BALTIC` : Freight Route TC14 (Baltic) Futures (NYMEX: FRC)
- `Futures.Energy.GASOLINE` : Gasoline RBOB Futures (NYMEX: RB)
- `Futures.Energy.GASOLINE_EUROBOB_OXY_NWE_BARGES_ARGUS` : Gasoline Euro-bob Oxy NWE Barges (Argus) Futures (NYMEX: B7H)
- `Futures.Energy.GROUP_THREE_SUBOCTANE_GASOLINE_PLATTS_VS_RBOB` : Group Three Sub-octane Gasoliine (Platts) vs. RBOB Futures (NYMEX: AA8)
- `Futures.Energy.GROUP_THREE_ULSD_PLATTS_VS_NY_HARBOR_ULSD` : Group Three ULSD (Platts) vs. NY Harbor ULSD Futures (NYMEX: AA6)
- `Futures.Energy.GULF_COAST_CBOB_GASOLINE_A_2_PLATTS_VS_RBOB_GASOLINE` : Gulf Coast CBOB Gasoline A2 (Platts) vs. RBOB Gasoline Futures (NYMEX: CRB)
- `Futures.Energy.GULF_COAST_HSFO_PLATTS_VS_EUROPEAN_THREE_POINT_FIVE_PERCENT_FUEL_OIL_BARGES_FOB_RDAM_PLATTS` : Gulf Coast HSFO (Platts) vs. European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: GCU)
- `Futures.Energy.HEATING_OIL` : Heating Oil Futures (NYMEX: HO)
- `Futures.Energy.LOS_ANGELES_CARBOB_GASOLINE_OPI_SVS_RBOB_GASOLINE` : Los Angeles CARBOB Gasoline (OPIS) vs. RBOB Gasoline Futures

(NYMEX: AJL)

- `Futures.Energy.LOS_ANGELES_CARB_DIESEL_OPI_SVS_NY_HARBOR_ULSD` : Los Angeles CARB Diesel (OPIS) vs. NY Harbor ULSD Futures (NYMEX: AKL)
- `Futures.Energy.LOS_ANGELES_JET_OPI_SVS_NY_HARBOR_ULSD` : Los Angeles Jet (OPIS) vs. NY Harbor ULSD Futures (NYMEX: AJS)
- `Futures.Energy.MARS_ARGUS_VS_WTI_FINANCIAL` : Mars (Argus) vs. WTI Financial Futures (NYMEX: AYX)
- `Futures.Energy.MARS_ARGUS_VS_WTI_TRADE_MONTH` : Mars (Argus) vs. WTI Trade Month Futures (NYMEX: AYV)
- `Futures.Energy.MICRO_CRUDE_OIL_WTI` : Micro WTI Crude Oil Futures (NYMEX: MCL)
- `Futures.Energy.MICRO_EUROPEAN_FOB_RDAM_MARINE_FUEL_ZERO_POINT_FIVE_PERCENT_BARGES_PLATTS` : Micro European FOB Rdam Marine Fuel 0.5% Barges (Platts) Futures (NYMEX: R5O)
- `Futures.Energy.MICRO_EUROPEAN_THREE_POINT_FIVE_PERCENT_OIL_BARGES_FOB_RDAM_PLATTS` : Micro European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: MEF)
- `Futures.Energy.MICRO_GASOIL_ZERO_POINT_ONE_PERCENT_BARGES_FOBARA_PLATTS` : Micro Gasoil 0.1% Barges FOB ARA (Platts) Futures (NYMEX: M1B)
- `Futures.Energy.MICRO_SINGAPORE_FOB_MARINE_FUEL_ZERO_POINT_FIVE_PERCET_PLATTS` : Micro Singapore FOB Marine Fuel 0.5% (Platts) Futures (NYMEX: S5O)
- `Futures.Energy.MICRO_SINGAPORE_FUEL_OIL_380_CST_PLATTS` : Micro Singapore Fuel Oil 380CST (Platts) Futures (NYMEX: MAF)
- `Futures.Energy.MINI_EUROPEAN_THREE_POINT_PERCENT_FIVE_FUEL_OIL_BARGES_PLATTS` : Mini European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: A0D)
- `Futures.Energy.MINI_SINGAPORE_FUEL_OIL_180_CST_PLATTS` : Mini Singapore Fuel Oil 180 cst (Platts) Futures (NYMEX: A0F)
- `Futures.Energy.MONT_BELVIEU_ETHANE_OPIS` : Mont Belvieu Ethane (OPIS) Futures (NYMEX: AC0)
- `Futures.Energy.MONT_BELVIEU_LDH_PROPANE_OPIS` : Mont Belvieu LDH Propane (OPIS) Futures (NYMEX: B0)
- `Futures.Energy.MONT_BELVIEU_NATURAL_GASOLINE_OPIS` : Mont Belvieu Natural Gasoline (OPIS) Futures (NYMEX: A7Q)
- `Futures.Energy.MONT_BELVIEU_NORMAL_BUTANE_OPIS` : Mont Belvieu Normal Butane (OPIS) Futures (NYMEX: AD0)
- `Futures.Energy.NATURAL_GAS` : Natural Gas Futures (NYMEX: NG)
- `Futures.Energy.NATURAL_GAS_HENRY_HUB_LAST_DAY_FINANCIAL` : Natural Gas (Henry Hub) Last-day Financial Futures (NYMEX: HH)
- `Futures.Energy.NATURAL_GAS_HENRY_HUB_PENULTIMATE_FINANCIAL` : Natural Gas (Henry Hub) Penultimate Financial Futures (NYMEX: HP)
- `Futures.Energy.ONE_PERCENT_FUEL_OIL_CARGOES_FOBNWE_PLATTS_VS_THREE_POINT_FIVE_PERCENT_FUEL_OIL_BARGES_FOB_RDAM_PLATTS` : 1% Fuel Oil Cargoes FOB NWE (Platts) vs. 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: FSS)
- `Futures.Energy.PREMIUM_UNLEADED_GASOLINE_10_PPM_FOBMED_PLATTS` : Premium Unleaded Gasoline 10 ppm FOB MED (Platts) Futures (NYMEX: A3G)
- `Futures.Energy.PROPANE_NON_LDH_MONT_BELVIEU_OPIS` : Propane Non-LDH Mont Belvieu (OPIS) Futures (NYMEX: A1R)
- `Futures.Energy.RBOB_GASOLINE_CRACK_SPREAD` : RBOB Gasoline Crack Spread Futures (NYMEX: ARE)
- `Futures.Energy.RBOB_GASOLINE_VS_EUROBOB_OXY_NWE_BARGES_ARGUS_THREE_HUNDRED_FIFTY_THOUSAND_GALLONS` : RBOB Gasoline vs. Eurobob Oxy NWE Barges (Argus) (350,000 gallons) Futures (NYMEX: EXR)
- `Futures.Energy.SINGAPORE_FUEL_OIL_380_CST_PLATTS_VS_EUROPEAN_THREE_POINT_FIVE_PERCENT_FUEL_OIL_BARGES_FOB_RDAM_PLATTS` : Singapore Fuel Oil 380 cst (Platts) vs. European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: EVC)
- `Futures.Energy.SINGAPORE_GASOIL_PLATTS_VS_LOW_SULPHUR_GASOIL_FUTURES` : Singapore Gasoil (Platts) vs. Low Sulphur Gasoil Futures (NYMEX: AGA)
- `Futures.Energy.SINGAPORE_MOGAS_92_UNLEADED_PLATTS_BRENT_CRACK_SPREAD` : Singapore Mogas 92 Unleaded (Platts) Brent Crack Spread Futures (NYMEX: D1N)
- `Futures.Energy.THREE_POINT_FIVE_PERCENT_FUEL_OIL_BARGES_FOB_RDAM_PLATTS_CRACK_SPREAD` : 3.5% Fuel Oil Barges FOB Rdam (Platts) Crack Spread Futures (NYMEX: FO)
- `Futures.Energy.THREE_POINT_FIVE_PERCENT_FUEL_OIL_BARGES_FOB_RDAM_PLATTS_CRACK_SPREAD_1000_MT` : 3.5% Fuel Oil Barges FOB Rdam (Platts) Crack Spread (1000mt) Futures (NYMEX: BOO)
- `Futures.Energy.WTI_BRENT_FINANCIAL` : WTI-Brent Financial Futures (NYMEX: BK)
- `Futures.Energy.WTI_FINANCIAL` : WTI Financial Futures (NYMEX: CSX)
- `Futures.Energy.WTI_HOUSTON_ARGUS_VS_WTI_TRADE_MONTH` : WTI Houston (Argus) vs. WTI Trade Month Futures (NYMEX: HTT)
- `Futures.Energy.WTI_HOUSTON_CRUDE_OIL` : WTI Houston Crude Oil Futures (NYMEX: HCL)
- `Futures.Financials.EURO_DOLLAR` : EuroDollar Futures (CME: GE)
- `Futures.Financials.FIVE_YEAR_USDMAC_SWAP` : 5-Year USD MAC Swap Futures (CBOT: F1U)
- `Futures.Financials.MICRO_Y_10_TREASURY_NOTE` : Micro 10-Year Yield Futures (CBOT: 10Y)
- `Futures.Financials.MICRO_Y_2_TREASURY_BOND` : Micro 2-Year Yield Futures (CBOT: 2YY)

- `Futures.Financials.MICRO_Y_30_TREASURY_BOND` : Micro 30-Year Yield Futures (CBOT: 30Y)
- `Futures.Financials.MICRO_Y_5_TREASURY_BOND` : Micro 5-Year Yield Futures (CBOT: 5YY)
- `Futures.Financials.ULTRA_TEN_YEAR_US_TREASURY_NOTE` : Ultra 10-Year U.S. Treasury Note Futures (CBOT: TN)
- `Futures.Financials.ULTRA_US_TREASURY_BOND` : Ultra U.S. Treasury Bond Futures (CBOT: UB)
- `Futures.Financials.Y_10_TREASURY_NOTE` : 10Y U.S. Treasury Note Futures (CBOT: ZN)
- `Futures.Financials.Y_2_TREASURY_NOTE` : 2Y U.S. Treasury Note Futures (CBOT: ZT)
- `Futures.Financials.Y_30_TREASURY_BOND` : 30Y U.S. Treasury Bond Futures (CBOT: ZB)
- `Futures.Financials.Y_5_TREASURY_NOTE` : 5Y U.S. Treasury Note Futures (CBOT: ZF)
- `Futures.Forestry.LUMBER` : Lumber Futures (CME: LBR)
- `Futures.Forestry.RANDOM_LENGTH_LUMBER` : Random Length Lumber Futures (CME: LBS)
- `Futures.Grains.BLACK_SEA_CORN_FINANCIALLY_SETTLED_PLATTS` : Black Sea Corn Financially Settled (Platts) Futures (CBOT: BCF)
- `Futures.Grains.BLACK_SEA_WHEAT_FINANCIALLY_SETTLED_PLATTS` : Black Sea Wheat Financially Settled (Platts) Futures (CBOT: BWF)
- `Futures.Grains.CORN` : Corn Futures (CBOT: ZC)
- `Futures.Grains.HRW_WHEAT` : KC HRW Wheat Futures (CBOT: KE)
- `Futures.Grains.OATS` : Oats Futures (CBOT: ZO)
- `Futures.Grains.SOYBEANS` : Soybeans Futures (CBOT: ZS)
- `Futures.Grains.SOYBEAN_MEAL` : Soybean Meal Futures (CBOT: ZM)
- `Futures.Grains.SOYBEAN_OIL` : Soybean Oil Futures (CBOT: ZL)
- `Futures.Grains.WHEAT` : Default wheat contract is SRWWheat (CBOT: ZW)
- `Futures.Indices.BLOOMBERG_COMMODITY_INDEX` : Bloomberg Commodity Index Futures (CBOT: AW)
- `Futures.Indices.DOW_30_E_MINI` : E-mini Dow Indu 30 Futures (CBOT: YM)
- `Futures.Indices.DOW_JONES_REAL_ESTATE` : Dow Jones Real Estate futures on CME (CME: RX)
- `Futures.Indices.FTSE_EMERGING_EMINI` : E-mini FTSE Emerging Index Futures (CME: EI)
- `Futures.Indices.MICRO_DOW_30_E_MINI` : Micro E-mini Dow Jones Industrial Average Index Futures (CBOT: MYM)
- `Futures.Indices.MICRO_NASDAQ_100_E_MINI` : Micro E-mini Nasdaq-100 Index Futures (CME: MNQ)
- `Futures.Indices.MICRO_RUSSELL_2000_E_MINI` : Micro E-mini Russell 2000 Index Futures (CME: M2K)
- `Futures.Indices.MICRO_SP_500_E_MINI` : Micro E-mini S&P 500 Index Futures (CME: MES)
- `Futures.Indices.NASDAQ_100_BIOTECHNOLOGY_E_MINI` : E-mini Nasdaq-100 Biotechnology Index Futures (CME: BIO)
- `Futures.Indices.NASDAQ_100_E_MINI` : E-mini NASDAQ 100 Futures (CME: NQ)
- `Futures.Indices.NIKKEI_225_DOLLAR` : Nikkei-225 Dollar Futures (CME: NKD)
- `Futures.Indices.NIKKEI_225_YEN_CME` : Nikkei-225 Yen denominated Futures on CME (CME: NIY)
- `Futures.Indices.RUSSELL_1000_E_MINI` : E-mini Russell 1000 futures on CME (CME: RS1)
- `Futures.Indices.RUSSELL_2000_E_MINI` : E-mini Russell 2000 Futures (CME: RTY)
- `Futures.Indices.SPGSCI_COMMODITY` : S&P-GSCI Commodity Index Futures (CME: GD)
- `Futures.Indices.SP_400_MID_CAP_EMINI` : E-mini S&P MidCap 400 Futures (CME: EMD)
- `Futures.Indices.SP_500_ANNUAL_DIVIDEND_INDEX` : (CME: SDA)
- `Futures.Indices.SP_500_E_MINI` : E-mini S&P 500 Futures (CME: ES)
- `Futures.Indices.TOPIXYEN` : YEN Denominated Topix Index Futures on CME (CME: TPY)
- `Futures.Indices.USD_DENOMINATED_IBOVESPA` : USD-Denominated Ibovespa Index Futures (CME: IBV)
- `Futures.Indices.VIX` : CBOE Volatility Index Futures (CFE: VX)
- `Futures.Meats.FEEDER_CATTLE` : Feeder Cattle Futures (CME: GF)
- `Futures.Meats.LEAN_HOGS` : Lean Hogs Futures (CME: HE)
- `Futures.Meats.LIVE_CATTLE` : Live Cattle Futures (CME: LE)
- `Futures.Metals.ALUMINIUM_EUROPEAN_PREMIUM_DUTY_PAID_METAL_BULLETIN` : Aluminium European Premium Duty-Paid (Metal Bulletin) Futures (COMEX: EDP)
- `Futures.Metals.ALUMINUM_MWUS_TRANSACTION_PREMIUM_PLATTS_25_MT` : Aluminum MW U.S. Transaction Premium Platts (25MT) Futures (COMEX: AUP)
- `Futures.Metals.COPPER` : Copper Futures (COMEX: HG)
- `Futures.Metals.GOLD` : Gold Futures (COMEX: GC)
- `Futures.Metals.MICRO_GOLD` : Micro Gold Futures (COMEX: MGC)
- `Futures.Metals.MICRO_GOLD_TAS` : Micro Gold TAS Futures (COMEX: MGT)
- `Futures.Metals.MICRO_PALLADIUM` : Micro Palladium Futures (NYMEX: PAM)

- `Futures.Metals.MICRO_SILVER` : Micro Silver Futures (COMEX: SIL)
- `Futures.Metals.PALLADIUM` : Palladium Futures (NYMEX: PA)
- `Futures.Metals.PLATINUM` : Platinum Futures (NYMEX: PL)
- `Futures.Metals.SILVER` : Silver Futures (COMEX: SI)
- `Futures.Metals.US_MIDWEST_DOMESTIC_HOT_ROLLED_COIL_STEEL_CRU_INDEX` : U.S. Midwest Domestic Hot-Rolled Coil Steel (CRU) Index Futures (NYMEX: HRC)
- `Futures.Softs.SUGAR_11` : Sugar #11 Futures ICE (ICE: SB)
- `Futures.Softs.SUGAR_11_CME` : Sugar #11 Futures CME (NYMEX: YO)

Example Applications

The US Futures dataset enables you to accurately design Futures strategies. Examples include the following strategies:

- Buying the Futures contract with the most open interest to reduce slippage and market impact
- Trading bull calendar spreads to reduce volatility and margin requirements

Classic Algorithm Example

The following example algorithm buys the Mini Gold Futures contract with the greatest open interest and sells the Micro Gold Futures contract with the greatest open interest. When the open interest of a different contract exceeds the open interest of a contract in the portfolio, the algorithm rebalances the portfolio.

```py
from AlgorithmImports import *

class USFuturesDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000000)
        # Setting the continuous contract mapping criteria for both Gold and Micro Gold contracts, since we want to order the highest
liquidity contracts
        self.settings.seed_initial_prices = True
        self.gold = self.add_future(Futures.Metals.GOLD,
            extended_market_hours=True,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0)
        self.micro_gold = self.add_future(Futures.Metals.MICRO_GOLD,
            extended_market_hours=True,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0)
        # The contract multiplier is cached in the Security symbol_properties property from the symbol properties database
        self.gold_multiplier = self.gold.symbol_properties.contract_multiplier
        self.micro_gold_multiplier = self.micro_gold.symbol_properties.contract_multiplier

    def on_data(self, slice: Slice) -> None:
        # Make sure to calculate the order size by the most updated price data of both contracts
        if not self.portfolio.invested and self.gold.symbol in slice.bars and self.micro_gold.symbol in slice.bars:
            # Calculate the order size for $500k
            # Get the quotient after dividing the contract multiplier since the order size must be whole number
            gold_quantity = 500000 / slice.bars[self.gold.symbol].close // self.gold_multiplier
            micro_gold_quantity = 500000 / slice.bars[self.micro_gold.symbol].close // self.micro_gold_multiplier

            self.market_order(self.gold.mapped, gold_quantity)
            self.market_order(self.micro_gold.mapped, micro_gold_quantity)

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            # Historical data
            history = self.history(security.symbol, 10, Resolution.MINUTE)
            self.debug(f"We got {len(history)} from our history request for {security.symbol}")
```

Framework Algorithm Example

The following example algorithm buys the front-month Mini Gold Futures contract and sells the front-month Micro Gold Futures contract. When the front-month contract changes, the algorithm rebalances the portfolio.

```py
from AlgorithmImports import *

class USFuturesDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.universe_settings.asynchronous = True
        # Set up an universe selection model that selects the front month contract
        self.set_universe_selection(FrontMonthFutureUniverseSelectionModel())
        self.add_alpha(ConstantFuturesAlphaModel())
        # A portfolio construction model that only order a single share per insight signal
        self.set_portfolio_construction(SingleSharePortfolioConstructionModel())

class FrontMonthFutureUniverseSelectionModel(FutureUniverseSelectionModel):
    def __init__(self,) -> None:

```

Data Point Attributes

The US Futures dataset provides `FuturesChain` , `Future` , and `OpenInterest` objects. To configure the continuous Future settings, use the `DataNormalizationMode` and `DataMappingMode` enumerations.

DataNormalizationMode Values

The `DataNormalizationMode` enumeration has the following values:

DataMappingMode Values

The `DataMappingMode` enumeration has the following values:

Future Attributes

`Future` objects have the following attributes:

FuturesChain Attributes

`FuturesChain` objects have the following attributes:

OpenInterest Attributes

`OpenInterest` objects have the following attributes:

AlgoSeek

US Index Options

Introduction

The US Index Options dataset by AlgoSeek provides Option data, including prices, strikes, expires, and open interest. The data covers European Option contracts for 3 US Indices: SPX, VIX, and NDX. It starts from January 2012 and is delivered on minute resolution. This dataset is created by monitoring the Options Price Reporting Authority (OPRA) data feed, which consolidates last sale and quotation information originating from the national securities exchanges that have been approved by the Securities and Exchange Commission.

The US Index Options dataset depends on the US Index Option Universe dataset because the US Index Options Universe dataset contains information on the available contracts, including their daily Greeks and implied volatility values.

For more information about the US Index Options dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

AlgoSeek is a leading historical intraday US market data provider offering the most comprehensive and detailed market data and analytics products in the financial industry covering Equities, Futures, Options, cash FOREX, and Cryptocurrencies. AlgoSeek data is built for quantitative trading and machine learning. For more information about AlgoSeek, visit algoseek.com .

Getting Started

The following snippet demonstrates how to request data from the US Index Options dataset:

```py
self.index_symbol = self.add_index('VIX').symbol
option = self.add_index_option(self.index_symbol)
option.set_filter(-2, 2, 0, 90)
self.option_symbol = option.symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2012
Asset Coverage	7 Index Options
Data Density	Regular
Resolution	Minute, Hourly, & Daily
Timezone	New York
Market Hours	Regular Only

Specification Over Time

According to the SPX Options contract specification , some SPX contracts expire every month and SPXW contracts expires every day. Before 2021, you could only trade SPX contracts with the following expiration dates:

- Expires within the next 4 months
- Expires in September within the next 14 months
- Expires in January, March, or June within the next 2 years
- Expires in December within the next 3 years

During this time, SPXW didn't have 0DTE every day.

- S&P 500 Weekly Options Now Expire Five Days a Week

Requesting Data

To add US Index Options data to your algorithm, call the `add_index_option` method. Save a reference to the Index Option `Symbol` so you can access the data later in your algorithm.

```
PY
class IndexOptionsDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2021, 1, 1);
        self.set_end_date(2021, 6, 1);
        self.set_cash(1000000);
        self.universe_settings.asynchronous = True
        self.index_symbol = self.add_index('VIX').symbol

        standard_option = self.add_index_option(self.index_symbol)
        standard_option.set_filter(-2, 2, 0, 90)
        self.standard_option_symbol = standard_option.symbol

        weekly_option = self.add_index_option(self.index_symbol, "VIXW")
        weekly_option.set_filter(-2, 2, 0, 90)
        self.weekly_option_symbol = weekly_option.symbol
```

The Index resolution must be less than or equal to the Index Option resolution. For example, if you set the Index resolution to minute, then you must set the Index Option resolution to minute, hour, or daily.

For more information about creating US Index Option subscriptions, see Requesting Data or Index Options Universes .

Accessing Data

To get the current US Index Options data, index the `option_chains` property of the current `Slice` with the canonical Index Option `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your Index Option at every time step.

```
PY
def on_data(self, slice: Slice) -> None:
    standard_chain = slice.option_chains.get(self.standard_option_symbol)
    if standard_chain:
        for contract in standard_chain:
            self.log(f"{contract.symbol} price at {slice.time}: {contract.last_price}")

    weekly_chain = slice.option_chains.get(self.weekly_option_symbol)
    if weekly_chain:
        for contract in weekly_chain:
            self.log(f"{contract.symbol} price at {slice.time}: {contract.last_price}")
```

You can also iterate through all of the `OptionChain` objects in the current `Slice` .

```
PY
def on_data(self, slice: Slice) -> None:
    for canonical_symbol, chain in slice.option_chains.items():
        for contract in chain:
            self.log(f"{contract.symbol} price at {slice.time}: {contract.last_price}")
```

For more information about accessing US Index Options data, see Handling Data .

Historical Data

You can get historical US Index Options data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Index Options data in an algorithm, call the `history` method with the Index Option contract `Symbol` . If there is no data in the period you request, the history result is empty.

```py
# DataFrame of trade and quote data
history_df = self.history(contract.symbol, 100, Resolution.MINUTE)

# DataFrame of open interest data
history_oi_df = self.history(OpenInterest, contract.symbol, 100, Resolution.MINUTE)

# TradeBar objects
history_trade_bars = self.history[TradeBar](contract.symbol, 100, Resolution.MINUTE)

# QuoteBar objects
history_quote_bars = self.history[QuoteBar](contract.symbol, 100, Resolution.MINUTE)

# OpenInterest objects
history_oi = self.history[OpenInterest](contract.symbol, 100, Resolution.MINUTE)
```

For more information about historical data in algorithms, see History Requests .

Historical Data In Research

To get historical US Index Options data in the Research Environment, call the `history` or `option_history` method. The `history` method returns the price, volume, and open interest history for some given Option contract(s). The `option_history` method returns the price and volume history for the contracts that pass your daily universe filter.

```py
qb = QuantBook()
index_symbol = qb.add_index('VIX').symbol
option = qb.add_index_option(index_symbol) # or qb.add_index_option(index_symbol, "VIXW")
option.set_filter(-2, 2, 0, 90)
history = qb.option_history(option.symbol, datetime(2020, 6, 1), datetime(2020, 6, 5))
history_df = history.data_frame
expiries = history.get_expiry_dates()
strikes = history.get_strikes()
```

To get historical data for arbitrary US Index Option contracts instead of just the that pass your universe filter, call the `history` method like you would in an algorithm, but on the `QuantBook` object. For more information about historical data in the Research Environment, see Key Concepts .

Historical Greeks and IV Data

To get historical data for the Greeks and implied volatility of Index Options, see the US Index Option Universe dataset.

Supported Assets

The following table shows the available Index Options:

Underlying Index	Underlying Ticker	Target Ticker	Standard Contracts	Weekly Contracts	Tradable on Expiry Day
NASDAQ-100	NDX		✓		
NASDAQ-100	NDX	NDXP	✓		✓
NASDAQ-100	NDX	NQX	✓	✓	✓
Russell 2000	RUT		✓		
Russell 2000	RUT	RUTW		✓	✓
S&P500	SPX		✓		
S&P500	SPX	SPXW		✓	✓
S&P500	VIX		✓		
S&P500	VIX	VIXW		✓	

For more information about each underlying Index, see Supported Indices .

Example Applications

The US Index Options dataset enables you to accurately design strategies for Index Options. Examples include the following strategies:

- Buying VIX call Options to hedge against upcoming volatility
- Buying VIX put Options to capture the natural downward price movement in the VIX index
- Buying SPX put Options to protect against downward price movement in the S&P 500

Classic Algorithm Example

The following example algorithm buys the VIX Index Option Bull Call Spread with the furthest expiration:

```py
from AlgorithmImports import *

class IndexOptionsDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(200000)
        # Asynchronous can use computational resources efficiently
        self.universe_settings.asynchronous = True
        # Filter to get ATM calls expiring in 180 days to form the Bull Call Spread
        option = self.add_index_option("SPX")
        option.set_filter(lambda u: u.calls_only().strikes(-2, +2).expiration(0, 180))
        self.option_symbol = option.symbol

    def on_data(self, slice: Slice) -> None:
        if not self.portfolio.invested and self.is_market_open(self.option_symbol):
            # Make sure getting the updated VIX option chain
            chain = slice.option_chains.get(self.option_symbol)
            if chain:
                expiry = max([c.expiry for c in chain])
                call_contracts = sorted([c for c in chain if c.expiry == expiry],
                    key=lambda c: c.strike)

                # Need 2 contracts to form a call spread
                if len(call_contracts) < 2:
                    return

                # Obtain 2 call contracts with different strike price to form the call spread
                longCall, shortCall = call_contracts[0:2]

                # Use all the buying power, but need to ensure the order size of the long and short call are the same
                quantity = min([
                    abs(self.calculate_order_quantity(shortCall.symbol, -1)),
                    abs(self.calculate_order_quantity(longCall.symbol, 1))])
                if not quantity:
                    return

                # Bull call spread consists of long a lower-strike call and short a higher-strike call
                self.market_order(shortCall.symbol, -quantity)
                self.market_order(longCall.symbol, quantity)

                expected_margin_usage = max((longCall.strike - shortCall.strike) *
self.securities[longCall.symbol].symbol_properties.contract_multiplier * quantity, 0)
                if expected_margin_usage != self.portfolio.total_margin_used:
                    raise Exception("Unexpect margin used!")

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            if security.type == SecurityType.INDEX_OPTION:
                # Historical data
                history = self.history(security.symbol, 10, Resolution.MINUTE)
```

Framework Algorithm Example

The following example algorithm buys the VIX Index Option Bull Call Spread with the furthest expiration:

```py
from AlgorithmImports import *

class IndexOptionsDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(200000)
        self.universe_settings.asynchronous = True
        self.set_universe_selection(VIXIndexOptionUniverseSelectionModel())

        self.set_alpha(BullCallSpreadAlphaModel())

        self.set_portfolio_construction(SingleSharePortfolioConstructionModel())

class VIXIndexOptionUniverseSelectionModel(OptionUniverseSelectionModel):

    def __init__(self):
        super().__init__(timedelta(1), self.option_chain_symbol_selector)

    def option_chain_symbol_selector(self, utc_time: datetime) -> List[Symbol]:
        # Only interest in VIX options
        return [Symbol.create("VIX", SecurityType.INDEX_OPTION, Market.USA)]

    def filter(self, option_filter_universe: OptionFilterUniverse) -> OptionFilterUniverse:
        # Filter to get ATM calls expiring in 180 days to form the Bull Call Spread
        return option_filter_universe.calls_only().strikes(-2, +2).expiration(0, 180)

class BullCallSpreadAlphaModel(AlphaModel):

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        if algorithm.portfolio.invested:
            return []

        for canonical_symbol, chain in slice.option_chains.items():
            if not chain:
                return []
            # Bull call spread legs are having the same expiry
            expiry = max([c.expiry for c in chain])
            call_contracts = sorted([c for c in chain if c.expiry == expiry],
                key=lambda c: c.strike)

            # Need 2 contracts to form a call spread
            if len(call_contracts) < 2:
                return []

            # Obtain 2 call contracts with different strike price to form the call spread
            long_call, short_call = call_contracts[0:2]

            # Bull call spread consists of long a lower-strike call and short a higher-strike call
            return Insight.group(
                [
                    Insight.price(long_call.symbol, expiry + timedelta(1), InsightDirection.UP),
                    Insight.price(short_call.symbol, expiry + timedelta(1), InsightDirection.DOWN)
                ])
        return []

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            if security.type == SecurityType.INDEX_OPTION:
                # Historical data
                history = algorithm.history(security.symbol, 10, Resolution.MINUTE)

class SingleSharePortfolioConstructionModel(PortfolioConstructionModel):

    def create_targets(self, algorithm: QCAlgorithm, insights: List[Insight]) -> List[PortfolioTarget]:
        if not insights:
            return []
        # Only a single contract toi ensure both legs size is equal
        quantity = min([abs(algorithm.calculate_order_quantity(i.symbol, int(i.direction)))
            for i in insights])

        return [PortfolioTarget(i.symbol, quantity * int(i.direction))
            for i in insights]
```

Data Point Attributes

Datasets

Morningstar

Morningstar was founded by Joe Mansueto in 1984 with the goal of empowering investors by connecting people to the investing information and tools they need. Morningstar provides access extensive line of products and services for individual investors, financial advisors, asset managers, and retirement plan providers. Morningstar provides data on approximately 525,000 investment offerings including stocks, mutual funds, and similar vehicles, along with real-time global market data on nearly 18 million equities, indexes, futures, options, commodities, and precious metals, in addition to foreign exchange and Treasury markets. Morningstar also offers investment management services through its investment advisory subsidiaries, with $244 billion in assets under advisement or management as of 2021.

US Fundamental Data

Morningstar

US Fundamental Data

Introduction

The US Fundamental Data by Morningstar tracks US Equity fundamentals. The data covers 8,000 US Equities, starts in January 1998, and is delivered on a daily frequency. The data does not include ETFs, ADRs, or OTC equities. This dataset is created by using a combination of string matching, Regular Expressions, and Machine Learning to gather the fundamental data published by companies.

For older symbols, the file date is approximated 45 days after the as of date. When a filing date is present on the Morningstar data, it is used. As we are a quant platform, all the data is loaded using "As Original Reported" figures. If there was a mistake reporting the figure, this will not be fixed later. The market typically responds quickly to these initially reported figures. Data is available for multiple periods depending on the property. Periods available include: 1 mo, 2 mo, 3 mo, 6 mo, 9 mo, 12 mo, 1 Yr, 2 Yr, 3 Yr, and 5 Yr. Morningstar symbols cover the NYSE, NASDAQ, AMEX, and BATS exchanges.

In live trading, Morningstar data is delivered to your algorithm at approximately 6 am each day. The majority of the fundamental data update occurs once per month. This includes updates to all of the key information for each security Morningstar supports. On top of this monthly update, there are daily updates of the financial ratios.

As Morningstar data arrives, it updates the master copy and is passed into your algorithm, similar to how TradeBars are fill-forwarded in your data feed. If there have been no updates for a day, you'll receive the same fundamental data.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

QuantConnect/LEAN combines the data of this dataset with US Coarse Universe data in runtime.

For more information about the US Fundamental Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Morningstar was founded by Joe Mansueto in 1984 with the goal of empowering investors by connecting people to the investing information and tools they need. Morningstar provides access extensive line of products and services for individual investors, financial advisors, asset managers, and retirement plan providers. Morningstar provides data on approximately 525,000 investment offerings including stocks, mutual funds, and similar vehicles, along with real-time global market data on nearly 18 million equities, indexes, futures, options, commodities, and precious metals, in addition to foreign exchange and Treasury markets. Morningstar also offers investment management services through its investment advisory subsidiaries, with $244 billion in assets under advisement or management as of 2021.

Getting Started

The following snippets demonstrate how to request data from the US Fundamental dataset:

- Direct Access using the Security object

```
equity = self.add_equity("IBM")
ibm_fundamental = equity.fundamentals
```

- Direct Access using the Symbol object

```
ibm = Symbol.create("IBM", SecurityType.EQUITY, Market.USA)
ibm_fundamental = self.fundamentals(ibm)
```

- Universe Selection

```
def initialize(self) -> None:
    self._universe = self.add_universe(self.fundamental_filter_function)

def fundamental_filter_function(self, fundamental: List[Fundamental]):
    filtered = [f for f in fundamental if f.has_fundamental_data and f.price > 10 and not np.isnan(f.valuation_ratios.pe_ratio)]
    sorted_by_pe_ratio = sorted(filtered, key=lambda f: f.valuation_ratios.pe_ratio)
    return [f.symbol for f in sorted_by_pe_ratio[:10]]
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1998
Asset Coverage	8,000 US Equities *
Corporate Indicators / Tracked Fields	900 Fields
Data Density	Sparse
Resolution	Daily
Timezone	New York

* The data does not include ETFs, ADRs, or OTC equities.

Requesting Data

You don't need any special code to request US Fundamental Data. You can access the current and historical fundamental data for any of the US Equities that this dataset includes.

```
class MorningStarDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2021, 1, 1)
        self.set_end_date(2021, 7, 1)
        self.set_cash(100000)
        self.universe_settings.asynchronous = True

        # Option 1: Subscribe to individual US Equity assets
        self.add_equity("IBM")

        # Option 2A: Create a fundamental universe (classic version)
        self._universe = self.add_universe(self.fundamental_function)

        # Option 2B: Create a fundamental universe (framework version)
        self.add_universe_selection(FundamentalUniverseSelectionModel(self.fundamental_function))
```

For more information about universe settings, see Settings .

Accessing Data

If you add a fundamental universe to your algorithm, you can access fundamental data in the universe selection function.

```
def fundamental_function(self, fundamental: List[Fundamental]) -> List[Symbol]:
    return [f.symbol for f in fundamental if f.price > 10 and f.valuation_ratios.pe_ratio > 30]
```

To get fundamental data for Equities in your algorithm, use the `fundamentals` property of the `Equity` objects. The fundamental data represent the corporate fundamentals for the current algorithm time.

```
fundamentals = self.securities[symbol].fundamentals
```

To get fundamental data for Equities, regardless of whether or not you have subscribed to them in your algorithm, call the `fundamentals` method. If

you pass one `Symbol`, the method returns a `Fundamental` object. If you pass a list of `Symbol` objects, the method returns a list of `Fundamental` objects.

```
# Single asset
ibm = Symbol.create("IBM", SecurityType.EQUITY, Market.USA)
ibm_fundamental = self.fundamentals(ibm)

# Multiple assets
nb = Symbol.create("NB", SecurityType.EQUITY, Market.USA)
fundamentals = self.fundamentals([ nb, ibm ])
```

Historical Data

You can get historical fundamental data in an algorithm and in the Research Environment.

Historical Data in Algorithms

To get historical fundamental data in an algorithm, call the `history` method with `Fundamental` type and the Equity `Symbol` or the `Universe` object. If there is no data in the period you request, the history result is empty.

```
ibm = Symbol.create("IBM", SecurityType.EQUITY, Market.USA)

# DataFrame object where the columns are the Fundamental attributes
asset_df_history = self.history(Fundamental, ibm, timedelta(30), flatten=True)

# Fundamental objects
fundamental_history= self.history[Fundamental](ibm, timedelta(30))

# Fundamentals objects for all US Equities (including delisted companies)
fundamentals_history = self.history[Fundamentals](timedelta(30))

# Multi-index Series objects where the values are lists of Fundamental objects
series_history = self.history(self.universe, 30, Resolution.DAILY)
for (universe_symbol, time), fundamentals in series_history.items():
    highest_market_cap = sorted(fundamentals, key=lambda x: x.market_cap)[-5:]
```

Historical Data in the Research Environment

To get historical data in the Research Environment, call any of the preceding methods or call the `universe_history` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. Alternatively, call the `get_fundamental` method with the Equity `Symbol`, a `Fundamental` property, a start date, and an end date. If there is no data in the period you request, the history result is empty.

```
# DataFrame object where the columns are the Fundamental attributes
universe_history_df = qb.universe_history(universe, qb.time-timedelta(30), qb.time, flatten=True)

# Multi-index Series objects where the values are lists of Fundamental objects
universe_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (universe_symbol, time), fundamentals in universe_history.items():
    for fundamental in fundamentals:
        print(f"{fundamental.symbol} market cap at {fundamental.end_time}: {fundamental.market_cap}")

# DataFrame of a single Fundamental attribute
history = qb.get_fundamental(symbol, "ValuationRatios.pe_ratios", datetime(2021, 1, 1), datetime(2021, 7, 1))
```

For more information about historical US Equity fundamental data, see Equity Fundamental Data .

Example Applications

The US Fundamentals dataset enables you to design strategies harnessing fundamental data points. Examples include the following strategies:

- Ranking a universe of securities by a value factor like the Piotroski F-score and buying a subset of the universe with the best factor ranking
- Using the Morningstar asset classification to target specific industries or to ensure your strategy is diversified across several sectors
- Trading securities that recently performed an IPO

Classic Algorithm Example

The following example algorithm creates a dynamic universe of US Equities. The first stage filter selects the 100 most liquid US Equities and the second stage filter selects the 10 assets with the greatest PE ratio. The algorithm then forms an equal-weighted portfolio with the 10 assets in the universe.

```py
from AlgorithmImports import *

class MorningStarDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        self.universe_settings.resolution = Resolution.DAILY
        self.universe_size = 10
        # Add universe selection to filter with fundamental data
        self.add_universe(self.fundamental_selection_function)

    def fundamental_selection_function(self, fundamental: List[Fundamental]) -> List[Symbol]:
        # Make sure fundamental data and PE ratio available
        # To avoid penny stocks with high volatility, set price above $1
        selected = [f for f in fundamental if f.has_fundamental_data and f.price > 1 and not np.isnan(f.valuation_ratios.pe_ratio)]
        # Filter the top 100 high dollar volume equities to ensure liquidity
        sorted_by_dollar_volume = sorted(selected, key=lambda f: f.dollar_volume, reverse=True)[:100]
        # Get the top 10 PE Ratio stocks to follow speculations of a large number of capital
        sorted_by_pe_ratio = sorted(sorted_by_dollar_volume, key=lambda f: f.valuation_ratios.pe_ratio, reverse=True)
[:self.universe_size]
        return [ f.symbol for f in sorted_by_pe_ratio ]

    def on_data(self, slice: Slice) -> None:
        # if we have no changes, do nothing
        if self._changes is None or not slice.bars: return

        # liquidate removed securities, as not being the most popular stocks anymore
        for security in self._changes.removed_securities:
            if security.invested:
                self.liquidate(security.symbol)

        # we want 1/N allocation in each security in our universe to evenly dissipate risk
        for security in self._changes.added_securities:
            self.set_holdings(security.symbol, 1 / self.universe_size)

        self._changes = None

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        self._changes = changes
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of US Equities. The first stage filter selects the 100 most liquid US Equities and the second stage filter selects the 10 assets with the greatest PE ratio. The algorithm then forms an equal-weighted portfolio with the 10 assets in the universe.

```py
from AlgorithmImports import *

class MorningStarDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Add universe selection to filter with fundamental data
        self.universe_settings.resolution = Resolution.DAILY
        self.set_universe_selection(CustomFundamentalUniverseSelectionModel())

        self.set_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(1)))

        # we want 1/N allocation in each security in our universe to evenly dissipate risk
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

        self.add_risk_management(NullRiskManagementModel())

        self.set_execution(ImmediateExecutionModel())

class CustomFundamentalUniverseSelectionModel(FundamentalUniverseSelectionModel):

    def select(self, algorithm: QCAlgorithm, fundamental: List[Fundamental]) -> List[Symbol]:
        # Make sure fundamental data and PE ratio available
        # To avoid penny stocks with high volatility, set price above $1
        # Filter the top 100 high dollar volume equities to ensure liquidity
        sorted_by_dollar_volume = sorted([x for x in fundamental if x.price > 1 and not np.isnan(x.valuation_ratios.pe_ratio)],
            key=lambda x: x.dollar_volume, reverse=True)[:100]
        # Get the top 10 PE Ratio stocks to follow speculations of a large number of capital
        sorted_by_pe_ratio = sorted(sorted_by_dollar_volume, key=lambda x: x.valuation_ratios.pe_ratio, reverse=True)[:10]

        # Take the top entries from our sorted collection
        return [ x.symbol for x in sorted_by_pe_ratio ]
```

Research Example

The following example selects the 100 most liquid US Equities and lists the 10 assets with the greatest PE ratio.:

```py
qb = QuantBook()

# Add Fundamental Universe Selection
def fundamental_selection_function(fundamentals):
    selected = [f for f in fundamentals if not np.isnan(f.valuation_ratios.pe_ratio)]
    sorted_by_dollar_volume = sorted(selected, key=lambda f: f.dollar_volume, reverse=True)[:100]

    sorted_by_pe_ratio = sorted(sorted_by_dollar_volume,
        key=lambda f: f.valuation_ratios.pe_ratio, reverse=True)[:10]
    return [ f.symbol for f in sorted_by_pe_ratio ]

universe = qb.add_universe(fundamental_selection_function)

# Historical Universe data
universe_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (universe_symbol, time), fundamentals in universe_history.items():
    for fundamental in fundamentals:
        print(f"{fundamental.symbol} PE ratio volume at {fundamental.end_time}: {fundamental.valuation_ratios.pe_ratio}")
```

Data Point Attributes

The US Fundamentals dataset provides `Fundamental` objects. To filter `Fundamental` objects, you can use one of the enumeration helpers.

Fundamental Attributes

`Fundamental` objects have the following attributes:

MorningstarSectorCode Enumeration

Sectors are large super categories of data. To access the sector of an Equity, use the `MorningstarSectorCode` property.

```py
filtered_fundamentals = [x for x in fundamental
    if x.asset_classification.morningstar_sector_code == MorningstarSectorCode.TECHNOLOGY]
```

The `MorningstarSectorCode` enumeration has the following members:

MorningstarIndustryGroupCode Enumeration

Industry groups are clusters of related industries that tie together. To access the industry group of an Equity, use the `MorningstarIndustryGroupCode` property.

```
PY
filtered_fundamentals = [x for x in fundamental
    if x.asset_classification.morningstar_industry_group_code == MorningstarIndustryGroupCode.APPLICATION_SOFTWARE]
```

The `MorningstarIndustryGroupCode` enumeration has the following members:

MorningstarIndustryCode Enumeration

Industries are the finest classification level available and are the individual industries according to the Morningstar classification system. To access the industry group of an Equity, use the `MorningstarIndustryCode` property.

```
PY
filtered_fundamentals = [x for x in fundamental
    if x.asset_classification.morningstar_industry_code == MorningstarIndustryCode.SOFTWARE_APPLICATION]
```

The `MorningstarIndustryCode` enumeration has the following members:

StockType Enumeration

The Stock Type classification groups companies according to the underlying fundamentals of their business. It answers the question: "If I buy this stock, what kind of company am I buying?" The emphasis is on income statement, balance sheet, and cash-flow data—not price data or valuation multiples. To access the stock type of an Equity, use the `StockType` property.

```
PY
filtered_fundamentals = [x for x in fundamental
    if x.asset_classification.stock_type == StockType.AGGRESSIVE_GROWTH]
```

The `StockType` enumeration has the following members:

StyleBox Enumeration

The Morningstar Equity Style Box is a grid that provides a graphical representation of the investment style of stocks and portfolios. It classifies securities according to market capitalization (vertical axis) and value-growth scores (horizontal axis). For stocks, the central column represents the core style. To access the style box of an Equity, use the `StyleBox` property.

```
PY
filtered_fundamentals = [x for x in fundamental
    if x.asset_classification.style_box == StyleBox.LARGE_VALUE]
```

The `StyleBox` enumeration has the following members:

MorningstarEconomySphereCode Enumeration

Sectors are consolidated into three major economic spheres or Super Sectors: Cyclical, Defensive, and Sensitive. To access the economy sphere (Super Sector) of an Equity, use the `MorningstarEconomySphereCode` property.

```
PY
filtered_fundamentals = [x for x in fundamental
    if x.asset_classification.morningstar_economy_sphere_code == MorningstarEconomySphereCode.CYCLICAL]
```

The `MorningstarEconomySphereCode` enumeration has the following members:

Exchange ID Values

The exchange ID represents the exchange that lists the Equity. To access the exchange ID of an Equity, use the `PrimaryExchangeID` property.

```py
filtered_fundamentals = [x for x in fundamental
    if x.company_reference.primary_exchange_id == "NAS"]
```

The exchanges are represented by the following string values:

String Representation	Exchange
NYS	New York Stock Exchange (NYSE)
NAS	NASDAQ
ASE	American Stock Exchange (AMEX)
TSE	Tokyo Stock Exchange
AMS	Amsterdam Internet Exchange
SGO	Santiago Stock Exchange
XMAD	Madrid Stock Exchange
ASX	Australian Securities Exchange
BVMF	B3 (stock exchange)
LON	London Stock Exchange
TKS	Istanbul Stock Exchange Settlement and Custody Bank
SHG	Shanghai Exchange
LIM	Lima Stock Exchange
FRA	Frankfurt Stock Exchange
JSE	Johannesburg Stock Exchange
MIL	Milan Stock Exchange
TAE	Tel Aviv Stock Exchange
STO	Stockholm Stock Exchange
ETR	Deutsche Boerse Xetra Core
PAR	Paris Stock Exchange
BUE	Buenos Aires Stock Exchange
KRX	Korea Exchange
SWX	SIX Swiss Exchange
PINX	Pink Sheets (OTC)
CSE	Canadian Securities Exchange
PHS	Philippine Stock Exchange
MEX	Mexican Stock Exchange
TAI	Taiwan Stock Exchange

IDX	Indonesia Stock Exchange
OSL	Oslo Stock Exchange
BOG	Colombia Stock Exchange
NSE	National Stock Exchange of India
HEL	Nasdaq Helsinki
MISX	Moscow Exchange
HKG	Hong Kong Stock Exchange
IST	Istanbul Stock Exchange
BOM	Bombay Stock Exchange
TSX	Toronto Stock Exchange
BRU	Brussels Stock Exchange
BATS	BATS Global Markets
ARCX	NYSE Arca
GREY	Grey Market (OTC)
DUS	Dusseldorf Stock Exchange
BER	Berlin Stock Exchange
ROCO	Taipei Exchange
CNQ	Canadian Trading and Quotation System Inc.
BSP	Bangko Sentral ng Pilipinas
NEOE	NEO Exchange

Datasets

TickData

TickData was founded by a futures broker and a programmer in 1984 as the first company in the world to offer historical tick-by-tick prices on the futures and index markets. TickData provides access to comprehensive and detailed market data and analytics products in the financial industry covering Equities, Futures, Options, cash FOREX, and Cash Indices.

International Futures

TickData

International Futures

Introduction

The International Futures dataset by TickData provides Futures data, including price, volume, open interest, and expiry. The data covers the 4 contracts, DAX, FESX, HSI, and NKD, starting in July 1998 and is delivered on any frequency from tick to daily. This dataset is created by TickData, which negotiates directly with exchanges for their official archive and partners with real-time data providers with direct exchange connections and multiple redundant ticker plants.

This dataset also depends on the US Futures Security Master because the US Futures Security Master dataset contains information to construct continuous Futures.

For more information about the International Futures dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

TickData was founded by a futures broker and a programmer in 1984 as the first company in the world to offer historical tick-by-tick prices on the futures and index markets. TickData provides access to comprehensive and detailed market data and analytics products in the financial industry covering Equities, Futures, Options, cash FOREX, and Cash Indices.

Getting Started

The following snippet demonstrates how to request data from the International Futures dataset:

```py
hsi = self.add_future(Futures.Indices.HANG_SENG, Resolution.MINUTE).symbol          # "HSI"
dax = self.add_future(Futures.Indices.DAX, Resolution.MINUTE).symbol                # "DAX"
fesx = self.add_future(Futures.Indices.EURO_STOXX_50, Resolution.MINUTE).symbol     # "FESX"
nkd = self.add_future(Futures.Indices.NIKKEI_225_DOLLAR, Resolution.MINUTE).symbol  # "NKD"
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	July 1998, see `Supported Assets` below for details
Coverage	4 Contracts
Data Density	Dense
Resolution	Minute, Hour, & Daily
Timezone	Various, refer to `Supported Assets` below
Market Hours	Regular and Extended

Volume Discrepancies

For Futures contracts trading in the US, for example, NKD, see US Futures .

Requesting Data

To add International Futures data to your algorithm, call the `add_future` method. Save a reference to the Future so you can access the data later in your algorithm.

```
class InternationalFuturesDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2013, 12, 20)
        self.set_end_date(2014, 2, 20)
        self.set_cash(1000000)
        self.universe_settings.asynchronous = True
        # Request Hang Seng Index Futures data
        future = self.add_future(Futures.Indices.HANG_SENG)
        # Set filter to obtain the contracts expire within 90 days
        future.set_filter(0, 90)
        self.future_symbol = future.symbol
```

For more information about creating Future subscriptions, see Requesting Data or Futures Universes .

Accessing Data

To get the current International Futures data, index the `futures_chains` property of the current `Slice` with the canonical Futures `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your Future at every time step.

```
def on_data(self, slice: Slice) -> None:
    # Get future chain of the canonical symbol
    chain = slice.futures_chains.get(self.future_symbol)
    if chain:
        # Iterate each contract in the future chain
        for contract in chain:
            self.log(f"{contract.symbol} price at {slice.time}: {contract.last_price}")
```

You can also iterate through all of the `FuturesChain` objects in the current `Slice` .

```
def on_data(self, slice: Slice) -> None:
    # Iterate all future chains
    for canonical_symbol, chain in slice.futures_chains.items():
        # Iterate each contract in the future chain
        for contract in chain:
            self.log(f"{contract.symbol} price at {slice.time}: {contract.last_price}")
```

For more information about accessing Futures data, see Handling Data .

Historical Data

You can get historical International Futures data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical International Futures data in an algorithm, call the `history` method with the canonical Futures `Symbol` or a Futures contract `Symbol` . If there is no data in the period you request, the history result is empty.

```
# DataFrame objects
contract_history_df = self.history(contract.symbol, 100, Resolution.MINUTE)
continuous_history_df = self.history(self.future_symbol,
    start=self.time - timedelta(days=15),
    end=self.time,
    resolution=Resolution.MINUTE,
    fill_forward=False,
    extended_market_hours=False,
    data_mapping_mode=DataMappingMode.OPEN_INTEREST,
    data_normalization_mode=DataNormalizationMode.RAW,
    contract_depth_offset=0)

# TradeBar objects
contract_history_trade_bars = self.history[TradeBar](contract.symbol, 100, Resolution.MINUTE)
continous_history_trade_bars = self.history[TradeBar](self.future_symbol, 100, Resolution.MINUTE)

# QuoteBar objects
contract_history_quote_bars = self.history[QuoteBar](contract.symbol, 100, Resolution.MINUTE)
continous_history_quote_bars = self.history[QuoteBar](self.future_symbol, 100, Resolution.MINUTE)

# Tick objects
contract_history_ticks = self.history[Tick](contract.symbol, timedelta(seconds=10), Resolution.TICK)
continous_history_ticks = self.history[Tick](self.future_symbol, timedelta(seconds=10), Resolution.TICK)
```

For more information about historical data in algorithms, see History Requests . For more information about the price adjustments for continuous contracts, see Continous Contracts .

Historical Data In Research

To get historical International Futures data in the Research Environment for an entire Futures chain, call the `future_history` method with the canonical Future `Symbol` .

```py
qb = QuantBook()
future = qb.add_future(Futures.Indices.HANG_SENG)
future.set_filter(0, 90)
history = qb.future_history(future.symbol, datetime(2020, 6, 1), datetime(2020, 6, 5))
history_df = history.data_frame
all_history = history.get_all_data()
expiries = history.get_expiry_dates()
```

To get historical data for a single International Futures contract or the continuous Futures contract, call the `history` method like you would in an algorithm but on the `QuantBook` object. For more information about historical data in the Research Environment, see Futures .

Supported Assets

The following table shows the available Futures:

Ticker	Future	Start Date	Time Zone	Currency
HSI	Hang Seng Index Futures	Jan 2010	Asia/Hong Kong	HKD
DAX	German Index Futures	Jan 2010	Europe/Berlin	EUR
FESX	EURO STOXX 50 Index Futures	Jul 1998	Europe/Berlin	EUR
NKD	Nikkei 225 Index Futures	Jan 2007	America/Chicago	USD

Example Applications

The International Futures dataset enables you to design Futures strategies accurately. Examples include the following strategies:

- Buying the Futures contract with the most open interest to reduce slippage and market impact
- Trade speculation on an International Index
- Trading bull calendar spreads to reduce volatility and margin requirements

Classic Algorithm Example -- HSI Futures

The following example algorithm uses ZigZag to determine the trend of Hang Seng Index. To trade the Indices, we make use of the HSI Futures.

```py
from AlgorithmImports import *

class InternationalFuturesDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Set the time zone to HKT to make it more comparable with the exchange.
        self.set_time_zone(TimeZones.HONG_KONG)
        # Set the account currency as HKD to trade HSI Futures.
        self.set_account_currency("HKD", 1000000)
        # Seed the last price of the contracts for filling.
        self.settings.seed_initial_prices = True

        # Request HSI Futures to trade.
        # Note that we will trade the contract with the highest open interest for liquidity.
        self.hsi_future = self.add_future(
            Futures.Indices.HANG_SENG,
            extended_market_hours=True,
            data_mapping_mode=DataMappingMode.LAST_TRADING_DAY,
            contract_depth_offset=0
        )
        # Request the corresponding underlying Index for feeding indicator for trade signal generation.
        hsi_index = self.add_index("HSI").symbol

        # Create a ZigZag indicator to trade Hang Seng Index price pivot points.
        self._zz = self.zz(hsi_index, 0.15, 5, Resolution.DAILY)
        # Warm up indicator for immediate readiness to trade.
        self.warm_up_indicator(hsi_index, self._zz, Resolution.DAILY)

    def on_data(self, slice: Slice) -> None:
        # Only place trade if the Future contracts is in market opening hours to avoid stale fills.
        if self.is_market_open(self.hsi_future.symbol) and self._zz.is_ready:
            pivot = self._zz.pivot_type
            # If the last pivot point is a low point, the current trend is increasing after this low point.
            if pivot == PivotPointType.LOW and not self.portfolio[self.hsi_future.symbol].is_long:
                self.set_holdings(self.hsi_future.mapped, 0.2)
            # If the last pivot point is a high point, the current trend is decreasing after this high point.
            elif pivot == PivotPointType.HIGH and not self.portfolio[self.hsi_future.symbol].is_short:
                self.set_holdings(self.hsi_future.mapped, -0.2)

        # Handle rollover in case the current mapped contract changes.
        for _, changed_event in slice.symbol_changed_events.items():
            old_symbol = changed_event.old_symbol
            new_symbol = self.add_future_contract(changed_event.new_symbol).symbol
            quantity = self.portfolio[old_symbol].quantity
            # Rolling over: to liquidate any position of the old mapped contract and switch to the newly mapped contract
            self.liquidate(old_symbol)
            if quantity != 0:
                self.market_order(new_symbol, quantity)
```

Classic Algorithm Example -- FESX Futures

The following example algorithm uses the MACD indicator to determine the trend of the EuroStoxx50 Index. To trade the Index, we make use of the FESX Futures.

```py
from AlgorithmImports import *

class InternationalFuturesDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Set the time zone to Berlin to make it more comparable with the exchange.
        self.set_time_zone(TimeZones.BERLIN)
        # Set the account currency as EUR to trade FSX Futures.
        self.set_account_currency("EUR", 1000000)
        # Seed the last price of the contracts for filling.
        self.settings.seed_initial_prices = True

        # Request FESX Futures to trade.
        # Note that we will trade the contract with the highest open interest for liquidity.
        self.fesx_future = self.add_future(
            Futures.Indices.EURO_STOXX_50,
            extended_market_hours=True,
            data_mapping_mode=DataMappingMode.LAST_TRADING_DAY,
            contract_depth_offset=0
        )
        # Request the corresponding underlying Index for feeding indicator for trade signal generation.
        fesx_index = self.add_index("SX5E").symbol

        # Create a MACD indicator to trade EuroStoxx trend changes on the fast-slow term trend convergence.
        self._macd = self.macd(fesx_index, 12, 26, 9, resolution=Resolution.DAILY)
        # Warm up indicator for immediate readiness to trade.
        self.warm_up_indicator(fesx_index, self._macd, Resolution.DAILY)

    def on_data(self, slice: Slice) -> None:
        # Only place trade if the Future contracts is in market opening hours to avoid stale fills.
        if self.is_market_open(self.fesx_future.symbol) and self._macd.is_ready:
            # To identify a sensitive change in trend, use the change in the histogram value of the MACD.
            histogram = self._macd.histogram
            histogram_chg = histogram.current.value - histogram.previous.value
            # Positive histogram value increasing means the fast trend is rising faster than the slow trend, indicating a strong uptrend.
            if histogram_chg > 0 and histogram.current.value > 0 and not self.portfolio[self.fesx_future.symbol].is_long:
                self.set_holdings(self.fesx_future.mapped, 0.2)
            # Negative histogram value decreasing means the slow trend is dropping faster than the fast trend, indicating a strong
downtrend.
            elif histogram_chg < 0 and histogram.current.value < 0 and not self.portfolio[self.fesx_future.symbol].is_short:
                self.set_holdings(self.fesx_future.mapped, -0.2)

        # Handle rollover in case the current mapped contract changes.
        for _, changed_event in slice.symbol_changed_events.items():
            old_symbol = changed_event.old_symbol
            new_symbol = self.add_future_contract(changed_event.new_symbol).symbol
            quantity = self.portfolio[old_symbol].quantity
            # Rolling over: to liquidate any position of the old mapped contract and switch to the newly mapped contract
            self.liquidate(old_symbol)
            if quantity != 0:
                self.market_order(new_symbol, quantity)
```

Data Point Attributes

The International Futures dataset provides `Future` , `FuturesChain` , and `OpenInterest` objects. To configure the continuous Future settings, use the `DataNormalizationMode` and `DataMappingMode` enumerations.

Future Attributes

`Future` objects have the following attributes:

FuturesChain Attributes

`FuturesChain` objects have the following attributes:

OpenInterest Attributes

`OpenInterest` objects have the following attributes:

DataNormalizationMode Values

The `DataNormalizationMode` enumeration has the following values:

DataMappingMode Values

The `DataMappingMode` enumeration has the following values:

Binance Crypto Future Price Data

Introduction

The Binance Crypto Future Price Data by CoinAPI is for Crypto-currency futures price and volume data points. The data covers 718 Cryptocurrency pairs, starts in August 2020, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on Binance.

The Binance Crypto Future Margin Rate Data dataset provides margin interest data to model margin costs.

For more information about the Binance Crypto Future Price Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CoinAPI was founded by Artur Pietrzyk in 2016 with the goal of providing real-time and historical cryptocurrency market data, collected from hundreds of exchanges. CoinAPI provides access to Cryptocurrencies for traders, market makers, and developers building third-party applications.

Getting Started

The following snippet demonstrates how to request data from the Binance Crypto Future Price dataset:

```
def initialize(self) -> None:
    self.set_brokerage_model(BrokerageName.BINANCE_FUTURES, AccountType.MARGIN)
    #self.set_brokerage_model(BrokerageName.BINANCE_COIN_FUTURES, AccountType.MARGIN)

    self.crypto_future_symbol = self.add_crypto_future("BTCBUSD", Resolution.MINUTE).symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	August 2020
Asset Coverage	718 Crypto Futures Pairs
Data Density	Dense
Resolution	Tick, Second, Minute, Hourly, & Daily
Timezone	UTC
Market Hours	Always Open

Requesting Data

To add Binance Crypto Future Price data to your algorithm, call the `add_crypto_future` method. Save a reference to the Crypto Future `Symbol` so you can access the data later in your algorithm.

```
class CoinAPIDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2020, 6, 1)
        self.set_end_date(2021, 6, 1)

        # Set Account Currency to Binance Stable Coin for USD
        self.set_account_currency("BUSD")
        self.set_cash(100000)

        self.set_brokerage_model(BrokerageName.BINANCE_FUTURES, AccountType.MARGIN)
        self.set_brokerage_model(BrokerageName.BINANCE_COIN_FUTURES, AccountType.MARGIN)

        crypto_future = self.add_crypto_future("BTCBUSD", Resolution.MINUTE)
        # perpetual futures does not have a filter function
        self.btcbusd = crypto_future.symbol
```

For more information about creating Crypto Future subscriptions, see Requesting Data .

Accessing Data

To get the current Binance Crypto Future Price data, index the `bars` , `quote_bars` , or `ticks` properties of the current `Slice` with the Crypto Future `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    if self.btcbusd in slice.bars:
        trade_bar = slice.bars[self.btcbusd]
        self.log(f"{self.btcbusd} close at {slice.time}: {trade_bar.close}")

    if self.btcbusd in slice.quote_bars:
        quote_bar = slice.quote_bars[self.btcbusd]
        self.log(f"{self.btcbusd} bid at {slice.time}: {quote_bar.bid.close}")

    if self.btcbusd in slice.ticks:
        ticks = slice.ticks[self.btcbusd]
        for tick in ticks:
            self.log(f"{self.btcbusd} price at {slice.time}: {tick.price}")
```

You can also iterate through all of the data objects in the current `Slice` .

```
def on_data(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.bars.items():
        self.log(f"{symbol} close at {slice.time}: {trade_bar.close}")

    for symbol, quote_bar in slice.quote_bars.items():
        self.log(f"{symbol} bid at {slice.time}: {quote_bar.bid.close}")

    for symbol, ticks in slice.ticks.items():
        for tick in ticks:
            self.log(f"{symbol} price at {slice.time}: {tick.price}")
```

For more information about accessing Crypto Future data, see Handling Data .

Historical Data

To get historical Binance Crypto Future Price data, call the `history` method with the Crypto Future `Symbol` . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.history(self.btcbusd, 100, Resolution.DAILY)

# TradeBar objects
history_trade_bars = self.history[TradeBar](self.btcbusd, 100, Resolution.MINUTE)

# QuoteBar objects
history_quote_bars = self.history[QuoteBar](self.btcbusd, 100, Resolution.MINUTE)

# Tick objects
history_ticks = self.history[Tick](self.btcbusd, timedelta(seconds=10), Resolution.TICK)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To unsubscribe from a Crypto Future contract that you added with the `add_crypto_future` method, call the `remove_security` method.

```
self.remove_security(self.btcbusd)
```

The `remove_security` method cancels your open orders for the security and liquidates your Crypto Future holdings.

Supported Assets

Example Applications

The Binance Crypto Future Price dataset enables you to accurately design strategies for Cryptocurrencies with term structure. Examples include the following strategies:

- Horizontal/Diagonal arbitrage with the underlying cryptocurrencies
- Trade Contango/Backwardation predictions

- Hedge for illiquid cryptocurrencies

Classic Algorithm Example

The following example algorithm buys BTCUSDT perpetual future contract if the last day's close price was close to ask close price than bid close price, sells short of that in opposite, through the Binance exchange:

```
from AlgorithmImports import * class BinanceCryptoFutureDataAlgorithm(QCAlgorithm): def initialize(self) -> None: self.
set_start_date(2024, 9, 1) self.set_end_date(2024, 12, 31) # Set the account currency to USDT, since you can't trade wi
th # USD and the algorithm doesn't automatically convert USD & USDT # holdings. self.set_account_currency("USDT", 10000
0) # Binance Futures Exchange accepts both Cash and Margin account # types. Select the one you need for the best realit
y modeling. self.set_brokerage_model(BrokerageName.BINANCE_FUTURES, AccountType.MARGIN) # Add BTCUSDT data from the Bin
ance Future exchange. # Perpetual futures does not have a filter function. self._btc = self.add_crypto_future("BTCUSDT"
, Resolution.DAILY) # Historical data history = self.history(self._btc, 10, Resolution.DAILY) def on_data(self, slice:
Slice) -> None: # Trade only based on updated price data. if self._btc.symbol not in slice.bars or self._btc.symbol not
in slice.quote_bars: return # Scalp-trade the bid-ask spread based on the supply-demand strength if self._btc.price - s
elf._btc.bid_price > self._btc.ask_price - self._btc.price: self.set_holdings(self._btc, -0.5) else: self.set_holdings(
self._btc, 1)
```

Framework Algorithm Example

The following example algorithm hold a long BTCUSDT Future portfolio if the last day's close price was close to ask close price than bid close price, while hold short of that in opposite, through the Binance exchange using the algorithm framework implementation:

```
from AlgorithmImports import * class BinanceCryptoFutureDataAlgorithm(QCAlgorithm): def initialize(self) -> None: self.
set_start_date(2024, 9, 1) self.set_end_date(2024, 12, 31) # Set the account currency to USDT, since you can't trade wi
th # USD and the algorithm doesn't automatically convert USD & USDT # holdings. self.set_account_currency("USDT", 10000
0) # Binance Futures Exchange accepts both Cash and Margin account types, select the one you need for the best reality
modeling. self.set_brokerage_model(BrokerageName.BINANCE_FUTURES, AccountType.MARGIN) self.universe_settings.resolution
= Resolution.DAILY self.universe_settings.leverage = 2 # We only trade on BTCUSDT Future in Binance Future exchange sym
bols = Symbol.create("BTCUSDT", SecurityType.CRYPTO_FUTURE, Market.BINANCE) self.add_universe_selection(ManualUniverseS
electionModel(symbols)) # Custom alpha model to emit insights based on the Crypto Future price data self.add_alpha(Cryp
toFutureAlphaModel()) # Equally invest to evenly dissipate the capital concentration risk of inidividual crypto pair se
lf.set_portfolio_construction(EqualWeightingPortfolioConstructionModel()) self.set_execution(ImmediateExecutionModel())
class CryptoFutureAlphaModel(AlphaModel): def __init__(self) -> None: self.symbols = [] def update(self, algorithm: QCA
lgorithm, slice: Slice) -> List[Insight]: insights = [] for symbol in self.symbols: # Trade only based on updated price
data if not slice.bars.contains_key(symbol) or not slice.quote_bars.contains_key(symbol): continue quote = slice.quote_
bars[symbol] price = slice.bars[symbol].price # Scalp-trade the bid-ask spread based on the supply-demand strength if p
rice - quote.bid.close > quote.ask.close - price: direction = InsightDirection.DOWN else: direction = InsightDirection.
UP insights.append(Insight.price(symbol, timedelta(1), direction)) return insights def on_securities_changed(self, algo
rithm: QCAlgorithm, changes: SecurityChanges) -> None: for security in changes.added_securities: symbol = security.symb
ol self.symbols.append(symbol) # Historical data history = algorithm.history(symbol, 10, Resolution.DAILY) for security
in changes.removed_securities: symbol = security.symbol if symbol in self.symbols: self.symbols.remove(symbol)
```

Data Point Attributes

The Binance Crypto Future Price dataset provides `TradeBar` , `QuoteBar` , and `Tick` objects.

TradeBar Attributes

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

Tick Attributes

`Tick` objects have the following attributes:

CoinAPI

Binance Crypto Price Data

Introduction

The Binance Crypto Price Data by CoinAPI is for Cryptocurrency price and volume data points. The data covers 3,320 Cryptocurrency pairs, starts in July 2017, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on Binance.

For more information about the Binance Crypto Price Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CoinAPI was founded by Artur Pietrzyk in 2016 with the goal of providing real-time and historical cryptocurrency market data, collected from hundreds of exchanges. CoinAPI provides access to Cryptocurrencies for traders, market makers, and developers building third-party applications.

Getting Started

The following snippet demonstrates how to request data from the Binance Crypto Price dataset:

```py
# Binance accepts both Cash and Margin account types only.
self.set_brokerage_model(BrokerageName.BINANCE, AccountType.CASH)
#self.set_brokerage_model(BrokerageName.BINANCE, AccountType.MARGIN)

self.btcbusd = self.add_crypto("BTCBUSD", Resolution.MINUTE, Market.BINANCE).symbol

self._universe = self.add_universe(CryptoUniverse.binance(self.universe_selection_filter))
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	July 2017
Asset Coverage	3,320 Currency Pairs
Data Density	Dense
Resolution	Tick, Second, Minute, Hourly, & Daily
Timezone	UTC
Market Hours	Always Open

Requesting Data

To add Binance Crypto Price data to your algorithm, call the `add_crypto` method. Save a reference to the Crypto `Symbol` so you can access the data later in your algorithm.

```py
class CoinAPIDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2020, 6, 1)
        self.set_end_date(2021, 6, 1)

        # Set Account Currency to Binance Stable Coin for USD
        self.set_account_currency("BUSD")
        self.set_cash(100000)

        # Binance accepts both Cash and Margin account types.
        self.set_brokerage_model(BrokerageName.BINANCE, AccountType.MARGIN)

        self.btcbusd = self.add_crypto("BTCBUSD", Resolution.MINUTE, Market.BINANCE).symbol
```

For more information about creating Crypto subscriptions, see Requesting Data .

Accessing Data

To get the current Binance Crypto Price data, index the `bars` , `quote_bars` , or `ticks` properties of the current `Slice` with the Crypto `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```py
def on_data(self, slice: Slice) -> None:
    if self.btcbusd in slice.bars:
        trade_bar = slice.bars[self.btcbusd]
        self.log(f"{self.btcbusd} close at {slice.time}: {trade_bar.close}")

    if self.btcbusd in slice.quote_bars:
        quote_bar = slice.quote_bars[self.btcbusd]
        self.log(f"{self.btcbusd} bid at {slice.time}: {quote_bar.bid.close}")

    if self.btcbusd in slice.ticks:
        ticks = slice.ticks[self.btcbusd]
        for tick in ticks:
            self.log(f"{self.btcbusd} price at {slice.time}: {tick.price}")
```

You can also iterate through all of the data objects in the current `Slice` .

```py
def on_data(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.bars.items():
        self.log(f"{symbol} close at {slice.time}: {trade_bar.close}")

    for symbol, quote_bar in slice.quote_bars.items():
        self.log(f"{symbol} bid at {slice.time}: {quote_bar.bid.close}")

    for symbol, ticks in slice.ticks.items():
        for tick in ticks:
            self.log(f"{symbol} price at {slice.time}: {tick.price}")
```

For more information about accessing Crypto data, see Handling Data .

Historical Data

To get historical Binance Crypto Price data, call the `history` method with the Crypto `Symbol` . If there is no data in the period you request, the history result is empty.

```py
# DataFrame
history_df = self.history(self.btcbusd, 100, Resolution.DAILY)

# TradeBar objects
history_trade_bars = self.history[TradeBar](self.btcbusd, 100, Resolution.MINUTE)

# QuoteBar objects
history_quote_bars = self.history[QuoteBar](self.btcbusd, 100, Resolution.MINUTE)

# Tick objects
history_ticks = self.history[Tick](self.btcbusd, timedelta(seconds=10), Resolution.TICK)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of Binance Crypto pairs, call the `add_universe` method with a `CryptoUniverse` object. A Crypto universe uses a selection function to select Crypto pairs based on their OHLCV and dollar volume of the previous day as of midnight Coordinated Universal Time (UTC).

```py
def initialize(self) -> None:
    self.universe_settings.asynchronous = True
    self.set_brokerage_model(BrokerageName.BINANCE, AccountType.MARGIN)
    self._universe = self.add_universe(CryptoUniverse.binance(self.universe_selection_filter))

def universe_selection_filter(self, universe_day):
    return [c.symbol for c in universe_day if c.volume >= 100 and c.volume_in_usd > 10000]
```

For more information about universe settings, see Settings .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `history` method with the `Universe` object, and the lookback period. If there is no data in the period you request, the history result is empty.

```py
# DataFrame example where the columns are the CryptoUniverse attributes:
history_df = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series example where the values are lists of CryptoUniverse objects:
history = self.history(self._universe, 30, Resolution.DAILY)
for (univere_symbol, time), universe_day in history.items():
    for universe_item in universe_day:
        self.log(f"{universe_item.symbol} price at {universe_item.end_time}: {universe_item.close}")
```

Historical Universe Data in Research

To get historical universe data in research, call the `universe_history` method with the `Universe` object, and the lookback period. The `universe_history` returns the filtered universe. If there is no data in the period you request, the history result is empty.

```py
# DataFrame example where the columns are the CryptoUniverse attributes:
history_df = qb.universe_history(universe, qb.time-timedelta(30), qb.time, flatten=True)

# Series example where the values are lists of CryptoUniverse objects:
universe_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (univere_symbol, time), universe_day in universe_history.items():
    for universe_item in universe_day:
        print(f"{universe_item.symbol} price at {universe_item.end_time}: {universe_item.close}")
```

You can call the `history` method in Research.

Remove Subcriptions

To unsubscribe from a Crypto pair that you added with the `add_crypto` method, call the `remove_security` method.

```py
self.remove_security(self.btcbusd)
```

The `remove_security` method cancels your open orders for the security and liquidates your holdings in the virtual pair .

Supported Assets

The following table shows the available Cryptocurrency pairs:

Pairs Available (3320)

Example Applications

The Binance Crypto Price dataset enables you to accurately design strategies for Cryptocurrencies. Examples include the following strategies:

- Buy and hold
- Trading Cryptocurrency volatility and price action
- Allocating a small portion of your portfolio to Cryptocurrencies to hedge against inflation

Classic Algorithm Example

The following example algorithm buys and holds Bitcoin through the Binance exchange:

```
from AlgorithmImports import * class CoinAPIDataAlgorithm(QCAlgorithm): def initialize(self) -> None: self.set_start_da
te(2024, 9, 1) self.set_end_date(2024, 12, 31) # Set the account currency to USDT, since you can't trade with # USD and
the algorithm doesn't automatically convert USD & USDT # holdings. self.set_account_currency("USDT", 100000) self.unive
rse_settings.asynchronous = True # Binance accepts both Cash and Margin account types. Select the # one you need for th
e best reality modeling. self.set_brokerage_model(BrokerageName.BINANCE, AccountType.MARGIN) # Add BTCUSDT data. self._
btc = self.add_crypto("BTCUSDT", Resolution.MINUTE, Market.BINANCE) # Historical data history = self.history(self._btc.
symbol, 30, Resolution.DAILY) # Add a Crypto universe that selects trading pairs on Binance. universe = self.add_univer
se(CryptoUniverse.binance(self._select_assets)) # Historical Universe data universe_history = self.history(universe, 30
, Resolution.DAILY) for (universe_symbol, time), universe_day in universe_history.items(): for universe_item in univers
e_day: symbol = universe_item.symbol price = universe_item.close def _select_assets(self, universe_day): # Filter for m
aterially traded Crypto pairs with significant # size and dollar volume, assuming higher capital flow in for # higher r
eturn. return [universe_item.symbol for universe_item in universe_day if universe_item.volume >= 100 and universe_item.
volume_in_usd > 10_000_000] def on_data(self, slice: Slice) -> None: # Speculate-invest all available free cash on BTCU
SDT, repecting # the order quantity restrictions to avoid invalid orders. if self.portfolio.cash_book['BTC'].amount !=
0: return # Define a buffer so that we can scale down the order size, # avoiding trading errors. buffer = max( BinanceF
eeModel.TAKER_TIER_1_FEE, self.settings.free_portfolio_value_percentage ) quantity = ( self.portfolio.cash_book['USDT']
.amount / self._btc.ask_price * (1-buffer) ) # Check if the quantity exceeds the minimum order size. On # Binance, the
minimum order size is measured in the quote # currency (USDT in this case). minimum_order_size = ( self._btc.symbol_pro
perties.minimum_order_size / self._btc.ask_price ) if abs(quantity) < minimum_order_size: return self.market_order(self
._btc, quantity)
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of Crypto pairs on the Binance exchange and then forms a equal-weighted portfolio of all the pairs in the universe:

PY

```
from AlgorithmImports import *

class CoinAPIDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Set Account Currency to Tether, since USD and USDT will not auto-convert and USD cannot be used to trade
        self.set_account_currency("USDT", 100000)
        self.settings.free_portfolio_value_percentage = 0.05

        # Binance accepts both Cash and Margin account types, select the one you need for the best reality modeling.
        self.set_brokerage_model(BrokerageName.BINANCE, AccountType.MARGIN)

        # Warm up the security with the last known price to avoid conversion error
        self.settings.seed_initial_prices = True
        self.universe_settings.asynchronous = True
        self.universe_settings.resolution = Resolution.MINUTE
        # Add Crypto Universe Selection that select crypto pairs in Binance exchange
        self.add_universe(CryptoUniverse.binance(self.universe_selection_filter))
        # Get the pairs on Binance that have USDT as the quote currency.
        self._market_pairs = [
            x.key.symbol
            for x in self.symbol_properties_database.get_symbol_properties_list(Market.BINANCE)
            if x.value.quote_currency == self.account_currency
        ]

        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(minutes = 20), 0.025, None))
        # Equally invest to evenly dissipate the capital concentration risk of inidividual crypto pair
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

    def universe_selection_filter(self, universe_day: List[CryptoUniverse]) -> List[Symbol]:
        # Select pairs where the quote currency is USDT.
        pairs = [c for c in universe_day if c.symbol.value in self._market_pairs]
        # Filter for materially traded crypto pairs with significant dollar volume, assuming higher capital flow in for higher return.
        pairs = sorted(pairs, key=lambda c: c.volume_in_usd)[-3:]
        return [c.symbol for c in pairs]

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            # Historical data
            history = self.history(security.symbol, 30, Resolution.DAILY)
```

Research Example

The following example lists crypto-currency pairs with the greatest dollar volume in the Binance exchange:

```py
qb = QuantBook()

# Add Cryptocurrency pair
symbol = qb.add_crypto("BTCUSDT", market=Market.BINANCE).symbol

# Historical data
history = qb.history(symbol, 30, Resolution.DAILY)
for (symbol, time), row in history.iterrows():
    print(f'{time} {symbol} {row.close}')

# Add Crypto Universe Selection
def universe_selection_filter(universe_day):
    selected = sorted([x for x in universe_day
        if x.volume_in_usd and x.volume_in_usd > 10000],
        key=lambda x: x.volume_in_usd, reverse=True)[:5]
    return [x.symbol for x in selected]

universe = qb.add_universe(CryptoUniverse.binance(universe_selection_filter))

# Historical Universe data
history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (univere_symbol, time), universe_day in history.items():
    print(f'=== {time} ===')
    for universe_item in sorted(universe_day, key=lambda x: x.volume_in_usd, reverse=True):
        print(f"{universe_item.symbol}: {universe_item.volume_in_usd}")
```

Data Point Attributes

The Binance Crypto Price dataset provides `TradeBar` , `QuoteBar` , `Tick` , and `CryptoUniverse` objects.

TradeBar Attributes

`TradeBar` objects have the following attributes:

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

Tick Attributes

`Tick` objects have the following attributes:

CryptoUniverse Attributes

`CryptoUniverse` objects have the following attributes:

CoinAPI

Binance US Crypto Price Data

Introduction

The Binance US Crypto Price Data by CoinAPI is for Cryptocurrency price and volume data points. The data covers 604 Cryptocurrency pairs, starts in October 2019, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on Binance US.

For more information about the Binance US Crypto Price Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CoinAPI was founded by Artur Pietrzyk in 2016 with the goal of providing real-time and historical cryptocurrency market data, collected from hundreds of exchanges. CoinAPI provides access to Cryptocurrencies for traders, market makers, and developers building third-party applications.

Getting Started

The following snippets demonstrates how to set the brokerage model, request data, and perform universe selection with the Binance US dataset:

```
# Binance US only accepts cash accounts
self.set_brokerage_model(BrokerageName.BINANCE_US, AccountType.CASH)

self.btcbusd = self.add_crypto("BTCUSD", Resolution.MINUTE, Market.BINANCE_US).symbol

self._universe = AddUniverse(CryptoUniverse.binance_us(self.universe_selection_filter));
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	October 2019
Asset Coverage	604 Cryptocurrency Pairs
Data Density	Dense
Resolution	Tick, Second, Minute, Hourly, & Daily
Timezone	UTC
Market Hours	Always Open

Requesting Data

To add Binance US Crypto Price data to your algorithm, call the `add_crypto` method. Save a reference to the Crypto `Symbol` so you can access the data later in your algorithm.

```
class CoinAPIDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2020, 6, 1)
        self.set_end_date(2021, 6, 1)
        self.set_cash(100000)

        # BinanceUS accepts Cash account type only, AccountType.MARGIN will result in an exception.
        self.set_brokerage_model(BrokerageName.BINANCE_US, AccountType.CASH)

        self.btcbusd = self.add_crypto("BTCUSD", Resolution.MINUTE, Market.BINANCE_US).symbol
```

For more information about creating Crypto subscriptions, see Requesting Data .

Accessing Data

To get the current Binance US Crypto Price data, index the `bars` , `quote_bars` , or `ticks` properties of the current `Slice` with the Crypto `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    if self.btcbusd in slice.bars:
        trade_bar = slice.bars[self.btcbusd]
        self.log(f"{self.btcbusd} close at {slice.time}: {trade_bar.close}")

    if self.btcbusd in slice.quote_bars:
        quote_bar = slice.quote_bars[self.btcbusd]
        self.log(f"{self.btcbusd} bid at {slice.time}: {quote_bar.bid.close}")

    if self.btcbusd in slice.ticks:
        ticks = slice.ticks[self.btcbusd]
        for tick in ticks:
            self.log(f"{self.btcbusd} price at {slice.time}: {tick.price}")
```

You can also iterate through all of the data objects in the current `Slice` .

```
PY
def on_data(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.bars.items():
        self.log(f"{symbol} close at {slice.time}: {trade_bar.close}")

    for symbol, quote_bar in slice.quote_bars.items():
        self.log(f"{symbol} bid at {slice.time}: {quote_bar.bid.close}")

    for symbol, ticks in slice.ticks.items():
        for tick in ticks:
            self.log(f"{symbol} price at {slice.time}: {tick.price}")
```

For more information about accessing Crypto data, see Handling Data .

Historical Data

To get historical Binance US Crypto Price data, call the `history` method with the Crypto `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.history(self.btcbusd, 100, Resolution.DAILY)

# TradeBar objects
history_trade_bars = self.history[TradeBar](self.btcbusd, 100, Resolution.MINUTE)

# QuoteBar objects
history_quote_bars = self.history[QuoteBar](self.btcbusd, 100, Resolution.MINUTE)

# Tick objects
history_ticks = self.history[Tick](self.btcbusd, timedelta(seconds=10), Resolution.TICK)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of Binance US Crypto pairs, call the `add_universe` method with a `CryptoUniverse` object. A Crypto universe uses a selection function to select Crypto pairs based on their OHLCV and dollar volume of the previous day as of midnight Coordinated Universal Time (UTC).

```
PY
def initialize(self) -> None:
    self.universe_settings.asynchronous = True
    self.set_brokerage_model(BrokerageName.BINANCE_US, AccountType.CASH)
    self._universe = self.add_universe(CryptoUniverse.binance_us(self.universe_selection_filter))

def universe_selection_filter(self, universe_day):
    return [c.symbol for c in universe_day if c.volume >= 100 and c.volume_in_usd > 10000]
```

For more information about universe settings, see Settings .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `history` method with the `Universe` object, and the lookback period. If there is no data in the period you request, the history result is empty.

```py
# DataFrame example where the columns are the CryptoUniverse attributes:
history_df = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series example where the values are lists of CryptoUniverse objects:
history = self.history(self._universe, 30, Resolution.DAILY)
for (univere_symbol, time), universe_day in history.items():
    for universe_item in universe_day:
        self.log(f"{universe_item.symbol} price at {universe_item.end_time}: {universe_item.close}")
```

Historical Universe Data in Research

To get historical universe data in research, call the `universe_history` method with the `Universe` object, and the lookback period. The `universe_history` returns the filtered universe. If there is no data in the period you request, the history result is empty.

```py
# DataFrame example where the columns are the CryptoUniverse attributes:
history_df = qb.universe_history(universe, qb.time-timedelta(30), qb.time, flatten=True)

# Series example where the values are lists of CryptoUniverse objects:
universe_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (univere_symbol, time), universe_day in universe_history.items():
    for universe_item in universe_day:
        print(f"{universe_item.symbol} price at {universe_item.end_time}: {universe_item.close}")
```

You can call the `history` method in Research.

Remove Subscriptions

To unsubscribe from a Crypto pair that you added with the `add_crypto` method, call the `remove_security` method.

```py
self.remove_security(self.btcbusd)
```

The `remove_security` method cancels your open orders for the security and liquidates your holdings in the virtual pair .

Supported Assets

The following table shows the available Cryptocurrency pairs:

Pairs Available (604)					
1000MOGUSDT	1000REKTUSDT	1INCHUSD	1INCHUSD4	1INCHUSDT	A2ZUSDT

Example Applications

The Binance US Crypto Price dataset enables you to accurately design strategies for Cryptocurrencies. Examples include the following strategies:

- Buy and hold
- Trading Cryptocurrency volatility and price action
- Allocating a small portion of your portfolio to Cryptocurrencies to hedge against inflation

Classic Algorithm Example

The following example algorithm buys and holds Bitcoin through the Binance US exchange:

```py
from AlgorithmImports import *

class CoinAPIDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.universe_settings.asynchronous = True
        # Set USDT as the account currency so we can trade BTCUSDT.
        self.set_account_currency('USDT', 100_000)
        # Binance US accepts Cash account type only. AccountType.MARGIN
        # results in an exception.
        self.set_brokerage_model(BrokerageName.BINANCE_US, AccountType.CASH)
        # Add BTCUSDT data.
        self._btc = self.add_crypto("BTCUSDT", Resolution.MINUTE, Market.BINANCE_US)
        # Historical data
        history = self.history(self._btc.symbol, 30, Resolution.DAILY)
        # Add a Crypto universe that selects Crypto pairs on Binance US.
        universe = self.add_universe(CryptoUniverse.binance_us(self._select_assets))
        # Historical Universe data
        universe_history = self.history(universe, 30, Resolution.DAILY)
        for (universe_symbol, time), universe_day in universe_history.items():
            for universe_item in universe_day:
                symbol = universe_item.symbol
                price = universe_item.close

    def _select_assets(self, universe_day):
        # Filter for materially traded Crypto pairs with significant
        # size and dollar volume, assuming higher capital flow in for
        # higher return.
        return [universe_item.symbol for universe_item in universe_day
                if universe_item.volume >= 100
                and universe_item.volume_in_usd > 10_000_000]

    def on_data(self, slice: Slice) -> None:
        # Speculate-invest all available free cash on BTCUSDT, repecting
        # the order quantity restrictions to avoid invalid orders.
        if self.portfolio.cash_book['BTC'].amount != 0:
            return
        # Define a buffer so that we can scale down the order size,
        # avoiding trading errors.
        buffer = max(
            BinanceFeeModel.TAKER_TIER_1_FEE,
            self.settings.free_portfolio_value_percentage
        )
        quantity = (
            self.portfolio.cash_book['USDT'].amount
            / self._btc.ask_price
            * (1-buffer)
        )
        # Check if the quantity exceeds the minimum order size. On
        # Binance US, the minimum order size is measured in the quote
        # currency (USDT in this case).
        minimum_order_size = (
            self._btc.symbol_properties.minimum_order_size
            / self._btc.ask_price
        )
        if abs(quantity) < minimum_order_size:
            return
        self.market_order(self._btc, quantity)
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of Crypto pairs on the Binance US exchange and then forms a equal-weighted portfolio of all the pairs in the universe:

```py
from AlgorithmImports import *

class CoinAPIDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1_000_000)
        self.settings.free_portfolio_value_percentage = 0.05
        # Warm up the security with the last known price to avoid conversion error
        self.settings.seed_initial_prices = True
        self.universe_settings.asynchronous = True
        # Add Crypto Universe Selection that select crypto pairs in BinanceUS exchange
        self.add_universe(CryptoUniverse.binance_us(self._select_assets))
        # Get the pairs on Binance US that have USD as the quote currency.
        self._market_pairs = [
            x.key.symbol
            for x in self.symbol_properties_database.get_symbol_properties_list(Market.BINANCE_US)
            if x.value.quote_currency == self.account_currency
        ]
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(minutes=20), 0.025, None))
        # Equally invest to evenly dissipate the capital concentration risk of inidividual crypto pair
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

    def _select_assets(self, universe_day: List[CryptoUniverse]) -> List[Symbol]:
        # Select pairs where the quote currency is USD.
        pairs = [c for c in universe_day if c.symbol.value in self._market_pairs]
        # Filter for materially traded crypto pairs with significant dollar volume, assuming higher capital flow in for higher return.
        pairs = sorted(pairs, key=lambda c: c.volume_in_usd)[-3:]
        return [c.symbol for c in pairs]

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            # Historical data
            history = self.history(security.symbol, 30, Resolution.DAILY)
            self.debug(f"We got {len(history)} items from our history request")
```

Research Example

The following example lists crypto-currency pairs with the greatest dollar volume in the BinanceUS exchange:

```py
qb = QuantBook()

# Add Cryptocurrency pair
symbol = qb.add_crypto("BTCUSDT", market=Market.BINANCE_US).symbol

# Historical data
history = qb.history(symbol, 30, Resolution.DAILY)
for (symbol, time), row in history.iterrows():
    print(f'{time} {symbol} {row.close}')

# Add Crypto Universe Selection
def universe_selection_filter(universe_day):
    selected = sorted([x for x in universe_day
        if x.volume_in_usd and x.volume_in_usd > 10000],
        key=lambda x: x.volume_in_usd, reverse=True)[:5]
    return [x.symbol for x in selected]

universe = qb.add_universe(CryptoUniverse.binance_us(universe_selection_filter))

# Historical Universe data
history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (univere_symbol, time), universe_day in history.items():
    print(f'=== {time} ===')
    for universe_item in sorted(universe_day, key=lambda x: x.volume_in_usd, reverse=True):
        print(f"{universe_item.symbol}: {universe_item.volume_in_usd}")
```

Data Point Attributes

The Binance US Crypto Price dataset provides `TradeBar` , `QuoteBar` , `Tick` , and `CryptoUniverse` objects.

TradeBar Attributes

`TradeBar` objects have the following attributes:

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

Tick Attributes

`Tick` objects have the following attributes:

CryptoUniverse Attributes

`CryptoUniverse` objects have the following attributes:

CoinAPI

Bitfinex Crypto Price Data

Introduction

The Bitfinex Crypto Price Data by CoinAPI is for Cryptocurrency price and volume data points. The data covers 570 Cryptocurrency pairs, starts in January 2013, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on Bitfinex.

For more information about the Bitfinex Crypto Price Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CoinAPI was founded by Artur Pietrzyk in 2016 with the goal of providing real-time and historical cryptocurrency market data, collected from hundreds of exchanges. CoinAPI provides access to Cryptocurrencies for traders, market makers, and developers building third-party applications.

Getting Started

The following snippet demonstrates how to request data from the Bitfinex Crypto Price dataset:

```py
# Bitfinex accepts both Cash and Margin type account.
self.set_brokerage_model(BrokerageName.BITFINEX, AccountType.CASH)
#self.set_brokerage_model(BrokerageName.BITFINEX, AccountType.MARGIN)

self.btcusd = self.add_crypto("BTCUSD", Resolution.MINUTE, Market.BITFINEX).symbol

self._universe = self.add_universe(CryptoUniverse.bitfinex(self.universe_selection_filter))
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2013
Asset Coverage	570 Currency Pairs
Data Density	Dense
Resolution	Tick, Second, Minute, Hourly, & Daily
Timezone	UTC
Market Hours	Always Open

Requesting Data

To add Bitfinex Crypto Price data to your algorithm, call the `add_crypto` method. Save a reference to the Crypto `Symbol` so you can access the data later in your algorithm.

```py
class CoinAPIDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2020, 6, 1)
        self.set_end_date(2021, 6, 1)
        self.set_cash(100000)

        # Bitfinex accepts both Cash and Margin type account.
        self.set_brokerage_model(BrokerageName.BITFINEX, AccountType.MARGIN)

        self.btcusd = self.add_crypto("BTCUSD", Resolution.MINUTE, Market.BITFINEX).symbol
```

For more information about creating Crypto subscriptions, see Requesting Data .

Accessing Data

To get the current Bitfinex Crypto Price data, index the `bars` , `quote_bars` , or `ticks` properties of the current `Slice` with the Crypto `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    if self.btcusd in slice.bars:
        trade_bar = slice.bars[self.btcusd]
        self.log(f"{self.btcusd} close at {slice.time}: {trade_bar.close}")

    if self.btcusd in slice.quote_bars:
        quote_bar = slice.quote_bars[self.btcusd]
        self.log(f"{self.btcusd} bid at {slice.time}: {quote_bar.bid.close}")

    if self.btcusd in slice.ticks:
        ticks = slice.ticks[self.btcusd]
        for tick in ticks:
            self.log(f"{self.btcusd} price at {slice.time}: {tick.price}")
```

You can also iterate through all of the data objects in the current `Slice` .

```
PY
def on_data(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.bars.items():
        self.log(f"{symbol} close at {slice.time}: {trade_bar.close}")

    for symbol, quote_bar in slice.quote_bars.items():
        self.log(f"{symbol} bid at {slice.time}: {quote_bar.bid.close}")

    for symbol, ticks in slice.ticks.items():
        for tick in ticks:
            self.log(f"{symbol} price at {slice.time}: {tick.price}")
```

For more information about accessing Crypto data, see Handling Data .

Historical Data

To get historical Bitfinex Crypto Price data, call the `history` method with the Crypto `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.history(self.btcusd, 100, Resolution.DAILY)

# TradeBar objects
history_trade_bars = self.history[TradeBar](self.btcusd, 100, Resolution.MINUTE)

# QuoteBar objects
history_quote_bars = self.history[QuoteBar](self.btcusd, 100, Resolution.MINUTE)

# Tick objects
history_ticks = self.history[Tick](self.btcusd, timedelta(seconds=10), Resolution.TICK)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of Bitfinex Crypto pairs, call the `add_universe` method with a `CryptoUniverse` object. A Crypto universe uses a selection function to select Crypto pairs based on their OHLCV and dollar volume of the previous day as of midnight Coordinated Universal Time (UTC).

```
PY
def initialize(self) -> None:
    self.universe_settings.asynchronous = True
    self.set_brokerage_model(BrokerageName.BITFINEX, AccountType.MARGIN)
    self._universe = self.add_universe(CryptoUniverse.bitfinex(self.universe_selection_filter))

def universe_selection_filter(self, universe_day):
    return [c.symbol for c in universe_day if c.volume >= 100 and c.volume_in_usd > 10000]
```

For more information about universe settings, see Settings .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `history` method with the `Universe` object, and the lookback period. If there is no data in the period you request, the history result is empty.

```py
# DataFrame example where the columns are the CryptoUniverse attributes:
history_df = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series example where the values are lists of CryptoUniverse objects:
history = self.history(self._universe, 30, Resolution.DAILY)
for (univere_symbol, time), universe_day in history.items():
    for universe_item in universe_day:
        self.log(f"{universe_item.symbol} price at {universe_item.end_time}: {universe_item.close}")
```

Historical Universe Data in Research

To get historical universe data in research, call the `universe_history` method with the `Universe` object, and the lookback period. The `universe_history` returns the filtered universe. If there is no data in the period you request, the history result is empty.

```py
# DataFrame example where the columns are the CryptoUniverse attributes:
history_df = qb.universe_history(universe, qb.time-timedelta(30), qb.time, flatten=True)

# Series example where the values are lists of CryptoUniverse objects:
universe_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (univere_symbol, time), universe_day in universe_history.items():
    for universe_item in universe_day:
        print(f"{universe_item.symbol} price at {universe_item.end_time}: {universe_item.close}")
```

You can call the `history` method in Research.

Remove Subscriptions

To unsubscribe from a Crypto pair that you added with the `add_crypto` method, call the `remove_security` method.

```py
self.remove_security(self.btcusd)
```

The `remove_security` method cancels your open orders for the security and liquidates your holdings in the virtual pair .

Supported Assets

The following table shows the available Cryptocurrency pairs:

Pairs Available (570)

Example Applications

The Bitfinex Crypto Price dataset enables you to accurately design strategies for Cryptocurrencies. Examples include the following strategies:

- Buy and hold
- Trading Cryptocurrency volatility and price action
- Allocating a small portion of your portfolio to Cryptocurrencies to hedge against inflation

Classic Algorithm Example

The following example algorithm buys and holds Bitcoin through the Bitfinex exchange:

```py
from AlgorithmImports import *

class CoinAPIDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.universe_settings.asynchronous = True
        self.set_cash(100_000)
        # Bitfinex accepts both Cash and Margin account types. Select the
        # one you need for the best reality modeling.
        self.set_brokerage_model(BrokerageName.BITFINEX, AccountType.MARGIN)
        # Add BTCUSD data.
        self._btc = self.add_crypto("BTCUSD", Resolution.MINUTE, Market.BITFINEX)
        # Historical data
        history = self.history(self._btc.symbol, 30, Resolution.DAILY)
        # Add a Crypto universe that selects Crypto pairs on Bitfinex.
        universe = self.add_universe(CryptoUniverse.bitfinex(self._select_assets))
        # Historical Universe data
        universe_history = self.history(universe, 30, Resolution.DAILY)
        for (universe_symbol, time), universe_day in universe_history.items():
            for universe_item in universe_day:
                symbol = universe_item.symbol
                price = universe_item.close

    def _select_assets(self, universe_day):
        # Filter for materially traded Crypto pairs with significant
        # size and dollar volume, assuming higher capital flow in for
        # higher return.
        return [universe_item.symbol for universe_item in universe_day
                if universe_item.volume >= 100
                and universe_item.volume_in_usd > 10_000_000]

    def on_data(self, slice: Slice) -> None:
        # Speculate-invest all available free cash on BTCUSD, repecting
        # the order quantity restrictions to avoid invalid orders.
        if self.portfolio.cash_book['BTC'].amount != 0:
            return
        # Define a buffer so that we can scale down the order size,
        # avoiding trading errors.
        buffer = max(
            BitfinexFeeModel.TAKER_FEE,
            self.settings.free_portfolio_value_percentage
        )
        quantity = (
            self.portfolio.cash_book['USD'].amount
            / self._btc.ask_price
            * (1-buffer)
        )
        # Check if the quantity exceeds the minimum order size. On
        # Bitfinex, the minimum order size is measured in the base
        # currency (BTC in this case).
        if abs(quantity) < self._btc.symbol_properties.minimum_order_size:
            return
        self.market_order(self._btc, quantity)
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of Crypto pairs on the Bitfinex exchange and then forms a equal-weighted portfolio of all the pairs in the universe:

```
from AlgorithmImports import *

class CoinAPIDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.settings.free_portfolio_value_percentage = 0.05
        # Bitfinex accepts both Cash and Margin account types, select the one you need for the best reality modeling.
        self.set_brokerage_model(BrokerageName.BITFINEX, AccountType.MARGIN)

        # Warm up the security with the last known price to avoid conversion error
        self.settings.seed_initial_prices = True
        self.universe_settings.asynchronous = True
        self.universe_settings.resolution = Resolution.MINUTE
        # Add Crypto Universe Selection that select crypto pairs in Bitfinex exchange
        self.add_universe(CryptoUniverse.bitfinex(self._select_assets))
        # Get the pairs on Bitfinex that have USD as the quote currency.
        self._market_pairs = [
            x.key.symbol
            for x in self.symbol_properties_database.get_symbol_properties_list(Market.BITFINEX)
            if x.value.quote_currency == self.account_currency
        ]
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(hours=4), 0.025, None))
        # Equally invest to evenly dissipate the capital concentration risk of inidividual crypto pair
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

    def _select_assets(self, universe_day: List[CryptoUniverse]) -> List[Symbol]:
        # Select pairs where the quote currency is USD.
        pairs = [c for c in universe_day if c.symbol.value in self._market_pairs]
        # Filter for materially traded crypto pairs with significant dollar volume, assuming higher capital flow in for higher return.
        pairs = sorted(pairs, key=lambda c: c.volume_in_usd)[-3:]
        return [c.symbol for c in pairs]

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            # Historical data
            history = self.history(security.symbol, 30, Resolution.DAILY)
            self.debug(f"We got {len(history)} items from our history request")
```

Research Example

The following example lists crypto-currency pairs with the greatest dollar volume in the Bitfinex exchange:

```
qb = QuantBook()

# Add Cryptocurrency pair
symbol = qb.add_crypto("BTCUSDT", market=Market.BITFINEX).symbol

# Historical data
history = qb.history(symbol, 30, Resolution.DAILY)
for (symbol, time), row in history.iterrows():
    print(f'{time} {symbol} {row.close}')

# Add Crypto Universe Selection
def universe_selection_filter(universe_day):
    selected = sorted([x for x in universe_day
        if x.volume_in_usd and x.volume_in_usd > 10000],
        key=lambda x: x.volume_in_usd, reverse=True)[:5]
    return [x.symbol for x in selected]

universe = qb.add_universe(CryptoUniverse.bitfinex(universe_selection_filter))

# Historical Universe data
history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (univere_symbol, time), universe_day in history.items():
    print(f'=== {time} ===')
    for universe_item in sorted(universe_day, key=lambda x: x.volume_in_usd, reverse=True):
        print(f"{universe_item.symbol}: {universe_item.volume_in_usd}")
```

Data Point Attributes

The Bitfinex Crypto Price dataset provides `TradeBar` , `QuoteBar` , `Tick` , and `CryptoUniverse` objects.

TradeBar Attributes

`TradeBar` objects have the following attributes:

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

Tick Attributes

`Tick` objects have the following attributes:

CryptoUniverse Attributes

`CryptoUniverse` objects have the following attributes:

CoinAPI

Bybit Crypto Future Price Data

Introduction

The Bybit Crypto Future Price Data by CoinAPI is for Cryptocurrency Futures price and volume data points. The data covers 631 Cryptocurrency pairs, starts in August 2020, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on Bybit.

The Bybit Crypto Future Margin Rate Data dataset provides margin interest rate data to model margin costs.

For more information about the Bybit Crypto Future Price Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CoinAPI was founded by Artur Pietrzyk in 2016 with the goal of providing real-time and historical cryptocurrency market data, collected from hundreds of exchanges. CoinAPI provides access to Cryptocurrencies for traders, market makers, and developers building third-party applications.

Getting Started

The following snippet demonstrates how to request data from the Bybit Crypto Future Price dataset:

```
PY
def initialize(self) -> None:
    self.set_brokerage_model(BrokerageName.BYBIT, AccountType.MARGIN)

    self.crypto_future_symbol = self.add_crypto_future("BTCUSDT", Resolution.MINUTE).symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	October 2019
Asset Coverage	631 Crypto Futures Pairs
Data Density	Dense
Resolution	Tick, Second, Minute, Hourly, & Daily
Timezone	UTC
Market Hours	Always Open

Requesting Data

To add Bybit Crypto Future Price data to your algorithm, call the `add_crypto_future` method. Save a reference to the Crypto Future `Symbol` so you can access the data later in your algorithm.

```
PY
class CoinAPIDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2020, 6, 1)
        self.set_end_date(2021, 6, 1)

        # Set Account Currency to Tether
        self.set_account_currency("USDT", 100000)

        self.set_brokerage_model(BrokerageName.BYBIT, AccountType.MARGIN)

        crypto_future = self.add_crypto_future("BTCUSDT", Resolution.MINUTE)
        self.btcusdt = crypto_future.symbol
```

For more information about creating Crypto Future subscriptions, see Requesting Data .

Accessing Data

To get the current Bybit Crypto Future Price data, index the `bars` , `quote_bars` , or `ticks` properties of the current `Slice` with the Crypto Future `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    if self.btcusdt in slice.bars:
        trade_bar = slice.bars[self.btcusdt]
        self.log(f"{self.btcusdt} close at {slice.time}: {trade_bar.close}")

    if self.btcusdt in slice.quote_bars:
        quote_bar = slice.quote_bars[self.btcusdt]
        self.log(f"{self.btcusdt} bid at {slice.time}: {quote_bar.bid.close}")

    if self.btcusdt in slice.ticks:
        ticks = slice.ticks[self.btcusdt]
        for tick in ticks:
            self.log(f"{self.btcusdt} price at {slice.time}: {tick.price}")
```

You can also iterate through all of the data objects in the current `Slice` .

```
PY
def on_data(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.bars.items():
        self.log(f"{symbol} close at {slice.time}: {trade_bar.close}")

    for symbol, quote_bar in slice.quote_bars.items():
        self.log(f"{symbol} bid at {slice.time}: {quote_bar.bid.close}")

    for symbol, ticks in slice.ticks.items():
        for tick in ticks:
            self.log(f"{symbol} price at {slice.time}: {tick.price}")
```

For more information about accessing Crypto Future data, see Handling Data .

Historical Data

To get historical Bybit Crypto Future Price data, call the `history` method with the Crypto Future `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.history(self.btcusdt, 100, Resolution.DAILY)

# TradeBar objects
history_trade_bars = self.history[TradeBar](self.btcusdt, 100, Resolution.MINUTE)

# QuoteBar objects
history_quote_bars = self.history[QuoteBar](self.btcusdt, 100, Resolution.MINUTE)

# Tick objects
history_ticks = self.history[Tick](self.btcusdt, timedelta(seconds=10), Resolution.TICK)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To unsubscribe from a Crypto Future contract that you added with the `add_crypto_future` method, call the `remove_security` method.

```
PY
self.remove_security(self.btcusdt)
```

The `remove_security` method cancels your open orders for the security and liquidates your Crypto Future holdings.

Supported Assets

The following table shows the available Crypto Future pairs:

Pairs Available (631)

Example Applications

The Bybit Crypto Future Price dataset enables you to accurately design strategies for Crypto Futures with term structure. Examples include the following strategies:

- Horizontal/Diagonal arbitrage with the underlying Cryptocurrencies
- Trade Contango/Backwardation predictions
- Hedge for illiquid Cryptocurrencies

Classic Algorithm Example

The following example algorithm buys BTCUSDT perpetual future contract if the last day's close price was close to ask close price than bid close price, sells short of that in opposite, through the Bybit exchange:

```py
from AlgorithmImports import *

class BybitCryptoFutureDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Set Account Currency to Tether, since USD and USDT will not auto-convert and USD cannot be used to trade
        self.set_account_currency("USDT", 100000)
        # Bybit accepts both Cash and Margin account types, select the one you need for the best reality modeling.
        self.set_brokerage_model(BrokerageName.BYBIT, AccountType.MARGIN)

        # Requesting data, we only trade on BTCUSDT Future in Bybit exchange
        crypto_future = self.add_crypto_future("BTCUSDT", Resolution.DAILY)
        # perpetual futures does not have a filter function
        self.btcusdt = crypto_future.symbol

        # Historical data
        history = self.history(self.btcusdt, 10, Resolution.DAILY)

    def on_data(self, slice: Slice) -> None:
        # Trade only based on updated price data
        if not slice.bars.contains_key(self.btcusdt) or not slice.quote_bars.contains_key(self.btcusdt):
            return

        quote = slice.quote_bars[self.btcusdt]
        price = slice.bars[self.btcusdt].price

        # Scalp-trade the bid-ask spread based on the supply-demand strength
        if price - quote.bid.close > quote.ask.close - price:
            self.set_holdings(self.btcusdt, -1)
        else:
            self.set_holdings(self.btcusdt, 1)
```

Framework Algorithm Example

The following example algorithm hold a 100% long BTCUST future portfolio if the last day's close price was close to ask close price than bid close price, while hold short of that in opposite, through the Bybit exchange using the algorithm framework implementation:

```py
from AlgorithmImports import *

class BybitCryptoFutureDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Set Account Currency to Tether, since USD and USDT will not auto-convert and USD cannot be used to trade
        self.set_account_currency("USDT", 100000)
        # Bybit accepts both Cash and Margin account types, select the one you need for the best reality modeling.
        self.set_brokerage_model(BrokerageName.BYBIT, AccountType.MARGIN)

        self.universe_settings.resolution = Resolution.DAILY
        self.universe_settings.leverage = 2
        # We only trade on BTCUSDT Future in Bybit exchange
        symbols = [Symbol.create("BTCUSDT", SecurityType.CRYPTO_FUTURE, Market.BYBIT)]
        self.add_universe_selection(ManualUniverseSelectionModel(symbols))
        # Custom alpha model to emit insights based on the Crypto Future price data
        self.add_alpha(CryptoFutureAlphaModel())
        # Equally invest to evenly dissipate the capital concentration risk of inidividual crypto pair
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())
        self.set_execution(ImmediateExecutionModel())

class CryptoFutureAlphaModel(AlphaModel):

    def __init__(self) -> None:
        self.symbols = []

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        insights = []

        for symbol in self.symbols:
            # Trade only based on updated price data
            if not slice.bars.contains_key(symbol) or not slice.quote_bars.contains_key(symbol):
                continue
            quote = slice.quote_bars[symbol]
            price = slice.bars[symbol].price

            # Scalp-trade the bid-ask spread based on the supply-demand strength
            if price - quote.bid.close > quote.ask.close - price:
                insights.append(Insight.price(symbol, timedelta(1), InsightDirection.DOWN))
            else:
                insights.append(Insight.price(symbol, timedelta(1), InsightDirection.UP))

        return insights

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            symbol = security.symbol
            self.symbols.append(symbol)

            # Historical data
            history = algorithm.history(symbol, 10, Resolution.DAILY)

        for security in changes.removed_securities:
            symbol = security.symbol
            if symbol in self.symbols:
                self.symbols.remove(symbol)
```

Data Point Attributes

The Bybit Crypto Future Price dataset provides `TradeBar` , `QuoteBar` , and `Tick` objects.

TradeBar Attributes

`TradeBar` objects have the following attributes:

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

Tick Attributes

`Tick` objects have the following attributes:

CoinAPI

Bybit Crypto Price Data

Introduction

The Bybit Crypto Price Data by CoinAPI is for Cryptocurrency price and volume data points. The data covers 956 Cryptocurrency pairs, starts in July 2017, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on Bybit.

For more information about the Bybit Crypto Price Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CoinAPI was founded by Artur Pietrzyk in 2016 with the goal of providing real-time and historical cryptocurrency market data, collected from hundreds of exchanges. CoinAPI provides access to Cryptocurrencies for traders, market makers, and developers building third-party applications.

Getting Started

The following snippet demonstrates how to request data from the Bybit Crypto Price dataset:

```py
# Bybit accepts both Cash and Margin account types only.
self.set_brokerage_model(BrokerageName.BYBIT, AccountType.CASH)
#self.set_brokerage_model(BrokerageName.BYBIT, AccountType.MARGIN)

self.btcusdt = self.add_crypto("BTCUSDT", Resolution.MINUTE, Market.BYBIT).symbol

self._universe = self.add_universe(CryptoUniverse.bybit(self.universe_selection_filter))
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	April 2022
Asset Coverage	956 Currency Pairs
Data Density	Dense
Resolution	Tick, Second, Minute, Hourly, & Daily
Timezone	UTC
Market Hours	Always Open

Requesting Data

To add Bybit Crypto Price data to your algorithm, call the `add_crypto` method. Save a reference to the Crypto `Symbol` so you can access the data later in your algorithm.

```py
class CoinAPIDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2020, 6, 1)
        self.set_end_date(2021, 6, 1)

        # Set Account Currency to Tether
        self.set_account_currency("USDT", 100000)

        # Bybit accepts both Cash and Margin account types.
        self.set_brokerage_model(BrokerageName.BYBIT, AccountType.MARGIN)

        self.btcusdt = self.add_crypto("BTCUSDT", Resolution.MINUTE, Market.BYBIT).symbol
```

For more information about creating Crypto subscriptions, see Requesting Data .

Accessing Data

To get the current Bybit Crypto Price data, index the `bars` , `quote_bars` , or `ticks` properties of the current `Slice` with the Crypto `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    if self.btcusdt in slice.bars:
        trade_bar = slice.bars[self.btcusdt]
        self.log(f"{self.btcusdt} close at {slice.time}: {trade_bar.close}")

    if self.btcusdt in slice.quote_bars:
        quote_bar = slice.quote_bars[self.btcusdt]
        self.log(f"{self.btcusdt} bid at {slice.time}: {quote_bar.bid.close}")

    if self.btcusdt in slice.ticks:
        ticks = slice.ticks[self.btcusdt]
        for tick in ticks:
            self.log(f"{self.btcusdt} price at {slice.time}: {tick.price}")
```

You can also iterate through all of the data objects in the current `Slice` .

```
PY
def on_data(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.bars.items():
        self.log(f"{symbol} close at {slice.time}: {trade_bar.close}")

    for symbol, quote_bar in slice.quote_bars.items():
        self.log(f"{symbol} bid at {slice.time}: {quote_bar.bid.close}")

    for symbol, ticks in slice.ticks.items():
        for tick in ticks:
            self.log(f"{symbol} price at {slice.time}: {tick.price}")
```

For more information about accessing Crypto data, see Handling Data .

Historical Data

To get historical Bybit Crypto Price data, call the `history` method with the Crypto `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.history(self.btcusdt, 100, Resolution.DAILY)

# TradeBar objects
history_trade_bars = self.history[TradeBar](self.btcusdt, 100, Resolution.MINUTE)

# QuoteBar objects
history_quote_bars = self.history[QuoteBar](self.btcusdt, 100, Resolution.MINUTE)

# Tick objects
history_ticks = self.history[Tick](self.btcusdt, timedelta(seconds=10), Resolution.TICK)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of Bybit Crypto pairs, call the `add_universe` method with a `CryptoUniverse` object. A Crypto universe uses a selection function to select Crypto pairs based on their OHLCV and dollar volume of the previous day as of midnight Coordinated Universal Time (UTC).

```
PY
def initialize(self) -> None:
    self.set_brokerage_model(BrokerageName.BYBIT, AccountType.MARGIN)
    self.universe_settings.asynchronous = True
    self._universe = self.add_universe(CryptoUniverse.bybit(self.universe_selection_filter))

def universe_selection_filter(self, universe_day):
    return [c.symbol for c in universe_day if c.volume >= 100 and c.volume_in_usd > 10000]
```

For more information about universe settings, see Settings .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `history` method with the `Universe` object, and the lookback period. If there is no data in the period you request, the history result is empty.

```py
# DataFrame example where the columns are the CryptoUniverse attributes:
history_df = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series example where the values are lists of CryptoUniverse objects:
history = self.history(self._universe, 30, Resolution.DAILY)
for (univere_symbol, time), universe_day in history.items():
    for universe_item in universe_day:
        self.log(f"{universe_item.symbol} price at {universe_item.end_time}: {universe_item.close}")
```

Historical Universe Data in Research

To get historical universe data in research, call the `universe_history` method with the `Universe` object, and the lookback period. The `universe_history` returns the filtered universe. If there is no data in the period you request, the history result is empty.

```py
# DataFrame example where the columns are the CryptoUniverse attributes:
history_df = qb.universe_history(universe, qb.time-timedelta(30), qb.time, flatten=True)

# Series example where the values are lists of CryptoUniverse objects:
universe_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (univere_symbol, time), universe_day in universe_history.items():
    for universe_item in universe_day:
        print(f"{universe_item.symbol} price at {universe_item.end_time}: {universe_item.close}")
```

You can call the `history` method in Research.

Remove Subscriptions

To unsubscribe from a Crypto pair that you added with the `add_crypto` method, call the `remove_security` method.

```py
self.remove_security(self.btcusdt)
```

The `remove_security` method cancels your open orders for the security and liquidates your holdings in the virtual pair .

Supported Assets

The following table shows the available Cryptocurrency pairs:

Pairs Available (956)

Example Applications

The Bybit Crypto Price dataset enables you to accurately design strategies for Cryptocurrencies. Examples include the following strategies:

- Buy and hold
- Trading Cryptocurrency volatility and price action
- Allocating a small portion of your portfolio to Cryptocurrencies to hedge against inflation

Classic Algorithm Example

The following example algorithm buys and holds Bitcoin through the Bybit exchange:

```
from AlgorithmImports import * class CoinAPIDataAlgorithm(QCAlgorithm): def initialize(self) -> None: self.set_start_da
te(2024, 9, 1) self.set_end_date(2024, 12, 31) # Set the account currency to USDT, since you can't trade with # USD and
the algorithm doesn't automatically convert USD & USDT # holdings. self.set_account_currency("USDT", 100_000) self.univ
erse_settings.asynchronous = True # Bybit accepts both Cash and Margin account types. Select the # one you need for the
best reality modeling. self.set_brokerage_model(BrokerageName.BYBIT, AccountType.MARGIN) # Add BTCUSDT data. self._btc
= self.add_crypto("BTCUSDT", Resolution.MINUTE, Market.BYBIT) # Historical data history = self.history(self._btc.symbol
, 30, Resolution.DAILY) # Add a Crypto universe that selects trading pairs on Bybit. universe = self.add_universe(Crypt
oUniverse.bybit(self._select_assets)) # Historical Universe data universe_history = self.history(universe, 30, Resoluti
on.DAILY) for (universe_symbol, time), universe_day in universe_history.items(): for universe_item in universe_day: sym
bol = universe_item.symbol price = universe_item.close def _select_assets(self, universe_day): # Filter for materially
traded Crypto pairs with significant # size and dollar volume, assuming higher capital flow in for # higher return. ret
urn [universe_item.symbol for universe_item in universe_day if universe_item.volume >= 100 and universe_item.volume_in_
usd > 10_000_000] def on_data(self, slice: Slice) -> None: # Speculate-invest all available free cash on BTCUSDT, repec
ting # the order quantity restrictions to avoid invalid orders. if self.portfolio.cash_book['BTC'].amount != 0: return
# Define a buffer so that we can scale down the order size, # avoiding trading errors. buffer = max( BybitFeeModel.TAKE
R_NON_VIP_FEE, self.settings.free_portfolio_value_percentage ) quantity = ( self.portfolio.cash_book['USDT'].amount / s
elf._btc.ask_price * (1-buffer) ) # Check if the quantity exceeds the minimum order size. On # Bybit, the minimum order
size is measured in the base # currency (BTC in this case). if abs(quantity) < self._btc.symbol_properties.minimum_orde
r_size: return self.market_order(self._btc, quantity)
```

```
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of Crypto pairs on the Bybit exchange and then forms a equal-weighted portfolio of all the pairs in the universe:

PY

```
from AlgorithmImports import *

class CoinAPIDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Set Account Currency to Tether, since USD and USDT will not auto-convert and USD cannot be used to trade
        self.set_account_currency("USDT", 100000)
        self.settings.free_portfolio_value_percentage = 0.05

        # Bybit accepts both Cash and Margin account types, select the one you need for the best reality modeling.
        self.set_brokerage_model(BrokerageName.BYBIT, AccountType.MARGIN)

        # Warm up the security with the last known price to avoid conversion error
        self.settings.seed_initial_prices = True
        self.universe_settings.asynchronous = True
        self.universe_settings.resolution = Resolution.MINUTE
        # Add Crypto Universe Selection that select crypto pairs in Bybit exchange
        self.add_universe(CryptoUniverse.bybit(self.universe_selection_filter))
        # Get the pairs on Bybit that have USDT as the quote currency.
        self._market_pairs = [
            x.key.symbol
            for x in self.symbol_properties_database.get_symbol_properties_list(Market.BYBIT)
            if x.value.quote_currency == self.account_currency
        ]

        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(minutes = 20), 0.025, None))
        # Equally invest to evenly dissipate the capital concentration risk of inidividual crypto pair
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

    def universe_selection_filter(self, universe_day: List[CryptoUniverse]) -> List[Symbol]:
        # Select pairs where the quote currency is USDT.
        pairs = [c for c in universe_day if c.symbol.value in self._market_pairs]
        # Filter for materially traded crypto pairs with significant dollar volume, assuming higher capital flow in for higher return.
        pairs = sorted(pairs, key=lambda c: c.volume_in_usd)[-3:]
        return [c.symbol for c in pairs]

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            # Historical data
            history = self.history(security.symbol, 30, Resolution.DAILY)
            self.debug(f"We got {len(history)} items from our history request")
```

Research Example

The following example lists crypto-currency pairs with the greatest dollar volume in the Bybit exchange:

```py
qb = QuantBook()

# Add Cryptocurrency pair
symbol = qb.add_crypto("BTCUSDT", market=Market.BYBIT).symbol

# Historical data
history = qb.history(symbol, 30, Resolution.DAILY)
for (symbol, time), row in history.iterrows():
    print(f'{time} {symbol} {row.close}')

# Add Crypto Universe Selection
def universe_selection_filter(universe_day):
    selected = sorted([x for x in universe_day
        if x.volume_in_usd and x.volume_in_usd > 10000],
        key=lambda x: x.volume_in_usd, reverse=True)[:5]
    return [x.symbol for x in selected]

universe = qb.add_universe(CryptoUniverse.bybit(universe_selection_filter))

# Historical Universe data
history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (univere_symbol, time), universe_day in history.items():
    print(f'=== {time} ===')
    for universe_item in sorted(universe_day, key=lambda x: x.volume_in_usd, reverse=True):
        print(f"{universe_item.symbol}: {universe_item.volume_in_usd}")
```

Data Point Attributes

The Bybit Crypto Price dataset provides `TradeBar` , `QuoteBar` , `Tick` , and `CryptoUniverse` objects.

TradeBar Attributes

`TradeBar` objects have the following attributes:

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

Tick Attributes

`Tick` objects have the following attributes:

CryptoUniverse Attributes

`CryptoUniverse` objects have the following attributes:

CoinAPI

Coinbase Crypto Price Data

Introduction

The Coinbase Crypto Price Data by CoinAPI provides Cryptocurrency price and volume data points. The data covers 970 Cryptocurrency pairs, starts in January 2015, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on Coinbase.

For more information about the Coinbase Crypto Price Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CoinAPI was founded by Artur Pietrzyk in 2016 with the goal of providing real-time and historical cryptocurrency market data, collected from hundreds of exchanges. CoinAPI provides access to Cryptocurrencies for traders, market makers, and developers building third-party applications.

Getting Started

The following snippet demonstrates how to request data from the Coinbase Crypto Price dataset:

```py
# Coinbase only accepts Cash account type
self.set_brokerage_model(BrokerageName.COINBASE, AccountType.CASH)

self.btcusd = self.add_crypto("BTCUSD", Resolution.MINUTE, Market.COINBASE).symbol

self._universe = self.add_universe(CryptoUniverse.coinbase(self.universe_selection_filter))
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2015
Asset Coverage	970 Currency Pairs
Data Density	Dense
Resolution	Tick, Second, Minute, Hourly, & Daily
Timezone	UTC
Market Hours	Always Open

Requesting Data

To add Coinbase Crypto Price data to your algorithm, call the `add_crypto` method. Save a reference to the Crypto `Symbol` so you can access the data later in your algorithm.

```py
class CoinAPIDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2020, 6, 1)
        self.set_end_date(2021, 6, 1)
        self.set_cash(100000)

        # Coinbase accepts Cash account type only, AccountType.MARGIN will result in an exception.
        self.set_brokerage_model(BrokerageName.COINBASE, AccountType.CASH)

        self.btcusd = self.add_crypto("BTCUSD", Resolution.MINUTE, Market.COINBASE).symbol
```

For more information about creating Crypto subscriptions, see Requesting Data .

Accessing Data

To get the current Coinbase Crypto Price data, index the `bars` , `quote_bars` , or `ticks` properties of the current `Slice` with the Crypto `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    if self.btcusd in slice.bars:
        trade_bar = slice.bars[self.btcusd]
        self.log(f"{self.btcusd} close at {slice.time}: {trade_bar.close}")

    if self.btcusd in slice.quote_bars:
        quote_bar = slice.quote_bars[self.btcusd]
        self.log(f"{self.btcusd} bid at {slice.time}: {quote_bar.bid.close}")

    if self.btcusd in slice.ticks:
        ticks = slice.ticks[self.btcusd]
        for tick in ticks:
            self.log(f"{self.btcusd} price at {slice.time}: {tick.price}")
```

You can also iterate through all of the data objects in the current `Slice` .

```
PY
def on_data(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.bars.items():
        self.log(f"{symbol} close at {slice.time}: {trade_bar.close}")

    for symbol, quote_bar in slice.quote_bars.items():
        self.log(f"{symbol} bid at {slice.time}: {quote_bar.bid.close}")

    for symbol, ticks in slice.ticks.items():
        for tick in ticks:
            self.log(f"{symbol} price at {slice.time}: {tick.price}")
```

For more information about accessing Crypto data, see Handling Data .

Historical Data

To get historical Coinbase Crypto Price data, call the `history` method with the Crypto `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.history(self.btcusd, 100, Resolution.DAILY)

# TradeBar objects
history_trade_bars = self.history[TradeBar](self.btcusd, 100, Resolution.MINUTE)

# QuoteBar objects
history_quote_bars = self.history[QuoteBar](self.btcusd, 100, Resolution.MINUTE)

# Tick objects
history_ticks = self.history[Tick](self.btcusd, timedelta(seconds=10), Resolution.TICK)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of Coinbase Crypto pairs, call the `add_universe` method with a `CryptoUniverse` object. A Crypto universe uses a selection function to select Crypto pairs based on their OHLCV and dollar volume of the previous day as of midnight Coordinated Universal Time (UTC).

```
PY
def initialize(self) -> None:
    self.universe_settings.asynchronous = True
    self.set_brokerage_model(BrokerageName.COINBASE, AccountType.CASH)
    self._universe = self.add_universe(CryptoUniverse.coinbase(self.universe_selection_filter))

def universe_selection_filter(self, universe_day):
    return [c.symbol for c in universe_day if c.volume >= 100 and c.volume_in_usd > 10000]
```

For more information about universe settings, see Settings .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `history` method with the `Universe` object, and the lookback period. If there is no data in the period you request, the history result is empty.

```py
# DataFrame example where the columns are the CryptoUniverse attributes:
history_df = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series example where the values are lists of CryptoUniverse objects:
history = self.history(self._universe, 30, Resolution.DAILY)
for (univere_symbol, time), universe_day in history.items():
    for universe_item in universe_day:
        self.log(f"{universe_item.symbol} price at {universe_item.end_time}: {universe_item.close}")
```

Historical Universe Data in Research

To get historical universe data in research, call the `universe_history` method with the `Universe` object, and the lookback period. The `universe_history` returns the filtered universe. If there is no data in the period you request, the history result is empty.

```py
# DataFrame example where the columns are the CryptoUniverse attributes:
history_df = qb.universe_history(universe, qb.time-timedelta(30), qb.time, flatten=True)

# Series example where the values are lists of CryptoUniverse objects:
universe_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (univere_symbol, time), universe_day in universe_history.items():
    for universe_item in universe_day:
        print(f"{universe_item.symbol} price at {universe_item.end_time}: {universe_item.close}")
```

You can call the `history` method in Research.

Remove Subscriptions

To unsubscribe from a Crypto pair that you added with the `add_crypto` method, call the `remove_security` method.

```py
self.remove_security(self.btcusd)
```

The `remove_security` method cancels your open orders for the security and liquidates your holdings in the virtual pair .

Supported Assets

The following table shows the available Cryptocurrency pairs:

Pairs Available (970)					
00USD	00USDC	1INCHBTC	1INCHEUR	1INCHGBP	1INCHUSD

Example Applications

The Coinbase Crypto Price dataset enables you to accurately design strategies for Cryptocurrencies. Examples include the following strategies:

- Buy and hold
- Trading Cryptocurrency volatility and price action
- Allocating a small portion of your portfolio to Cryptocurrencies to hedge against inflation

Classic Algorithm Example

The following example algorithm buys and holds Bitcoin through the Coinbase exchange:

```py
from AlgorithmImports import *

class CoinAPIDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.universe_settings.asynchronous = True
        self.set_cash(100_000)
        # Coinbase accepts Cash account type only. AccountType.MARGIN
        # results in an exception.
        self.set_brokerage_model(BrokerageName.COINBASE, AccountType.CASH)
        # Add BTCUSD data.
        self._btc = self.add_crypto("BTCUSD", Resolution.MINUTE, Market.COINBASE)
        # Historical data
        history = self.history(self._btc.symbol, 30, Resolution.DAILY)
        # Add a Crypto universe that selects Crypto pairs on Coinbase.
        universe = self.add_universe(CryptoUniverse.coinbase(self._select_assets))
        # Historical Universe data
        universe_history = self.history(universe, 30, Resolution.DAILY)
        for (universe_symbol, time), universe_day in universe_history.items():
            for universe_item in universe_day:
                symbol = universe_item.symbol
                price = universe_item.close

    def _select_assets(self, universe_day):
        # Filter for materially traded Crypto pairs with significant
        # size and dollar volume, assuming higher capital flow in for
        # higher return.
        return [universe_item.symbol for universe_item in universe_day
                if universe_item.volume >= 100
                and universe_item.volume_in_usd > 10_000_000]

    def on_data(self, slice: Slice) -> None:
        # Speculate-invest all available free cash on BTCUSD, repecting
        # the order quantity restrictions to avoid invalid orders.
        if self.portfolio.cash_book['BTC'].amount != 0:
            return
        # Define a buffer so that we can scale down the order size,
        # avoiding trading errors.
        buffer = max(
            CoinbaseFeeModel.TAKER_ADVANCED_1,
            self.settings.free_portfolio_value_percentage
        )
        quantity = (
            self.portfolio.cash_book['USD'].amount
            / self._btc.ask_price
            * (1-buffer)
        )
        # Check if the quantity exceeds the minimum order size. On
        # Coinbase, the minimum order size is measured in the base
        # currency (BTC in this case).
        if abs(quantity) < self._btc.symbol_properties.minimum_order_size:
            return
        self.market_order(self._btc, quantity)
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of Crypto pairs on the Coinbase exchange and then forms a equal-weighted portfolio of all the pairs in the universe:

```
from AlgorithmImports import *

class CoinAPIDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2020, 6, 1)
        self.set_end_date(2021, 2, 1)
        self.set_cash(100000)
        self.settings.free_portfolio_value_percentage = 0.05
        # Warm up the security with the last known price to avoid conversion error
        self.settings.seed_initial_prices = True
        self.universe_settings.asynchronous = True
        self.universe_settings.resolution = Resolution.MINUTE
        # Add Crypto Universe Selection that select crypto pairs in Coinbase exchange
        self.add_universe(CryptoUniverse.coinbase(self._select_assets))
        # Get the pairs on Coinbase that have USD as the quote currency.
        self._market_pairs = [
            x.key.symbol
            for x in self.symbol_properties_database.get_symbol_properties_list(Market.COINBASE)
            if x.value.quote_currency == self.account_currency
        ]
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(hours=4), 0.025, None))
        # Equally invest to evenly dissipate the capital concentration risk of inidividual crypto pair
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

    def _select_assets(self, universe_day: List[CryptoUniverse]) -> List[Symbol]:
        # Select pairs where the quote currency is USD.
        pairs = [c for c in universe_day if c.symbol.value in self._market_pairs]
        # Filter for materially traded crypto pairs with significant dollar volume, assuming higher capital flow in for higher return.
        pairs = sorted(pairs, key=lambda c: c.volume_in_usd)[-3:]
        return [c.symbol for c in pairs]

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            # Historical data
            history = self.history(security.symbol, 30, Resolution.DAILY)
            self.debug(f"We got {len(history)} items from our history request")
```

Research Example

The following example lists crypto-currency pairs with the greatest dollar volume in the Coinbase exchange:

```
qb = QuantBook()

# Add Cryptocurrency pair
symbol = qb.add_crypto("BTCUSDT", market=Market.COINBASE).symbol

# Historical data
history = qb.history(symbol, 30, Resolution.DAILY)
for (symbol, time), row in history.iterrows():
    print(f'{time} {symbol} {row.close}')

# Add Crypto Universe Selection
def universe_selection_filter(universe_day):
    selected = sorted([x for x in universe_day
        if x.volume_in_usd and x.volume_in_usd > 10000],
        key=lambda x: x.volume_in_usd, reverse=True)[:5]
    return [x.symbol for x in selected]

universe = qb.add_universe(CryptoUniverse.coinbase(universe_selection_filter))

# Historical Universe data
history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (univere_symbol, time), universe_day in history.items():
    print(f'=== {time} ===')
    for universe_item in sorted(universe_day, key=lambda x: x.volume_in_usd, reverse=True):
        print(f"{universe_item.symbol}: {universe_item.volume_in_usd}")
```

Data Point Attributes

The Coinbase Crypto Price dataset provides `TradeBar` , `QuoteBar` , `Tick` , and `CryptoUniverse` objects.

TradeBar Attributes

`TradeBar` objects have the following attributes:

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

Tick Attributes

`Tick` objects have the following attributes:

CryptoUniverse Attributes

`CryptoUniverse` objects have the following attributes:

CoinAPI

Kraken Crypto Price Data

Introduction

The Kraken Crypto Price Data by CoinAPI provides Cryptocurrency price and volume data points. The data covers 1,262 Cryptocurrency pairs, starts in October 2013, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on the Cryptocurrency markets/exchanges supported by QuantConnect.

For more information about the Kraken Crypto Price Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CoinAPI was founded by Artur Pietrzyk in 2016 with the goal of providing real-time and historical cryptocurrency market data, collected from hundreds of exchanges. CoinAPI provides access to Cryptocurrencies for traders, market makers, and developers building third-party applications.

Getting Started

The following snippet demonstrates how to request data from the Kraken Crypto Price dataset:

```py
# Kraken accepts both Cash and Margin type account.
self.set_brokerage_model(BrokerageName.KRAKEN, AccountType.CASH)
#self.set_brokerage_model(BrokerageName.KRAKEN, AccountType.MARGIN)

self.btcusd = self.add_crypto("BTCUSD", Resolution.MINUTE, Market.KRAKEN).symbol

self._universe = self.add_universe(CryptoUniverse.kraken(self.universe_selection_filter));
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	October 2013
Asset Coverage	1,262 Currency Pairs
Data Density	Dense
Resolution	Tick, Second, Minute, Hourly, & Daily
Timezone	UTC
Market Hours	Always Open

Requesting Data

To add Kraken Crypto Price data to your algorithm, call the `AddCrypto` method. Save a reference to the Crypto `Symbol` so you can access the data later in your algorithm.

```py
class CoinAPIDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2020, 6, 1)
        self.set_end_date(2021, 6, 1)
        self.set_cash(100000)

        # Kraken accepts both Cash and Margin type account.
        self.set_brokerage_model(BrokerageName.KRAKEN, AccountType.MARGIN)

        self.btcusd = self.add_crypto("BTCUSD", Resolution.MINUTE, Market.KRAKEN).symbol
```

For more information about creating Crypto subscriptions, see Requesting Data .

Accessing Data

To get the current Kraken Crypto Price data, index the `bars` , `quote_bars` , or `ticks` properties of the current `Slice` with the Crypto `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    if self.btcusd in slice.bars:
        trade_bar = slice.bars[self.btcusd]
        self.log(f"{self.btcusd} close at {slice.time}: {trade_bar.close}")

    if self.btcusd in slice.quote_bars:
        quote_bar = slice.quote_bars[self.btcusd]
        self.log(f"{self.btcusd} bid at {slice.time}: {quote_bar.bid.close}")

    if self.btcusd in slice.ticks:
        ticks = slice.ticks[self.btcusd]
        for tick in ticks:
            self.log(f"{self.btcusd} price at {slice.time}: {tick.price}")
```

You can also iterate through all of the data objects in the current `Slice` .

```
PY
def on_data(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.bars.items():
        self.log(f"{symbol} close at {slice.time}: {trade_bar.close}")

    for symbol, quote_bar in slice.quote_bars.items():
        self.log(f"{symbol} bid at {slice.time}: {quote_bar.bid.close}")

    for symbol, ticks in slice.ticks.items():
        for tick in ticks:
            self.log(f"{symbol} price at {slice.time}: {tick.price}")
```

For more information about accessing Crypto data, see Handling Data .

Historical Data

To get historical Kraken Crypto Price data, call the `history` method with the Crypto `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.history(self.btcusd, 100, Resolution.DAILY)

# TradeBar objects
history_trade_bars = self.history[TradeBar](self.btcusd, 100, Resolution.MINUTE)

# QuoteBar objects
history_quote_bars = self.history[QuoteBar](self.btcusd, 100, Resolution.MINUTE)

# Tick objects
history_ticks = self.history[Tick](self.btcusd, timedelta(seconds=10), Resolution.TICK)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of Kraken Crypto pairs, call the `add_universe` method with a `CryptoUniverse` object. A Crypto universe uses a selection function to select Crypto pairs based on their OHLCV and dollar volume of the previous day as of midnight Coordinated Universal Time (UTC).

```
PY
def initialize(self) -> None:
    self.set_brokerage_model(BrokerageName.KRAKEN, AccountType.MARGIN)
    self.universe_settings.asynchronous = True
    self._universe = self.add_universe(CryptoUniverse.kraken(self.universe_selection_filter))

def universe_selection_filter(self, universe_day):
    return [c.symbol for c in universe_day if c.volume >= 100 and c.volume_in_usd > 10000]
```

For more information about universe settings, see Settings .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `history` method with the `Universe` object, and the lookback period. If there is no data in the period you request, the history result is empty.

```py
# DataFrame example where the columns are the CryptoUniverse attributes:
history_df = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series example where the values are lists of CryptoUniverse objects:
history = self.history(self._universe, 30, Resolution.DAILY)
for (univere_symbol, time), universe_day in history.items():
    for universe_item in universe_day:
        self.log(f"{universe_item.symbol} price at {universe_item.end_time}: {universe_item.close}")
```

Historical Universe Data in Research

To get historical universe data in research, call the `universe_history` method with the `Universe` object, and the lookback period. The `universe_history` returns the filtered universe. If there is no data in the period you request, the history result is empty.

```py
# DataFrame example where the columns are the CryptoUniverse attributes:
history_df = qb.universe_history(universe, qb.time-timedelta(30), qb.time, flatten=True)

# Series example where the values are lists of CryptoUniverse objects:
universe_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (univere_symbol, time), universe_day in universe_history.items():
    for universe_item in universe_day:
        print(f"{universe_item.symbol} price at {universe_item.end_time}: {universe_item.close}")
```

You can call the `history` method in Research.

Remove Subscriptions

To unsubscribe from a Crypto pair that you added with the `add_crypto` method, call the `remove_security` method.

```py
self.remove_security(self.btcusd)
```

The `remove_security` method cancels your open orders for the security and liquidates your holdings in the virtual pair .

Supported Assets

The following table shows the available Cryptocurrency pairs:

Pairs Available (1262)

Example Applications

The Kraken Crypto Price dataset enables you to accurately design strategies for Cryptocurrencies. Examples include the following strategies:

- Buy and hold
- Trading Cryptocurrency volatility and price action
- Allocating a small portion of your portfolio to Cryptocurrencies to hedge against inflation

Classic Algorithm Example

The following example algorithm buys and holds Bitcoin through the Kraken exchange:

```py
from AlgorithmImports import *

class CoinAPIDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.universe_settings.asynchronous = True
        self.set_cash(100_000)
        # Kraken accepts both Cash and Margin account types. Select the
        # one you need for the best reality modeling.
        self.set_brokerage_model(BrokerageName.KRAKEN, AccountType.MARGIN)
        # Add BTCUSD data.
        self._btc = self.add_crypto("BTCUSD", Resolution.MINUTE, Market.KRAKEN)
        # Historical data
        history = self.history(self._btc.symbol, 30, Resolution.DAILY)
        # Add a Crypto universe that selects Crypto pairs on Kraken.
        universe = self.add_universe(CryptoUniverse.kraken(self._select_assets))
        # Historical Universe data
        universe_history = self.history(universe, 30, Resolution.DAILY)
        for (universe_symbol, time), universe_day in universe_history.items():
            for universe_item in universe_day:
                symbol = universe_item.symbol
                price = universe_item.close

    def _select_assets(self, universe_day):
        # Filter for materially traded Crypto pairs with significant
        # size and dollar volume, assuming higher capital flow in for
        # higher return.
        return [universe_item.symbol for universe_item in universe_day
                if universe_item.volume >= 100
                and universe_item.volume_in_usd > 10_000_000]

    def on_data(self, slice: Slice) -> None:
        # Speculate-invest all available free cash on BTCUSD, repecting
        # the order quantity restrictions to avoid invalid orders.
        if self.portfolio.cash_book['BTC'].amount != 0:
            return
        # Define a buffer so that we can scale down the order size,
        # avoiding trading errors.
        buffer = max(
            KrakenFeeModel.TAKER_TIER_1_CRYPTO_FEE,
            self.settings.free_portfolio_value_percentage
        )
        quantity = (
            self.portfolio.cash_book['USD'].amount
            / self._btc.ask_price
            * (1-buffer)
        )
        # Check if the quantity exceeds the minimum order size. On
        # Kraken, the minimum order size is measured in the base
        # currency (BTC in this case).
        if abs(quantity) < self._btc.symbol_properties.minimum_order_size:
            return
        self.market_order(self._btc, quantity)
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of Crypto pairs on the Kraken exchange and then forms a equal-weighted portfolio of all the pairs in the universe:

```py
from AlgorithmImports import *

class CoinAPIDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.settings.free_portfolio_value_percentage = 0.05

        # Kraken accepts both Cash and Margin type account, select the one you need for the best reality modeling.
        self.set_brokerage_model(BrokerageName.KRAKEN, AccountType.MARGIN)

        # Warm up the security with the last known price to avoid conversion error
        self.settings.seed_initial_prices = True

        # Get the pairs on Kraken that have USD as the quote currency.
        self._market_pairs = [
            x.key.symbol
            for x in self.symbol_properties_database.get_symbol_properties_list(Market.KRAKEN)
            if x.value.quote_currency == self.account_currency
        ]
        # Add Crypto Universe Selection that select crypto pairs in Kraken exchange
        self.add_universe(CryptoUniverse.kraken(self.universe_selection_filter))

        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(hours=4), 0.025, None))
        # Equally invest to evenly dissipate the capital concentration risk of inidividual crypto pair
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

    def universe_selection_filter(self, universe_day: List[CryptoUniverse]) -> List[Symbol]:
        # Select pairs where the quote currency is USD.
        pairs = [c for c in universe_day if c.symbol.value in self._market_pairs]
        # Filter for materially traded crypto pairs with significant dollar volume, assuming higher capital flow in for higher return.
        pairs = sorted(pairs, key=lambda c: c.volume_in_usd)[-3:]
        return [c.symbol for c in pairs]

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            # Historical data
            history = self.history(security.symbol, 30, Resolution.DAILY)
            self.debug(f"We got {len(history)} items from our history request")
```

Research Example

The following example lists crypto-currency pairs with the greatest dollar volume in the Kraken exchange:

```py
qb = QuantBook()

# Add Cryptocurrency pair
symbol = qb.add_crypto("BTCUSDT", market=Market.KRAKEN).symbol

# Historical data
history = qb.history(symbol, 30, Resolution.DAILY)
for (symbol, time), row in history.iterrows():
    print(f'{time} {symbol} {row.close}')

# Add Crypto Universe Selection
def universe_selection_filter(universe_day):
    selected = sorted([x for x in universe_day
        if x.volume_in_usd and x.volume_in_usd > 10000],
        key=lambda x: x.volume_in_usd, reverse=True)[:5]
    return [x.symbol for x in selected]

universe = qb.add_universe(CryptoUniverse.kraken(universe_selection_filter))

# Historical Universe data
history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (univere_symbol, time), universe_day in history.items():
    print(f'=== {time} ===')
    for universe_item in sorted(universe_day, key=lambda x: x.volume_in_usd, reverse=True):
        print(f"{universe_item.symbol}: {universe_item.volume_in_usd}")
```

Data Point Attributes

The Kraken Crypto Price dataset provides `TradeBar` , `QuoteBar` , `Tick` , and `CryptoUniverse` objects.

TradeBar Attributes

`TradeBar` objects have the following attributes:

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

Tick Attributes

`Tick` objects have the following attributes:

CryptoUniverse Attributes

`CryptoUniverse` objects have the following attributes:

Datasets

Benzinga

Benzinga was founded by Jason Raznick in 2010 with goal of connecting the world with news, data, and education that makes the path to financial prosperity easier for everyone, everyday. Benzinga provides access to real-time news for individual investors.

Benzinga News Feed

Benzinga

Benzinga News Feed

Introduction

The Benzinga News Feed dataset by Benzinga tracks US Equity news releases. The data covers about 1,250 articles per day across 8,000 Equities, starts in January 2016, and is delivered on a second frequency. This dataset is created by structuring the content produced by Benzinga's editorial team.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Benzinga News Feed dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Benzinga was founded by Jason Raznick in 2010 with goal of connecting the world with news, data, and education that makes the path to financial prosperity easier for everyone, everyday. Benzinga provides access to real-time news for individual investors.

Getting Started

The following snippet demonstrates how to request data from the Benzinga News Feed dataset:

```
self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
self.dataset_symbol = self.add_data(BenzingaNews, self.symbol).symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	September 2017
Asset Coverage	8,000 Equities
Data Density	Sparse
Resolution	Second (1,250 Articles/Day)
Timezone	New York

Requesting Data

To add Benzinga News Feed data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
class BenzingaNewsDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2021, 1, 1)
        self.set_end_date(2021, 6, 1)
        self.set_cash(100000)

        self.aapl = self.add_equity("AAPL", Resolution.MINUTE).symbol
        self.dataset_symbol = self.add_data(BenzingaNews, self.aapl).symbol
```

Accessing Data

To get the current Benzinga News Feed data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm

as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY

def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        article = slice[self.dataset_symbol]
        self.log(f"{self.dataset_symbol} title at {slice.time}: {article.title}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
PY

def on_data(self, slice: Slice) -> None:
    for dataset_symbol, article in slice.get(BenzingaNews).items():
        self.log(f"{dataset_symbol} title at {slice.time}: {article.title}")
```

Historical Data

To get historical Benzinga News Feed data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY

# DataFrame
history_df = self.history(self.dataset_symbol, 100, Resolution.DAILY)

# Dataset objects
history_bars = self.history[BenzingaNews](self.dataset_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
PY

self.remove_security(self.dataset_symbol)
```

If you subscribe to Benzinga News Feed data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Benzinga News Feed enables you to accurately design strategies harnessing real-time news releases. Examples include the following strategies:

- Creating a dictionary of sentiment scores for various words and assigning a sentiment score to the content of each news release
- Calculating the sentiment of news releases with Natural Language Processing (NLP)
- Trading securities when their news releases that Benzinga tags with current buzzwords

Classic Algorithm Example

The following example algorithm parses the Benzinga news articles related to Apple. If the sentiment is positive, the algorithm buys Apple. Otherwise, it holds cash.

```py
from AlgorithmImports import *

class BenzingaNewsDataAlgorithm(QCAlgorithm):

    current_holdings = 0
    target_holdings = 0
    # A custom word-score map for calculating the total sentiment score
    word_scores = {
        'good': 1, 'great': 1, 'best': 1, 'growth': 1,
        'bad': -1, 'terrible': -1, 'worst': -1, 'loss': -1}

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Requesting data to obtain the updated news for sentiment score calculation
        self.aapl = self.add_equity("AAPL", Resolution.MINUTE).symbol
        self.benzinga_symbol = self.add_data(BenzingaNews, self.aapl).symbol

        # Historical data
        history = self.history(self.benzinga_symbol, 14, Resolution.DAILY)
        self.debug(f"We got {len(history)} items from our history request")

    def on_data(self, slice: Slice) -> None:
        if slice.contains_key(self.benzinga_symbol):
            # Assign a sentiment score to the news article by specific word appearance scoring
            content_words = slice[self.benzinga_symbol].contents.lower()
            score = 0
            for word, word_score in self.word_scores.items():
                score += (content_words.count(word) * word_score)
            self.target_holdings = int(score > 0)

        # Ensure we have AAPL data in the current Slice to avoid stale filling
        if not (slice.contains_key(self.aapl) and slice[self.aapl] is not None and not slice[self.aapl].is_fill_forward):
            return

        # Buy or sell if the sentiment has changed from our current holdings
        if self.current_holdings != self.target_holdings:
            self.set_holdings(self.aapl, self.target_holdings)
            self.current_holdings = self.target_holdings
```

Framework Algorithm Example

The following example algorithm parses the Benzinga news articles related to Apple. If the sentiment is positive, the algorithm buys Apple. Otherwise, it holds cash.

```py
from AlgorithmImports import *

class BenzingaNewsDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        symbols = [ Symbol.create("AAPL", SecurityType.EQUITY, Market.USA) ]
        self.add_universe_selection(ManualUniverseSelectionModel(symbols))

        self.add_alpha(BenzingaNewsAlphaModel())

        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

        self.add_risk_management(NullRiskManagementModel())

        self.set_execution(ImmediateExecutionModel())

class BenzingaNewsAlphaModel(AlphaModel):

    symbol_data_by_symbol = {}
    # A custom word-score map for calculating the total sentiment score
    word_scores = {'good': 1, 'great': 1, 'best': 1, 'growth': 1,
                   'bad': -1, 'terrible': -1, 'worst': -1, 'loss': -1}

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        insights = []

        for symbol, symbol_data in self.symbol_data_by_symbol.items():
            if slice.contains_key(symbol_data.benzinga_symbol):
                # Assign a sentiment score to the news article by specific word appearance scoring
                content_words = slice[symbol_data.benzinga_symbol].contents.lower()
                score = 0
                for word, word_score in self.word_scores.items():
                    score += (content_words.count(word) * word_score)
                symbol_data.target_direction = InsightDirection.UP if score > 0 else InsightDirection.FLAT

            # Ensure we have security data in the current Slice to avoid stale filling
            if not (slice.contains_key(symbol) and slice[symbol] is not None and not slice[symbol].is_fill_forward):
                continue

            # Buy or sell if the sentiment has changed from our current holdings
            if symbol_data.current_direction != symbol_data.target_direction:
                symbol_data.current_direction = symbol_data.target_direction
                insights.append(Insight.price(symbol, timedelta(days=14), symbol_data.target_direction))

        return insights

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            symbol = security.symbol
            self.symbol_data_by_symbol[symbol] = SymbolData(algorithm, symbol)

        for security in changes.removed_securities:
            symbol_data = self.symbol_data_by_symbol.pop(security.symbol, None)
            if symbol_data:
                symbol_data.dispose()

class SymbolData:

    current_direction = InsightDirection.FLAT
    target_direction = InsightDirection.FLAT

    def __init__(self, algorithm: QCAlgorithm, symbol: Symbol) -> None:
        self.algorithm = algorithm

        # Requesting data to obtain the updated news for sentiment score calculation
        self.benzinga_symbol = algorithm.add_data(BenzingaNews, symbol).symbol

        # Historical data
        history = algorithm.history(self.benzinga_symbol, 14, Resolution.DAILY)
        algorithm.debug(f"We got {len(history)} items from our history request")

    def dispose(self) -> None:
        # Unsubscribe from Benzinga news feed for this security to release computational resources
        self.algorithm.remove_security(self.benzinga_symbol)
```

Data Point Attributes

The Benzinga News Feed dataset provides `BenzingaNews` objects, which have the following attributes:

Datasets

Blockchain

Blockchain is a website that publishes data related to Bitcoin. It has been online since 2011 and publishes the Bitcoin Metadata history back to 2009.

Bitcoin Metadata

Blockchain

Bitcoin Metadata

Introduction

The Bitcoin Metadata dataset by Blockchain provides 23 fundamental metadata of Bitcoin directly fetched from the Bitcoin blockchain. The data starts in January 2009 and delivered on a daily frequency. This dataset contains mining statistics like hash rate and miner revenue; transaction metadata like transaction per block, transaction fee, and number of addresses; and blockchain metadata like blockchain size and block size.

For more information about the Bitcoin Metadata dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Blockchain is a website that publishes data related to Bitcoin. It has been online since 2011 and publishes the Bitcoin Metadata history back to 2009.

Getting Started

The following snippet demonstrates how to request data from the Bitcoin Metadata dataset:

```
self.btcusd = self.add_crypto("BTCUSD", Resolution.DAILY, Market.BITFINEX).symbol
self.dataset_symbol = self.add_data(BitcoinMetadata, self.btcusd).symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2009
Coverage	Bitcoin blockchain
Data Density	Regular
Resolution	Daily
Timezone	UTC

Requesting Data

To add Bitcoin Metadata data to your algorithm, call the `add_data` method with the BTCUSD `Symbol` . Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
class BlockchainBitcoinMetadataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        self.btcusd = self.add_crypto("BTCUSD", Resolution.DAILY, Market.BITFINEX).symbol
        self.dataset_symbol = self.add_data(BitcoinMetadata, self.btcusd).symbol
```

Accessing Data

To get the current Bitcoin Metadata data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.log(f"{self.dataset_symbol} miner revenue at {slice.time}: {data_point.miners_revenue}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.get(BlockchainBitcoinData).items():
        self.log(f"{dataset_symbol} miner revenue at {slice.time}: {data_point.miners_revenue}")
```

Historical Data

To get historical Bitcoin Metadata data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.history(self.dataset_symbol, 100, Resolution.DAILY)

# Dataset objects
history_bars = self.history[BlockchainBitcoinData](self.dataset_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
self.remove_security(self.dataset_symbol)
```

Example Applications

The Bitcoin Metadata dataset enables you to incorporate metadata from the Bitcoin blockchain into your strategies. Examples include the following strategies:

- Comparing mining and transaction statistics to provide insight on the supply-demand relationship of the Bitcoin blockchain service.
- Measuring the activity and popularity of the Bitcoin blockchain to predict the price movements of the Cryptocurrency.

Classic Algorithm Example

The following example algorithm tracks the transaction-to-hash-rate ratio of the Bitcoin network. The algorithm holds Bitcoin when the ratio increases. Otherwise, it holds dollars.

```py
from AlgorithmImports import *

class BlockchainBitcoinMetadataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Request BTCUSD as the trading vehicle on Bitcoin Metadata
        self.btcusd = self.add_crypto("BTCUSD", Resolution.MINUTE, Market.BITFINEX).symbol
        # Request Bitcoin Metadata for trade signal generation
        self.bitcoin_metadata_symbol = self.add_data(BitcoinMetadata, self.btcusd).symbol

        # Historical data
        history = self.history(BitcoinMetadata, self.bitcoin_metadata_symbol, 60, Resolution.DAILY)
        self.debug(f"We got {len(history)} items from our history request for {self.btcusd} Blockchain Bitcoin Metadata")

        # Cache the last supply-demand ratio for comparison
        self.last_demand_supply = None

    def on_data(self, slice: Slice) -> None:
        # Trade only based on updated Bitcoin Metadata
        data = slice.get(BitcoinMetadata)

        if self.bitcoin_metadata_symbol in data and data[self.bitcoin_metadata_symbol] != None and
data[self.bitcoin_metadata_symbol].hash_rate:
            # Calculate the supply-demand ratio to estimate the microeconomy structure of Bitcoin for scalp-trading
            # Transaction number as demand, hash production rate as supply
            current_demand_supply = data[self.bitcoin_metadata_symbol].numberof_transactions /
data[self.bitcoin_metadata_symbol].hash_rate

            # Comparing the average transaction-to-hash-rate ratio changes, buy Bitcoin if demand is higher than supply, sell vice versa
            if self.last_demand_supply != None and current_demand_supply > self.last_demand_supply:
                self.set_holdings(self.btcusd, 1)
            else:
                self.set_holdings(self.btcusd, 0)

            self.last_demand_supply = current_demand_supply
```

Framework Algorithm Example

The following example algorithm tracks the transaction-to-hash-rate ratio of the Bitcoin network. The algorithm holds Bitcoin when the ratio increases. Otherwise, it holds dollars.

```py
from AlgorithmImports import *

class BlockchainBitcoinMetadataFrameworkAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Universe contains only BTCUSD as the trading vehicle on Bitcoin Metadata
        self.add_universe_selection(
            ManualUniverseSelectionModel(
            Symbol.create("BTCUSD", SecurityType.CRYPTO, Market.BITFINEX)
        ))
        # Custom alpha model that emit insights based on Bitcoin Metadata
        self.add_alpha(BlockchainBitcoinMetadataAlphaModel())
        # Equally invest to evenly dissipate the capital concentration risk from non-sysmtematic risky events
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

class BlockchainBitcoinMetadataAlphaModel(AlphaModel):

    def __init__(self) -> None:
        self.bitcoin_metadata_symbol_by_symbol = {}
        # Cache the last supply-demand ratio for comparison
        self.last_demand_supply = {}

    def update(self, algorithm:QCAlgorithm, slice: Slice) -> List[Insight]:
        insights = []

        # Trade only based on updated Bitcoin Metadata
        data = slice.Get(BitcoinMetadata)

        for symbol, bitcoin_metadata_symbol in self.bitcoin_metadata_symbol_by_symbol.items():
            if data.contains_key(bitcoin_metadata_symbol) and data[bitcoin_metadata_symbol] != None and
data[bitcoin_metadata_symbol].hash_rate:
                # Calculate the supply-demand ratio to estimate the microeconomy structure of the crypto pair for scalp-trading
                # Transaction number as demand, hash production rate as supply
                current_demand_supply = data[bitcoin_metadata_symbol].numberof_transactions / data[bitcoin_metadata_symbol].hash_rate

                # Comparing the average transaction-to-hash-rate ratio changes, buy coin if demand is higher than supply
                if symbol in self.last_demand_supply and current_demand_supply > self.last_demand_supply[symbol]:
                    insights.append(Insight.price(symbol, timedelta(1), InsightDirection.UP))

                self.last_demand_supply[symbol] = current_demand_supply

        return insights

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            symbol = security.symbol

            # Request Bitcoin Metadata for trade signal generation
            bitcoin_metadata_symbol = algorithm.add_data(BitcoinMetadata, symbol).symbol

            self.bitcoin_metadata_symbol_by_symbol[symbol] = bitcoin_metadata_symbol

            # Historical data
            history = algorithm.history(BitcoinMetadata, bitcoin_metadata_symbol, 60, Resolution.DAILY)
```

Data Point Attributes

The Bitcoin Metadata dataset provides `BitcoinMetadata` objects, which have the following attributes:

Brain Language Metrics on Company Filings

Introduction

The Brain Language Metrics on Company Filings dataset provides the results of an NLP system that monitors several language metrics on 10-K and 10-Q company reports for US Equities. The data covers 5,000 US Equities, starts in January 2010, and is delivered on a daily frequency. The dataset is made of two parts; the first one includes the language metrics of the most recent 10-K or 10-Q report for each firm, namely:

1. Financial sentiment
2. Percentage of words belonging to financial domain classified by language types (e.g. “litigious” or “constraining” language)
3. Readability score
4. Lexical metrics such as lexical density and richness
5. Text statistics such as the report length and the average sentence length

The second part includes the differences between the two most recent 10-Ks or 10-Qs reports of the same period for each company, namely:

1. Difference of the various language metrics (e.g. delta sentiment, delta readability score, delta percentage of a specific language type etc.)
2. Similarity metrics between documents, also with respect to a specific language type (for example similarity with respect to “litigious” language or “uncertainty” language)

The analysis is available for the whole report and for specific sections of the report (e.g. Risk Factors and MD&A).

For more information, refer to Brain's summary paper .

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Brain Language Metrics on Company Filings dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Brain is a Research Company that creates proprietary datasets and algorithms for investment strategies, combining experience in financial markets with strong competencies in Statistics, Machine Learning, and Natural Language Processing. The founders share a common academic background of research in Physics as well as extensive experience in Financial markets.

Getting Started

The following snippet demonstrates how to request data from the Brain Language Metrics on Company Filings dataset:

```
self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
self.dataset_10k_symbol = self.add_data(BrainCompanyFilingLanguageMetrics10K , self.aapl).symbol
self.dataset_all_symbol = self.add_data(BrainCompanyFilingLanguageMetricsAll, self.aapl).symbol

self.universe_10k = self.add_universe(BrainCompanyFilingLanguageMetricsUniverse10K, self.universe_selection)
self.universe_all = self.add_universe(BrainCompanyFilingLanguageMetricsUniverseAll, self.universe_selection)
```

PY

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2010
Asset Coverage*	5,000 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

The coverage includes all assets since the start date. It increases over time.

Requesting Data

To add Brain Language Metrics on Company Filings data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
PY
class BrainCompanyFilingNLPDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2010, 1, 1)
        self.set_end_date(2021, 7, 8)
        self.set_cash(100000)

        self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
        self.dataset_10k_symbol = self.add_data(BrainCompanyFilingLanguageMetrics10K, self.aapl).symbol
        self.dataset_all_symbol = self.add_data(BrainCompanyFilingLanguageMetricsAll, self.aapl).symbol
```

Accessing Data

To get the current Brain Language Metrics on Company Filings data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_10k_symbol):
        data_point = slice[self.dataset_10k_symbol]
        self.log(f"{self.dataset_10k_symbol} report sentiment at {slice.time}: {data_point.report_sentiment.sentiment}")

    if slice.contains_key(self.dataset_all_symbol):
        data_point = slice[self.dataset_all_symbol]
        self.log(f"{self.dataset_all_symbol} report sentiment at {slice.time}: {data_point.report_sentiment.sentiment}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
PY
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.get(BrainCompanyFilingLanguageMetrics10K).items():
        self.log(f"{dataset_symbol} report sentiment at {slice.time}: {data_point.report_sentiment.sentiment}")

    for dataset_symbol, data_point in slice.get(BrainCompanyFilingLanguageMetricsAll).items():
        self.log(f"{dataset_symbol} report sentiment at {slice.time}: {data_point.report_sentiment.sentiment}")
```

Historical Data

To get historical Brain Language Metrics on Company Filings data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrames
ten_k_history_df = self.history(self.dataset_10k_symbol, 100, Resolution.DAILY)
all_history_df = self.history(self.dataset_all_symbol, 100, Resolution.DAILY)
history_df = self.history([self.dataset_10k_symbol, self.dataset_all_symbol], 100, Resolution.DAILY)

# Dataset objects
ten_k_history_bars = self.history[BrainCompanyFilingLanguageMetrics10K](self.dataset_10k_symbol, 100, Resolution.DAILY)
all_history_bars = self.history[BrainCompanyFilingLanguageMetricsAll](self.dataset_all_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on Brain Language Metrics on Company Filings data, call the `add_universe` method with the `BrainCompanyFilingLanguageMetricsUniverseAll` class or the `BrainCompanyFilingLanguageMetricsUniverse10K` class and a selection function.

```py
def initialize(self) -> None:
    self._universe = self.add_universe(BrainCompanyFilingLanguageMetricsUniverseAll, self.universe_selection)

def universe_selection(self, alt_coarse: List[BrainCompanyFilingLanguageMetricsUniverseAll]) -> List[Symbol]:
    return [d.symbol for d in alt_coarse \
                if d.report_sentiment.sentiment > 0 \
                and d.management_discussion_analysis_of_financial_condition_and_results_of_operations.sentiment > 0]
```

For more information about dynamic universes, see Universes .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `history` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```py
# DataFrame example where the columns are the universe object attributes:
history_df = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series example where the values are lists of the universe objects:
universe_history = self.history(self._universe, 30, Resolution.DAILY)
for (_, time), universeDay in universe_history.items():
    for language_metrics in universeDay:
        self.log(f"{language_metrics.symbol} sentiment at {language_metrics.end_time}: {language_metrics.report_sentiment.sentiment}")
```

Historical Universe Data in Research

To get historical universe data in research, call the `universe_history` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```py
# DataFrame example where the columns are the universe object attributes:
history_df = qb.universe_history(universe, qb.time-timedelta(30), qb.time, flatten=True)

# Series example where the values are lists of the universe objects:
universe_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (_, time), universeDay in universe_history.items():
    for language_metrics in universeDay:
        print(f"{language_metrics.symbol} sentiment at {language_metrics.end_time}: {language_metrics.report_sentiment.sentiment}")
```

You can call the `history` method in Research.

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```py
self.remove_security(self.dataset_10k_symbol)
self.remove_security(self.dataset_all_symbol)
```

If you subscribe to Brain Language Metrics on Company Filings data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Brain Language Metrics on Company Filings dataset enables you to test strategies using language metrics and their differences gathered from 10K and 10Q reports. Examples include the following strategies:

- Using the similarity among reports to determine position sizing of securities. Some examples are discussed in Lazy Prices, Cohen et al. 2018 and The Positive Similarity of Company Filings and the Cross-section of Stock Returns, M. Padyšák 2020 .
- Using the sentiment of the latest report to determine the portfolio allocation to give to each security in the universe.
- Using levels of uncertainty, readability, or litigious language in the report to determine position sizing of securities.

Classic Algorithm Example

The following example algorithm buys Apple when the sentiment of their 10K report is positive. Otherwise, it holds cash.

```py
from AlgorithmImports import *

class BrainCompanyFilingNLPDataAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Requesting data -- we aim to obtain a sentiment score from the company filings
        # Combining both fundamental and sentiment factor, as well as past performance and future provision
        self._symbol = self.add_equity("AAPL", Resolution.DAILY).symbol
        self.dataset_symbol = self.add_data(BrainCompanyFilingLanguageMetrics10K , self._symbol).symbol

        # Historical data
        history = self.history(self.dataset_symbol, 365, Resolution.DAILY)
        self.debug(f"We got {len(history)} items from our history request for {self.dataset_symbol}")

    def on_data(self, data):
        # Trade base on the updated report sentiment
        if data.contains_key(self.dataset_symbol):
            sentiment = data[self.dataset_symbol].report_sentiment.sentiment
            # Buy for a positive sentiment score for the positive return projection
            self.set_holdings(self._symbol, int(sentiment > 0))
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of US Equities that have positive sentiment in their 10K report and then forms an equal-weighted portfolio:

```
PY
from AlgorithmImports import *

class BrainCompanyFilingNLPDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.settings.free_portfolio_value_percentage = 0.1
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        self.universe_settings.resolution = Resolution.DAILY

Brain

Brain ML Stock Ranking

Introduction

The Brain ML Stock Ranking dataset by Brain generates a daily ranking for US Equities based on their predicted ranking of future returns relative to the universe median across four-time horizons: next 2, 3, 5, 10, and 21 days (one trading month). The data covers 1,000 US Equities (universe updated yearly by including the largest 1,000 US companies of the previous year), starts in January 2010, and is delivered on a daily frequency. This dataset is created by a voting scheme of machine learning classifiers that non-linearly combine a variety of features with a series of techniques aimed at mitigating the well-known overfitting problem for financial data with a low signal-to-noise ratio. Examples of features are time-varying stock-specific features like price and volume-related metrics or fundamentals; time-fixed stock-specific features like the sector and other database information; market regime features such as volatility and other financial stress indicators; calendar features representing possible anomalies, for example, the month of the year.

More precisely the ML Stock Ranking score is related to the confidence of a Machine Learning classifier in predicting top or bottom quintile returns for the next N trading days (e.g. next 21 trading days) for a stock with the respect to the median of the universe and ranges from -1 to +1.

A negative score means that the system is more confident that the stock belongs to the lower returns quintile, a positive score means that the system is more confident that the stock belongs to the higher returns quintile. It is important to note that the score has a meaning only if used to compare different stocks to perform a ranking.

Typical use is to download the score for a large stock universe for a given day, e.g. 500 stocks or the full universe of 1000 stocks, order the stocks by mlAlpha score and go long the top K stocks, or build a long-short strategy going long the top K and short the bottom K stocks.

For more information, refer to Brain's summary paper .

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Brain ML Stock Ranking dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Brain is a Research Company that creates proprietary datasets and algorithms for investment strategies, combining experience in financial markets with strong competencies in Statistics, Machine Learning, and Natural Language Processing. The founders share a common academic background of research in Physics as well as extensive experience in Financial markets.

Getting Started

The following snippet demonstrates how to request data from the Brain ML Stock Ranking dataset:

```
self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
self.dataset_symbol = self.add_data(BrainStockRanking2Day, self.aapl).symbol

self._universe = self.add_universe(BrainStockRankingUniverse, self.universe_selection)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2010
Asset Coverage*	1,000 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

The coverage includes all assets since the start date. It increases over time.

Requesting Data

To add Brain ML Stock Ranking data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
PY
class BrainMLRankingDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2021, 1, 1)
        self.set_end_date(2021, 7, 8)
        self.set_cash(100000)

        self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
        self.two_day_symbol = self.add_data(BrainStockRanking2Day, self.aapl).symbol
        self.three_day_symbol = self.add_data(BrainStockRanking3Day, self.aapl).symbol
        self.five_day_symbol = self.add_data(BrainStockRanking5Day, self.aapl).symbol
        self.ten_day_symbol = self.add_data(BrainStockRanking10Day, self.aapl).symbol
        self.month_symbol = self.add_data(BrainStockRanking21Day, self.aapl).symbol
```

Accessing Data

To get the current Brain ML Stock Ranking data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.two_day_symbol):
        data_point = slice[self.two_day_symbol]
        self.log(f"{self.two_day_symbol} rank at {slice.time}: {data_point.rank}")

    if slice.contains_key(self.three_day_symbol):
        data_point = slice[self.three_day_symbol]
        self.log(f"{self.three_day_symbol} rank at {slice.time}: {data_point.rank}")

    if slice.contains_key(self.five_day_symbol):
        data_point = slice[self.five_day_symbol]
        self.log(f"{self.five_day_symbol} rank at {slice.time}: {data_point.rank}")

    if slice.contains_key(self.ten_day_symbol):
        data_point = slice[self.ten_day_symbol]
        self.log(f"{self.ten_day_symbol} rank at {slice.time}: {data_point.rank}")

    if slice.contains_key(self.month_symbol):
        data_point = slice[self.month_symbol]
        self.log(f"{self.month_symbol} rank at {slice.time}: {data_point.rank}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.get(BrainStockRanking2Day).items():
        self.log(f"{dataset_symbol} rank at {slice.time}: {data_point.rank}")

    for dataset_symbol, data_point in slice.get(BrainStockRanking3Day).items():
        self.log(f"{dataset_symbol} rank at {slice.time}: {data_point.rank}")

    for dataset_symbol, data_point in slice.get(BrainStockRanking5Day).items():
        self.log(f"{dataset_symbol} rank at {slice.time}: {data_point.rank}")

    for dataset_symbol, data_point in slice.get(BrainStockRanking10Day).items():
        self.log(f"{dataset_symbol} rank at {slice.time}: {data_point.rank}")

    for dataset_symbol, data_point in slice.get(BrainStockRanking21Day).items():
        self.log(f"{dataset_symbol} rank at {slice.time}: {data_point.rank}")
```

Historical Data

To get historical Brain ML Stock Ranking data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
# DataFrames
two_day_history_df = self.history(self.two_day_symbol, 100, Resolution.DAILY)
three_day_history_df = self.history(self.three_day_symbol, 100, Resolution.DAILY)
five_day_history_df = self.history(self.five_day_symbol, 100, Resolution.DAILY)
ten_day_history_df = self.history(self.ten_day_symbol, 100, Resolution.DAILY)
thirty_day_history_df = self.history(self.month_symbol, 100, Resolution.DAILY)
history_df = self.history([self.two_day_symbol,
                           self.three_day_symbol,
                           self.five_day_symbol,
                           self.ten_day_symbol,
                           self.month_symbol], 100, Resolution.DAILY)

# Dataset objects
two_day_history_bars = self.history[BrainStockRanking2Day](self.two_day_symbol, 100, Resolution.DAILY)
three_day_history_bars = self.history[BrainStockRanking3Day](self.three_day_symbol, 100, Resolution.DAILY)
five_day_history_bars = self.history[BrainStockRanking5Day](self.five_day_symbol, 100, Resolution.DAILY)
ten_day_history_bars = self.history[BrainStockRanking10Day](self.ten_day_symbol, 100, Resolution.DAILY)
month_history_bars = self.history[BrainStockRanking21Day](self.month_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on Brain ML Stock Ranking data, call the `add_universe` method with the `BrainStockRankingUniverse` class and a selection function.

```
def initialize(self) -> None:
    self._universe = self.add_universe(BrainStockRankingUniverse, self.universe_selection)

def universe_selection(self, alt_coarse: List[BrainStockRankingUniverse]) -> List[Symbol]:
    return [d.symbol for d in alt_coarse \
                if d.rank2_days > 0 \
                and d.rank3_days > 0 \
                and d.rank5_days > 0]
```

For more information about dynamic universes, see Universes .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `history` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```
PY

# DataFrame example where the columns are the BrainStockRankingUniverse attributes:
history_df = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series example where the values are lists of BrainStockRankingUniverse objects:
universe_history = self.history(self._universe, 30, Resolution.DAILY)
for (_, time), ranks in universe_history.items():
    for rank in ranks:
        self.log(f"{rank.symbol} 2-day rank at {rank.end_time}: {rank.rank2_days}")
```

Historical Universe Data in Research

To get historical universe data in research, call the `universe_history` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```
PY

# DataFrame example where the columns are the BrainStockRankingUniverse attributes:
history_df = qb.universe_history(universe, qb.time-timedelta(30), qb.time, flatten=True)

# Series example where the values are lists of BrainStockRankingUniverse objects:
universe_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (_, time), ranks in universe_history.items():
    for rank in ranks:
        print(f"{rank.symbol} 2-day rank at {rank.end_time}: {rank.rank2_days}")
```

You can call the `history` method in Research.

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
PY

self.remove_security(self.two_day_symbol)
self.remove_security(self.three_day_symbol)
self.remove_security(self.five_day_symbol)
self.remove_security(self.ten_day_symbol)
self.remove_security(self.month_symbol)
```

If you subscribe to Brain ML Stock Ranking data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Brain ML Stock Ranking dataset enables you to test strategies using the machine learning ranking provided by Brain. Examples include the following strategies:

- Constructing a portfolio of securities with each security's weight in the portfolio reflecting its Brain ML Stock Ranking
- Buying stocks with the largest Brain ML Stock Ranking
- Building a market-neutral strategy based on the top N and bottom N stocks in the Brain ML Stock Ranking

Classic Algorithm Example

The following example algorithm constructs a portfolio where the weight of each security in the portfolio is scaled based on its Brain ML Ranking. It gives a larger allocation to securities that have a higher Brain ML Ranking.

```py
from AlgorithmImports import *

class BrainMLRankingDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # We cherry picked 5 largest stocks, high trading volume provides better information and credibility for ML ranking
        tickers = ["AAPL", "TSLA", "MSFT", "F", "KO"]
        self.symbol_by_dataset_symbol = {}
        for ticker in tickers:
            # Requesting data to get 2 days estimated relative ranking
            symbol = self.add_equity(ticker, Resolution.DAILY).symbol
            dataset_symbol = self.add_data(BrainStockRanking2Day, symbol).symbol
            self.symbol_by_dataset_symbol[dataset_symbol] = symbol

            # Historical data
            history = self.history(dataset_symbol, 365, Resolution.DAILY)
            self.debug(f"We got {len(history)} items from our history request for {symbol}")

    def on_data(self, slice: Slice) -> None:
        # Collect rankings for all selected symbols for ranking them
        points = slice.Get(BrainStockRanking2Day)
        if points is None:
            return
        symbols = []
        ranks = []
        for point in points.Values:
            symbols.append(self.symbol_by_dataset_symbol[point.symbol])
            ranks.append(point.rank)

        # Rank each symbol's Brain ML ranking relative to each other for positional sizing
        if len(ranks) == 0:
            return
        ranks = [sorted(ranks).index(rank) + 1 for rank in ranks]

        # Place orders according to the ML ranking, the better the rank, the higher the estimated return and hence weight
        for i, rank in enumerate(ranks):
            weight = rank / sum(ranks)
            self.set_holdings(symbols[i], weight)
```

Framework Algorithm Example

The following example algorithm constructs a portfolio where the weight of each security in the portfolio is scaled based on its Brain ML Ranking. It gives a larger allocation to securities that have a higher Brain ML Ranking.

PY

```
from AlgorithmImports import *

class BrainMLRankingDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        self.universe_settings.resolution = Resolution.DAILY
        # Select based on ML ranking data
        self.add_universe(BrainStockRankingUniverse, self.universe_selection)

        self.add_alpha(BrainMLRankingAlphaModel())

        self.set_portfolio_construction(InsightWeightingPortfolioConstructionModel())

        self.add_risk_management(NullRiskManagementModel())

        self.set_execution(ImmediateExecutionModel())

    def universe_selection(self, alt_coarse: List[BrainStockRankingUniverse]) -> List[Symbol]:
        # Select the ones that expected to out-perform the median of the whole market in 2-3 days
        return [d.symbol for d in alt_coarse \
                if d.Rank2Days > 0.2  \
                and d.Rank3Days > 0.2]

class BrainMLRankingAlphaModel(AlphaModel):

    symbol_data_by_symbol = {}
    symbol_by_dataset_symbol = {}

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        insights = []

        # Collect rankings for all selected symbols for ranking them
        points = slice.Get(BrainStockRanking2Day)
        if points is None:
            return []
        symbols = []
        ranks = []
        for point in points.Values:
            symbols.append(self.symbol_by_dataset_symbol[point.symbol])
            ranks.append(point.rank)

        # Rank each symbol's Brain ML ranking relative to each other for positional sizing
        if len(ranks) == 0:
            return []
        ranks = [sorted(ranks).index(rank) + 1 for rank in ranks]

        # Place orders according to the ML ranking, the better the rank, the higher the estimated return and hence weight
        for i, rank in enumerate(ranks):
            weight = rank / sum(ranks)
            insights.append(Insight.price(symbols[i], timedelta(days=7), InsightDirection.UP, None, None, None, weight))

        return insights

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            symbol = security.symbol
            symbol_data = SymbolData(algorithm, symbol)
            self.symbol_data_by_symbol[symbol] = symbol_data
            self.symbol_by_dataset_symbol[symbol_data.dataset_symbol] = symbol

        for security in changes.removed_securities:
            symbol_data = self.symbol_data_by_symbol.pop(security.symbol, None)
            if symbol_data:
                symbol_data.dispose()

            for dataset_symbol, symbol in self.symbol_by_dataset_symbol.items():
                if symbol == security.symbol:
                    self.symbol_by_dataset_symbol.pop(dataset_symbol)
                    break

class SymbolData:
    def __init__(self, algorithm, symbol):
        self.algorithm = algorithm

        # Requesting data to get 2 days estimated relative ranking
        self.dataset_symbol = algorithm.add_data(BrainStockRanking2Day, symbol).symbol

        # Historical data
        history = algorithm.history(self.dataset_symbol, 365, Resolution.DAILY)
        algorithm.debug(f"We got {len(history)} items from our history request for {symbol}")

    def dispose(self):
        # Unsubscribe from the Brain ML Ranking feed for this security to release computation resources
        self.algorithm.remove_security(self.dataset_symbol)
```

Research Example

The following example lists US Equities having the highest 2-day rank.

```py
qb = QuantBook()

# Requesting Data
aapl = qb.add_equity("AAPL", Resolution.DAILY).symbol
symbol = qb.add_data(BrainStockRanking2Day, aapl).symbol

# Historical data
history = qb.history(BrainStockRanking2Day, symbol, 30, Resolution.DAILY)
for (symbol, time), row in history.iterrows():
    print(f"{symbol} rank at {time}: {row['rank']}")

# Add Universe Selection
def universe_selection(alt_coarse: List[BrainStockRankingUniverse]) -> List[Symbol]:
    return [d.symbol for d in sorted(alt_coarse, key=lambda x: x.Rank2Days, reverse=True)[:10]]

universe = qb.add_universe(BrainStockRankingUniverse, universe_selection)

# Historical Universe data
universe_history = qb.universe_history(universe, qb.time-timedelta(5), qb.time)
for (_, time), ranks in universe_history.items():
    for rank in ranks:
        print(f"{rank.symbol} 2-day rank at {rank.end_time}: {rank.Rank2Days}")
```

BrainStockRankingUniverse Attributes

`BrainStockRankingUniverse` objects have the following attributes:

Brain

Brain Sentiment Indicator

Introduction

The Brain Sentiment Indicator dataset by Brain tracks the public sentiment around US Equities. The data covers 4,500 US Equities, starts in August 2016, and is delivered on a daily frequency. This dataset is created by analyzing financial news using Natural Language Processing techniques while taking into account the similarity and repetition of news on the same topic. The sentiment score assigned to each stock ranges from -1 (most negative) to +1 (most positive). The sentiment score corresponds to the average sentiment for each piece of news. The score is updated daily and is available on two time scales: 7 days and 30 days. For more information, see Brain's summary paper .

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Brain Sentiment Indicator dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Brain is a Research Company that creates proprietary datasets and algorithms for investment strategies, combining experience in financial markets with strong competencies in Statistics, Machine Learning, and Natural Language Processing. The founders share a common academic background of research in Physics as well as extensive experience in Financial markets.

Getting Started

The following snippet demonstrates how to request data from the Brain Sentiment Indicator dataset:

```
PY
self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
self.dataset_7day_symbol = self.add_data(BrainSentimentIndicator7Day, self.aapl).symbol
self.dataset_30day_symbol = self.add_data(BrainSentimentIndicator30Day, self.aapl).symbol

self._universe = self.add_universe(BrainSentimentIndicatorUniverse, self.universe_selection)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	August 2016
Asset Coverage*	4,500 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

The coverage includes all assets since the start date. It increases over time.

Requesting Data

To add Brain Sentiment Indicator data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
class BrainSentimentDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2021, 7, 8)
        self.set_cash(100000)

        symbol = self.add_equity("AAPL", Resolution.DAILY).symbol
        self.dataset_7day_symbol = self.add_data(BrainSentimentIndicator7Day, symbol).symbol
        self.dataset_30day_symbol = self.add_data(BrainSentimentIndicator30Day, symbol).symbol
```

Accessing Data

To get the current Brain Sentiment Indicator data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_7day_symbol):
        data_point = slice[self.dataset_7day_symbol]
        self.log(f"{self.dataset_7day_symbol} sentiment at {slice.time}: {data_point.sentiment}")

    if slice.contains_key(self.dataset_30day_symbol):
        data_point = slice[self.dataset_30day_symbol]
        self.log(f"{self.dataset_30day_symbol} sentiment at {slice.time}: {data_point.sentiment}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.get(BrainSentimentIndicator7Day).items():
        self.log(f"{dataset_symbol} sentiment at {slice.time}: {data_point.sentiment}")

    for dataset_symbol, data_point in slice.get(BrainSentimentIndicator30Day).items():
        self.log(f"{dataset_symbol} sentiment at {slice.time}: {data_point.sentiment}")
```

Historical Data

To get historical Brain Sentiment Indicator data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
# DataFrames
week_history_df = self.history(self.dataset_7day_symbol, 100, Resolution.DAILY)
month_history_df = self.history(self.dataset_30day_symbol, 100, Resolution.DAILY)
history_df = self.history([self.dataset_7day_symbol, self.dataset_30day_symbol], 100, Resolution.DAILY)

# Dataset objects
week_history_bars = self.history[BrainSentimentIndicator7Day](self.dataset_7day_symbol, 100, Resolution.DAILY)
month_history_bars = self.history[BrainSentimentIndicator30Day](self.dataset_30day_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on Brain Sentiment Indicator data, call the `add_universe` method with the `BrainSentimentIndicatorUniverse` class and a selection function.

```
def initialize(self) -> None:
    self._universe = self.add_universe(BrainSentimentIndicatorUniverse, self.universe_selection)

def universe_selection(self, alt_coarse: List[BrainSentimentIndicatorUniverse]) -> List[Symbol]:
    return [d.symbol for d in alt_coarse \
                if d.total_article_mentions7_days > 0 \
                and d.sentiment7_days]
```

The Brain Sentiment Indicator universe runs at 7 AM Eastern Time (ET) in live trading. For more information about dynamic universes, see Universes .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `history` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame example where the columns are the BrainSentimentIndicatorUniverse attributes:
history_df = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series example where the values are lists of BrainSentimentIndicatorUniverse objects:
universe_history = self.history(self._universe, 30, Resolution.DAILY)
for (_, time), sentiments in universe_history.items():
    for sentiment in sentiments:
        self.log(f"{sentiment.symbol} 7-day sentiment at {sentiment.end_time}: {sentiment.sentiment7_days}")
```

Historical Universe Data in Research

To get historical universe data in research, call the `universe_history` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame example where the columns are the BrainSentimentIndicatorUniverse attributes:
history_df = qb.universe_history(universe, qb.time-timedelta(30), qb.time, flatten=True)

# Series example where the values are lists of BrainSentimentIndicatorUniverse objects:
universe_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (_, time), sentiments in universe_history.items():
    for sentiment in sentiments:
        print(f"{sentiment.symbol} 7-day sentiment at {sentiment.end_time}: {sentiment.sentiment7_days}")
```

You can call the `history` method in Research.

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
PY
self.remove_security(self.dataset_7day_symbol)
self.remove_security(self.dataset_30day_symbol)
```

If you subscribe to Brain Sentiment Indicator data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Brain Sentiment Indicator dataset enables you to incorporate sentiment from financial news sources into your strategies. Examples include the following strategies:

- Buying when the public sentiment for a security is increasing
- Short selling when the public sentiment for a security is decreasing
- Scaling the position sizing of securities based on how many times they are mentioned in financial news articles
- Sector rotation based on news sentiment

Classic Algorithm Example

The following example algorithm buys Apple when the 30-day Brain Sentiment indicator increases. Otherwise, it remains in cash.

```
from AlgorithmImports import *

class BrainSentimentDataAlgorithm(QCAlgorithm):

    latest_sentiment_value = None
    target_holdings = 0

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Requesting the processed longer term (30-day) sentiment score data for sentiment trading
        self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
        self.dataset_symbol = self.add_data(BrainSentimentIndicator30Day, self.aapl).symbol

        # Historical data
        history = self.history(self.dataset_symbol, 100, Resolution.DAILY)
        self.debug(f"We got {len(history)} items from our history request for {self.dataset_symbol}")
        if history.empty:
            return

        # Warm up historical sentiment values, cache for comparing last sentiment score to trade, making it immediately tradable signal
        previous_sentiment_values = history.loc[self.dataset_symbol].sentiment.values
        for sentiment in previous_sentiment_values:
            self.update(sentiment)

    def update(self, sentiment: float) -> None:
        # Comparing the last sentiment score and decide to buy if the sentiment increases to ride the popularity
        if self.latest_sentiment_value is not None:
            self.target_holdings = int(sentiment > self.latest_sentiment_value)
        self.latest_sentiment_value = sentiment

    def on_data(self, slice: Slice) -> None:
        # Update trade direction based on updated data
        if slice.contains_key(self.dataset_symbol):
            sentiment = slice[self.dataset_symbol].sentiment
            self.update(sentiment)

        # Ensure we have security data in the current slice to avoid stale fill
        if not (slice.contains_key(self.aapl) and slice[self.aapl] is not None):
            return

        # Buy if sentiment increase, liquidate otherwise to ride on the popularity of the equity
        if self.target_holdings != self.portfolio.invested:
            self.set_holdings(self.aapl, self.target_holdings)
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of US Equities that have been mentioned in an article over the last seven days. It then buys the subset of Equities that have increasing sentiment and forms an equal-weighted portfolio.

```
from AlgorithmImports import *

class BrainSentimentDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 10)
        self.set_cash(100000)

        self.settings.minimum_order_margin_portfolio_percentage = 0
        self.universe_settings.resolution = Resolution.DAILY
        # Filter base on sentiment data
        self.add_universe(BrainSentimentIndicatorUniverse, self.universe_selection)

        self.add_alpha(BrainSentimentAlphaModel())

        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

        self.add_risk_management(NullRiskManagementModel())

        self.set_execution(ImmediateExecutionModel())

    def universe_selection(self, alt_coarse: List[BrainSentimentIndicatorUniverse]) -> List[Symbol]:
        # Filter for any sentiment on last 7 days to trade on sentiment news
        return [d.symbol for d in alt_coarse \
        if d.SentimentalArticleMentions7Days is not None and d.SentimentalArticleMentions7Days > 0]

class BrainSentimentAlphaModel(AlphaModel):

    symbol_data_by_symbol = {}

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        insights = []
```

```
        insights = []

        for symbol, symbol_data in self.symbol_data_by_symbol.items():
            # Update trade direction based on updated data
            if slice.contains_key(symbol_data.dataset_symbol) and slice[symbol_data.dataset_symbol] is not None:
                sentiment = slice[symbol_data.dataset_symbol].sentiment
                symbol_data.update(sentiment)

            # Ensure we have security data in the current slice to avoid stale fill
            if not (slice.contains_key(symbol) and slice[symbol] is not None):
                continue

            # Buy if sentiment increase, liquidate otherwise to ride on the popularity of the equity
            if symbol_data.target_direction == InsightDirection.UP != algorithm.portfolio[symbol].invested:
                insights.append(Insight.price(symbol, timedelta(days=100), symbol_data.target_direction))
        return insights

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            symbol = security.symbol
            self.symbol_data_by_symbol[symbol] = SymbolData(algorithm, symbol)

        for security in changes.removed_securities:
            symbol_data = self.symbol_data_by_symbol.pop(security.symbol, None)
            if symbol_data:
                symbol_data.dispose()

class SymbolData:

    target_direction = InsightDirection.FLAT
    _latest_sentiment_value = None

    def __init__(self, algorithm: QCAlgorithm, symbol: Symbol) -> None:
        self.algorithm = algorithm

        # Requesting the processed longer term (30-day) sentiment score data for sentiment trading
        self.dataset_symbol = algorithm.add_data(BrainSentimentIndicator30Day, symbol).symbol

        # Historical data
        history = algorithm.history(self.dataset_symbol, 100, Resolution.DAILY)
        if history.empty or 'sentiment' not in history.columns:
            return

        # Warm up historical sentiment values, cache for comparing last sentiment score to trade, making it immediately tradable signal
        previous_sentiment_values = history.loc[self.dataset_symbol].sentiment.values
        for sentiment in previous_sentiment_values:
            self.update(sentiment)

    def dispose(self) -> None:
        # Unsubscribe from the Brain Sentiment feed for this security to release computational resources
        self.algorithm.remove_security(self.dataset_symbol)

    def update(self, sentiment: float) -> None:
        # Comparing the last sentiment score and decide to buy if the sentiment increases to ride the popularity
        if self._latest_sentiment_value is not None:
            if sentiment > self._latest_sentiment_value:
                self.target_direction = InsightDirection.UP
            else:
                self.target_direction = InsightDirection.FLAT
        self._latest_sentiment_value = sentiment
```

Research Example

The following example lists US Equities having the highest 7-day sentiment.

```
qb = QuantBook()

# Requesting Data
aapl = qb.add_equity("AAPL", Resolution.DAILY).symbol
symbol = qb.add_data(BrainSentimentIndicator30Day, aapl).symbol

# Historical data
history = qb.history(BrainSentimentIndicator30Day, symbol, 30, Resolution.DAILY)
for (symbol, time), row in history.iterrows():
    print(f"{symbol} sentiment at {time}: {row['sentiment']}")

# Add Universe Selection
def universe_selection(alt_coarse: List[BrainSentimentIndicatorUniverse]) -> List[Symbol]:
    return [d.symbol for d in sorted([x for x in alt_coarse if x.SentimentalArticleMentions7Days],
        key=lambda x: x.SentimentalArticleMentions7Days, reverse=True)[:10]]

universe = qb.add_universe(BrainSentimentIndicatorUniverse, universe_selection)

# Historical Universe data
universe_history = qb.universe_history(universe, qb.time-timedelta(5), qb.time)
for (_, time), sentiments in universe_history.items():
    for sentiment in sentiments:
        print(f"{sentiment.symbol} 7-day sentiment at {sentiment.end_time}: {sentiment.SentimentalArticleMentions7Days}")
```

Data Point Attributes

The Brain Sentiment Indicator dataset provides `BrainSentimentIndicatorBase` and `BrainSentimentIndicatorUniverse` objects.

BrainSentimentIndicatorBase Attributes

`BrainSentimentIndicatorBase` objects have the following attributes:

BrainSentimentIndicatorUniverse Attributes

`BrainSentimentIndicatorUniverse` objects have the following attributes:

Brain

Brain Wikipedia Page Views

Introduction

The Brain Wikipedia Page Views dataset by Brain tracks investor attention toward large U.S. equities by monitoring traffic on company Wikipedia pages. The dataset covers approximately 1,000 of the largest U.S. companies, broadly corresponding to the Russell 1000, and is available starting from February 2023. Data is delivered at a daily frequency.

The dataset is constructed by analyzing the number of views on each company's Wikipedia page, including both the main page and any secondary pages that redirect to it. Only English-language Wikipedia pages are considered. The data is published daily, typically by 12:00 PM UTC, and reflects attention metrics calculated relative to the reporting date.

In addition to raw page-view counts, the dataset includes buzz metrics, which normalize current attention levels relative to historical behavior. Buzz scores are computed as the distance between current page views and the company's own historical average over the previous six months, expressed in units of standard deviations. As a result, positive buzz values indicate unusually high attention, while negative values indicate lower-than-normal attention.

Metrics are provided across multiple time horizons, including 1-day, 7-day, and 30-day rolling windows, enabling users to study short-term spikes in attention as well as more persistent trends. These features make the dataset well-suited for research into investor attention, behavioral finance signals, event-driven strategies, and alpha models that incorporate information demand.

This dataset depends on the US Equity Security Master dataset, which provides essential information such as symbol mappings, corporate actions, and identifier consistency required for accurate historical analysis and backtesting.

For more information about the Brain Wikipedia Page Views dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Brain is a Research Company that creates proprietary datasets and algorithms for investment strategies, combining experience in financial markets with strong competencies in Statistics, Machine Learning, and Natural Language Processing. The founders share a common academic background of research in Physics as well as extensive experience in Financial markets.

Getting Started

The following snippet demonstrates how to request data from the Brain Wikipedia Page Views dataset:

```PY
self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
self.dataset_symbol = self.add_data(BrainWikipediaPageViews, self.aapl).symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	February 2023
Asset Coverage*	~1,000 US Equities (approximately Russell 1000)
Data Density	Sparse
Resolution	Daily
Timezone	UTC

* The coverage includes the largest U.S. equities since the start date and may evolve over time.

Requesting Data

To add Brain Wikipedia Page Views Indicator data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
PY
class BrainWikipediaPageViews(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2021, 1, 1)
        self.set_end_date(2021, 7, 8)
        self.set_cash(100000)
        self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
        self.dataset_symbol = self.add_data(BrainWikipediaPageViews, self.aapl).symbol
```

Accessing Data

To get the current Brain Wikipedia Page Views Indicator data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.log(f"{self.dataset_symbol} sentiments at {slice.time}: {data_point.NumberViews1}, {data_point.Buzz1}"
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
PY
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.get(BrainWikipediaPageViews).items():
         self.log(f"{dataset_symbol} metric at {slice.time}: {data_point.NumberViews1} , {data_point.Buzz1}")
```

Historical Data

To get historical Brain Wikipedia Page Views data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY
history_df = self.history(self.dataset_symbol, 100, Resolution.DAILY)
```

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
PY
self.remove_security(self.dataset_symbol)
```

Example Applications

The Brain Wikipedia Page Views dataset enables you to incorporate investor attention signals derived from Wikipedia traffic into your strategies. Examples include the following strategies:

- Buying securities that experience unusually high spikes in Wikipedia page views, indicating elevated public interest.
- Avoiding or reducing exposure to securities with declining or abnormally low attention relative to their historical baseline.
- Scaling position sizes based on short-term or long-term attention intensity using page view and buzz metrics.
- Building cross-sectional ranking strategies that favor stocks with sustained increases in public visibility.

Classic Algorithm Example

The following example algorithm ranks large-cap U.S. stocks daily using Brain Wikipedia Page Views attention and buzz metrics, then allocates portfolio weights proportionally to each stock's relative attention score.

```py
from AlgorithmImports import *

class BrainWikipediaPageViewsRankingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2025, 1, 1)
        self.set_end_date(2025, 11, 23)
        self.set_cash(100000)

        # Seed prices so we don't get "no price" trading errors
        self.settings.seed_initial_prices = True

        # We cherry-picked 5 largest stocks, high trading volume provides better information and credibility for ML ranking
        tickers = ["AAPL", "TSLA", "MSFT", "F", "KO"]

        for ticker in tickers:
            # Requesting data to get 2 days estimated relative ranking
            equity = self.add_equity(ticker, Resolution.DAILY)
            equity.dataset_symbol = self.add_data(BrainWikipediaPageViews, equity.symbol).symbol

            # Historical data
            history = self.history(equity.dataset_symbol, 365, Resolution.DAILY)
            self.debug(f"We got {len(history)} items from our history request for {equity.symbol}")

    def on_data(self, slice: Slice) -> None:
        points = slice.get(BrainWikipediaPageViews)

        if not points:
            return

        scores = {}

        for point in points.Values:
            # Example composite signal:
            number_of_views = point.NumberViews1 if point.NumberViews1 else 0
            buzz1day = point.Buzz1 if point.Buzz1 else 0

            symbol = point.symbol.underlying
            scores[symbol] = buzz1day * math.sqrt(number_of_views)

        if len(scores) == 0:
            return

        # Rank by score (higher score = better)
        ranked = sorted(scores.items(), key=lambda x: x[1], reverse=True)

        # Convert ranks to weights (same style as your example)
        ranks = list(range(len(ranked), 0, -1))  # best gets highest rank number
        denom = sum(ranks)
        top = ", ".join([f"{sym.value}:{sc:.4f}" for sym, sc in ranked[:3]])
        self.debug(f"{self.time.date()} top: {top}")

        # Place orders according to the ML ranking, the better the rank, the higher the estimated return and hence weight
        for i, (sym, sc) in enumerate(ranked):
            w = ranks[i] / denom
            self.set_holdings(sym, w)
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of liquid U.S. equities, ranks them daily using Brain Wikipedia Page Views attention and buzz metrics, and emits weighted bullish insights for the most attention-driven stocks using the Alpha Framework.

```py
from AlgorithmImports import *
import math

class BrainWikipediaPageViewsFrameworkRankingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2025, 1, 1)
        self.set_end_date(2025, 11, 23)
        self.set_cash(100000)

        self.universe_settings.resolution = Resolution.DAILY

        # Universe: pick liquid names
        self.add_universe(self._select)
        alpha = BrainWikipediaPageViewsRankingAlpha()
        self.add_alpha(alpha)

        self.schedule.on(
            self.date_rules.every_day(),
            self.time_rules.at(9, 0),
            alpha.emit_insights
        )

        self.set_portfolio_construction(InsightWeightingPortfolioConstructionModel())
        self.add_risk_management(NullRiskManagementModel())
        self.set_execution(ImmediateExecutionModel())
```

```
        self.set_warmup(30, Resolution.DAILY)

    def _select(self, fundamental: List[Fundamental]) -> List[Symbol]:
        # Liquid universe
        filtered = [c for c in fundamental if c.market_cap and c.price > 10]
        filtered.sort(key=lambda c: c.dollar_volume, reverse=True)

        # Keep it manageable
        return [c.symbol for c in filtered[:50]]

class BrainWikipediaPageViewsRankingAlpha(AlphaModel):
    def __init__(self):
        self.symbol_data_by_symbol = {}
        self.symbol_by_dataset_symbol = {}

        # Cache latest score per equity symbol
        self.latest_scores = {}     # Symbol -> float
        self.last_score_date = None # date of the latest cache refresh (algorithm.time.date())

        # Store algorithm reference for scheduled emission
        self.algorithm = None

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        self.algorithm = algorithm

```

Research Example

The following example retrieves historical Brain Wikipedia Page Views data for Apple and prints the daily number of Wikipedia page views over the past six months.

```
PY
qb = QuantBook()
# Requesting Data
aapl = qb.AddEquity("AAPL", Resolution.Daily).Symbol
symbol = qb.AddData(BrainWikipediaPageViews, aapl).Symbol

# Historical data
history = qb.History(BrainWikipediaPageViews, symbol, 180, Resolution.Daily)
for (symbol, time), row in history.iterrows():
    print(f"{symbol} views at {time}: {row['numberviews1']}")
```

Data Point Attributes

The Brain Wikipedia Page Views dataset provides `BrainWikipediaPageViews` objects.

`BrainWikipediaPageViews` objects have the following attributes:

Datasets

CoinGecko

CoinGecko was founded in 2014 by TM Lee (CEO) and Bobby Ong (COO) with the mission to democratize the access of crypto data and empower users with actionable insights. We also deep dive into the crypto space to deliver valuable insights to our users through our cryptocurrency reports, as well as our publications, newsletter, and more.

Crypto Market Cap

CoinGecko

Crypto Market Cap

Introduction

The Crypto Market Cap dataset by CoinGecko tracks the market cap of cryptocurrencies. The data covers 620 cryptocurrencies that are supported by QuantConnect, starts in 28 April 2013, and is delivered on a daily frequency. This dataset is created by scraping CoinGecko's Market Chart.

For more information about the Crypto Market Cap dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CoinGecko was founded in 2014 by TM Lee (CEO) and Bobby Ong (COO) with the mission to democratize the access of crypto data and empower users with actionable insights. We also deep dive into the crypto space to deliver valuable insights to our users through our cryptocurrency reports, as well as our publications, newsletter, and more.

Getting Started

The following snippet demonstrates how to request data from the CoinGecko Crypto Market Cap dataset:

```
self.btc = self.add_data(CoinGecko, "BTC").symbol
self._universe = self.add_universe(CoinGeckoUniverse, self.universe_selection)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	28 April 2013
Asset Coverage	620 cryptocurrencies
Resolution	Daily
Timezone	UTC

Requesting Data

To add CoinGecko Crypto Market Cap data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
from AlgorithmImports import *

class CoinGeckoMarketCapDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        self.btcusd = self.add_crypto("BTCUSD", Resolution.DAILY).symbol
        self.dataset_symbol = self.add_data(CoinGecko, "BTC").symbol
```

Accessing Data

To get the current Crypto Market Cap data, index the current `Slice` with the dataset `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.log(f"{self.dataset_symbol} market cap::volume at {slice.time}: {data_point.market_cap}::{data_point.volume}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.get(CoinGecko).items():
        self.log(f"{dataset_symbol} market cap::volume at {slice.time}: {data_point.market_cap}::{data_point.volume}")
```

Historical Data

To get historical CoinGecko Crypto Market Cap data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.history(self.dataset_symbol, 100, Resolution.DAILY)

# Dataset objects
history_bars = self.history[CoinGecko](self.dataset_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of Cryptos based on CoinGecko Crypto Market Cap data, call the `add_universe` method with the `CoinGeckoUniverse` class and a selection function. Note that the filtered output is a list of names of the coins. If corresponding tradable crypto pairs are preferred, call `create_symbol(market, quoteCurrency)` method for each output item.

```
class CryptoMarketCapUniverseAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_account_currency("USD")
        self._market = Market.COINBASE
        self._market_pairs = [
            x.key.symbol
            for x in self.symbol_properties_database.get_symbol_properties_list(self._market)
            if x.value.quote_currency == self.account_currency
        ]
        self._universe = self.add_universe(CoinGeckoUniverse, 'CoinGeckoUniverse', Resolution.DAILY, self._select_assets)

    def _select_assets(self, data: List[CoinGecko]) -> List[Symbol]:
        for datum in data:
            self.debug(f'{datum.coin},{datum.market_cap},{datum.price}')

        # Select the coins that our brokerage supports and have a quote currency that matches
        # our account currency.
        tradable_coins = [d for d in data if d.coin + self.account_currency in self._market_pairs]
        # Select the largest coins and create their Symbol objects.
        return [
            c.create_symbol(self._market, self.account_currency)
            for c in sorted(tradable_coins, key=lambda x: x.market_cap)[-10:]
        ]
```

For more information about dynamic universes, see Universes .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `history` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```py
# DataFrame example where the columns are the CoinGeckoUniverse attributes:
history_df = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series example where the values are lists of CoinGeckoUniverse objects:
universe_history = self.history(self._universe, 30, Resolution.DAILY)
for (_, time), coins in universe_history.items():
    for coin in coins:
        self.log(f"{coin.symbol.value} market cap at {coin.end_time}: {coin.market_cap}")
```

Historical Universe Data in Research

To get historical universe data in research, call the `universe_history` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```py
# DataFrame example where the columns are the CoinGeckoUniverse attributes:
history_df = qb.universe_history(universe, qb.time-timedelta(30), qb.time, flatten=True)

# Series example where the values are lists of CoinGeckoUniverse objects:
universe_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (_, time), coins in universe_history.items():
    for coin in coins:
        print(f"{coin.symbol.value} market cap at {coin.end_time}: {coin.market_cap}")
```

You can call the `history` method in Research.

Remove Subscriptions

To remove your subscription to CoinGecko Crypto Market Cap data, call the `remove_security` method.

```py
self.remove_security(self.dataset_symbol)
```

Supported Assets

Example Applications

The CoinGecko Crypto Market Cap dataset provides information on the size of the crypto coin and can be used to compare the size of one coin to another. Examples include the following strategies:

- Construct a major crypto index fund.
- Invest in the cryptos with the fastest growth in market size.
- Red flag stop when there might be a crypto bank run.

Classic Algorithm Example

The following example algorithm buy BTCUSD when the market cap of BTC is rising, while sell it when the market cap of BTC is dropping.

```py
from AlgorithmImports import *

class CoinGeckoAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Request BTCUSD crypto data for trading
        self.crypto_symbol = self.add_crypto("BTCUSD").symbol
        # Request CoinGecko Market Cap data of BTC for trade signal generation
        self.custom_data_symbol = self.add_data(CoinGecko, "BTC").symbol
        # Use RollingWindow to save the last 2 market cap data for capital flow analysis
        self.window = RollingWindow(2)

    def on_data(self, slice: Slice) -> None:
        # Trade based on updated market cap data
        data = slice.get(CoinGecko)
        if data and self.custom_data_symbol in data:
            # Update RollingWindow for updated comparison
            self.window.add(data[self.custom_data_symbol])
            if not self.window.is_ready:
                return

            # Buy BTCUSD if the market cap of BTC is increasing, which suggests the capital flow towards BTC market and drive up the
demand
            if self.window[0].market_cap > self.window[1].market_cap:
                self.set_holdings(self.crypto_symbol, 1)
            # Sell otherwise, since the capital is flowing out and the demand of BTC lowered
            else:
                self.set_holdings(self.crypto_symbol, -0.5)

    def on_order_event(self, orderEvent: OrderEvent) -> None:
        if orderEvent.status == OrderStatus.FILLED:
            self.debug(f'Purchased Crypto: {orderEvent.symbol}')
```

Framework Algorithm Example

The following example algorithm buy BTCUSD when the market cap of BTC is rising, while sell it when the market cap of BTC is dropping with framework implementation.

```py
from AlgorithmImports import *

class CoinGeckoAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Request CoinGecko Market Cap data of BTC for trade signal generation
        symbol = self.add_data(CoinGecko, "BTC").symbol
        # Request BTCUSD crypto data for trading
        crypto = self.add_crypto("BTCUSD", market=Market.COINBASE).symbol
        symbol_dict = {symbol: crypto}
        # Use RollingWindow to save the last 2 market cap data for capital flow analysis
        window = {symbol: RollingWindow[CoinGecko](2)}

        # Custom alpha model that emit insights based on updated market cap data
        self.add_alpha(CoinGeckoAlphaModel(symbol_dict, window))
        # Equal invest to evenly dissipate capital concentration risk from non-systematic individual risky event
        self.set_portfolio_construction(InsightWeightingPortfolioConstructionModel())

class CoinGeckoAlphaModel(AlphaModel):

    def __init__(self, symbol_dict: Dict[Symbol, Symbol], window: Dict[Symbol, RollingWindow[CoinGecko]]) -> None:
        self.symbol_dict = symbol_dict
        self.window = window

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        insights = []

        # Trade based on updated market cap data
        data = slice.Get(CoinGecko)
        for dataset_symbol, crypto_symbol in self.symbol_dict.items():
            if not data.contains_key(dataset_symbol):
                continue

            # Update RollingWindow for updated comparison
            self.window[dataset_symbol].add(data[dataset_symbol])

            # Can only compare market cap if the RollingWindow is ready
            window = self.window[dataset_symbol]
            if not window.is_ready:
                continue

            # Buy BTCUSD if the market cap of BTC is increasing, which suggests the capital flow towards BTC market and drive up the
demand
            if window[0].market_cap > window[1].market_cap:
                insight = Insight.price(crypto_symbol, timedelta(1), InsightDirection.UP, weight=1)
                insights.append(insight)
            # Sell otherwise, since the capital is flowing out and the demand of BTC lowered
            else:
                insight = Insight.price(crypto_symbol, timedelta(1), InsightDirection.DOWN, weight=0.25)
                insights.append(insight)

        return insights
```

Research Example

The following example lists US Equities having the highest 7-day sentiment.

```py
qb = QuantBook()

# Requesting Data
symbol = qb.add_data(CoinGecko, "BTC").symbol

# Historical data
history = qb.history(CoinGecko, symbol, 30, Resolution.DAILY)
for (symbol, time), row in history.iterrows():
    print(f"{symbol} sentiment at {time}: {row['marketcap']}")

# Add Universe Selection
def universe_selection(alt_coarse: List[CoinGeckoUniverse]) -> List[Symbol]:
    return [d.symbol for d in sorted([x for x in alt_coarse if x.market_cap],
        key=lambda x: x.market_cap, reverse=True)[:10]]

universe = qb.add_universe(CoinGeckoUniverse, universe_selection)

# Historical Universe data
universe_history = qb.universe_history(universe, qb.time-timedelta(10), qb.time)
for (_, time), coins in universe_history.items():
    for coin in coins:
        print(f"{coin.symbol.value} market cap at {coin.end_time}: {coin.market_cap}")
```

Data Point Attributes

The Crypto Market Cap dataset provides `CoinGecko` and `CoinGeckoUniverse` objects.

CoinGecko Attributes

`CoinGecko` objects have the following attributes:

CoinGeckoUniverse Attributes

`CoinGeckoUniverse` objects have the following attributes:

Datasets

EOD Historical Data

EODHD was a France financial data provider founded in April 2015. They focus on providing clean financial data, including stock prices, splits, dividends, fundamentals, macroeconomy indicators, technical indicators, and alternative data sources, through 24/7 API seamlessly.

Economic Events

Macroeconomics Indicators

Upcoming Dividends

Upcoming Earnings

Upcoming IPOs

Upcoming Splits

EOD Historical Data

Economic Events

Introduction

The Economic Events dataset, provided by EODHD, offers daily alerts for major economic events or announcements of global markets within the upcoming 7 days, with estimation and previous record if available. The data starts in January 2019, and is delivered on a daily frequency.

For more information about the Economic Events dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

EODHD was a France financial data provider founded in April 2015. They focus on providing clean financial data, including stock prices, splits, dividends, fundamentals, macroeconomy indicators, technical indicators, and alternative data sources, through 24/7 API seamlessly.

Getting Started

The following snippet demonstrates how to request data from the Economic Events dataset:

```py
self.add_data(EODHDEconomicEvents, Country.UNITED_STATES)
self.add_data(EODHDEconomicEvents, EODHD.Events.UnitedStates.CPI)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2019
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add Economic Events data to your algorithm, call the `add_data` method.

```py
class EconomicEventsDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        ticker = EODHD.Events.UnitedStates.CPI
        # ticker = Country.UNITED_STATES
        self.dataset_symbol = self.add_data(EODHDEconomicEvents, ticker).symbol
```

Accessing Data

To get the current Economic Events data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    events = slice.get(EODHDEconomicEvents).get(self.dataset_symbol)
    for event in events:
        self.log(f"{event.event_type} of {event.country} over {event.event_period} with be held at {event.event_time} with estimated
value {event.estimate}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
def on_data(self, slice: Slice) -> None:
    for symbol, events in slice.get(EODHDEconomicEvents).items():
        for event in events:
            self.log(f"{event.event_type} of {event.country} over {event.event_period} with be held at {event.event_time} with estimated
value {event.estimate}")
```

Historical Data

To get historical Economic Events data, call the `history` method with the type `EODHDEconomicEvents` cast and the underlying `Symbol` . If there is no data in the period you request, the history result is empty.

```
history_bars = self.history[EODHDEconomicEvents](self.dataset_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
self.remove_security(self.dataset_symbol)
```

Example Applications

The Economic Events dataset provides timely notifications about upcoming economic events, allowing traders to trade on that volatility. Examples include the following strategies:

- Long straddle to trade the volatility of the economic events.
- Trade market representative ETFs based on estimated figures for the upcoming events.
- Statistical arbitrage on two or more correlated global markets based on economic events of different locations.

Classic Algorithm Example

The following example algorithm trade Industrial sector ETF based on US PMI estimated change direction. If the estimated PMI of the upcoming announcement is above the previous PMI, buy the Industrial ETF, and sell it otherwise.

```py
from AlgorithmImports import *

class EODHDEconomicEventsAlgorithm(QCAlgorithm):
    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Use industrial sector ETF as a vehicle to trade.
        self.equity_symbol = self.add_equity("XLI").symbol
        # Request US PMI economic event data to generate trade signals.
        ticker = EODHD.Events.UnitedStates.MARKIT_MANUFACTURING_PURCHASING_MANAGERS_INDEX
        self.dataset_symbol = self.add_data(EODHDEconomicEvents, ticker).symbol

    def on_data(self, slice):
        # Trade based on the updated economic events.
        if self.dataset_symbol in slice.get(EODHDEconomicEvents):
            # Use the Manufacturing Index to generate trade signals on manufacturing industry vehicles.
            # Make sure previous and estimate are available to estimate the direction of the industry.
            event = slice[self.dataset_symbol].data[0]
            if event.previous and event.estimate:
                # If the estimated PMI is higher than the previous PMI, the manufacturing ETF price is expected to rise.
                if event.previous > event.estimate:
                    self.set_holdings(self.equity_symbol, 1)
                # Otherwise, it is expected manufacturing ETF prices will drop.
                else:
                    self.set_holdings(self.equity_symbol, -1)
```

Framework Algorithm Example

The following example algorithm trade Industrial sector ETF based on US PMI estimated change direction using algorithm framework. If the estimated PMI of the upcoming announcement is above the previous PMI, buy the Industrial ETF, sell it otherwise.

```py
from AlgorithmImports import *

class EODHDEconomicEventsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Use industrial sector ETF as a vehicle to trade.
        symbol = Symbol.create("XLI", SecurityType.EQUITY, Market.USA)
        self.add_universe_selection(ManualUniverseSelectionModel(symbol))
        # Custom alpha model to emit insights according to economic events.
        self.add_alpha(EconomicEventAlphaModel(self))
        # Equal weighting position sizing to dissipate capital risk evenly.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel(Expiry.END_OF_MONTH))

class EconomicEventAlphaModel(AlphaModel):
    def __init__(self, algorithm: QCAlgorithm) -> None:
        # Request US PMI economic event data to generate trade signals.
        ticker = EODHD.Events.UnitedStates.MARKIT_MANUFACTURING_PURCHASING_MANAGERS_INDEX
        self.dataset_symbol = algorithm.add_data(EODHDEconomicEvents, ticker).symbol
        self._symbol = None

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        # Trade based on the updated economic events.
        if self.dataset_symbol not in slice.get(EODHDEconomicEvents):
            return []
        # Use the US Manufacturing Index to generate trade signals on manufacturing industry vehicles.
        # Make sure previous and estimate are available to estimate the direction of the industry.
        event = slice[self.dataset_symbol].data[0]
        # If the estimated PMI is higher than the previous PMI, the manufacturing ETF price is expected to rise.
        # Otherwise, it is expected manufacturing ETF prices will drop.
        direction = InsightDirection.UP if event.previous > event.estimate else InsightDirection.DOWN
        return [Insight.price(self._symbol, timedelta(5), direction)]

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for added in changes.added_securities:
            self._symbol = added.symbol
```

Data Point Attributes

The EODHD Economic Events dataset provides `EODHDEconomicEvent` objects, which have the following attributes:

The `EODHDEconomicEvents` objects represent a collection of `EODHDEconomicEvent` object

Country Enumeration

To filter the countries of the economic events, you can make use of the `Country` enumeration. The `Country` enumeration has the following members:

Events Enumeration

To filter the event types of the economic events, you can make use of the `Events` enumeration. The `Events` enumeration has the following members:

EOD Historical Data

Macroeconomics Indicators

Introduction

The Macroeconomic Indicators dataset, provided by EODHD, provides data on 39 major macroeconomic indicators of 249 countries and regions. The data starts in January 1998, and is delivered on indicators update.

For more information about the Macroeconomics Indicators dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

EODHD was a France financial data provider founded in April 2015. They focus on providing clean financial data, including stock prices, splits, dividends, fundamentals, macroeconomy indicators, technical indicators, and alternative data sources, through 24/7 API seamlessly.

Getting Started

The following snippet demonstrates how to request data from the Macroeconomic Indicators dataset:

```
PY
self.add_data(EODHDMacroIndicators, Country.UNITED_STATES)
self.add_data(EODHDMacroIndicators, EODHD.MacroIndicators.UnitedStates.GDP_CURRENT_USD)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1998
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add Macroeconomic Indicators data to your algorithm, call the `add_data` method.

```
PY
class EODHDMacroIndicatorsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        self.dataset_symbol = self.add_data(
            EODHDMacroIndicators,
            EODHD.MacroIndicators.UnitedStates.GDP_CURRENT_USD    # Country.UNITED_STATES
        ).symbol
```

Accessing Data

To get the current Macroeconomic Indicators data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.log(f"{data_point.frequency} {data_point.indicator} of {data_point.country} at {data_point.time} with value
{data_point.value}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
def on_data(self, slice: Slice) -> None:
    for _, data_point in slice.get(EODHDMacroIndicators).items():
        self.log(f"{data_point.frequency} {data_point.indicator} of {data_point.country} at {data_point.time} with value
{data_point.value}")
```

Historical Data

To get historical Macroeconomic Indicators data, call the `history` method with the type `EODHDMacroIndicators` cast and the underlying `Symbol` . If there is no data in the period you request, the history result is empty.

```
history_bars = self.history[EODHDMacroIndicators](self.dataset_symbol, 100)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
self.remove_security(self.dataset_symbol)
```

Example Applications

The Macroeconomic Indicators dataset provides data on global macro indicators, allowing traders to react to market sentiment. Examples include the following strategies:

- Long straddle to trade the market shock brought by the macro indicators.
- Hold long or short position of the market representative ETF based on the expected market direction.
- Statistical arbitrage on 2 or more correlated global markets based on market strength indicated by macro indicators.

Classic Algorithm Example

The following example algorithm holds long position of SPY if the US GDP is in positive growth, while holds short position if it is the opposite case.

```
from AlgorithmImports import *

class EODHDMacroIndicatorsAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.equity_symbol = self.add_equity("SPY", Resolution.Daily).symbol

        ticker = EODHD.MacroIndicators.UnitedStates.GDP_GROWTH_ANNUAL
        self.dataset_symbol = self.add_data(EODHDMacroIndicators, ticker).Symbol

    def on_data(self, slice):
        indicators = slice.get(EODHDMacroIndicators).get(self.dataset_symbol)
        if indicators:
            gdp = indicators.data[0].value
            self.SetHoldings(self.equity_symbol, 1 if gdp > 0 else -1)
```

Framework Algorithm Example

The following example algorithm holds the long position of SPY if the US GDP is in positive growth while holding a short position if it is the opposite case. It is implemented in the framework algorithm.

```py
from AlgorithmImports import *

class EODHDMacroIndicatorsAlgorithm(QCAlgorithm):

   def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Use market ETF as a vehicle to trade.
        symbol = Symbol.create("SPY", SecurityType.EQUITY, Market.USA)
        self.add_universe_selection(ManualUniverseSelectionModel(symbol))
        # Custom alpha model to emit insights according to macroeconomic indicators.
        self.add_alpha(MacroIndicatorAlphaModel(self))
        # Equal weighting position sizing to dissipate capital risk evenly.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel(Expiry.END_OF_MONTH))

class MacroIndicatorAlphaModel(AlphaModel):

    def __init__(self, algorithm: QCAlgorithm) -> None:
        # Request US GDP growth indicator data to generate trade signal.
        ticker = EODHD.MacroIndicators.UnitedStates.GDP_GROWTH_ANNUAL
        self.dataset_symbol = algorithm.add_data(EODHDMacroIndicators, ticker).symbol
        self._symbol = None

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        # Trade based on the updated macroeconomic indicator.
        indicators = slice.get(EODHDMacroIndicators).get(self.dataset_symbol)
        if not indicators:
            return []
        gdp = indicators.data[0].value
        # If the GDP gap is positive, the market ETF is expected to rise.
        # Otherwise, it is expected the market ETF will drop.
        direction = InsightDirection.UP if gdp > 0 else InsightDirection.DOWN
        return [Insight.price(self._symbol, timedelta(5), direction)]

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for added in changes.added_securities:
            self._symbol = added.symbol
```

Data Point Attributes

The EODHD Macro Indicators dataset provides `EODHDMacroIndicators` objects, which have the following attributes:

Country Enumeration

To filter the country of the macro indicators, you can make use of the `Country` enumeration. The `Country` enumeration has the following members:

Frequency Enumeration

To filter the indicator frequency of the macro indicators, you can make use of the `Frequency` enumeration. The `Frequency` enumeration has the following members:

EOD Historical Data

Upcoming Dividends

Introduction

The Upcoming Dividends dataset, provided by EODHD, offers daily alerts for US Equities that will have a dividend event within the upcoming 7 days. The data starts in January 2015 and is delivered on a daily frequency.

Compared to US Equity Security Master as a benchmark, the Upcoming Dividends dataset has a 98.56% coverage of all dividend events, while having a 99.71% precision on the exact dividend dates of the covered ones and a 99.90% precision within +/- 3 days.

For more information about the Upcoming Dividends dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

EOD Historical Data (EODHD) is a financial data provider based in France, and founded in April 2015. They focus on providing clean financial data, including stock prices, splits, dividends, fundamentals, macroeconomic indicators, technical indicators, and alternative data sources, through 24/7 API seamlessly. For more information about EODHD, visit https://eodhd.com/ .

Getting Started

The following snippet demonstrates how to request data from the Upcoming Dividends dataset:

```
self.add_data(EODHDUpcomingDividends, "dividends")
self.add_universe(EODHDUpcomingDividends, self.selection_function)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2015
Data Density	Sparse
Resolution	Daily
Timezone	New York

Universe Selection

To select a dynamic universe of US Equities based on the Upcoming Dividends dataset, call the `add_universe` method with a `EODHDUpcomingDividends` cast.

```
def initialize(self) -> None:
    self._universe = self.add_universe(EODHDUpcomingDividends, self.universe_selection_filter)

def universe_selection_filter(self, dividends: List[EODHDUpcomingDividends]) -> List[Symbol]:
    return [d.symbol for d in dividends if d.dividend_date <= self.time + timedelta(1) and d.dividend > 0.05]
```

For more information about universe settings, see Settings .

Requesting Data

To add Upcoming Dividends data to your algorithm, call the `add_data` method.

```
class UpcomingDividendsDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        self._symbol = self.add_equity("AAPL", Resolution.DAILY).symbol
        self.dataset_symbol = self.add_data(EODHDUpcomingDividends, "dividends").symbol
```

Accessing Data

To get the current Upcoming Dividends data, call the `get(EODHDUpcomingDividends)` method from the current `Slice` and index the result with the security `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    upcomings_dividends = slice.get(EODHDUpcomingDividends)
    if upcomings_dividends and self._symbol in upcomings_dividends:
        upcomings_dividends_data_point = upcomings_dividends[self._symbol]
        self.log(f"{self._symbol} will pay dividend at {upcomings_dividends_data_point.dividend_date} with dividend per share of
${upcomings_dividends_data_point.dividend}")
```

You can also iterate through all of the dataset objects in the current `Slice`

```
def on_data(self, slice: Slice) -> None:
    for equity_symbol, upcomings_dividends_data_point in slice.get(EODHDUpcomingDividends).items():
        self.log(f"{equity_symbol} will pay dividend at {upcomings_dividends_data_point.dividend_date} with dividend per share of
${upcomings_dividends_data_point.dividend}")
```

Historical Data

To get historical Upcoming Dividends data, call the `history` method with the type `EODHDUpcomingDividends` cast and the period of request. If there is no data in the period you request, the history result is empty.

```
history = self.history[EODHDUpcomingDividends](timedelta(100), Resolution.DAILY)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
self.remove_security(self.dataset_symbol)
```

Example Applications

The Upcoming Dividends dataset allows traders to trade the price change due to dividends. Examples include the following strategies:

- Short the stocks on dividend report day to earn the dividend discount on pricing.
- Avoid volatility on securities with upcoming dividends

Classic Algorithm Example

The following example algorithm shorts each equity in equal size with an upcoming dividend by the next day. It selects stocks with dividend recording over $0.5 per share to capitalize on the price shock momentum due to dividend payment.

```py
from AlgorithmImports import *

class UpcomingDividendsExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Universe consists of equities with upcoming dividend events.
        self._universe = self.add_universe(EODHDUpcomingDividends, self.selection)
        # Add a Scheduled Event to rebalance the portfolio every morning
        # based on upcoming dividend signals.
        spy = Symbol.create('SPY', SecurityType.EQUITY, Market.USA)
        self.schedule.on(
            self.date_rules.every_day(spy),
            self.time_rules.after_market_open(spy, 1),
            self._rebalance
        )

    def selection(self, dividends: List[EODHDUpcomingDividends]) -> List[Symbol]:
        # Select the stocks with upcoming dividend record date, with a sufficient dividend size.
        return [x.symbol for x in dividends if x.dividend_date < self.time + timedelta(1) and x.dividend > 0.5]

    def _rebalance(self) -> None:
        # Equally invest in each member of the universe to evenly dissipate the capital risk.
        symbols = [s for s in self._universe.selected if self.securities[s].price]
        total_count = len(symbols)
        targets = [PortfolioTarget(symbol, -1. / total_count) for symbol in symbols]
        self.set_holdings(targets, liquidate_existing_holdings=True)
```

Framework Algorithm Example

The following example implements a strategy of shorting each equity in equal size with an upcoming dividend by the next day using the framework. It selects stocks with dividend recording over $0.5 per share to capitalize on the price shock momentum due to dividend payment.

```py
from AlgorithmImports import *

class UpcomingDividendsExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Trade on a daily basis based on upcoming dividend signals daily.
        self.universe_settings.resolution = Resolution.DAILY
        # Universe consists of equities with upcoming dividend events.
        self._universe = self.add_universe(EODHDUpcomingDividends, self.selection)

        # A constant alpha model will emit insights for the stocks with dividend events in the upcoming day.
        # It is expecting a price shock due to pricing after the dividend, which might affect some momentum traders.
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.DOWN, timedelta(1)))

        # Equal weighting for each signal to dissipate the capital risk evenly.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel(Expiry.END_OF_DAY))

    def selection(self, dividends: List[EODHDUpcomingDividends]) -> List[Symbol]:
        # Select the stocks with upcoming dividend record dates with a sufficient dividend size.
        return [x.symbol for x in dividends if x.dividend_date < self.time + timedelta(1) and x.dividend > 0.5]
```

Data Point Attributes

The EODHD Upcoming Dividends dataset provides `EODHDUpcomingDividends` objects, which have the following attributes:

EOD Historical Data

Upcoming Earnings

Introduction

The Upcoming Earnings dataset, provided by EOD Historical Data (EODHD), is a daily universe of US Equities with an earnings report publication in the upcoming 7 days. The data starts in January 1998 and is delivered on a daily frequency.

Compared to Nasdaq's Earning Reports as a benchmark, the Upcoming Earnings dataset has captured 96.79% of the scheduled earnings report, with a 97.25% exact-date precision of the captured events, while having a 99.28% precision within +/- 3 days. Note that the Upcoming Earnings dataset also contains unscheduled special earning reports.

For more information about the Upcoming Earnings dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

EOD Historical Data (EODHD) is a financial data provider based in France, and founded in April 2015. They focus on providing clean financial data, including stock prices, splits, dividends, fundamentals, macroeconomic indicators, technical indicators, and alternative data sources, through 24/7 API seamlessly. For more information about EODHD, visit https://eodhd.com/ .

Getting Started

The following snippet demonstrates how to request data from the Upcoming Earnings dataset:

```
self.add_universe(EODHDUpcomingEarnings, self.selection_function)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1998
Data Density	Sparse
Resolution	Daily
Timezone	New York

Universe Selection

To select a dynamic universe of US Equities based on the Upcoming Earnings dataset, call the `add_universe` method with a `EODHDUpcomingEarnings` cast.

```
def initialize(self) -> None:
    self._universe = self.add_universe(EODHDUpcomingEarnings, self.universe_selection_filter)

def universe_selection_filter(self, earnings: List[EODHDUpcomingEarnings]) -> List[Symbol]:
    return [d.symbol for d in earnings if d.report_date <= self.time + timedelta(3) and d.estimate > 0]
```

For more information about universe settings, see Settings .

Requesting Data

This dataset is designed for universe selection. However, you can add Upcoming Earnings data to your algorithm using the `add_data` method.

```
class UpcomingEarningsDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        self._symbol = self.add_equity("AAPL", Resolution.DAILY).symbol
        self._dataset_symbol = self.add_data(EODHDUpcomingEarnings, "earnings").symbol
```

Accessing Data

To get the current Upcoming Earnings data, call the `get(EODHDUpcomingEarnings)` method from the current `Slice` and index the result with the security `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    upcomings_earnings_for_symbol = slice.get(EODHDUpcomingEarnings).get(self._symbol)
        if upcomings_earnings_for_symbol:
            self.log(f"{self._symbol} will report earnings at {upcomings_earnings_for_symbol.report_date}
{upcomings_earnings_for_symbol.report_time} with estimated EPS {upcomings_earnings_for_symbol.estimate}")
```

You can also iterate through all of the dataset objects in the current `Slice`

```
def on_data(self, slice: Slice) -> None:
    for equity_symbol, upcomings_earnings_data_point in slice.get(EODHDUpcomingEarnings).items():
        self.log(f"{equity_symbol} will report earnings at {upcomings_earnings_data_point.report_date}
{upcomings_earnings_data_point.report_time} with estimated EPS {upcomings_earnings_data_point.estimate}")
```

Historical Data

To get historical Upcoming Earnings for the universe, call the `history` method with the type `EODHDUpcomingEarning` .

```
history = self.history(EODHDUpcomingEarnings, timedelta(100), Resolution.DAILY)
```

To get historical Upcoming Earnings data for a known security, call the `history` method with the type `EODHDUpcomingEarning` cast and the security `Symbol` .

```
history = self.history[EODHDUpcomingEarnings](timedelta(100), Resolution.DAILY).loc[self._symbol]
```

If there is no data in the period you request, the history result is empty. For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
self.remove_security(self.dataset_symbol)
```

Example Applications

The Upcoming Earnings dataset provides timely notifications about earnings announcements, allowing traders to make capitalize on potential price movements and manage risks effectively. Examples include the following strategies:

- Short Straddle to trade on heightened volatility during earnings report.
- Filter universe for the stocks with or without upcoming earnings report to trade or avoid volatility.
- Hold the stocks with upcoming earnings estimated to be positive.

Classic Algorithm Example

The following example algorithm long a straddle on the stocks with upcoming earnings report within 5 days to trade the volatility. It allows 5 days to

build up the volatility and capitalize the positions 1 day after the earnings announcement.

```
class UpcomingEarningsExampleAlgorithm(QCAlgorithm):
    options_by_symbol = {}

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Seed the last price as price since we need to use the underlying price for option contract filtering when it join the universe.
        self.settings.seed_initial_prices = True

        # Trade on daily basis based on daily upcoming earnings signals.
        self.universe_settings.resolution = Resolution.DAILY
        # Option trading requires raw price for strike price comparison.
        self.universe_settings.data_normalization_mode = DataNormalizationMode.RAW
        # Universe consists of equities with upcoming earnings events.
        self.add_universe(EODHDUpcomingEarnings, self.selection)

Data Point Attributes

The EODHD Upcoming Earnings dataset provides `EODHDUpcomingEarnings` objects, which have the following attributes:

To filter the EODHD Upcoming Earnings data with their reporting timing, use the `EODHD.ReportTime` enum, which have the following attributes:

EOD Historical Data

Upcoming IPOs

Introduction

The Upcoming IPOs dataset, provided by EODHD, offers daily alerts for US Equities that will start their IPOs or have any updates on their IPO registrations within the upcoming 7 days. The data started in February 2013 and is delivered on a daily basis.

`Notice that this dataset might have a +/-2 days accuracy due to the data provider.`

For more information about the Upcoming IPOs dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

EODHD was a France financial data provider founded in April 2015. They focus on providing clean financial data, including stock prices, splits, dividends, fundamentals, macroeconomy indicators, technical indicators, and alternative data sources, through 24/7 API seamlessly.

Getting Started

The following snippet demonstrates how to request data from the Upcoming IPOs dataset:

```
self.add_data(EODHDUpcomingIPOs, "ipos")
self.add_universe(EODHDUpcomingIPOs, self.selection_function)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	February 2013
Data Density	Sparse
Resolution	Daily
Timezone	New York

Universe Selection

To select a dynamic universe of US Equities based on the Upcoming IPOs dataset, call the `add_universe` method with a `EODHDUpcomingIPOs` cast.

```
def initialize(self) -> None:
    self.universe_settings.asynchronous = True
    self._universe = self.add_universe(EODHDUpcomingIPOs, self.universe_selection_filter)

def universe_selection_filter(self, ipos: List[EODHDUpcomingIPOs]) -> List[Symbol]:
    # confirmed non-penny stock IPO that launches within 7 days.
    return [d.symbol for d in ipos if d.deal_type in [DealType.EXPECTED, DealType.PRICED] and d.ipo_date and min(x for x in
[d.lowest_price, d.highest_price, d.offer_price] if x) > 1]
```

For more information about universe settings, see Settings .

Requesting Data

To add Upcoming IPOs data to your algorithm, call the `add_data` method.

```
class UpcomingIPOsDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        self.dataset_symbol = self.add_data(EODHDUpcomingIPOs, "ipos").symbol
```

Accessing Data

To get the current Upcoming IPOs data, call the `get(EODHDUpcomingIPOs)` method from the current `Slice` . Then, iterate through all of the dataset objects in the current `Slice`

```
def on_data(self, slice: Slice) -> None:
    for equity_symbol, upcomings_ipos_data_point in slice.get(EODHDUpcomingIPOs).items():
        self.log(f"{equity_symbol} will start IPO at {upcomings_ipos_data_point.ipo_date} with price
{upcomings_ipos_data_point.offer_price} and {upcomings_ipos_data_point.shares} shares")
```

Historical Data

To get historical Upcoming IPOs data, call the `history` method with the type `EODHDUpcomingIPOs` cast and the period of request. If there is no data in the period you request, the history result is empty.

```
history_bars = self.history[EODHDUpcomingIPOs](timedelta(100), Resolution.DAILY)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
self.remove_security(self.dataset_symbol)
```

Example Applications

The Upcoming IPOs dataset provides timely notifications about upcoming IPOs start, allowing traders to capitalize on the high volatility of new stocks. Examples include the following strategies:

- Long straddle to trade the volatility of the new IPO stock.
- Arbitration on fair price versus IPO price.
- Use SMA of IPO number to estimate the IPO trend and market popularity.

Classic Algorithm Example

Example 1: New Stock

The following example algorithm holds new stocks for its IPO day to capitalize its hype.

```py
from AlgorithmImports import *

class UpcomingIPOsExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Filter for new stocks to trade their hype using EODHDUpcomingIPOs.
        self._universe = self.add_universe(EODHDUpcomingIPOs, self.selection)

    def selection(self, ipos: List[EODHDUpcomingIPOs]) -> List[Symbol]:
        # Select the stocks that IPO starts today and traded in Nasdaq
        return [
            x.symbol for x in ipos
            if (x.ipo_date and
                x.ipo_date <= self.time + timedelta(1) and
                x.exchange == Exchange.NASDAQ)
        ]

    def on_data(self, slice: Slice) -> None:
        # Invest in new stocks and trade on their first day for their hype.
        # Equally invest in each new stocks to evenly dissipate the capital risk.
        for symbol in self._universe.selected:
            security = self.securities[symbol]
            if not security.holdings.invested and security.price:
                self.set_holdings(symbol, 0.1/len(self._universe.selected))

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        # Liquidate the new stocks traded today/yesterday to capitalize the first-day hype.
        for removed in changes.removed_securities:
            self.liquidate(removed.symbol)
```

Example 2: Market Popularity

The following example algorithm buy QQQ if the number of IPO in Nasdaq is in increasing trend, sell otherwise.

```py
from AlgorithmImports import *

class UpcomingIPOsExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Create a EMA indicator to estimate the trend of IPO number to reflect the market popularity.
        self._ema = ExponentialMovingAverage(50)

        self.universe_settings.resolution = Resolution.DAILY
        # Filter for new stocks to trade their hype using EODHDUpcomingIPOs.
        self.add_universe(EODHDUpcomingIPOs, self.selection)
        # Request QQQ data to trade.
        self.qqq = self.add_equity("QQQ", Resolution.DAILY).symbol

        self.set_warm_up(50, Resolution.DAILY)

    def selection(self, ipos: List[EODHDUpcomingIPOs]) -> List[Symbol]:
        # Filter for the stocks that IPO starts today and traded in Nasdaq.
        universe = [x.symbol for x in ipos if x.ipo_date and x.ipo_date <= self.time + timedelta(1) and x.exchange == Exchange.NASDAQ]
        # Feed to the EMA indicator.
        self._ema.update(self.time, len(universe))
        return Universe.UNCHANGED

    def on_data(self, slice: Slice) -> None:
        if not self.is_warming_up and self._ema.is_ready:
            # If the EMA is decreasing, we estimate the market popularity is decreasing, so we sell QQQ.
            if self._ema.previous.value > self._ema.current.value:
                self.set_holdings(self.qqq, -1)
            # Otherwise, we estimate the market popularity is increasing, so we buy QQQ.
            else:
                self.set_holdings(self.qqq, 1)
```

Framework Algorithm Example

The following example algorithm holds new stocks for its IPO day to capitalize its hype using framework algorithm.

```py
from AlgorithmImports import *

class UpcomingIPOsExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Filter for new stocks to trade their hype using EODHDUpcomingIPOs.
        self.add_universe(EODHDUpcomingIPOs, self.selection)

        # Invest in new stocks and trade on their first day for their hype.
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(1), None, None, 0.01))

        # Equally invest in each new stocks to evenly dissipate the capital risk.
        self.set_portfolio_construction(InsightWeightingPortfolioConstructionModel(Expiry.END_OF_DAY))

    def selection(self, ipos: List[EODHDUpcomingIPOs]) -> List[Symbol]:
        # Select the stocks that IPO starts today and traded in Nasdaq
        return [
            x.symbol for x in ipos
            if (x.ipo_date and
                x.ipo_date <= self.time + timedelta(1) and
                x.exchange == Exchange.NASDAQ)
        ]
```

Data Point Attributes

The EODHD Upcoming IPOs dataset provides `EODHDUpcomingIPOs` objects, which have the following attributes:

EOD Historical Data

Upcoming Splits

Introduction

The Upcoming Splits dataset, provided by EODHD, offers daily alerts for US Equities that will have a split event within the upcoming 7 days. The data starts in January 2010, and is delivered on a daily frequency.

Compared to US Equity Security Master as a benchmark, the Upcoming Splits dataset has an 85.18% coverage of all splits since 2015, while having a 92.74% precision on the exact split dates of the covered ones and a 97.18% precision within +/- 3 days.

For more information about the Upcoming Splits dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

EOD Historical Data (EODHD) is a financial data provider based in France, and founded in April 2015. They focus on providing clean financial data, including stock prices, splits, dividends, fundamentals, macroeconomic indicators, technical indicators, and alternative data sources, through 24/7 API seamlessly. For more information about EODHD, visit https://eodhd.com/ .

Getting Started

The following snippet demonstrates how to request data from the Upcoming Splits dataset:

```
self.add_universe(EODHDUpcomingSplits, self.selection_function)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2010
Data Density	Sparse
Resolution	Daily
Timezone	New York

Universe Selection

To select a dynamic universe of US Equities based on the Upcoming Splits dataset, call the `add_universe` method with a `EODHDUpcomingSplits` cast.

```
def initialize(self) -> None:
    self._universe = self.add_universe(EODHDUpcomingSplits, self.universe_selection_filter)

def universe_selection_filter(self, splits: List[EODHDUpcomingSplits]) -> List[Symbol]:
    return [d.symbol for d in splits if d.split_date <= self.time + timedelta(3) and d.split_factor > 1]
```

For more information about universe settings, see Settings .

Requesting Data

To add Upcoming Splits data to your algorithm, call the `add_data` method.

```
class UpcomingSplitsDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        self._symbol = self.add_equity("AAPL", Resolution.DAILY).symbol
        self.dataset_symbol = self.add_data(EODHDUpcomingSplits, "splits").symbol
```

Accessing Data

To get the current Upcoming Splits data, call the `get(EODHDUpcomingSplits)` method from the current `Slice` and index the result with the security `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    upcomings_splits = slice.get(EODHDUpcomingSplits)
    if upcomings_splits and self._symbol in upcomings_splits:
        upcomings_splits_data_point = upcomings_splits[self._symbol]
        self.log(f"{self._symbol} will split at {upcomings_splits_data_point.split_date} with split factor
{upcomings_splits_data_point.split_factor}")
```

You can also iterate through all of the dataset objects in the current `Slice`

```
def on_data(self, slice: Slice) -> None:
    for equity_symbol, upcomings_splits_data_point in slice.get(EODHDUpcomingSplits).items():
        self.log(f"{equity_symbol} will split at {upcomings_splits_data_point.split_date} with split factor
{upcomings_splits_data_point.split_factor}")
```

Historical Data

To get historical Upcoming Splits data, call the `history` method with the type `EODHDUpcomingSplits` cast and the period of request. If there is no data in the period you request, the history result is empty.

```
history = self.history[EODHDUpcomingSplits](timedelta(100), Resolution.DAILY)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
self.remove_security(self.dataset_symbol)
```

Example Applications

The Upcoming Splits dataset provides timely notifications about upcoming share split or reverse split events, allowing traders to capitalize on potential price movements and manage risks effectively. Examples include the following strategies:

- Splits into shares with lower price will provide higher liquidity for market making algorithms.
- Select a universe of stocks with upcoming splits event and trade their volatility using options.
- Buy stocks with split factor higher than 1, sell vice versa for self-defeating ones.

Classic Algorithm Example

The following example algorithm holds each equity in equal size with upcoming splits within 7 days. It selects stocks that split up to more shares with lower price and tries to capitalize the higher demand of the more afforable stocks.

```
from AlgorithmImports import *

class UpcomingSplitsExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

```

Framework Algorithm Example

The following example algorithm holds each equity in equal size with upcoming splits within 7 days using algorithm framework. It selects stocks that split up to more shares with lower price and tries to capitalize the higher demand of the more afforable stocks.

```
class UpcomingSplitsExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.settings.free_portfolio_value_percentage = 0.1

        # Trade on daily basis based on daily upcoming splits signals.
        self.universe_settings.resolution = Resolution.DAILY
        # Universe consists of equities with upcoming splits events.
        self.add_universe(EODHDUpcomingSplits, self.selection)

        # Constant alpha model to emit insights for the stocks with split up event within a week, estimating their demand and price will
go up.
        # Signal stays for 2 days to fully digest the driven up demands.
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(2)))

        # Equal weighting for each signal to evenly dissipate the capital risk.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel(Expiry.END_OF_DAY))

    def selection(self, splits: List[EODHDUpcomingSplits]) -> List[Symbol]:
        # Split (more shares with lower price) will make the stock more affordable and drive up the demand.
        # Hence, include the stocks with the lowest split factor that will have a split within the next 7 days.
        # Note that spliting up the stock means the split factor > 1.
        count = 5
        splits = [x for x in splits if x.split_factor > 1]
        if len(splits) > count:
            splits = sorted([x for x in splits if x.split_factor > 1], key=lambda x: x.split_factor)[:count]
        return [x.symbol for x in splits]
```

Data Point Attributes

The EODHD Upcoming Splits dataset provides `EODHDUpcomingSplits` objects, which have the following attributes:

Datasets

Energy Information Administration

The Treasury Department is the executive agency responsible for promoting economic prosperity and ensuring the financial security of the United States. The Department is responsible for a wide range of activities such as advising the President on economic and financial issues, encouraging sustainable economic growth, and fostering improved governance in financial institutions. The Department of the Treasury operates and maintains systems that are critical to the nation's financial infrastructure, such as the production of coin and currency, the disbursement of payments to the American public, revenue collection, and the borrowing of funds necessary to run the federal government.

US Energy Information Administration (EIA)

Energy Information Administration

US Energy Information Administration (EIA)

Introduction

The US Energy Information Administration (EIA) datasets by the Department of the Treasury tracks national and international oil production and consumption. The data covers 190 datasets, starts in January 1991, and is delivered on a daily frequency. This dataset is created by QuantConnect processing and caching the EIA archives.

For more information about the US Energy Information Administration (EIA) dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

The Treasury Department is the executive agency responsible for promoting economic prosperity and ensuring the financial security of the United States. The Department is responsible for a wide range of activities such as advising the President on economic and financial issues, encouraging sustainable economic growth, and fostering improved governance in financial institutions. The Department of the Treasury operates and maintains systems that are critical to the nation's financial infrastructure, such as the production of coin and currency, the disbursement of payments to the American public, revenue collection, and the borrowing of funds necessary to run the federal government.

Getting Started

The following snippet demonstrates how to request data from the EIA dataset:

```
self.dataset_symbol = self.add_data(USEnergy, USEnergy.Petroleum.UnitedStates.WEEKLY_NET_IMPORTS_OF_TOTAL_PETROLEUM_PRODUCTS).symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1991
Asset Coverage	190 Datasets
Data Density	Sparse
Resolution	Daily
Timezone	New York

Requesting Data

To add EIA data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
class USEnergyDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        self.dataset_symbol = self.add_data(USEnergy,
USEnergy.Petroleum.UnitedStates.WEEKLY_NET_IMPORTS_OF_TOTAL_PETROLEUM_PRODUCTS).symbol
```

Accessing Data

To get the current EIA data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you

index it.

```
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.log(f"{self.dataset_symbol} value at {slice.time}: {data_point.value}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.get(USEnergy).items():
        self.log(f"{dataset_symbol} value at {slice.time}: {data_point.value}")
```

Historical Data

To get historical EIA data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.history(self.dataset_symbol, 100, Resolution.DAILY)

# Dataset objects
history_bars = self.history[USEnergy](self.dataset_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove your subscription to EIA data, call the `remove_security` method.

```
self.remove_security(self.dataset_symbol)
```

Supported Datasets

The following table shows the accessor code you need to add each EIA dataset to your algorithm:

Symbol	Accessor Code	Description
`UnitedStates`		
PET.WGFRPUS2.W	`USEnergy.Petroleum.UnitedStates.WeeklyRefinerAndBlenderAdjustedNetProductionOfFinishedMotorGasoline`	U.S. Refiner and Blender Adjusted Net Production of Finished Motor Gasoline in Thousand Barrels per Day (Mbbl/d)
PET.WGFSTUS1.W	`USEnergy.Petroleum.UnitedStates.WeeklyEndingStocksOfFinishedMotorGasoline`	U.S. Ending Stocks of Finished Motor Gasoline in Thousand Barrels (Mbbl)
PET.WGFUPUS2.W	`USEnergy.Petroleum.UnitedStates.WeeklyProductSuppliedOfFinishedMotorGasoline`	U.S. Product Supplied of Finished Motor Gasoline in Thousand Barrels per Day (Mbbl/d)
PET.WCSSTUS1.W	`USEnergy.Petroleum.UnitedStates.WeeklyEndingStocksOfCrudeOilInSpr`	U.S. Ending Stocks of Crude Oil in SPR in Thousand Barrels (Mbbl)
PET.WDGRPUS2.W	`USEnergy.Petroleum.UnitedStates.WeeklyRefinerAndBlenderNetProductionOfDistillateFuelOilGreaterThan500PpmSulfur`	U.S. Refiner and Blender Net Production of Distillate Fuel Oil Greater than 500 ppm Sulfur in Thousand Barrels per Day (Mbbl/d)
PET.WDGSTUS1.W	`USEnergy.Petroleum.UnitedStates.WeeklyEndingStocksOfDistillateFuelOilGreaterThan500PpmSulfur`	U.S. Ending Stocks of Distillate Fuel Oil, Greater Than 500 ppm Sulfur in Thousand Barrels (Mbbl)

PET.WDIEXUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyExportsOfTotalDistillate	U.S. Exports of Total Distillate in Thousand Barrels per Day (Mbbl/d)
PET.WDIIMUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyImportsOfDistillateFuelOil	U.S. Imports of Distillate Fuel Oil in Thousand Barrels per Day (Mbbl/d)
PET.WDIRPUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyRefinerAndBlenderNetProductionOfDistillateFuelOil	U.S. Refiner and Blender Net Production of Distillate Fuel Oil in Thousand Barrels per Day (Mbbl/d)
PET.WKJSTUS1.W	USEnergy.Petroleum.UnitedStates.WeeklyEndingStocksOfKeroseneTypeJetFuel	U.S. Ending Stocks of Kerosene-Type Jet Fuel in Thousand Barrels (Mbbl)
PET.WKJUPUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyProductSuppliedOfKeroseneTypeJetFuel	U.S. Product Supplied of Kerosene-Type Jet Fuel in Thousand Barrels per Day (Mbbl/d)
PET.WGTIMUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyImportsOfTotalGasoline	U.S. Imports of Total Gasoline in Thousand Barrels per Day (Mbbl/d)
PET.WGTSTUS1.W	USEnergy.Petroleum.UnitedStates.WeeklyEndingStocksOfTotalGasoline	U.S. Ending Stocks of Total Gasoline in Thousand Barrels (Mbbl)
PET.WGIRIUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyGrossInputsIntoRefineries	U.S. Gross Inputs into Refineries in Thousand Barrels per Day (Mbbl/d)
PET.WGRIMUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyImportsOfReformulatedMotorGasoline	U.S. Imports of Reformulated Motor Gasoline in Thousand Barrels per Day (Mbbl/d)
PET.WGRRPUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyRefinerAndBlenderNetProductionOfReformulatedMotorGasoline	U.S. Refiner and Blender Net Production of Reformulated Motor Gasoline in Thousand Barrels per Day (Mbbl/d)
PET.WGRSTUS1.W	USEnergy.Petroleum.UnitedStates.WeeklyEndingStocksOfReformulatedMotorGasoline	U.S. Ending Stocks of Reformulated Motor Gasoline in Thousand Barrels (Mbbl)
PET.WDISTUS1.W	USEnergy.Petroleum.UnitedStates.WeeklyEndingStocksOfDistillateFuelOil	U.S. Ending Stocks of Distillate Fuel Oil in Thousand Barrels (Mbbl)
PET.WDIUPUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyProductSuppliedOfDistillateFuelOil	U.S. Product Supplied of Distillate Fuel Oil in Thousand Barrels per Day (Mbbl/d)
PET.WKMRPUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyRefinerAndBlenderNetProductionOfMilitaryKeroseneTypeJetFuel	U.S. Refiner and Blender Net Production of Military Kerosene-Type Jet Fuel in Thousand Barrels per Day (Mbbl/d)
PET.WOCLEUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyOperableCrudeOilDistillationCapacity	U. S. Operable Crude Oil Distillation Capacity in Thousand Barrels per Calendar Day (Mbbl/d)
PET.WPLSTUS1.W	USEnergy.Petroleum.UnitedStates.WeeklyPropyleneNonfuelUseStocksAtBulkTerminals	U.S. Propylene Nonfuel Use Stocks at Bulk Terminals in Thousand Barrels (Mbbl)
PET.WPRSTUS1.W	USEnergy.Petroleum.UnitedStates.WeeklyEndingStocksOfPropaneAndPropylene	U.S. Ending Stocks of Propane and Propylene in Thousand Barrels (Mbbl)
PET.WPULEUS3.W	USEnergy.Petroleum.UnitedStates.WeeklyPercentUtilizationOfRefineryOperableCapacity	U.S. Percent Utilization of Refinery Operable Capacity in Percent (%)
PET.WREEXUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyExportsOfResidualFuelOil	U.S. Exports of Residual Fuel Oil in Thousand Barrels per Day (Mbbl/d)
PET.WREIMUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyImportsOfResidualFuelOil	U.S. Imports of Residual Fuel Oil in Thousand Barrels per Day (Mbbl/d)

PET.WKCRPUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyRefinerAndBlenderNetProductionOfCommercialKeroseneTypeJetFuel	U.S. Refiner and Blender Net Production of Commercial Kerosene-Type Jet Fuel in Thousand Barrels per Day (Mbbl/d)
PET.WKJEXUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyExportsOfKeroseneTypeJetFuel	U.S. Exports of Kerosene-Type Jet Fuel in Thousand Barrels per Day (Mbbl/d)
PET.WKJIMUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyImportsOfKeroseneTypeJetFuel	U.S. Imports of Kerosene-Type Jet Fuel in Thousand Barrels per Day (Mbbl/d)
PET.WKJRPUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyRefinerAndBlenderNetProductionOfKeroseneTypeJetFuel	U.S. Refiner and Blender Net Production of Kerosene-Type Jet Fuel in Thousand Barrels per Day (Mbbl/d)
PET.WCESTUS1.W	USEnergy.Petroleum.UnitedStates.WeeklyEndingStocksExcludingSprOfCrudeOil	U.S. Ending Stocks excluding SPR of Crude Oil in Thousand Barrels (Mbbl)
PET.WCREXUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyExportsOfCrudeOil	U.S. Exports of Crude Oil in Thousand Barrels per Day (Mbbl/d)
PET.WCRFPUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyFieldProductionOfCrudeOil	U.S. Field Production of Crude Oil in Thousand Barrels per Day (Mbbl/d)
PET.WCRIMUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyImportsOfCrudeOil	U.S. Imports of Crude Oil in Thousand Barrels per Day (Mbbl/d)
PET.WCRNTUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyNetImportsOfCrudeOil	U.S. Net Imports of Crude Oil in Thousand Barrels per Day (Mbbl/d)
PET.WCRRIUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyRefinerNetInputOfCrudeOil	U.S. Refiner Net Input of Crude Oil in Thousand Barrels per Day (Mbbl/d)

Example Applications

The EIA dataset enables you to monitor national and international oil production and consumption in you trading strategies. Examples include the following strategies:

- Trading petroleum companies when there is a change in net imports of petroleum products
- Trading country ETFs when there is a change in the country's net import of resources
- Adjusting exposure to vehicle manufacturer stocks when the supply of gasoline is higher/lower than historical levels

Classic Algorithm Example

The following example algorithm buy a petroleum company when net imports of petroleum products are increasing. When the net imports are decreasing, it short sells the company.

```py
from AlgorithmImports import *

class USEnergyDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Requesting data, we trade Exxon Mobil Corp (XOM) as the proxy of petroleum investment
        self._xom = self.add_equity("XOM", Resolution.DAILY).symbol
        us_energy_symbol = self.add_data(USEnergy, USEnergy.Petroleum.UnitedStates.WEEKLY_NET_IMPORTS_OF_TOTAL_PETROLEUM_PRODUCTS).symbol

        # Historical data
        history = self.history(USEnergy, us_energy_symbol, 60, Resolution.DAILY)
        self.log(f"We got {len(history)} items from our history request")

        # Get latest value for net imports of petroleum products
        self.previous_value = history.loc[us_energy_symbol].values[-1, -1]

    def on_data(self, slice: Slice) -> None:
        # Gather the current net imports of petroleum products
        points = slice.get(USEnergy).values()
        if not points:
            return
        current_value = points[-1].value
        self.plot('Net Imports', 'Petroleum', current_value)

        # Buy when net imports of petroleum products are increasing
        if current_value > self.previous_value:
            self.set_holdings(self._xom, 1)

        # Short sell when net imports of petroleum products are decreasing
        elif current_value < self.previous_value:
            self.set_holdings(self._xom, -1)

        self.previous_value = current_value
```

Framework Algorithm Example

The following example algorithm buy a petroleum company when net imports of petroleum products are increasing. When the net imports are decreasing, it short sells the company.

```
PY
```

```
from AlgorithmImports import *

ExtractAlpha

Cross Asset Model

Introduction

The Cross Asset Model by ExtractAlpha provides stock scoring values based on the trading activity in the Options market. Since the Options market has a higher proportion of institutional traders than the Equities market, the Options market is composed of investors who are more informed and information-driven on average. The data covers a dynamic universe of over 3,000 US Equities, starts in July 2005, and is delivered on a daily frequency. This dataset is created by feature engineering on the Options market put-call spread, volatility skewness, and volume.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Cross Asset Model dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

ExtractAlpha was founded by Vinesh Jha in 2013 with the goal of providing alternative data for investors. ExtractAlpha's rigorously researched data sets and quantitative stock selection models leverage unique sources and analytical techniques, allowing users to gain an investment edge.

Getting Started

The following snippet demonstrates how to request data from the Cross Asset Model dataset:

```
self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
self.dataset_symbol = self.add_data(ExtractAlphaCrossAssetModel, self.aapl).symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	July 2005
Asset Coverage	Over 3,000 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add Cross Asset Model data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
class ExtractAlphaCrossAssetModelDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
        self.dataset_symbol = self.add_data(ExtractAlphaCrossAssetModel, self.aapl).symbol
```

Accessing Data

To get the current Cross Asset Model data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.log(f"{self.dataset_symbol} score at {slice.time}: {data_point.score}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.get(ExtractAlphaCrossAssetModel).items():
        self.log(f"{dataset_symbol} score at {slice.time}: {data_point.score}")
```

Historical Data

To get historical Cross Asset Model data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.history(self.dataset_symbol, 100, Resolution.DAILY)

# Dataset objects
history_bars = self.history[ExtractAlphaCrossAssetModel](self.dataset_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
self.remove_security(self.dataset_symbol)
```

If you subscribe to Cross Asset Model data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Cross Asset Model dataset by ExtractAlpha enables you to utilize Options market information to extract alpha. Examples include the following strategies:

- Predicting price and volatility changes in Equities.
- Signaling arbitrage opportunities between Options and underlying assets.
- Using it as a stock selection indicator.

Classic Algorithm Example

The following example algorithm creates a dynamic universe of the 100 most liquid US Equities. Each day, the algorithm forms an equal-weighted dollar-neutral portfolio of the 10 companies most likely to outperform and the 10 companies most likely to underperform.

```py
from AlgorithmImports import *

class ExtractAlphaCrossAssetModelAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100_000)
        self._points = {}
        self.add_universe(self._select_assets)
        # Add a Scheduled Event to rebalance the portfolio each day.
        spy = Symbol.create('SPY', SecurityType.EQUITY, Market.USA)
        self.schedule.on(
            self.date_rules.every_day(spy),
            self.time_rules.after_market_open(spy, 30),
            self._rebalance
        )

    def _select_assets(self, coarse: List[Fundamental]) -> List[Symbol]:
        # Select non-penny stocks with highest dollar volume due to better informed information from more market activities
        # Only the ones with fundamental data are supported by cross asset model data
        sorted_by_dollar_volume = sorted(
            [x for x in coarse if x.has_fundamental_data and x.price > 4],
            key=lambda x: x.dollar_volume
        )
        return [x.symbol for x in sorted_by_dollar_volume[-100:]]

    def on_data(self, slice: Slice) -> None:
        # Get the current data from the cross asset model.
        points = slice.get(ExtractAlphaCrossAssetModel)
        if points:
            self._points = points
            ## Demonstrate how to iterate through the data and access its members:
            #for dataset_symbol, model in points.items():
            #    self.quit(
            #        f"{self.time} -- "
            #        f"Asset Symbol: {dataset_symbol.underlying}; "
            #        f"Score: {model.score} "
            #    )

    def _rebalance(self):
        # Long the ones with the highest return estimates based on option trade data
        # Short the lowest return ones
        sorted_by_score = sorted(
            [
                x for x in self._points.items()
                # Remove assets that have no price or score.
                if self.securities[x[0].underlying].price and x[1].score
            ],
            key=lambda x: x[1].score
        )
        long_symbols = [x[0].underlying for x in sorted_by_score[-10:]]
        short_symbols = [x[0].underlying for x in sorted_by_score[:10]]

        # Liquidate the ones without a strong trading signal
        # Invest equally and dollar-neutral to evenly dissipate capital risk and hedge systematic risk
        long_targets = [PortfolioTarget(symbol, 0.05) for symbol in long_symbols]
        short_targets = [PortfolioTarget(symbol, -0.05) for symbol in short_symbols]
        self.set_holdings(long_targets + short_targets, True)

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            # Requesting cross asset model data for trading signal generation
            security.cross_asset_model = self.add_data(
                ExtractAlphaCrossAssetModel, security.symbol
            ).symbol
            # Historical Data
            history = self.history(security.cross_asset_model, 2, Resolution.DAILY)
        for security in changes.removed_securities:
            # Remove the cross asset model data for this asset when it leaves the universe.
            self.remove_security(security.cross_asset_model)
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of the 100 most liquid US Equities. Each day, the algorithm forms an equal-weighted dollar-neutral portfolio of the 10 companies most likely to outperform and the 10 companies most likely to underperform.

```py
from AlgorithmImports import *

class ExtractAlphaCrossAssetModelFrameworkAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.add_universe_selection(LiquidEquitiesUniverseSelectionModel())
        # Custom alpha model emits insights based on cross asset model data
        self.add_alpha(ExtractAlphaCrossAssetModelAlphaModel())
        # Invest equally and dollar-neutral to evenly dissipate capital risk and hedge systematic risk
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())
        self.set_execution(ImmediateExecutionModel())

class LiquidEquitiesUniverseSelectionModel(FundamentalUniverseSelectionModel):

    def select(self, algorithm: QCAlgorithm, fundamentals: List[Fundamental]) -> List[Symbol]:
        # Select non-penny stocks with highest dollar volume due to better informed information from more market activities
        # Only the ones with fundamental data are supported by cross asset model data
        sorted_by_dollar_volume = sorted(
            [x for x in fundamentals if x.has_fundamental_data and x.price > 4],
            key=lambda x: x.dollar_volume
        )
        return [x.symbol for x in sorted_by_dollar_volume[-100:]]

class ExtractAlphaCrossAssetModelAlphaModel(AlphaModel):

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        # Get the current data from the cross asset model.
        points = slice.get(ExtractAlphaCrossAssetModel)
        ## Demonstrate how to iterate through the data and access its members:
        #for dataset_symbol, model in points.items():
        #    algorithm.quit(
        #        f"{algorithm.time} -- "

            # Remove the cross asset model data for this asset when it leaves the universe.
            algorithm.remove_security(security.cross_asset_model)
```

Data Point Attributes

The Cross Asset Model dataset provides `ExtractAlphaCrossAssetModel` objects, which have the following attributes:

ExtractAlpha

Estimize

Introduction

The Estimize dataset by ExtractAlpha estimates the financials of companies, including EPS, and revenues. The data covers over 2,800 US-listed Equities' EPS/Revenue. The data starts in January 2011 and is updated on a daily frequency. The data is sparse, and it doesn't have new updates every day. This dataset is crowdsourced from a community of 100,000+ contributors via the data provider's web platform.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Estimize dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

ExtractAlpha was founded by Vinesh Jha in 2013 with the goal of providing alternative data for investors. ExtractAlpha's rigorously researched data sets and quantitative stock selection models leverage unique sources and analytical techniques, allowing users to gain an investment edge.

Getting Started

The following snippet demonstrates how to request data from the Estimize dataset:

```
self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
self.estimize_consensus_symbol = self.add_data(EstimizeConsensus, self.symbol).symbol
self.estimize_estimate_symbol = self.add_data(EstimizeEstimate, self.symbol).symbol
self.estimize_release_symbol = self.add_data(EstimizeRelease, self.symbol).symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2011
Asset Coverage	2,800 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add Estimize data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
class ExtractAlphaEstimizeDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
        self.estimize_consensus_symbol = self.add_data(EstimizeConsensus, self.aapl).symbol
        self.estimize_estimate_symbol = self.add_data(EstimizeEstimate, self.aapl).symbol
        self.estimize_release_symbol = self.add_data(EstimizeRelease, self.aapl).symbol
```

Accessing Data

To get the current Estimize data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.estimize_consensus_symbol):
        data_point = slice[self.estimize_consensus_symbol]
        self.log(f"{self.estimize_consensus_symbol} mean at {slice.time}: {data_point.mean}")

    if slice.contains_key(self.estimize_estimate_symbol):
        data_point = slice[self.estimize_estimate_symbol]
        self.log(f"{self.estimize_estimate_symbol} EPS at {slice.time}: {data_point.eps}")

    if slice.contains_key(self.estimize_release_symbol):
        data_point = slice[self.estimize_release_symbol]
        self.log(f"{self.estimize_release_symbol} EPS at {slice.time}: {data_point.eps}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
PY
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.get(EstimizeConsensus).items():
        self.log(f"{dataset_symbol} mean at {slice.time}: {data_point.mentions}")

    for dataset_symbol, data_point in slice.get(EstimizeEstimate).items():
        self.log(f"{dataset_symbol} EPS at {slice.time}: {data_point.eps}")

    for dataset_symbol, data_point in slice.get(EstimizeRelease).items():
        self.log(f"{dataset_symbol} EPS at {slice.time}: {data_point.eps}")
```

Historical Data

To get historical Estimize data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrames
consensus_history_df = self.history(self.estimize_consensus_symbol, 100, Resolution.DAILY)
estimate_history_df = self.history(self.estimize_estimate_symbol, 100, Resolution.DAILY)
release_history_df = self.history(self.estimize_release_symbol, 100, Resolution.DAILY)
history_df = self.history([
    self.estimize_consensus_symbol,
    self.estimize_estimate_symbol,
    self.estimize_release_symbol], 100, Resolution.DAILY)

# Dataset objects
consensus_history_bars = self.history[EstimizeConsensus](self.estimize_consensus_symbol, 100, Resolution.DAILY)
estimate_history_bars = self.history[EstimizeEstimate](self.estimize_estimate_symbol, 100, Resolution.DAILY)
release_history_bars = self.history[EstimizeRelease](self.estimize_release_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
PY
self.remove_security(self.estimize_consensus_symbol)
self.remove_security(self.estimize_estimate_symbol)
self.remove_security(self.estimize_release_symbol)
```

If you subscribe to Estimize data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Estimize dataset enables you to estimate the financial data of a company more accurately for alpha. Examples include the following use cases:

- Fundamental estimates for ML regression/classification models

- Arbitrage/Sentiment trading on market “surprise” from ordinary expectations based on the better expectation by the dataset
- Using industry-specific KPIs to predict the returns of individual sectors

Classic Algorithm Example

The following example algorithm creates a dynamic universe of the 250 most liquid US Equities. Each morning, the algorithm forms an equal-weighted with the companies that have a new EPS estimate.

```py
from AlgorithmImports import *

class ExtractAlphaEstimizeAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Add a dictionary to hold the latest Consensus data since this dataset is sparse.
        self._consensus_by_symbol = {}
        # Add a universe of liquid US Equities.
        self.add_universe(self._select_assets)
        # Add a Scheduled Event to rebalance the portfolio each day.
        spy = Symbol.create('SPY', SecurityType.EQUITY, Market.USA)
        self.schedule.on(
            self.date_rules.every_day(spy),
            self.time_rules.after_market_open(spy, 1),
            self._rebalance
        )

    def _select_assets(self, fundamentals: List[Fundamental]) -> List[Symbol]:
        # Select the non-penny stocks with the highest dollar volume,
        # since they have more stable price (lower risk) and more
        # informed insights from high market activities
        sorted_by_dollar_volume = sorted(
            [x for x in fundamentals if x.has_fundamental_data and x.price > 4],
            key=lambda x: x.dollar_volume
        )
        return [x.symbol for x in sorted_by_dollar_volume[-250:]]

    def on_data(self, slice: Slice) -> None:
        # Record the latest Consensus data.
        consensus = slice.get(EstimizeConsensus)
        if not consensus:
            return
        for dataset_symbol, value in consensus.items():
            self._consensus_by_symbol[dataset_symbol.underlying] = value

    def _rebalance(self):
        if not self._consensus_by_symbol:
            return
        # If there has been new Consensus data released since the previous
        # market open, form an equal-weighted portfolio of all the assets
        # that have new Consensus data.
        symbols = [
            symbol for symbol in self._consensus_by_symbol.keys()
            if self.securities[symbol].price
        ]
        targets = [PortfolioTarget(symbol, 1/len(symbols)) for symbol in symbols]
        self.set_holdings(targets, True)
        self._consensus_by_symbol.clear()

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            # Requesting data for trading signal generation
            security.consensus = self.add_data(EstimizeConsensus, security.symbol).symbol
            # Historical data
            history = self.history(security.consensus, 100, Resolution.DAILY)
        for security in changes.removed_securities:
            # Remove the Consensus data for this asset when it leaves the universe.
            self.remove_security(security.consensus)
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of the 250 most liquid US Equities. Each morning, the algorithm emits insights for the companies that have a new EPS estimate.

```py
from AlgorithmImports import *

class ExtractAlphaEstimizeFrameworkAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.add_universe_selection(LiquidEquitiesUniverseSelectionModel())
        # Custom alpha model that emit signal according to Estimize data
        self.add_alpha(ExtractAlphaEstimizeAlphaModel())
        # Invest equally to evenly dissipate capital concentration risk
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())
        self.set_execution(ImmediateExecutionModel())

class LiquidEquitiesUniverseSelectionModel(FundamentalUniverseSelectionModel):

    def select(self, algorithm: QCAlgorithm, fundamentals: List[Fundamental]) -> List[Symbol]:
        # Select the non-penny stocks with the highest dollar volume,
        # since they have more stable price (lower risk) and more
        # informed insights from high market activities
        sorted_by_dollar_volume = sorted(
            [x for x in fundamentals if x.has_fundamental_data and x.price > 4],
            key=lambda x: x.dollar_volume
        )
        return [x.symbol for x in sorted_by_dollar_volume[-250:]]

class ExtractAlphaEstimizeAlphaModel(AlphaModel):

    # Add a dictionary to hold the latest Consensus data since this dataset is sparse.
    _consensus_by_symbol = {}
    _day = -1

Data Point Attributes

The Estimize dataset provides `EstimizeConsensus` , `EstimizeEstimate` , and `EstimizeRelease` objects.

EstimizeConsensus Attributes

`EstimizeConsensus` objects have the following attributes:

EstimizeEstimate Attributes

`EstimizeEstimate` objects have the following attributes:

EstimizeRelease Attributes

`EstimizeRelease` objects have the following attributes:

ExtractAlpha

Tactical

Introduction

The Tactical dataset by ExtractAlpha is a stock scoring algorithm that captures the technical dynamics of individual US Equities over one to ten trading day horizons. It can assist a longer-horizon investor in timing their entry or exit points or be used in combination with existing systematic or qualitative strategies with similar holding periods.

The data covers a dynamic universe of around 4,700 US Equities per day on average, starts in January 2000, and is delivered on a daily frequency. The Tactical dataset expands upon simple reversal, liquidity, and seasonality factors to identify stocks that are likely to trend or reverse.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Tactical dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

ExtractAlpha was founded by Vinesh Jha in 2013 with the goal of providing alternative data for investors. ExtractAlpha's rigorously researched data sets and quantitative stock selection models leverage unique sources and analytical techniques, allowing users to gain an investment edge.

Getting Started

The following snippet demonstrates how to request data from the Tactical dataset:

```
self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
self.dataset_symbol = self.add_data(ExtractAlphaTacticalModel, self.aapl).symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2000
Asset Coverage	5,000 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add Tactical data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
class ExtractAlphaTacticalModelDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
        self.dataset_symbol = self.add_data(ExtractAlphaTacticalModel, self.aapl).symbol
```

Accessing Data

To get the current Tactical data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.log(f"{self.dataset_symbol} score at {slice.time}: {data_point.score}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
PY
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.get(ExtractAlphaTacticalModel).items():
        self.log(f"{dataset_symbol} score at {slice.time}: {data_point.score}")
```

Historical Data

To get historical Tactical data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.history(self.dataset_symbol, 100, Resolution.DAILY)

# Dataset objects
history_df = self.history[ExtractAlphaTacticalModel](self.dataset_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
PY
self.remove_security(self.dataset_symbol)
```

If you subscribe to Tactical data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Tactical dataset enables you to gain insight into short-term stock dynamics for trading. Examples include the following strategies:

- Optimizing entry and exit times in a portfolio construction model.
- Using the raw factor values as technical indicators.
- Inputting the data into machine learning classifier models as trend/reversal labels.

Classic Algorithm Example

The following example algorithm creates a dynamic universe of the 100 most liquid US Equities. Each day, it then forms an equal-weighted dollar-neutral portfolio of the 10 companies that are most likely to outperform and the 10 that are most likely to underperform.

```py
from AlgorithmImports import *

class ExtractAlphaTacticalModelAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100_000)
        self.add_universe(self._select_assets)

    def _select_assets(self, coarse: List[Fundamental]) -> List[Symbol]:
        # Select non-penny stocks with highest dollar volume due to better informed information from more market activities
        # Only the ones with fundamental data are supported by tactical data
        sorted_by_dollar_volume = sorted(
            [x for x in coarse if x.has_fundamental_data and x.price > 4],
            key=lambda x: x.dollar_volume
        )
        return [x.symbol for x in sorted_by_dollar_volume[-100:]]

    def on_data(self, slice: Slice) -> None:
        # Get the current data from the tactical dataset.
        points = slice.get(ExtractAlphaTacticalModel)
        ## Demonstrate how to iterate through the data and access its members:
        #for dataset_symbol, model in points.items():
        #    self.quit(
        #        f"{self.time} -- "
        #        f"Asset Symbol: {dataset_symbol.underlying}; "
        #        f"Score: {model.score} "
        #    )

        # Remove assets that have no price.
        points = [x for x in points.items() if self.securities[x[0].underlying].price]
        # Only rebalance when there are new tactical factors.
        if not points:
            return

        # Long the ones with the highest return estimates riding from tactical strategies
        # Short the lowest that predicted stock price goes down
        sorted_by_score = sorted(points, key=lambda x: x[1].score)
        long_symbols = [x[0].underlying for x in sorted_by_score[-10:]]
        short_symbols = [x[0].underlying for x in sorted_by_score[:10]]
        long_targets = [PortfolioTarget(symbol, 0.05) for symbol in long_symbols]
        short_targets = [PortfolioTarget(symbol, -0.05) for symbol in short_symbols]
        self.set_holdings(long_targets + short_targets, True)

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            # Requesting tactical data for trading signal generation
            security.tactical_model = self.add_data(
                ExtractAlphaTacticalModel, security.symbol
            ).symbol
            # Historical Data
            history = self.history(security.tactical_model, 2, Resolution.DAILY)
        for security in changes.removed_securities:
            # Remove the tactical model data for this asset when it leaves the universe.
            self.remove_security(security.tactical_model)
```

```

Data Point Attributes

The Tactical dataset provides `ExtractAlphaTacticalModel` objects, which have the following attributes:

ExtractAlpha

True Beats

Introduction

The True Beats dataset by ExtractAlpha provides quantitative predictions of EPS and Revenues for US Equities. The data covers a dynamic universe of around 4,000-5,000 US-listed Equities on a daily average. The data starts in January 2000 and is delivered on a daily frequency. This dataset is created by incorporating the opinions of expert analysts, historical earnings, revenue trends for the company and its peers, and metrics on company earnings management.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the True Beats dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

ExtractAlpha was founded by Vinesh Jha in 2013 with the goal of providing alternative data for investors. ExtractAlpha's rigorously researched data sets and quantitative stock selection models leverage unique sources and analytical techniques, allowing users to gain an investment edge.

Getting Started

The following snippet demonstrates how to request data from the True Beats dataset:

```
self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
self.dataset_symbol = self.add_data(ExtractAlphaTrueBeats, self.aapl).symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2000
Asset Coverage	Over 5,000 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add True Beats data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
class ExtractAlphaTrueBeatsDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
        self.dataset_symbol = self.add_data(ExtractAlphaTrueBeats, self.aapl).symbol
```

Accessing Data

To get the current True Beats data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.log(f"{self.dataset_symbol} True beat at {slice.time}: {data_point.true_beat}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.get(ExtractAlphaTrueBeats).items():
        self.log(f"{dataset_symbol} True beat at {slice.time}: {data_point.true_beat}")
```

Historical Data

To get historical True Beats data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.history(self.dataset_symbol, 100, Resolution.DAILY, flatten=True)

# Series
history_series = self.history(self.dataset_symbol, 100, Resolution.DAILY)

# Dataset objects
history_bars = self.history[ExtractAlphaTrueBeats](self.dataset_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
self.remove_security(self.dataset_symbol)
```

If you subscribe to True Beats data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The True Beats dataset enables you to predict EPS and revenue of US-listed Equities for trading. Examples include the following strategies:

- Finding surprise in EPS or revenue for sentiment/arbitrage trading
- Stock or sector selections based on EPS or revenue predictions
- Calculate expected return by valuation models based on EPS or revenue predictions (e.g. Black-Litterman)

Classic Algorithm Example

The following example algorithm creates a dynamic universe of the 100 most liquid US Equities. Each day, it then forms an equal-weighted dollar-neutral portfolio of the 10 best and 10 worst companies based on their predicted earnings per share.

```
from AlgorithmImports import *

Data Point Attributes

The True Beats dataset provides `ExtractAlphaTrueBeats` and `ExtractAlphaTrueBeat` objects.

ExtractAlphaTrueBeats

`ExtractAlphaTrueBeats` objects have the following attributes:

ExtractAlphaTrueBeat

`ExtractAlphaTrueBeat` objects have the following attributes:

Datasets

FRED

The Research Division of the Federal Reserve bank of St. Louis, MO expands the frontier of economic knowledge by producing high-quality original research in the areas of macroeconomics, money and banking, and applied microeconomics. They contribute to monetary policy discussions by advising the Bank president on a range of topics, especially in preparation for Federal Open Market Committee (FOMC) meetings. The Research Division is in the top 1% of all economics research departments worldwide.

US Federal Reserve (FRED)

FRED

US Federal Reserve (FRED)

Introduction

The Federal Reserve Economic Data (FRED) by the Research Division of the Federal Reserve bank of St. Louis, MO provides various time series relating to macro-economic data. The data covers 560 datasets, starts in January 1999, and is delivered on a daily frequency. The data is created by aggregating daily updates from more than 85 public and proprietary sources.

For more information about the US Federal Reserve (FRED) dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

The Research Division of the Federal Reserve bank of St. Louis, MO expands the frontier of economic knowledge by producing high-quality original research in the areas of macroeconomics, money and banking, and applied microeconomics. They contribute to monetary policy discussions by advising the Bank president on a range of topics, especially in preparation for Federal Open Market Committee (FOMC) meetings. The Research Division is in the top 1% of all economics research departments worldwide.

Getting Started

The following snippet demonstrates how to request data from the FRED dataset:

```
PY
self.dataset_symbol = self.add_data(Fred, "USARECDM", Resolution.DAILY).symbol
```

QuantConnect provides helpers to find some of the available datasets from FRED:

```
PY
self.dataset_symbol = self.add_data(Fred, Fred.OECDRecessionIndicators.UNITED_STATES_FROM_PEAK_THROUGH_THE_TROUGH,
Resolution.DAILY).symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1990
Asset Coverage	560 Datasets
Data Density	Sparse
Resolution	Daily
Timezone	New York

Requesting Data

To add FRED data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
class FredAlternativeDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2003, 1, 1)
        self.set_end_date(2019, 10, 11)
        self.set_cash(100000)

        self.dataset_symbol = self.add_data(Fred, Fred.OECDRecessionIndicators.UNITED_STATES_FROM_PEAK_THROUGH_THE_TROUGH,
Resolution.DAILY).symbol
```

Accessing Data

To get the current FRED data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.log(f"{self.dataset_symbol} value at {slice.time}: {data_point.value}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.get(Fred).items():
        self.log(f"{dataset_symbol} value at {slice.time}: {data_point.value}")
```

Historical Data

To get historical FRED data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.history(self.dataset_symbol, 100, Resolution.DAILY)

# Dataset objects
history_bars = self.history[Fred](self.dataset_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove your subscription to FRED data, call the `remove_security` method.

```
self.remove_security(self.dataset_symbol)
```

Supported Datasets

The following lists show the accessor code you need to add each FRED dataset to your algorithm. This list does `not` include all fields from the FRED database. Please refer to FRED website for additional fields.

CBOE

- `Fred.CBOE.VIX_ON_GOOGLE` : CBOE Equity VIX on Google (in Index) (`VXGOGCLS`)
- `Fred.CBOE.VXD` : CBOE DJIA Volatility Index (in Index) (`VXDCLS`)
- `Fred.CBOE.VIX_ON_GOLDMAN_SACHS` : CBOE Equity VIX on Goldman Sachs (in Index) (`VXGSCLS`)
- `Fred.CBOE.VIX_ON_IBM` : CBOE Equity VIX on IBM (in Index) (`VXIBMCLS`)
- `Fred.CBOE.VIX_ON_AMAZON` : CBOE Equity VIX on Amazon (in Index) (`VXAZNCLS`)
- `Fred.CBOE.VXO` : CBOE S&P 100 Volatility Index: VXO (in Index) (`VXOCLS`)
- `Fred.CBOE.VXN` : CBOE NASDAQ 100 Volatility Index (in Index) (`VXNCLS`)

- Fred.CBOE.TEN_YEAR_TREASURY_NOTE_VOLATILITY_FUTURES : CBOE 10-Year Treasury Note Volatility Futures (in Index) (VXTYN)
- Fred.CBOE.RVX : CBOE Russell 2000 Volatility Index (in Index) (RVXCLS)
- Fred.CBOE.SP_500_THREE_MONTH_VOLATILITY_INDEX : CBOE S&P 500 3-Month Volatility Index (in Index) (VXVCLS)
- Fred.CBOE.VIX_ON_APPLE : CBOE Equity VIX on Apple (in Index) (VXAPLCLS)
- Fred.CBOE.GOLD_MINERS_ETF_VOLATILITY_INDEX : CBOE Gold Miners ETF Volatility Index (in Index) (VXGDXCLS)
- Fred.CBOE.CHINA_ETF_VOLATILITY_INDEX : CBOE China ETF Volatility Index (in Index) (VXFXICLS)
- Fred.CBOE.BRAZIL_ETF_VOLATILITY_INDEX : CBOE Brazil ETF Volatility Index (in Index) (VXEWZCLS)
- Fred.CBOE.EMERGING_MARKETS_ETF_VOLATILITY_INDEX : CBOE Emerging Markets ETF Volatility Index (in Index) (VXEEMCLS)
- Fred.CBOE.EURO_CURRENCY_ETF_VOLATILITY_INDEX : CBOE EuroCurrency ETF Volatility Index (in Index) (EVZCLS)
- Fred.CBOE.GOLD_ETF_VOLATILITY_INDEX : CBOE Gold ETF Volatility Index (in Index) (GVZCLS)
- Fred.CBOE.CRUDE_OIL_ETF_VOLATILITY_INDEX : CBOE Crude Oil ETF Volatility Index (in Index) (OVXCLS)
- Fred.CBOE.SILVER_ETF_VOLATILITY_INDEX : CBOE Silver ETF Volatility Index (in Index) (VXSLVCLS)
- Fred.CBOE.ENERGY_SECTOR_ETF_VOLATILITY_INDEX : CBOE Energy Sector ETF Volatility Index (in Index) (VXXLECLS)
- Fred.CBOE.VIX : CBOE Volatility Index: VIX (in Index) (VIXCLS)

Central Bank Interventions

- Fred.CentralBankInterventions.JAPANESE_BANK_PURCHASES_OF_DM_EURO_AGAINST_JPY : Japan Intervention: Japanese Bank purchases of DM/Euro against JPY (in 100 Million Yen) (JPINTDDMEJPY)
- Fred.CentralBankInterventions.JAPANESE_BANK_PURCHASES_OF_USD_AGAINST_DM : Japan Intervention: Japanese Bank purchases of USD against DM (in 100 Million Yen) (JPINTDEXR)
- Fred.CentralBankInterventions.JAPANESE_BANK_PURCHASES_OF_USD_AGAINST_RUPIAH : Japan Intervention: Japanese Bank purchases of USD against Rupiah (in 100 Million Yen) (JPINTDUSDRP)
- Fred.CentralBankInterventions.US_INTERVENTION_IN_MARKET_TRANSACTIONS_IN_THE_JPY_USD : U.S. Intervention: in Market Transactions in the JPY/USD (Millions of USD) (in Millions of USD) (USINTDMRKTJPY)
- Fred.CentralBankInterventions.US_INTERVENTION_WITH_CUSTOMER_TRANSACTIONS_IN_OTHER_CURRENCIES : U.S. Intervention: With-Customer Transactions in Other Currencies (Millions of USD) (in Millions of USD) (USINTDCSOTH)
- Fred.CentralBankInterventions.US_INTERVENTION_WITH_CUSTOMER_TRANSACTIONS_IN_THE_JPY_USD : U.S. Intervention: With-Customer Transactions in the JPY/USD (Millions of USD) (in Millions of USD) (USINTDCSJPY)
- Fred.CentralBankInterventions.US_INTERVENTION_WITH_CUSTOMER_TRANSACTIONS_IN_THE_DEM_USD_EURO : U.S. Intervention: With-Customer Transactions in the DEM/USD (Euro since 1999) (Millions of USD) (in Millions of USD) (USINTDCSDM)
- Fred.CentralBankInterventions.US_INTERVENTION_IN_MARKET_TRANSACTIONS_IN_OTHER_CURRENCIES : U.S. Intervention: in Market Transactions in Other Currencies (Millions of USD) (in Millions of USD) (USINTDMRKTOTH)
- Fred.CentralBankInterventions.CENTRAL_BANK_OF_TURKEY_PURCHASES_OF_USD : Turkish Intervention: Central Bank of Turkey Purchases of USD (Millions of USD) (in Millions of USD) (TRINTDEXR)
- Fred.CentralBankInterventions.JAPANESE_BANK_PURCHASES_OF_USD_AGAINST_JPY : Japan Intervention: Japanese Bank purchases of USD against JPY (in 100 Million Yen) (JPINTDUSDJPY)
- Fred.CentralBankInterventions.US_INTERVENTION_IN_MARKET_TRANSACTIONS_IN_THE_DEM_USD_EURO : U.S. Intervention: in Market Transactions in the DEM/USD (Euro since 1999) (Millions of USD) (in Millions of USD) (USINTDMRKTDM)
- Fred.CentralBankInterventions.SWISS_NATIONAL_BANK_PURCHASES_OF_DEM_AGAINST_CHF_MILLIONS_OF_DEM : Swiss Intervention: Swiss National Bank Purchases of DEM against CHF (Millions of DEM) (in Millions of DEM) (CHINTDCHFDM)
- Fred.CentralBankInterventions.SWISS_NATIONAL_BANK_PURCHASES_OF_USD_AGAINST_DEM : Swiss Intervention: Swiss National Bank Purchases of USD against DEM (Millions of USD) (in Millions of USD) (CHINTDUSDDM)
- Fred.CentralBankInterventions.SWISS_NATIONAL_BANK_PURCHASES_OF_USD_AGAINST_JPY : Swiss Intervention: Swiss National Bank Purchases of USD against JPY (Millions of USD) (in Millions of USD) (CHINTDUSDJPY)
- Fred.CentralBankInterventions.SWISS_NATIONAL_BANK_PURCHASES_OF_USD_AGAINST_CHF : Swiss Intervention: Swiss National Bank Purchases of USD against CHF (Millions of USD) (in Millions of USD) (CHINTDCHFUSD)
- Fred.CentralBankInterventions.BANCO_DE_MEXICO_PURCHASE_ON_THE_USD : Mexican Intervention: Banco de Mexico Purchase on the USD (in Millions of USD) (MEXINTDUSD)

Commercial Paper

- Fred.CommercialPaper.THREE_MONTH_AA_NONFINANCIAL_COMMERCIAL_PAPER_RATE : 3-Month AA Nonfinancial Commercial Paper Rate (in Percent) (DCPN3M)

- `Fred.CommercialPaper.ONE_MONTH_AA_NONFINANCIAL_COMMERCIAL_PAPER_RATE` : 1-Month AA Nonfinancial Commercial Paper Rate (in Percent) (`DCPN30`)
- `Fred.CommercialPaper.TWO_MONTH_AA_NONFINANCIAL_COMMERCIAL_PAPER_RATE` : 2-Month AA Nonfinancial Commercial Paper Rate (in Percent) (`DCPN2M`)

- `Fred.OECDRecessionIndicators.SOUTH_AFRICA_FROM_PEAK_THROUGH_THE_PERIOD_PRECEDINGTHE_TROUGH` : OECD based Recession Indicators for South Africa from the Peak through the Period preceding the Trough (in +1 or 0) (`ZAFRECDP`)

Trade Weighted Indexes

- `Fred.TradeWeightedIndexes.MAJOR_CURRENCIES_GOODS` : Trade Weighted U.S. Dollar Index: Major Currencies, Goods (in Index Mar 1973=100) (`DTWEXM`)
- `Fred.TradeWeightedIndexes.OTHER_IMPORTANT_TRADING_PARTNERS_GOODS` : Trade Weighted U.S. Dollar Index: Other Important Trading Partners, Goods (in Index Jan 1997=100) (`DTWEXO`)
- `Fred.TradeWeightedIndexes.BROAD_GOODS` : Trade Weighted U.S. Dollar Index: Broad, Goods (in Index Jan 1997=100) (`DTWEXB`)
- `Fred.TradeWeightedIndexes.ADVANCED_FOREIGN_ECONOMIES_GOODS_AND_SERVICES` : Trade Weighted U.S. Dollar Index: Advanced Foreign Economies, Goods and Services (in Index Jan 2006=100) (`DTWEXAFEGS`)
- `Fred.TradeWeightedIndexes.BROAD_GOODS_AND_SERVICES` : Trade Weighted U.S. Dollar Index: Broad, Goods and Services (in Index Jan 2006=100) (`DTWEXBGS`)
- `Fred.TradeWeightedIndexes.EMERGING_MARKETS_ECONOMIES_GOODS_AND_SERVICES` : Trade Weighted U.S. Dollar Index: Emerging Markets Economies, Goods and Services (in Index Jan 2006=100) (`DTWEXEMEGS`)

Example Applications

The FRED dataset enables you to accurately design strategies utilizing macroeconomic indicators. Examples include the following strategies:

- Trading on macroeconomic factors
- Macroeconomic risk modeling

Classic Algorithm Example

The following example algorithm buys SPY when the FRED Peak to Trough value is 1. Otherwise, it holds cash.

```py
from AlgorithmImports import *

class FredAlternativeDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        self.spy = self.add_equity("SPY", Resolution.DAILY).symbol

        # Requesting FED US peak-to-trough OECD recession indicators for trade signal generation
        self.fred_peak_to_trough = self.add_data(Fred, Fred.OECDRecessionIndicators.UNITED_STATES_FROM_PEAK_THROUGH_THE_TROUGH,
Resolution.DAILY).symbol

        # Historical data
        history = self.history(self.fred_peak_to_trough, 60, Resolution.DAILY)
        self.debug(f"We got {len(history)} items from our history request")

    def on_data(self, slice: Slice) -> None:
        # Trade with updated FED peak-to-trough indicator
        if slice.contains_key(self.fred_peak_to_trough) and slice.contains_key(self.spy):
            peak_to_trough = slice.Get(Fred, self.fred_peak_to_trough).value

            # Buy SPY if peak to trough value is 0, which is the expansionary period
            if peak_to_trough == 0 and not self.portfolio.invested:
                self.set_holdings(self.spy, 1)

            # Liquidate holdings if peak to trough value is 1, which is recessionary period
            elif peak_to_trough == 1 and self.portfolio.invested:
                self.liquidate(self.spy)
```

Framework Algorithm Example

The following example algorithm buys SPY when the FRED Peak to Trough value is 1. Otherwise, it holds cash.

```
from AlgorithmImports import *

class FredAlternativeDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Universe contains only SPY as the market representative
        symbols = [ Symbol.create("SPY", SecurityType.EQUITY, Market.USA) ]
        self.add_universe_selection(ManualUniverseSelectionModel(symbols))
        # Invest equally to evenly dissipate the capital concentration risk
        self.add_alpha(FredAlphaModel(self))
        # Custom alpha model that use FED data as trade signals
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

class FredAlphaModel(AlphaModel):

    symbols = []
    peak_to_trough_value = None

    def __init__(self, algorithm: QCAlgorithm) -> None:
        # Requesting FED US peak-to-trough OECD recession indicators for trade signal generation
        self.fred_peak_to_trough = algorithm.add_data(Fred, Fred.OECDRecessionIndicators.UNITED_STATES_FROM_PEAK_THROUGH_THE_TROUGH,
Resolution.DAILY).symbol

        # Historical data
        history = algorithm.history(self.fred_peak_to_trough, 60, Resolution.DAILY)
        algorithm.debug(f"We got {len(history)} items from our history request")
        if history.empty:
            return
        self.peak_to_trough_value = history.loc[self.fred_peak_to_trough].value.iloc[-1]

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        insights = []

        # Trade with updated FED peak-to-trough indicator
        if slice.contains_key(self.fred_peak_to_trough):
            self.peak_to_trough_value = slice.Get(Fred, self.fred_peak_to_trough).value

        # Ensure we have a FRED peak to trough value
        if self.peak_to_trough_value is None:
            return []

        for symbol in self.symbols:
            # Ensure we have data for the security in the current Slice to avoid stale filling
            if not (slice.contains_key(symbol) and slice[symbol] is not None):
                continue

            # Buy SPY if peak to trough value is 0, which is the expansionary period
            if self.peak_to_trough_value == 0 and not algorithm.portfolio[symbol].invested:
                insights += [Insight.price(symbol, timedelta(days=365*2), InsightDirection.UP)]

            # Liquidate holdings if peak to trough value is 1, which is recessionary period
            elif self.peak_to_trough_value == 1 and algorithm.portfolio.invested:
                insights += [Insight.price(symbol, timedelta(days=365*2), InsightDirection.FLAT)]

        return insights

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            self.symbols.append(security.symbol)

        for security in changes.removed_securities:
            if symbol in self.symbols:
                self.symbols.remove(security.symbol)
```

Data Point Attributes

The FRED dataset provides `Fred` objects, which have the following attributes:

Datasets

Federal Reserve Bank of St Louis

The Federal Reserve Bank of St. Louis, often referred to as the St. Louis Fed, is one of the 12 regional banks that make up the United States Federal Reserve System. It is responsible for the Eighth Federal Reserve District, which includes the states of Arkansas, Illinois, Indiana, Kentucky, Mississippi, Missouri, and Tennessee, as well as portions of eastern Kansas and southern Illinois.

The St. Louis Fed, like other regional banks, participates in the formulation and implementation of monetary policy in the United States. It contributes to the Federal Open Market Committee (FOMC) meetings, where key decisions regarding interest rates and other monetary policy tools are made.

US Interest Rate

Federal Reserve Bank of St Louis

US Interest Rate

Introduction

The US Interest Rate dataset provides the primary credit rate from the Federal Open Market Committee (FOMC). The data starts in January 2003 and is updated on a daily frequency. This dataset is created using information from the FOMC meetings.

For more information about the US Interest Rate dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

The Federal Reserve Bank of St. Louis, often referred to as the St. Louis Fed, is one of the 12 regional banks that make up the United States Federal Reserve System. It is responsible for the Eighth Federal Reserve District, which includes the states of Arkansas, Illinois, Indiana, Kentucky, Mississippi, Missouri, and Tennessee, as well as portions of eastern Kansas and southern Illinois.

The St. Louis Fed, like other regional banks, participates in the formulation and implementation of monetary policy in the United States. It contributes to the Federal Open Market Committee (FOMC) meetings, where key decisions regarding interest rates and other monetary policy tools are made.

Getting Started

The following snippet demonstrates how to access data from the US Interest Rate dataset:

```
interest_rate = self.risk_free_interest_rate_model.get_interest_rate(self.time)
```

To find the average interest rate between two dates, call the `GetRiskFreeRate` method.

```
avg_risk_free_rate = RiskFreeInterestRateModelExtensions.get_risk_free_rate(
    self.risk_free_interest_rate_model,
    self.time-timedelta(365), self.time
)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2003
Data Density	Sparse
Resolution	Daily
Timezone	New York

Requesting Data

You don't need any special code to request US Interest Rate data. `QCAlgorithm` automatically subscribes to the data by setting its default risk free interest rate model .

Accessing Data

To get the current US Interest Rate data, call the `get_interest_rate` method of the `RiskFreeInterestRateModel` object with the current time.

```
interest_rate = self.risk_free_interest_rate_model.get_interest_rate(self.time)
```

Historical Data

To get the average risk free interest rate for a window of time, call the `get_risk_free_rate` method with the start date and end date.

```
PY
risk_free_rate = RiskFreeInterestRateModelExtensions.get_risk_free_rate(
    self.risk_free_interest_rate_model,
    self.time-timedelta(365), self.time
)
```

To get the average risk free interest rate for a set of dates, call the `get_average_risk_free_rate` method with the list of dates.

```
PY
risk_free_rate = RiskFreeInterestRateModelExtensions.get_average_risk_free_rate(
    self.risk_free_interest_rate_model,
    [self.time, self.time-timedelta(180), self.time-timedelta(365)]
)
```

Example Applications

The US Interest Rate dataset provides an important economic indicator. Examples include the following applications:

- Accurately calculating indicators that are a function of the risk-free rate, like Sharpe ratios.
- Forming a portfolio of assets that have a history of outperforming when the rate is increasing/decreasing.
- Canceling orders in a Risk Management model when the expected return of the asset is less than the risk-free rate.

Classic Algorithm Example

The following example algorithm plots the current interest rate and the last year's average.

```
PY
from AlgorithmImports import *

class RiskFreeInterestRateModelAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.add_equity("SPY")

    def on_end_of_day(self, symbol):
        self.set_holdings(symbol, 1)
        # Get the average risk free rate of the last year at the current time
        risk_free_rate = RiskFreeInterestRateModelExtensions.get_risk_free_rate(self.risk_free_interest_rate_model, self.time -
timedelta(365), self.time)
        # Plot the current interest rate and the 1-year average rate for comparison
        self.plot('Interest', 'EOD', self.risk_free_interest_rate_model.get_interest_rate(self.time))
        self.plot('Interest', '1Y-RW', risk_free_rate)
```

Datasets

Kavout

Kavout was created by ex-Googlers and the founding team used to work at Google, Microsoft, Baidu, and financial firms with a proven track record of building many mission-critical machine learning systems where billions of data points were processed in real-time to predict the best outcome for core search ranking, ads monetization, recommendations, and trading platforms.

Their mission is to build machine investing solutions to find alpha with adaptive learning algorithms and to create an edge by assimilating vast quantities of complex data through the latest AI and Machine Learning methods to generate signals to uncover hidden, dynamic, and nonlinear patterns in the financial markets.

Composite Factor Bundle

Kavout

Composite Factor Bundle

Introduction

The Composite Factor Bundle dataset by Kavout provides ensemble scores for popular market factors. Kavout signals are machine-learning enhanced scores that capture the returns of systematic factors such as quality, value, momentum, growth, and low volatility. There are many different anomalies discovered by researchers and practitioners across these factor categories and there is no good common definition of each style across the literature. Kavout creates an ensemble score for each style that gauges the different factors considered in the literature and industry practice.

In this data set, you will find Kavout's proprietary signals for quality, value, momentum, growth, and low volatility, which have been adopted by some of the multi-billion dollar quant funds in New York and London. Each signal is generated by an ensemble model consisting of inputs from hundreds of anomalies. The data is generated on a daily basis and covers all the stocks traded in US major markets such as NYSE and Nasdaq since 2003. You could leverage this abundant set of signals to construct and backtest your strategies.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Composite Factor Bundle dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Kavout was created by ex-Googlers and the founding team used to work at Google, Microsoft, Baidu, and financial firms with a proven track record of building many mission-critical machine learning systems where billions of data points were processed in real-time to predict the best outcome for core search ranking, ads monetization, recommendations, and trading platforms.

Their mission is to build machine investing solutions to find alpha with adaptive learning algorithms and to create an edge by assimilating vast quantities of complex data through the latest AI and Machine Learning methods to generate signals to uncover hidden, dynamic, and nonlinear patterns in the financial markets.

Getting Started

The following snippet demonstrates how to request data from the Composite Factor Bundle dataset:

```
self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
self.dataset_symbol = self.add_data(KavoutCompositeFactorBundle, self.aapl).symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2003
Asset Coverage	8,000 US Equities
Data Density	Regular
Resolution	Daily
Timezone	UTC

Requesting Data

To add Composite Factor Bundle data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
class KavoutCompositeFactorBundleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
        self.dataset_symbol = self.add_data(KavoutCompositeFactorBundle, self.aapl).symbol
```

```

```

Accessing Data

To get the current Composite Factor Bundle data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.log(f"{self.dataset_symbol} momentum at {slice.time}: {data_point.momentum}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.get(KavoutCompositeFactorBundle).items():
        self.log(f"{dataset_symbol} momentum at {slice.time}: {data_point.momentum}")
```

Historical Data

To get historical Composite Factor Bundle data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.history(self.dataset_symbol, 100, Resolution.DAILY)

# Dataset objects
history_bars = self.history[KavoutCompositeFactorBundle](self.dataset_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
self.remove_security(self.dataset_symbol)
```

If you subscribe to Composite Factor Bundle data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Composite Factor Bundle dataset enables you to access the performance of 5 different factors in order to engineer strategies. Examples include the following strategies:

- Performing return-risk optimization based on performance and volatility scoring.
- Weighing stocks based on regression analysis in factor-vector space.

Classic Algorithm Example

The following example algorithm creates a dynamic universe of the 100 most liquid US Equities. Each day, it then forms a equal-weighted dollar-neutral portfolio of the 10 companies most likely to outperform and the 10 companies most likely to underperform.

PY

```
from AlgorithmImports import *

class KavoutCompositeFactorBundleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.add_universe(self._select_assets)

    def _select_assets(self, fundamentals: List[Fundamental]) -> List[Symbol]:
        # Filter for the highly traded stocks for more informed data from frequent market activities, which may translate to more
accurate prediction
        # Factors scores are only available for the ones with fundamentals
        sorted_by_dollar_volume = sorted(
            [x for x in fundamentals if x.has_fundamental_data],
            key=lambda x: x.dollar_volume
        )
        return [x.symbol for x in sorted_by_dollar_volume[-100:]]

    def on_data(self, slice: Slice) -> None:
        # Get the current data from the Kavout dataset.
        points = slice.get(KavoutCompositeFactorBundle)
        ## Demonstrate how to iterate through the data and access its members:
        #for dataset_symbol, factors in points.items():
        #    self.quit(
        #        f"{self.time} -- "
        #        f"Asset Symbol: {dataset_symbol.underlying}; "
        #        f"Growth factor: {factors.growth} "
        #    )

        # Drop factors for assets that have no price.
        points = [x for x in points.items() if self.securities[x[0].underlying].price]
        # Only rebalance when there are new Kavout factors.
        if not points:
            return

        # Long the stocks with highest factor scores, which indicate higher return from various factors
        # Short the ones with lowest factor scores for lower return estimates
        sorted_by_score = sorted(points, key=self._total_score)
        long_symbols = [x[0].underlying for x in sorted_by_score[-10:]]
        short_symbols = [x[0].underlying for x in sorted_by_score[:10]]

        # Invest in equal-size and dollar-neutral to evenly dissipate individual capital risk, avoid non-systematic risk, and better
margin
        long_targets = [PortfolioTarget(symbol, 0.05) for symbol in long_symbols]
        short_targets = [PortfolioTarget(symbol, -0.05) for symbol in short_symbols]
        self.set_holdings(long_targets + short_targets, True)

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            # Requesting factor bundle data for trade signal generation
            security.kavout_symbol = self.add_data(KavoutCompositeFactorBundle, security.symbol).symbol
            # Historical Data
            history = self.history(security.kavout_symbol, 2, Resolution.DAILY)
        for security in changes.removed_securities:
            # Remove the factor bundle data for this asset when it leaves the universe.
            self.remove_security(security.kavout_symbol)

    def _total_score(self, value) -> float:
        # Return the total score to integrate overall likelihood to outcompete, take equal weighting for each factor
        value = value[1]
        return value.growth + value.low_volatility + value.momentum + value.quality + value.value_factor
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of the 100 most liquid US Equities. Each day, it then forms a equal-weighted dollar-neutral portfolio of the 10 companies most likely to outperform and the 10 companies most likely to underperform.

```py
from AlgorithmImports import *

class KavoutCompositeFactorBundleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:

        # Filter for the highly traded stocks for more informed data from frequent market activities, which may translate to more
accurate prediction
        # Factors scores are only available for the ones with fundamentals
        sorted_by_dollar_volume = sorted(
            [x for x in fundamentals if x.has_fundamental_data],
            key=lambda x: x.dollar_volume
        )
        return [x.symbol for x in sorted_by_dollar_volume[-100:]]

class KavoutCompositeFactorBundleAlphaModel(AlphaModel):

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        # Get the current data from the Kavout dataset.
        points = slice.get(KavoutCompositeFactorBundle)
        ## Demonstrate how to iterate through the data and access its members:
        #for dataset_symbol, factors in points.items():
        #    algorithm.quit(
        #        f"{algorithm.time} -- "
        #        f"Asset Symbol: {dataset_symbol.underlying}; "
        #        f"Growth factor: {factors.growth} "
        #    )

        # Drop factors for assets that have no price.
        points = [x for x in points.items() if algorithm.securities[x[0].underlying].price]
        # Only rebalance when there are new Kavout factors.
        if not points:
            return []

        # Long the stocks with highest factor scores, which indicate higher return from various factors
        # Short the ones with lowest factor scores for lower return estimates
        sorted_by_score = sorted(points, key=self._total_score)
        long_symbols = [x[0].underlying for x in sorted_by_score[-10:]]
        short_symbols = [x[0].underlying for x in sorted_by_score[:10]]

        insights = []
        for symbol in long_symbols:
            insights.append(Insight.price(symbol, Expiry.END_OF_DAY, InsightDirection.UP))
        for symbol in short_symbols:
            insights.append(Insight.price(symbol, Expiry.END_OF_DAY, InsightDirection.DOWN))
        return insights

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            # Requesting factor bundle data for trade signal generation
            security.kavout_symbol = algorithm.add_data(KavoutCompositeFactorBundle, security.symbol).symbol
            # Historical Data
            history = algorithm.history(security.kavout_symbol, 10, Resolution.DAILY)
        for security in changes.removed_securities:
            # Remove the factor bundle data for this asset when it leaves the universe.
            algorithm.remove_security(security.kavout_symbol)

    def _total_score(self, value) -> float:
        # Return the total score to integrate overall likelihood to outcompete, take equal weighting for each factor
        value = value[1]
        return value.growth + value.low_volatility + value.momentum + value.quality + value.value_factor
```

Data Point Attributes

The Composite Factor Bundle dataset provides `KavoutCompositeFactorBundle` objects, which have the following attributes:

Datasets

Nasdaq

" Nasdaq " was initially an acronym for the National Association of Securities Dealers Automated Quotations. It was founded in 1971 by the National Association of Securities Dealers (NASD), now known as the Financial Industry Regulatory Authority (FINRA), with the goal to provide financial services and operate stock exchanges.

On Dec. 4th, 2018, Nasdaq announced it had acquired Quandl, Inc. , a leading provider of alternative and core financial data. Quandl was founded by Tammer Kamel in 2012, with goal of making it easy for anyone to find and use high-quality data effectively in their professional decision-making. In 2021, Quandl was replaced by Nasdaq Data Link .

Data Link

Nasdaq

Data Link

Introduction

The Data Link dataset by Nasdaq, previously known as Quandl, is a collection of alternative data sets. It has indexed millions of time-series datasets from over 400 sources, which start in different years. This dataset is delivered on several frequencies, but the free data sets have often a daily frequency.

For more information about the Data Link dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

" Nasdaq " was initially an acronym for the National Association of Securities Dealers Automated Quotations. It was founded in 1971 by the National Association of Securities Dealers (NASD), now known as the Financial Industry Regulatory Authority (FINRA), with the goal to provide financial services and operate stock exchanges.

On Dec. 4th, 2018, Nasdaq announced it had acquired Quandl, Inc. , a leading provider of alternative and core financial data. Quandl was founded by Tammer Kamel in 2012, with goal of making it easy for anyone to find and use high-quality data effectively in their professional decision-making. In 2021, Quandl was replaced by Nasdaq Data Link .

Getting Started

The following snippet demonstrates how to request data from the Data Link dataset:

```py
# For premium datasets, provide your API Key
# NasdaqDataLink.set_auth_code(self.get_parameter("nasdaq-data-link-api-key"))

self.bitcoin_chain_symbol = self.add_data(NasdaqDataLink, "QDL/BCHAIN", Resolution.DAILY).symbol
# This dataset has one data column ("Value")

self.bitfinex_exchange_rate_symbol = self.add_data(NasdaqCustomColumns, "QDL/BITFINEX", Resolution.DAILY).symbol
# This dataset has multiple data columns. Create a subclass to set the default value column.

class NasdaqCustomColumns(NasdaqDataLink):
    def __init__(self) -> None:
        # Select the column "mid".
        self.value_column_name = "mid"
```

Our Nasdaq Data Link integration supports any dataset from Nasdaq that has a URL starting with `data.nasdaq.com/data/` . To import a dataset from Data Link, you need to get the dataset code. Follow these steps to get the dataset code:

1. Open the Data Link catalog .
2. *(Optional)* Use the filters on the left side bar to narrow down the catalog results.
3. Click one of the data products.
4. On the data product page, click one of the table names.
5. In the top-right corner of the dataset page, copy the Nasdaq Data Link Code.

Data Summary

The data summary depends on the specific Data Link dataset you use. Follow these steps to view the data summary of a dataset:

1. Open the Data Link catalog .
2. Click one of the data products.
3. On the data product page, click one of the table names.
4. View the data frequency and description in the left sidebar.
5. Above the chart, click `Table` to view the start date, end date, and data point attributes.

Backward Compatibility

QuantConnect/LEAN has supported Quandl since 2015. On January, 12, 2022, we moved the implementation from the LEAN GitHub repository to the

Lean.DataSource.NasdaqDataLink GitHub repository . Through this transition, we maintained backward compatibility. All of the preceding code snippets work if you replace `NasdaqDataLink` with `Quandl` .

Requesting Data

To add Data Link data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm. If there is more than one value column in the Data Link dataset, to set the `Value` property of the data objects, create a sublcass of the `NasdaqDataLink` class and set its `value_column_name` property to the column name.

```
PY
class NasdaqDataLinkDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2022, 1, 1)
        self.set_end_date(2022, 7, 1)
        self.set_cash(100000)

        # For premium datasets, provide your API Key
        # NasdaqDataLink.set_auth_code(self.get_parameter("nasdaq-data-link-api-key"))

        self.bitcoin_chain_symbol = self.add_data(NasdaqDataLink, "QDL/BCHAIN", Resolution.DAILY).symbol
        # This dataset has one data column ("Value")
        # Source : https://data.nasdaq.com/databases/BCHAIN

        self.bitfinex_exchange_rate_symbol = self.add_data(NasdaqCustomColumns, "QDL/BITFINEX", Resolution.DAILY).symbol
        # This dataset has multiple data columns
        # Source: https://data.nasdaq.com/databases/BITFINEX

class NasdaqCustomColumns(NasdaqDataLink):
    def __init__(self) -> None:
        # Select the column "mid".
        self.value_column_name = "mid"
```

Accessing Data

To get the current Data Link data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

To get the default value of the dataset, use the `value` property. To get the value of a specific column in the dataset, call the `get_storage_dictionary` method and index the result with the column name.

```
PY
def on_data(self, slice: Slice) -> None:
    point = slice.get(self.bitcoin_chain_symbol)
    if point:
        value = point.value
        self.log(f"{self.bitcoin_chain_symbol} at {slice.time}: {value}")

    point = slice.get(self.bitfinex_exchange_rate_symbol)
    if point:
        value = point.value
        storage_dictionary = point.get_storage_dictionary()
        volume = storage_dictionary["volume"]
        self.log(f"{self.bitfinex_exchange_rate_symbol} Bitfinex exchange rate at {slice.time}: {value}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
PY
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.get(NasdaqDataLink).items():
        self.log(f"{dataset_symbol} value at {slice.time}: {data_point.value}")

    for dataset_symbol, data_point in slice.get(NasdaqCustomColumns).items():
        self.log(f"{dataset_symbol} value at {slice.time}: {data_point.value}")
```

Historical Data

The process to get historical Data Link data depends on your environment.

In Algorithms

To get historical Data Link data in an algorithm, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
# DataFrames
bitcoin_chain_df = self.history(self.bitcoin_chain_symbol, 100, Resolution.DAILY)
bitfinex_exchange_rate_df = self.history(self.bitfinex_exchange_rate_symbol, 100, Resolution.DAILY)

# Dataset objects
bitcoin_chain_history = self.history[NasdaqDataLink](self.bitcoin_chain_symbol, 100, Resolution.DAILY)
bitfinex_exchange_rate_history = self.history[NasdaqCustomColumns](self.bitfinex_exchange_rate_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

In Research Notebooks

To get historical Data Link data in the Research Environment, call the `download` method with the data URL.

```
from io import StringIO
data = qb.download("https://data.nasdaq.com/api/v3/datatables/QDL/BCHAIN.csv?")
df = pd.read_csv(StringIO(data), index_col=0)
```

To receive a notification when you can use the `history` method in the Research Environment to get data from Data Link, subscribe to Lean.DataSource.NasdaqDataLink GitHub Issue #10 .

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
self.remove_security(self.bitcoin_chain_symbol)
self.remove_security(self.bitfinex_exchange_rate_symbol)
```

Example Applications

The Nasdaq Data Link sources allow you to explore different kinds of data in their database to develop trading strategies. Examples include the following strategies:

- Using alternative data to regress market regime/asset price.
- Backtesting exotic derivatives or private Equity investments.

Classic Algorithm Example

The following example algorithm subscribes to the Bitfinex Crypto Exchange Rate datasets. The algorithm takes a long position in Bitfinex BTCUSD.

```
from AlgorithmImports import *

class NasdaqImporterAlgorithm(QCAlgorithm):

    def initialize(self):
        self.nasdaq_code = "QDL/BITFINEX"
        ## Optional argument - personal token necessary for restricted dataset
        # NasdaqDataLink.set_auth_code(self.get_parameter("nasdaq-data-link-api-key"))
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(25000)
        # Request nasdaq data link data to trade
        self.add_data(NasdaqCustomColumns, self.nasdaq_code, Resolution.DAILY, TimeZones.NEW_YORK)
        # Create SMA indicator that feed with nasdaq data link data, which can be used to determine trend for trend following trade
        self.sma = self.SMA(self.nasdaq_code, 14)

    def on_data(self, data):
        if not self.portfolio.hold_stock:
            self.set_holdings(self.nasdaq_code, 1)
            self.debug("Purchased {0} >> {1}".format(self.nasdaq_code, self.time))

        self.plot(self.nasdaq_code, "PriceSMA", self.sma.current.value)

# NasdaqDataLink often doesn't use close columns so need to tell LEAN which is the "value" column.
class NasdaqCustomColumns(NasdaqDataLink):
    def __init__(self):
        # Define ValueColumnName: cannot be None, Empty or non-existant column name
        super().__init__("mid")
        self.value_column_name = "mid"
```

Framework Algorithm Example

The following example algorithm subscribes to the Bitcoin Chain dataset and Bitfinex Crypto Exchange Rate dataset. The algorithm takes a long position in Bitfinex BTCUSD.

PY

```
from AlgorithmImports import *

class NasdaqDataLinkFrameworkAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000000)

        ### Requesting Data
        # For premium datasets, provide your API Key
        # NasdaqDataLink.set_auth_code(self.get_parameter("nasdaq-data-link-api-key"))

        # Add nasdaq data link data as trading vehicle
        bitfinex_exchange_rate_symbol = self.add_data(NasdaqDataLink, 'QDL/BCHAIN', Resolution.DAILY).symbol

        ### Historical Data
        history = self.history(bitfinex_exchange_rate_symbol, 1000, Resolution.DAILY)
        self.debug(f"We got {len(history)} items from our history request for {bitfinex_exchange_rate_symbol} Nasdaq Data Link")

        # Custom alpha model that emit insights based on updated nasdaq data link data
        self.add_alpha(NasdaqDataLinkAlphaModel(self))

        # Invest equally to evenly dissipate the capital concentration risk
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel(lambda time: None))

class NasdaqDataLinkAlphaModel(AlphaModel):
    def __init__(self, algorithm: QCAlgorithm) -> None:
        ### Requesting NASDAQ data link custom data
        self.bitfinex_exchange_rate_symbol = algorithm.add_data(NasdaqCustomColumns, "QDL/BITFINEX", Resolution.DAILY).symbol
        # This dataset has multiple data columns, so create a custom class to set the value column name

        ### Historical Data
        history = algorithm.history(self.bitfinex_exchange_rate_symbol, 100, Resolution.DAILY)
        algorithm.debug(f"We got {len(history)} items from our history request for {self.bitfinex_exchange_rate_symbol} Nasdaq Data
Link")

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        insights = []

        # Trade only based on updated NASDAQ data link data
        for dataset_symbol, data_point in slice.Get(NasdaqCustomColumns).items():
            if dataset_symbol != self.bitfinex_exchange_rate_symbol or algorithm.portfolio[dataset_symbol].invested:
                continue
            insights.append(Insight.price(dataset_symbol, timedelta(days=6*22), InsightDirection.UP))

        return insights

# NasdaqDataLink often doesn't use close columns so need to tell LEAN which is the "value" column.
class NasdaqCustomColumns(NasdaqDataLink):
    def __init__(self) -> None:
        # Select the column "mid".
        self.value_column_name = "mid"
```

Datasets

Quiver Quantitative

Quiver Quantitative was founded by two college students in February 2020 with the goal of bridging the information gap between Wall Street and non-professional investors. Quiver allows retail investors to tap into the power of big data and have access to actionable, easy to interpret data that hasn't already been dissected by Wall Street.

Quiver Quantitative

CNBC Trading

Introduction

The CNBC Trading dataset by Quiver Quantitative tracks the recommendations made by media personalities on CNBC and their historical performance. The data covers over 1,500 US Equities, starts in December 2020, and is delivered on a daily frequency. This dataset covers recommendations made on Mad Money, Halftime Report, and Fast Money.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the CNBC Trading dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Quiver Quantitative was founded by two college students in February 2020 with the goal of bridging the information gap between Wall Street and non-professional investors. Quiver allows retail investors to tap into the power of big data and have access to actionable, easy to interpret data that hasn't already been dissected by Wall Street.

Getting Started

The following snippet demonstrates how to request data from the CNBC Trading dataset:

```
self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
self.dataset_symbol = self.add_data(QuiverCNBCs, self.aapl).symbol

self._universe = self.add_universe(QuiverCNBCsUniverse, self.universe_selection)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	December 25, 2020
Asset Coverage	1,515 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add CNBC Trading data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
class QuiverCNBCDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
        self.dataset_symbol = self.add_data(QuiverCNBCs, self.aapl).symbol
```

Accessing Data

To get the current CNBC Trading data, index the current `Slice` with the dataset `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY

def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        data_points = slice[self.dataset_symbol]
        for data_point in data_points:
            self.log(f"{self.dataset_symbol} direction at {slice.time}: {data_point.direction}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
PY

def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_points in slice.get(QuiverCNBCs).items():
        for data_point in data_points:
            self.log(f"{dataset_symbol} direction at {slice.time}: {data_point.direction}")
```

Historical Data

To get historical CNBC Trading data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY

# DataFrame
history_df = self.history(self.dataset_symbol, 100, Resolution.DAILY)

# Dataset objects
history_bars = self.history[QuiverCNBCs](self.dataset_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on CNBC Trading data, call the `add_universe` method with the `QuiverCNBCsUniverse` class and a selection function.

```
PY

def initialize(self):
    self._uinverse = self.add_universe(QuiverCNBCsUniverse, self.universe_selection)

def universe_selection(self, alt_coarse: List[QuiverCNBCsUniverse]) -> List[Symbol]:
    cnbc_data_by_symbol = {}

    for datum in alt_coarse:
        symbol = datum.symbol

        if symbol not in cnbc_data_by_symbol:
            cnbc_data_by_symbol[symbol] = []
        cnbc_data_by_symbol[symbol].append(datum)

    # define our selection criteria
    return [symbol for symbol, d in cnbc_data_by_symbol.items()
            if len([x for x in d if x.direction == OrderDirection.BUY]) >= 3]
```

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `history` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```
# DataFrame example where the columns are the QuiverCNBCsUniverse attributes:
history_df = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series example where the values are lists of QuiverCNBCsUniverse objects:
universe_history = self.history(self._universe, 30, Resolution.DAILY)
for (_, time), cbncs in universe_history.items():
    for cbnc in cbncs:
        self.log(f"{cbnc.symbol} traders at {cbnc.end_time}: {cbnc.traders}")
```

PY

Historical Universe Data in Research

To get historical universe data in research, call the `universe_history` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```
# DataFrame example where the columns are the QuiverCNBCsUniverse attributes:
history_df = qb.universe_history(universe, qb.time-timedelta(30), qb.time, flatten=True)

# Series example where the values are lists of QuiverCNBCsUniverse objects:
universe_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (_, time), cbncs in universe_history.items():
    for cbnc in cbncs:
        print(f"{cbnc.symbol} traders at {cbnc.end_time}: {cbnc.traders}")
```

PY

You can call the `history` method in Research.

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
self.remove_security(self.dataset_symbol)
```

PY

If you subscribe to CNBC Trading data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Quiver Quantitative CNBC Trading dataset enables you to create strategies using the latest recommendations made by media personalities on CNBC. Examples include the following strategies:

- Taking short positions in securities that were mentioned by Jim Cramer (CNBC commentator) in the last week
- Trading securities that were most/least discussed across CNBC programs over the last year

Classic Algorithm Example

The following example algorithm buys Apple stock if the net recommendation of media personalities on CNBC for Apple is positive. Otherwise, it holds cash.

```py
from AlgorithmImports import *

class QuiverCNBCsAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
        # Subscribe to CNBC data for AAPL to generate trade signal
        self.dataset_symbol = self.add_data(QuiverCNBCs, self.aapl).symbol
        # Define a mapping from OrderDirection to int.
        self._int_by_direction = {
            OrderDirection.BUY: 1,
            OrderDirection.HOLD: 0,
            OrderDirection.SELL: -1
        }

        # history request
        history = self.history(self.dataset_symbol, 10, Resolution.DAILY)
        self.debug(f"We got {len(history)} items from historical data request of {self.dataset_symbol}.")

    def on_data(self, slice: Slice) -> None:
        for cnbcs in slice.Get(QuiverCNBCs).values():
            # Using mean prediction from CNBC analysts to be the trade signal
            # If the average CNBC insight is upward movement, invest AAPL
            if np.mean([self._int_by_direction[cnbc.direction] for cnbc in cnbcs]) > 0:
                self.set_holdings(self.aapl, 1)
            else:
                self.set_holdings(self.aapl, 0)
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of US Equities that have at least 3 positive opinions from CNBC sources. Each day, it then forms a equal-weighted portfolio with all the securities in the universe.

```py
from AlgorithmImports import *

class QuiverCNBCsDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        self.dataset_symbol_by_symbol = {}
        # Filter universe based on CNBC data
        self.add_universe(QuiverCNBCsUniverse, self.universe_selection)

        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(1)))

        # Invest equally to evenly dissipate the capital concentration risk
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

    def universe_selection(self, data: List[QuiverCNBCsUniverse]) -> List[Symbol]:
        cnbc_data_by_symbol = {}

        for datum in data:
            symbol = datum.symbol

            if symbol not in cnbc_data_by_symbol:
                cnbc_data_by_symbol[symbol] = []
            cnbc_data_by_symbol[symbol].append(datum)

        # Select the stocks with at least 3 CNBC analysts to suggest buy, reassuring the signal
        return [symbol for symbol, d in cnbc_data_by_symbol.items()
                if len([x for x in d if x.direction == OrderDirection.BUY]) >= 3]

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            # Requesting CNBC Data
            symbol = security.symbol
            dataset_symbol = self.add_data(QuiverCNBCs, symbol).symbol
            self.dataset_symbol_by_symbol[symbol] = dataset_symbol

            # Historical Data
            history = self.history(dataset_symbol, 10, Resolution.DAILY)
            self.debug(f"We got {len(history)} items from our history request on {dataset_symbol}.")

        for security in changes.removed_securities:
            dataset_symbol = self.dataset_symbol_by_symbol.pop(security.symbol, None)
            if dataset_symbol:
                # Remove subscription of CNBC data to release computation resources
                self.remove_security(dataset_symbol)
```

Research Example

The following example lists US Equities mentioned by Jim Cramer.

```py
qb = QuantBook()

# Requesting Data
aapl = qb.add_equity("AAPL", Resolution.DAILY).symbol
symbol = qb.add_data(QuiverCNBCs, aapl).symbol

# Historical data
history = qb.history(QuiverCNBCs, symbol, 60, Resolution.DAILY)
for (symbol, time), cbncs in history.items():
    for cbnc in cbncs:
        print(f"{cbnc.symbol} traders at {cbnc.end_time}: {cbnc.traders}")

# Add Universe Selection
def universe_selection(alt_coarse: List[QuiverCNBCsUniverse]) -> List[Symbol]:
    return [d.symbol for d in alt_coarse if 'Cramer' in d.traders]

universe = qb.add_universe(QuiverCNBCsUniverse, universe_selection)

# Historical Universe data
universe_history = qb.universe_history(universe, qb.time-timedelta(60), qb.time)
for (_, time), cbncs in universe_history.items():
    for cbnc in cbncs:
        print(f"{cbnc.symbol} traders at {cbnc.end_time}: {cbnc.traders}")
```

Data Point Attributes

The Quiver Quantitative CNBC Trading dataset provides `QuiverCNBCs` , `QuiverCNBC` , and `QuiverCNBCsUniverse` objects.

QuiverCNBCs

`QuiverCNBCs` objects have the following attributes:

QuiverCNBC

`QuiverCNBC` objects have the following attributes:

QuiverCNBCsUniverse

`QuiverCNBCsUniverse` objects have the following attributes:

Quiver Quantitative

Corporate Lobbying

Introduction

The Corporate Lobbying dataset by Quiver Quantitative tracks the lobbying activity of US Equities. The Lobbying Disclosure Act of 1995 requires lobbyists in the United States to disclose information about their activities, such as their clients, which issues they are lobbying on, and how much they are being paid. Quiver Quantiative scrapes this data and maps it to stock tickers to track which companies are spending money for legislative influence.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Corporate Lobbying dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Quiver Quantitative was founded by two college students in February 2020 with the goal of bridging the information gap between Wall Street and non-professional investors. Quiver allows retail investors to tap into the power of big data and have access to actionable, easy to interpret data that hasn't already been dissected by Wall Street.

Getting Started

The following snippet demonstrates how to request data from the Corporate Lobbying dataset:

```
PY
self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
self.dataset_symbol = self.add_data(QuiverLobbyings, self.symbol).symbol

self._universe = self.add_universe(QuiverLobbyingUniverse, self.universe_selection_filter)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 4, 1999
Asset Coverage	1,418 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add Corporate Lobbying data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
PY
class QuiverLobbyingDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        symbol = self.add_equity("AAPL", Resolution.DAILY).symbol
        self.dataset_symbol = self.add_data(QuiverLobbyings, symbol).symbol
```

Accessing Data

To get the current Corporate Lobbying data, index the current `Slice` with the dataset `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        data_points = slice[self.dataset_symbol]
        for data_point in data_points:
            self.log(f"{self.dataset_symbol} amount at {slice.time}: {data_point.amount}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
PY
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_points in slice.get(QuiverLobbyings).items():
        for data_point in data_points:
            self.log(f"{dataset_symbol} amount at {slice.time}: {data_point.amount}")
```

Historical Data

To get historical Corporate Lobbying data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.history(self.dataset_symbol, 100, Resolution.DAILY)

# Dataset objects
history_bars = self.history[QuiverLobbyings](self.dataset_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on Corporate Lobbying data, call the `add_universe` method with the `QuiverLobbyingUniverse` class and a selection function.

```
PY
def initialize(self):
    self._universe = self.add_universe(QuiverLobbyingUniverse, "QuiverLobbyingUniverse", Resolution.DAILY, self.universe_selection)

def universe_selection(self, alt_coarse: List[QuiverLobbyingUniverse]) -> List[Symbol]:
    lobby_data_by_symbol = {}

    for datum in alt_coarse:
        symbol = datum.symbol

        if symbol not in lobby_data_by_symbol:
            lobby_data_by_symbol[symbol] = []
        lobby_data_by_symbol[symbol].append(datum)

    return [symbol for symbol, d in lobby_data_by_symbol.items()
            if sum([x.amount for x in d]) >= 100000]
```

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `history` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```
# DataFrame example where the columns are the QuiverLobbyingUniverse attributes:
history_df = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series example where the values are lists of QuiverLobbyingUniverse objects:
universe_history = self.history(self._universe, 30, Resolution.DAILY)
for (symbol, time), lobbyings in universe_history.items():
    for lobbying in lobbyings:
        print(f"{lobbying.symbol} issue at {lobbying.end_time}: {lobbying.issue}")
```

PY

Historical Universe Data in Research

To get historical universe data in research, call the `universe_history` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```
# DataFrame example where the columns are the QuiverLobbyingUniverse attributes:
history_df = qb.universe_history(universe, qb.time-timedelta(30), qb.time, flatten=True)

# Series example where the values are lists of QuiverLobbyingUniverse objects:
universe_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (symbol, time), lobbyings in universe_history.items():
    for lobbying in lobbyings:
        print(f"{lobbying.symbol} issue at {lobbying.end_time}: {lobbying.issue}")
```

PY

You can call the `history` method in Research.

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
self.remove_security(self.dataset_symbol)
```

PY

If you subscribe to Corporate Lobbying data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Corporate Lobbying dataset enables you to create strategies using the latest information on lobbying activity. Examples include the following strategies:

- Trading securities that have spent the most on lobbying over the last quarter
- Trading securities that have had the biggest change in lobbying spend for privacy legislation over the last year

Classic Algorithm Example

The following example algorithm tracks the lobbying activity of Apple. When the company initiates a lobbying activity worth more than 50K, the algorithm buys Apple stock. When the company initiates a lobbying activity worth less than 10K, the algorithm short sells Apple stock.

```py
from AlgorithmImports import *

class QuiverLobbyingDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self._symbol = self.add_equity("AAPL", Resolution.DAILY).symbol
        # Subscribe to lobbying data for AAPL to generate trade signal
        self._dataset_symbol = self.add_data(QuiverLobbyings, self._symbol).symbol

        # history request
        history = self.history(self._dataset_symbol, 10, Resolution.DAILY)
        self.debug(f"We got {len(history)} items from historical data request of {self._dataset_symbol}.")

    def on_data(self, slice: Slice) -> None:
        # Trade only base on lobbying data
        for lobbyings in slice.get(QuiverLobbyings).values():
            # Buy if over 50000 lobbying amount, suggesting a favored political prospect and sentiment
            if any([lobbying.amount > 50000 for lobbying in lobbyings]):
                self.set_holdings(self._symbol, 1)
            # Sell if below 10000 lobbying amount, suggesting a less favorable political prospect and sentiment
            elif any([lobbying.amount < 10000 for lobbying in lobbyings]):
                self.set_holdings(self._symbol, -1)
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of US Equities that have at least $100K worth of new lobbying activity. Each day, it then forms an equal-weighted portfolio with all of the securities in the universe.

```py
from AlgorithmImports import *

class QuiverLobbyingDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # To hold the lobbying dataset symbol for managing subscription
        self.dataset_symbol_by_symbol = {}

        # Filter universe based on the lobbying data
        self.add_universe(QuiverLobbyingUniverse, self.universe_selection)

        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(1)))

        # Invest equally to evenly dissipate the capital concentration risk
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

    def universe_selection(self, data: List[QuiverLobbyingUniverse]) -> List[Symbol]:
        lobby_data_by_symbol = {}

        for datum in data:
            symbol = datum.symbol

            if symbol not in lobby_data_by_symbol:
                lobby_data_by_symbol[symbol] = []
            lobby_data_by_symbol[symbol].append(datum)

        # Select and invest all stocks with lobbying amount above 100000, suggesting a more favorable political prospect and sentiment
        return [symbol for symbol, d in lobby_data_by_symbol.items()
                if sum([x.amount for x in d if x.amount]) >= 100000]

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            # Requesting lobbying data for trading
            symbol = security.symbol
            dataset_symbol = self.add_data(QuiverLobbyings, symbol).symbol
            self.dataset_symbol_by_symbol[symbol] = dataset_symbol
            # Historical Data
            history = self.history(dataset_symbol, 10, Resolution.DAILY)

        for security in changes.removed_securities:
            dataset_symbol = self.dataset_symbol_by_symbol.pop(security.symbol, None)
            if dataset_symbol:
                # Remove lobbying data subscription to release computation resources
                self.remove_security(dataset_symbol)
```

Research Example

The following example lists US Equities that have brought health related issues.

```py
qb = QuantBook()

# Requesting Data
aapl = qb.add_equity("AAPL", Resolution.DAILY).symbol
symbol = qb.add_data(QuiverLobbyings, aapl).symbol

# Historical data
history = qb.history(QuiverLobbyings, symbol, 60, Resolution.DAILY)
for (symbol, time), lobbyings in history.items():
    for lobbying in lobbyings:
        print(f"{lobbying.symbol} issue at {lobbying.end_time}: {lobbying.issue}")

# Add Universe Selection
def universe_selection(alt_coarse: List[QuiverLobbyingUniverse]) -> List[Symbol]:
    return [d.symbol for d in alt_coarse if 'health' in d.issue.lower()]

universe = qb.add_universe(QuiverLobbyingUniverse, universe_selection)

# Historical Universe data
history = qb.universe_history(universe, qb.time-timedelta(60), qb.time)
for (symbol, time), lobbyings in history.items():
    for lobbying in lobbyings:
        print(f"{lobbying.symbol} issue at {lobbying.end_time}: {lobbying.issue}")
```

Insider Trading

Introduction

Corporate insiders are required to disclose purchases or sales of their own stock within two business days of when they occur. Using these disclosures, we collect data on insider trading activity, which can give hints on whether executives are bullish or bearish on their own companies. Here is a blog that we did on this dataset: https://www.quiverquant.com/blog/081121

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Insider Trading dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Quiver Quantitative was founded by two college students in February 2020 with the goal of bridging the information gap between Wall Street and non-professional investors. Quiver allows retail investors to tap into the power of big data and have access to actionable, easy to interpret data that hasn't already been dissected by Wall Street.

Getting Started

The following snippet demonstrates how to request data from the Insider Trading dataset:

```
self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
self.dataset_symbol = self.add_data(QuiverInsiderTrading, aapl).symbol
self._universe = self.add_universe(QuiverInsiderTradingUniverse, self.universe_selection)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	25 April 2014
Asset Coverage	4994 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add Insider Trading data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
class QuiverInsiderTradingDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        symbol = self.add_equity("AAPL", Resolution.DAILY).symbol
        self.dataset_symbol = self.add_data(QuiverInsiderTrading, symbol).symbol
```

Accessing Data

To get the current Insider Trading data, index the current `Slice` with the dataset `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        data_points = slice[self.dataset_symbol]
        for data_point in data_points:
            self.log(f"{self.dataset_symbol} shares at {slice.time}: {data_point.shares}")
```

Note that `data_points` is a list of `QuiverInsiderTrading` object since we can have several trades per symbol in a day. You need to iterate `data_points` to access the data.

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
PY
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_points in slice.get(QuiverInsiderTrading).items():
        for data_point in data_points:
            self.log(f"{dataset_symbol} shares at {slice.time}: {data_point.shares}")
```

Historical Data

To get historical Insider Trading data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.history(self.dataset_symbol, 100, Resolution.DAILY)

# Dataset objects
self.history[QuiverInsiderTrading](self.dataset_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on Insider Trading data, call the `add_universe` method with the `QuiverInsiderTradingUniverse` class and a selection function.

```
PY
class InsiderTradingUniverseAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2023, 1, 1)
        self._universe = self.add_universe(QuiverInsiderTradingUniverse, self._select_assets)

    def _select_assets(self, alt_coarse: List[QuiverInsiderTradingUniverse]) -> List[Symbol]:
        dollar_volume_by_symbol = {}
        for data in alt_coarse:
            symbol = data.symbol
            if not data.price_per_share:
                continue
            if symbol not in dollar_volume_by_symbol:
                dollar_volume_by_symbol[symbol] = 0
            dollar_volume_by_symbol[symbol] += (data.shares or 0) * data.price_per_share
        return [
            symbol for symbol, _ in sorted(dollar_volume_by_symbol.items(), key=lambda kvp: kvp[1])[-10:]
        ]
```

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `history` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```
# DataFrame example where the columns are the QuiverInsiderTradingUniverse attributes:
history_df = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series example where the values are lists of QuiverInsiderTradingUniverse objects:
universe_history = self.history(self._universe, 30, Resolution.DAILY)
for (_, time), insiders in universe_history.items():
    for insider in insiders:
        if insider.price_per_share:
            self.log(f"{insider.symbol} volume at {insider.end_time}: {insider.shares * insider.price_per_share}")
```

PY

Historical Universe Data in Research

To get historical universe data in research, call the `universe_history` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```
# DataFrame example where the columns are the QuiverInsiderTradingUniverse attributes:
history_df = qb.universe_history(universe, qb.time-timedelta(30), qb.time, flatten=True)

# Series example where the values are lists of QuiverInsiderTradingUniverse objects:
universe_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (_, time), insiders in universe_history.items():
    for insider in insiders:
        if insider.price_per_share:
            print(f"{insider.symbol} volume at {insider.end_time}: {insider.shares * insider.price_per_share}")
```

PY

You can call the `history` method in Research.

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
self.remove_security(self.dataset_symbol)
```

PY

If you subscribe to Insider Trading data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Quiver Quantitative Insider Trading dataset enables researchers to create strategies using the latest information on insider trading activity. Examples include:

- Taking a short position in securities that have had the most insider selling over the last 5 days
- Buying any security that has had over $100,000 worth of shares purchased by insiders in the last month

Classic Algorithm Example

In this example, we would 100% long AAPL if there was any insider buying event. Otherwise, we liquidate it.

```py
from AlgorithmImports import *

class QuiverInsiderTradingAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self._symbol = self.add_equity("AAPL", Resolution.DAILY).symbol
        # Subscribe to insider trade data for AAPL to generate trade signal
        self.dataset_symbol = self.add_data(QuiverInsiderTrading, self._symbol).symbol

        # history request
        history = self.history(self.dataset_symbol, 10, Resolution.DAILY)
        self.debug(f"We got {len(history)} items from historical data request of {self.dataset_symbol}.")

    def on_data(self, slice: Slice) -> None:
        # Trade only base on insider trade data
        for insider_trades in slice.Get(QuiverInsiderTrading).values():
            for insider_trade in insider_trades:
                # Any buy insider trade will result in buying, assuming insider have confidence in stock price with more informed
information and projection
                if insider_trade.shares > 0:
                    self.set_holdings(self._symbol, 1)
                # Any sell insider trade will result in liquidation, assuming insiders believe the stock price has reached maximum or
poor future confidence
                else:
                    self.liquidate(self._symbol)
```

Framework Algorithm Example

In this example, we long a equal-sized portfolio with equities that having insider trading for over $100000 USD in the previous day.

```py
from AlgorithmImports import *

class QuiverInsiderTradingDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # To hold the insider trade dataset symbol for managing subscription
        self.data_symbols = {}

        # Filter universe using insider trade data
        self.add_universe(QuiverInsiderTradingUniverse, self.universe_selection)

        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(1)))

        # Invest equally to evenly dissipate the capital concentration risk
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

    def universe_selection(self, data: List[QuiverInsiderTradingUniverse]) -> List[Symbol]:
        symbol_data = {}

        for datum in data:
            symbol = datum.symbol

            if symbol not in symbol_data:
                symbol_data[symbol] = []
            symbol_data[symbol].append(datum)

        # Select the ones with insider trading dollar amount above 100k, assuming insider have confidence in stock price with more
informed information and projection
        return [symbol for symbol, d in symbol_data.items()
                if sum([x.shares * x.price_per_share for x in d if x.shares and x.price_per_share]) >= 100000]

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            # Requesting insider trade data for trading
            symbol = security.symbol
            dataset_symbol = self.add_data(QuiverInsiderTrading, symbol).symbol
            self.data_symbols[symbol] = dataset_symbol
            # Historical Data
            history = self.history(dataset_symbol, 10, Resolution.DAILY)

        for security in changes.removed_securities:
            dataset_symbol = self.data_symbols.pop(security.symbol, None)
            if dataset_symbol:
                # Remove insider trade data subscription to release computation resources
                self.remove_security(dataset_symbol)
```

Research Example

The following example lists US Equities having insider trading for over $10,000,000.

```py
qb = QuantBook()

# Requesting Data
aapl = qb.add_equity("AAPL", Resolution.DAILY).symbol
symbol = qb.add_data(QuiverInsiderTrading, aapl).symbol

# Historical data
history = qb.history(QuiverInsiderTrading, symbol, 60, Resolution.DAILY)
for (symbol, time), insiders in history.items():
    for insider in insiders:
        print(f"{insider.symbol} shares at {insider.end_time}: {insider.shares}")

# Add Universe Selection
def universe_selection(alt_coarse: List[QuiverInsiderTradingUniverse]) -> List[Symbol]:
    return [d.symbol for d in alt_coarse if d.price_per_share and d.shares * d.price_per_share >= 10000000]

universe = qb.add_universe(QuiverInsiderTradingUniverse, universe_selection)

# Historical Universe data
universe_history = qb.universe_history(universe, qb.time-timedelta(5), qb.time)
for (_, time), insiders in universe_history.items():
    for insider in insiders:
        if insider.price_per_share:
            print(f"{insider.symbol} volume at {insider.end_time}: {insider.shares * insider.price_per_share}")
```

Data Point Attributes

The Insider Trading dataset provides `QuiverInsiderTrading` and `QuiverInsiderTradingUniverse` object.

QuiverInsiderTrading

`QuiverInsiderTrading` objects have the following attributes:

QuiverInsiderTradingUniverse

`QuiverInsiderTradingUniverse` objects have the following attributes:

Quiver Quantitative

US Congress Trading

Introduction

The US Congress Trading dataset by Quiver Quantitative tracks US Equity trades made by members of Congress in the Senate and the House of Representatives. The data covers 1,800 US Equities, starts in January 2016, and is delivered on a daily frequency. This dataset is created by scraping SEC reports.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the US Congress Trading dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Quiver Quantitative was founded by two college students in February 2020 with the goal of bridging the information gap between Wall Street and non-professional investors. Quiver allows retail investors to tap into the power of big data and have access to actionable, easy to interpret data that hasn't already been dissected by Wall Street.

Getting Started

The following snippet demonstrates how to request data from the US Congress Trading dataset:

```
self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
self.dataset_symbol = self.add_data(QuiverCongress, self.aapl).symbol

self._universe = self.add_universe(QuiverQuantCongressUniverse, self.universe_selection)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2016
Asset Coverage	1,800 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add US Congress Trading data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
class QuiverCongressDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        symbol = self.add_equity("AAPL", Resolution.DAILY).symbol
        self.dataset_symbol = self.add_data(QuiverCongress, symbol).symbol
```

Accessing Data

To get the current US Congress Trading data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        data_points = slice[self.dataset_symbol]
        for data_point in data_points:
            self.log(f"{self.dataset_symbol} transaction amount at {slice.time}: {data_point.amount}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.get(QuiverCongress).items():
        self.log(f"{dataset_symbol} transaction amount at {slice.time}: {data_point.amount}")
```

Historical Data

To get historical US Congress Trading data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.history(self.dataset_symbol, 100, Resolution.DAILY)

# Dataset objects
history_bars = self.history[QuiverCongress](self.dataset_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on US Congress Trading data, call the `add_universe` method with the `QuiverQuantCongressUniverse` class and a selection function.

```
def initialize(self) -> None:
    self._universe = self.add_universe(QuiverQuantCongressUniverse, self.universe_selection)

def universe_selection(self, alt_coarse: List[QuiverQuantCongresssUniverse]) -> List[Symbol]:
    return [d.symbol for d in alt_coarse \
        if d.amount > 200000 and d.transaction == OrderDirection.BUY]
```

For more information about dynamic universes, see Universes .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `history` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```
# DataFrame example where the columns are the QuiverQuantCongressUniverse attributes:
history_df = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series example where the values are lists of QuiverQuantCongressUniverse objects:
history = self.history(self._universe, 30, Resolution.DAILY)
for (univere_symbol, time), trades in universe_history.items():
    for trade in trades:
        self.log(f"{trade.symbol} amount at {trade.end_time}: {trade.amount} {trade.representative}") {trade.Representative}")
```

Historical Universe Data in Research

To get historical universe data in research, call the `universe_history` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```py
# DataFrame example where the columns are the QuiverQuantCongressUniverse attributes:
history_df = qb.universe_history(universe, qb.time-timedelta(30), qb.time, flatten=True)

# Series example where the values are lists of QuiverQuantCongressUniverse objects:
universe_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (univere_symbol, time), trades in universe_history.items():
    for trade in trades:
        print(f"{trade.symbol} amount at {trade.end_time}: {trade.amount} {trade.representative}")
```

You can call the `history` method in Research.

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```py
self.remove_security(self.dataset_symbol)
```

If you subscribe to US Congress Trading data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The US Congress Trading dataset enables you to take immediate action on trades made by informed Members of Congress. Examples include the following strategies:

- Following the trades of specific representatives on the premise that the representatives are more informed
- Assigning a long/short-bias to securities on a daily frequency based on how Members of Congress are trading them

Classic Algorithm Example

The following example algorithm follows the net bias of the trades made by Members of Congress each day. When Members of Congress are net buyers, the algorithm buys. When they are net sellers, the algorithm short sells.

```py
from AlgorithmImports import *

class QuiverCongressDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Requesting data per underlying data to subscribe to updated congress members' trade information
        aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
        quiver_congress_symbol = self.add_data(QuiverCongress, aapl).symbol

        # Historical data
        history = self.history(QuiverCongress, quiver_congress_symbol, 60, Resolution.DAILY)
        self.debug(f"We got {len(history)} items from our history request");

    def on_data(self, slice: Slice) -> None:
        congress_by_symbol = slice.Get(QuiverCongress)

        # Determine net direction of Congress trades for each security to estimate the sentiment direction due to political factor
        net_quantity_by_symbol = {}
        for symbol, points in congress_by_symbol.items():
            symbol = symbol.underlying
            if symbol not in net_quantity_by_symbol:
                net_quantity_by_symbol[symbol] = 0
            # Voting weight is by order size
            for point in points:
                net_quantity_by_symbol[symbol] += (1 if point.transaction == OrderDirection.BUY else -1) * point.amount

        for symbol, net_quantity in net_quantity_by_symbol.items():
            if net_quantity == 0:
                self.liquidate(symbol)
                continue
            # Buy when Congress members have bought, short otherwise
            self.set_holdings(symbol, 1 if net_quantity > 0 else -1)
```

Framework Algorithm Example

The following example algorithm follows the net bias of the trades made by Members of Congress each day. When Members of Congress are net buyers, the algorithm buys. When they are net sellers, the algorithm short sells.

```py
from AlgorithmImports import *

class QuiverCongressDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Filter according to QuiverCongress data
        self.add_universe(QuiverQuantCongressUniverse, "QuiverQuantCongresssUniverse", Resolution.DAILY, self.universe_selection)
        self.add_alpha(CongressAlphaModel())
        self.set_portfolio_construction(InsightWeightingPortfolioConstructionModel(lambda time: None))
        self.add_risk_management(NullRiskManagementModel())
        self.set_execution(ImmediateExecutionModel())

    def universe_selection(self, alt_coarse: List[QuiverQuantCongressUniverse]) -> List[Symbol]:
        # Only include the ones with large size buy, since they are estimated to be materially confident to go up
        return [d.symbol for d in alt_coarse if d.amount > 10_000 and d.transaction == OrderDirection.BUY]

class CongressAlphaModel(AlphaModel):

    symbol_data_by_symbol = {}
    insight_by_symbol = {}

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        congress_by_symbol = slice.get(QuiverCongress)
        if congress_by_symbol:
            self.insight_by_symbol.clear()
            # Determine net direction of Congress trades for each security to estimate the sentiment direction due to political factor
            net_quantity_by_symbol = {}
            for symbol, points in congress_by_symbol.items():
                symbol = symbol.underlying
                if symbol not in net_quantity_by_symbol:
                    net_quantity_by_symbol[symbol] = 0
                # Voting weight is by order size
                for point in points:
                    net_quantity_by_symbol[symbol] += (1 if point.transaction == OrderDirection.BUY else -1) * point.amount

            for symbol, net_quantity in net_quantity_by_symbol.items():
                # Buy when Congress members have bought, as they may have advance information to be confident to the return direction
                if net_quantity > 0 and not algorithm.portfolio[symbol].is_long:
                    direction = InsightDirection.UP
                # Short sell when Congress members have sold
                elif net_quantity < 0 and not algorithm.portfolio[symbol].is_short:
                    direction = InsightDirection.DOWN
                else:
                    continue
                self.insight_by_symbol[symbol] = Insight.price(symbol, timedelta(7), direction, weight=0.5)
        # To avoid error messages, emit the insights when the algorithm has a price for the asset.
        return [
            self.insight_by_symbol.pop(symbol)
            for symbol, i in list(self.insight_by_symbol.items())
            if algorithm.securities[symbol].price
        ]

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            symbol = security.symbol
            self.symbol_data_by_symbol[symbol] = SymbolData(algorithm, symbol)

        for security in changes.removed_securities:
            symbol_data = self.symbol_data_by_symbol.pop(security.symbol, None)
            if symbol_data:
                symbol_data.dispose()

class SymbolData:

    def __init__(self, algorithm: QCAlgorithm, symbol: Symbol):
        self.algorithm = algorithm

        # Requesting data per underlying data to subscribe to updated congress members' trade information
        self.quiver_congress_symbol = algorithm.add_data(QuiverCongress, symbol).symbol

        # Historical data
        history = algorithm.history(self.quiver_congress_symbol, 14, Resolution.DAILY)

    def dispose(self) -> None:
        # Unsubscribe from Quiver Congress feed for this security to release computational resources
        self.algorithm.remove_security(self.quiver_congress_symbol)
```

Research Example

The following example lists trades made by Members of Congress daily as buyers.

```py
qb = QuantBook()

# Add QuiverCongress
aapl = qb.add_equity("AAPL", Resolution.DAILY).symbol
quiver_congress_symbol = qb.add_data(QuiverCongress, aapl).symbol

# Historical data
history = qb.history(QuiverCongress, quiver_congress_symbol, 60, Resolution.DAILY)
for (symbol, time), trades in history.items():
    for trade in trades:
        print(f'{time} {trade.symbol.value} {trade.representative} {trade.amount}')

# Add Universe Selection
def universe_selection(alt_coarse: List[QuiverQuantCongressUniverse]) -> List[Symbol]:
    return [d.symbol for d in alt_coarse if d.transaction == OrderDirection.BUY]

universe = qb.add_universe(QuiverQuantCongressUniverse, universe_selection)

# Historical Universe data
history = qb.universe_history(universe, qb.time-timedelta(60), qb.time)
for (univere_symbol, time), trades in history.items():
    for trade in trades:
        print(f'{time} {trade.symbol.value} {trade.representative} {trade.amount}')
```

`QuiverQuantCongressUniverse` object has the following attributes:

Quiver Quantitative

US Government Contracts

Introduction

The US Government Contracts dataset by Quiver Quantitative tracks the transactions of government contracts with publicly traded companies. The data covers over 700 US Equities, starts in October 2019, and is delivered on a daily frequency. Quiver Quantitative creates this dataset by using the API for USASpending.gov , which has the official open data source of federal spending information. The rows in this dataset only show new contracts, not payments or modifications to existing contracts. The dollar amounts are based on the total dollars obligated from each contract.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the US Government Contracts dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Quiver Quantitative was founded by two college students in February 2020 with the goal of bridging the information gap between Wall Street and non-professional investors. Quiver allows retail investors to tap into the power of big data and have access to actionable, easy to interpret data that hasn't already been dissected by Wall Street.

Getting Started

The following snippet demonstrates how to request data from the US Government Contracts dataset:

```
PY
self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
self.dataset_symbol = self.add_data(QuiverGovernmentContract, self.aapl).symbol

self._universe = self.add_universe(QuiverGovernmentContractUniverse, self.universe_selection)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	October 15, 2019
Asset Coverage	748 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add US Government Contracts data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
PY
class QuiverGovernmentContractDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        symbol = self.add_equity("AAPL", Resolution.DAILY).symbol
        self.dataset_symbol = self.add_data(QuiverGovernmentContract, symbol).symbol
```

Accessing Data

To get the current US Government Contract data, index the current `Slice` with the dataset `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        data_points = slice[self.dataset_symbol]
        for data_point in data_points:
            self.log(f"{self.dataset_symbol} amount at {slice.time}: {data_point.amount}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
PY
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_points in slice.get(QuiverGovernmentContract).items():
        for data_point in data_points:
            self.log(f"{dataset_symbol} amount at {slice.time}: {data_point.amount}")
```

Historical Data

To get historical US Government Contracts data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.history(self.dataset_symbol, 100, Resolution.DAILY)

# Dataset objects
history_bars = self.history[QuiverGovernmentContract](self.dataset_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on US Government Contract data, call the `add_universe` method with the `QuiverGovernmentContractUniverse` class and a selection function.

```
PY
def initialize(self):
    self._universe = self.add_universe(QuiverGovernmentContractUniverse, self.universe_selection)

def universe_selection(self, alt_coase: List[QuiverGovernmentContractUniverse]) -> List[Symbol]:
    gov_contract_data_by_symbol = {}

    for datum in alt_coarse:
        symbol = datum.symbol

        if symbol not in gov_contract_data_by_symbol:
            gov_contract_data_by_symbol[symbol] = []
        gov_contract_data_by_symbol[symbol].append(datum)

    return [symbol for symbol, d in gov_contract_data_by_symbol.items()
            if len(d) >= 3 and sum([x.amount for x in d]) > 50000]
```

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `history` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```
# DataFrame example where the columns are the QuiverGovernmentContractUniverse attributes:
history_df = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series example where the values are lists of QuiverGovernmentContractUniverse objects:
universe_history = self.history(self._universe, 30, Resolution.DAILY)
for (_, time), contracts in universe_history.items():
    for contract in contracts:
        self.log(f"{contract.symbol} amount at {contract.end_time}: {contract.amount}")
```

PY

Historical Universe Data in Research

To get historical universe data in research, call the `universe_history` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```
# DataFrame example where the columns are the QuiverGovernmentContractUniverse attributes:
history_df = qb.universe_history(universe, qb.time-timedelta(30), qb.time, flatten=True)

# Series example where the values are lists of QuiverGovernmentContractUniverse objects:
universe_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (_, time), contracts in universe_history.items():
    for contract in contracts:
        print(f"{contract.symbol} amount at {contract.end_time}: {contract.amount}")
```

PY

You can call the `history` method in Research.

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
self.remove_security(self.dataset_symbol)
```

PY

If you subscribe to US Government Contracts data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Quiver Quantitative US Government Contracts dataset enables you to create strategies using the latest information on government contracts activity. Examples include the following strategies:

- Buying securities that have received the most new government contract awards over the last month
- Trading securities that have had the biggest change in government contracts awards over the last year

Classic Algorithm Example

The following example algorithm buys Apple stock when they receive a new government contract worth over 50K. If they receive a new contract worth under 10K, the algorithm short sells Apple.

```py
from AlgorithmImports import *

class QuiverGovernmentContractAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
        # Subscribe to government contract data for AAPL to generate trade signal
        self.dataset_symbol = self.add_data(QuiverGovernmentContract, self.aapl).symbol

        # history request
        history = self.history(self.dataset_symbol, 10, Resolution.DAILY)
        self.debug(f"We got {len(history)} items from historical data request of {self.dataset_symbol}.")

    def on_data(self, slice: Slice) -> None:
        # Trade only base on government contract data
        for gov_contracts in slice.Get(QuiverGovernmentContract).values():
            # Buy if over 50000 government contract amount, suggesting a large income
            if any([gov_contract.amount > 50000 for gov_contract in gov_contracts]):
                self.set_holdings(self.aapl, 1)
            # Sell if below 10000 government contract amount, suggesting a smaller than usual income
            elif any([gov_contract.amount < 10000 for gov_contract in gov_contracts]):
                self.set_holdings(self.aapl, -1)
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of US Equities that have just received a government contract worth at least $5K. Each day, it then forms an equal-weighted dollar-neutral portfolio with the 10 companies that received the largest contracts and the 10 companies that received the smallest contracts.

```py
from AlgorithmImports import *

class QuiverGovernmentContractDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Filter universe using government contract data
        self.add_universe(QuiverGovernmentContractUniverse, self.universe_selection)

        # Custom alpha model that emit insights based on updated government contract data
        self.add_alpha(QuiverGovernmentContractAlphaModel())

        # Invest equally to evenly dissipate the capital concentration risk
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

        self.set_execution(ImmediateExecutionModel())

    def universe_selection(self, data: List[QuiverGovernmentContractUniverse]) -> List[Symbol]:
        gov_contract_data_by_symbol = {}

        for datum in data:
            symbol = datum.symbol

            if symbol not in gov_contract_data_by_symbol:
                gov_contract_data_by_symbol[symbol] = []
            gov_contract_data_by_symbol[symbol].append(datum)

        # Only select the stocks with over 5000 government contracts, which is considered material information
        return [symbol for symbol, d in gov_contract_data_by_symbol.items()
                if sum([x.amount for x in d]) > 5000]

class QuiverGovernmentContractAlphaModel(AlphaModel):

    def __init__(self) -> None:
        # A variable to control the rebalancing time
        self.last_time = datetime.min
        # To hold the government contract dataset symbol for managing subscription
        self.dataset_symbol_by_symbol = {}

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        if self.last_time > algorithm.time: return []

        # Trade signal only based on government contract data
        data_points = slice.Get(QuiverGovernmentContract)

        if not data_points: return []

        gov_contracts = {}
        # To aggregate all data per symbol for analysis
```

```
        # To aggregate all data per symbol for analysis
        for data_point in data_points:
            if not algorithm.securities[data_point.key.underlying].price:
                continue
            if data_point.Key not in gov_contracts:
                gov_contracts[data_point.Key] = 0

            for gov_contract in data_point.Value:
                gov_contracts[data_point.Key] += gov_contract.amount

        # Long the top 10 highest government contract amount, predicting a higher expected income and return
        # Short the lowest 10 government contract amount, predicting a lower expected income and return
        sorted_by_gov_contracts = sorted(gov_contracts.items(), key=lambda x: x[1])
        long_symbols = [x[0].underlying for x in sorted_by_gov_contracts[-10:]]
        short_symbols = [x[0].underlying for x in sorted_by_gov_contracts[:10]]

        insights = []
        for symbol in long_symbols:
            insights.append(Insight.price(symbol, Expiry.END_OF_DAY, InsightDirection.UP))
        for symbol in short_symbols:
            insights.append(Insight.price(symbol, Expiry.END_OF_DAY, InsightDirection.DOWN))

        self.last_time = Expiry.END_OF_DAY(algorithm.Time)

        return insights

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            # Requesting government contract data for trade signal generation
            symbol = security.symbol
            dataset_symbol = algorithm.add_data(QuiverGovernmentContract, symbol).symbol
            self.dataset_symbol_by_symbol[symbol] = dataset_symbol
            # Historical Data
            history = algorithm.history(dataset_symbol, 10, Resolution.DAILY)

        for security in changes.removed_securities:
            dataset_symbol = self.dataset_symbol_by_symbol.pop(security.symbol, None)
            if dataset_symbol:
                # Remove government contract data subscription to release computation resources
                algorithm.remove_security(dataset_symbol)
```

Research Example

The following example lists all US Equities with Government contracts in the past year.

```
PY
qb = QuantBook()

# Requesting Data
aapl = qb.add_equity("AAPL", Resolution.DAILY).symbol
symbol = qb.add_data(QuiverGovernmentContract, aapl).symbol

# Historical data
history = qb.history(QuiverGovernmentContract, symbol, 360, Resolution.DAILY)
for (symbol, time), contracts in history.items():
    for contract in contracts:
        print(f"{contract.symbol} amount at {contract.end_time}: {contract.amount}")

# Add Universe Selection
def universe_selection(alt_coarse: List[QuiverGovernmentContractUniverse]) -> List[Symbol]:
    return [d.symbol for d in alt_coarse]

universe = qb.add_universe(QuiverGovernmentContractUniverse, universe_selection)

# Historical Universe data
universe_history = qb.universe_history(universe, qb.time-timedelta(360), qb.time)
for (_, time), contracts in universe_history.items():
    for contract in contracts:
        print(f"{contract.symbol} amount at {contract.end_time}: {contract.amount}")
```

Data Point Attributes

The US Government Contracts dataset provides `QuiverGovernmentContract` and `QuiverGovernmentContractUniverse` objects.

QuiverGovernmentContract

`QuiverGovernmentContract` objects have the following attributes:

QuiverGovernmentContractUniverse

`QuiverGovernmentContractUniverse` objects have the following attributes:

Quiver Quantitative

WallStreetBets

Introduction

The WallStreetBets dataset by Quiver Quantitative tracks daily mentions of different equities on Reddit's popular WallStreetBets forum. The data covers 6,000 Equities, starts in August 2018, and is delivered on a daily frequency. The dataset is created by scraping the daily discussion threads on r/WallStreetBets and parsing the comments for ticker mentions.

`This dataset ends in February 2025. You are free to use it on QuantConnect Cloud for research purposes.`

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the WallStreetBets dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Quiver Quantitative was founded by two college students in February 2020 with the goal of bridging the information gap between Wall Street and non-professional investors. Quiver allows retail investors to tap into the power of big data and have access to actionable, easy to interpret data that hasn't already been dissected by Wall Street.

Getting Started

The following snippet demonstrates how to request data from the WallStreetBets dataset:

```
PY
self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
self.dataset_symbol = self.add_data(QuiverWallStreetBets, self.aapl).symbol

self._universe = self.add_universe(QuiverWallStreetBetsUniverse, self.universe_selection)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	August 2018
End Date	February 2025
Asset Coverage	6,000 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add WallStreetBets data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
class QuiverWallStreetBetsDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        self.aapl = self.add_equity("AAPL", Resolution.DAILY).symbol
        self.dataset_symbol = self.add_data(QuiverWallStreetBets, self.aapl).symbol
```

Accessing Data

To get the current WallStreetBets data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        data_points = slice[self.dataset_symbol]
        for data_point in data_points:
            self.log(f"{self.dataset_symbol} mentions at {slice.time}: {data_point.mentions}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_points in slice.get(QuiverWallStreetBets).items():
        for data_point in data_points:
            self.log(f"{dataset_symbol} mentions at {slice.time}: {data_point.mentions}")
```

Historical Data

To get historical WallStreetBets data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.history(self.dataset_symbol, 100, Resolution.DAILY)

# Dataset objects
history_bars = self.history[QuiverWallStreetBets](self.dataset_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on WallStreetBets data, call the `add_universe` method with the `QuiverWallStreetBetsUniverse` class and a selection function.

```
def initialize(self) -> None:
    self.universe = self.add_universe(QuiverWallStreetBetsUniverse, self.universe_selection)

def universe_selection(self, alt_coarse: List[QuiverWallStreetBetsUniverse]) -> List[Symbol]:
    return [d.symbol for d in alt_coarse if d.mentions > 100  and d.rank < 100]
```

For more information about dynamic universes, see Universes .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `history` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```
# DataFrame example where the columns are the QuiverWallStreetBetsUniverse attributes:
history_df = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series example where the values are lists of QuiverWallStreetBetsUniverse objects:
universe_history = self.history(self._universe, 30, Resolution.DAILY)
for (univere_symbol, time), bets in universe_history.items():
    for bet in bets:
        self.log(f"{bet.symbol} mentions at {bet.end_time}: {bet.mentions}")
```

PY

Historical Universe Data in Research

To get historical universe data in research, call the `universe_history` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```
# DataFrame example where the columns are the QuiverWallStreetBetsUniverse attributes:
history_df = qb.universe_history(universe, qb.time-timedelta(30), qb.time, flatten=True)

# Series example where the values are lists of QuiverWallStreetBetsUniverse objects:
universe_history = qb.universe_history(universe, qb.time-timedelta(30), qb.time)
for (univere_symbol, time), bets in universe_history.items():
    for bet in bets:
        print(f"{bet.symbol} rank at {bet.end_time}: {bet.rank}")
```

PY

You can call the `history` method in Research.

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
self.remove_security(self.dataset_symbol)
```

PY

If you subscribe to WallStreetBets data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The WallStreetBets dataset enables you to create strategies using the latest activity on the WallStreetBets daily discussion thread. Examples include the following strategies:

- Trading any security that is being mentioned
- Trading securities that are receiving more/less mentions than they were previously
- Trading the security that is being mentioned the most/least for the day

Classic Algorithm Example

The following example algorithm creates a dynamic universe of US Equities based on daily WallStreetBets data. When a security is mentioned on r/WallStreetBets more than five times in a day, the algorithm buys the security. When a security is mentioned five time in a day or less, the algorithm short sells the security.

```py
from AlgorithmImports import *

class QuiverWallStreetBetsDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        self.universe_settings.resolution = Resolution.DAILY
        # Filter using wall street bet insights
        self._universe = self.add_universe(QuiverWallStreetBetsUniverse, self.universe_selection)

    def on_data(self, slice: Slice) -> None:
        points = slice.Get(QuiverWallStreetBets)
        for point in points.Values:
            symbol = point.symbol.underlying
            security = self.securities[symbol]
            if not security.is_tradable:
                continue

            # Buy if the stock was mentioned more than 5 times in the WallStreetBets daily discussion, which translate into high
popularity of rise
            if point.mentions > 5 and not security.holdings.is_long:
                self.market_order(symbol, 1)

            # Otherwise, short sell
            elif point.mentions <= 5 and not security.holdings.is_short:
                self.market_order(symbol, -1)

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for added in changes.added_securities:
            # Requesting wall street bet data to obtain the trader's insights
            quiver_wsb_symbol = self.add_data(QuiverWallStreetBets, added.symbol).symbol

            # Historical data
            history = self.history(QuiverWallStreetBets, quiver_wsb_symbol, 60, Resolution.DAILY)

    def universe_selection(self, alt_coarse: List[QuiverWallStreetBetsUniverse]) -> List[Symbol]:
        # Select the ones with popularity (mentions) of better-than-others performance (rank)
        return [d.symbol for d in alt_coarse \
                    if d.mentions > 10 \
                    and d.rank < 100]
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of US Equities based on daily WallStreetBets data. When a security is mentioned on r/WallStreetBets more than five times in a day, the algorithm buys the security. When a security is mentioned five time in a day or less, the algorithm short sells the security.

```py
from AlgorithmImports import *

class QuiverWallStreetBetsDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        self.universe_settings.resolution = Resolution.DAILY
        # Filter using wall street bet insights
        self._universe = self.add_universe(QuiverWallStreetBetsUniverse, self.universe_selection)

        self.add_alpha(WallStreamBetsAlphaModel())

        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

        self.add_risk_management(NullRiskManagementModel())

        self.set_execution(ImmediateExecutionModel())

    def universe_selection(self, alt_coarse: List[QuiverWallStreetBetsUniverse]) -> List[Symbol]:
        # Select the ones with popularity (mentions) of better-than-others performance (rank)
        return [d.symbol for d in alt_coarse
                    if d.mentions > 10 and d.rank < 100]

class WallStreamBetsAlphaModel(AlphaModel):

    symbol_data_by_symbol = {}

    def __init__(self, mentions_threshold: int = 5) -> None:
        self.mentions_threshold = mentions_threshold

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        insights = []

        points = slice.Get(QuiverWallStreetBets)
        for point in points.Values:
            # Buy if the stock was mentioned more than 5 times in the WallStreetBets daily discussion, which translate into high
popularity of rise
            # Otherwise short sell
            target_direction = InsightDirection.UP if point.mentions > self.mentions_threshold else InsightDirection.DOWN
            self.symbol_data_by_symbol[point.symbol.underlying].target_direction = target_direction

        for symbol, symbol_data in self.symbol_data_by_symbol.items():
            # Ensure we have security data for the current Slice to avoid stale fill
            if not (slice.contains_key(symbol) and slice[symbol] is not None):
                continue

            if symbol_data.target_direction is not None:
                insights += [Insight.price(symbol, timedelta(1), symbol_data.target_direction)]
                symbol_data.target_direction = None

        return insights

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            symbol = security.symbol
            self.symbol_data_by_symbol[symbol] = SymbolData(algorithm, symbol)

        for security in changes.removed_securities:
            symbol_data = self.symbol_data_by_symbol.pop(security.symbol, None)
            if symbol_data:
                symbol_data.dispose()

class SymbolData:
    target_direction = None

    def __init__(self, algorithm: QCAlgorithm, symbol: Symbol) -> None:
        self.algorithm = algorithm

        # Requesting wall street bet data to obtain the trader's insights
        self.quiver_wsb_symbol = algorithm.add_data(QuiverWallStreetBets, symbol).symbol

        # Historical data
        history = algorithm.history(self.quiver_wsb_symbol, 60, Resolution.DAILY)

    def dispose(self) -> None:
        # Unsubscribe from the Quiver WallStreetBets feed for this security to release computationa resources
        self.algorithm.remove_security(self.quiver_wsb_symbol)
```

Research Example

The following example lists low-ranking US Equities that are mentioned more than ten times on r/WallStreetBets.

```py
qb = QuantBook()

# Requesting data
aapl = qb.add_equity("AAPL", Resolution.DAILY).symbol
symbol = qb.add_data(QuiverWallStreetBets, aapl).symbol

# Historical data
history = qb.history(QuiverWallStreetBets, symbol, 60, Resolution.DAILY)
for (symbol, time), bet in history.iterrows():
    print(f"{symbol} rank at {time}: {bet['rank']}")

# Add Universe Selection
def universe_selection(alt_coarse: List[QuiverWallStreetBetsUniverse]) -> List[Symbol]:
    return [d.symbol for d in alt_coarse if d.mentions > 10 and d.rank < 100]

universe = qb.add_universe(QuiverWallStreetBetsUniverse, universe_selection)

# Historical Universe data
universe_history = qb.universe_history(universe, qb.time-timedelta(60), qb.time)
for (univere_symbol, time), bets in universe_history.items():
    for bet in bets:
        print(f"{bet.symbol} rank at {bet.end_time}: {bet.rank}")
```

RegAlytics

RegAlytics was founded by Mary Kopczynski, Aaron Heisler, Alexander Appugliese, and Werner Pauliks in 2019 with the goal of significantly reducing the time and cost required to mitigate regulatory risk. RegAlytics provides access to accurate and clean regulatory data from all global regulators in all sectors that is enriched by regulatory experts for risk and compliance teams everywhere. Please come to RegAlytics directly if you would like data on other sectors or countries!

US Regulatory Alerts - Financial Sector

RegAlytics

US Regulatory Alerts - Financial Sector

Introduction

The US Regulatory Alerts dataset by RegAlytics tracks changes from over 8,000 globally governing bodies. The data covers over 2.5 million alerts, starts from January 2020, and is delivered on a daily basis. This dataset is created by sourcing information from over 8,000 regulators and using proprietary technology to gather and structure the regulatory data. Once prepared, the data is thoroughly reviewed by RegAlytics' team of regulatory experts and delivered each morning by 8AM for industry use.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the US Regulatory Alerts - Financial Sector dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

RegAlytics was founded by Mary Kopczynski, Aaron Heisler, Alexander Appugliese, and Werner Pauliks in 2019 with the goal of significantly reducing the time and cost required to mitigate regulatory risk. RegAlytics provides access to accurate and clean regulatory data from all global regulators in all sectors that is enriched by regulatory experts for risk and compliance teams everywhere. Please come to RegAlytics directly if you would like data on other sectors or countries!

Getting Started

The following snippet demonstrates how to request data from the US Regulatory Alerts - Financial Sector dataset:

```
self.dataset_symbol = self.add_data(RegalyticsRegulatoryArticles, "REG").symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2020
Coverage	2,500,000 Alerts
Data Density	Sparse
Resolution	Daily
Timezone	New York

Requesting Data

To add US Regulatory Alerts data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
class RegalyticsDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2021, 1, 1)
        self.set_end_date(2021, 6, 1)
        self.set_cash(100000)

        self.dataset_symbol = self.add_data(RegalyticsRegulatoryArticles, "REG").symbol
```

Accessing Data

To get the current US Regulatory Alerts data, index the current `Slice` with the dataset `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        data_points = slice[self.dataset_symbol]
        for data_point in data_points:
            self.log(f"{self.dataset_symbol} title at {slice.time}: {data_point.title}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
PY
def on_data(self, slice: Slice) -> None:
    data = slice.get(RegalyticsRegulatoryArticles)
    if data:
        for articles in data.values():
            self.log(f"{self.time} {articles.to_string()}")

            for article in articles:
                self.log(f"{self.dataset_symbol} article title at {slice.time}: {article.title}")
```

Historical Data

To get historical US Regulatory Alerts data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame where the columns are the RegalyticsRegulatoryArticle attributes:
history_df = self.history(self.dataset_symbol, 100, Resolution.DAILY, flatten=True)

# Series where the values are lists of RegalyticsRegulatoryArticle objects:
history_series = self.history(self.dataset_symbol, 100, Resolution.DAILY)

# Dataset objects:
history_bars =  self.history[RegalyticsRegulatoryArticles](self.dataset_symbol, 100, Resolution.DAILY)
```

Remove Subscriptions

To remove your subscription to US Regulatory Alerts data, call the `remove_security` method.

```
PY
self.remove_security(self.dataset_symbol)
```

Example Applications

This regulatory dataset enables you to accurately design strategies while mitigating regulatory risk. Examples include the following strategies:

- Temporarily increasing/decreasing exposure to securities when new regulations are announced
- Parsing the content of regulatory announcements to determine market or sector impact
- Country rotation based on regulatory alert sentiment

Classic Algorithm Example

The following example algorithm sells short 100% SPY if any predetermined negative sentimental phrase was present in any of the previous day's regulatory articles. Otherwise, it buys and hold 100% SPY.

```py
from AlgorithmImports import *

class RegalyticsDataAlgorithm(QCAlgorithm):
    # Pre-defined list of negative sentiment phrases as indicator for short selling, since these words will decrease confident in equity performance
    _negative_sentiment_phrases = [
        "emergency rule", "proposed rule change", "development of rulemaking"
    ]

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        self.spy = self.add_equity("SPY", extended_market_hours=True).symbol
        # Requesting data to receive updated regulatory news for timely short selling
        self.regalytics_symbol = self.add_data(RegalyticsRegulatoryArticles, "REG").symbol

        # Historical data for past articles
        history = self.history(self.regalytics_symbol, 7, Resolution.DAILY)
        self.debug(f"We got {len(history)} items from our history request")

    def on_data(self, slice: Slice) -> None:
        # Only trade on regulatory news data
        data = slice.get(RegalyticsRegulatoryArticles)
        if not data:
            return
        # If any of the negative phrases appeared in regulatory news, we expect a market drop for the day
        detected_negativity = False
        for articles in data.values():
            if detected_negativity:
                break
            detected_negativity = any(
                [p in article.title.lower() for p in self._negative_sentiment_phrases for article in articles]
            )
        self.transactions.cancel_open_orders()
        quantity = self.calculate_order_quantity(self.spy, -1 if detected_negativity else 1)
        if quantity:
            self.market_order(self.spy, quantity)
```

Framework Algorithm Example

The following example algorithm buys and holds the S&P 500 ETF, SPY. To reduce regulatory risk, it liquidates your holdings for 2 days following regulatory announcements regarding new rules.

```py
from AlgorithmImports import *

class RegalyticsDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        self.universe_settings.resolution = Resolution.DAILY
        # Trade SPY as the proxy of the whole equity market movement on the regulatory news
        symbols = [ Symbol.create("SPY", SecurityType.EQUITY, Market.USA) ]
        self.add_universe_selection(ManualUniverseSelectionModel(symbols))

        self.add_alpha(RegAnalyticsAlphaModel(self))

        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel(lambda time: None))

        self.add_risk_management(NullRiskManagementModel())

        self.set_execution(ImmediateExecutionModel())

class RegAnalyticsAlphaModel(AlphaModel):

    symbols = []
    last_news_date = datetime.min
    target_direction = InsightDirection.UP
    # Pre-defined list of negative sentiment phrases as indicator for short selling, since these words will decrease confident in equity
performance
    negative_sentiment_phrases = ["emergency rule", "proposed rule change", "development of rulemaking"]
    # Assuming the negative impact of the regulatory news will last for 2 days
    news_affect_duration = timedelta(days = 2)

    def __init__(self, algorithm: QCAlgorithm) -> None:
        # Requesting data to receive updated regulatory news for timely short selling
        self.regalytics_symbol = algorithm.add_data(RegalyticsRegulatoryArticles, "REG").symbol

        # Historical data for past articles
        history = algorithm.history(self.regalytics_symbol, 14, Resolution.DAILY)
        algorithm.debug(f"We got {len(history)} from our history request")

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        insights = []

        # Only trade on regulatory news data
        if slice.contains_key(self.regalytics_symbol) and slice[self.regalytics_symbol] is not None:
            for article in slice[self.regalytics_symbol]:
                title = article.title.lower()
                # If any of the negative phrases appeared in regulatory news, we expect a market drop for the day
                # Signal an exit from the market when regulatory articles with negative sentiment are released
                if any(phrase in title for phrase in self.negative_sentiment_phrases):
                    self.target_direction = InsightDirection.FLAT
                    self.last_news_date = slice.time

        # Signal an entry if we've waited long enough for the market to digest the negative news
        if self.last_news_date + self.news_affect_duration < slice.time:
            self.target_direction = InsightDirection.UP

        for symbol in self.symbols:
            # Ensure we have security data in the current Slice to avoid stale fill
            if not (slice.contains_key(symbol) and slice[symbol] is not None):
                continue

            if self.target_direction == InsightDirection.UP and not algorithm.portfolio[symbol].invested:
                insights += [Insight.price(symbol, timedelta(days=90), InsightDirection.UP)]
            elif self.target_direction == InsightDirection.FLAT and algorithm.portfolio[symbol].invested:
                insights += [Insight.price(symbol, self.news_affect_duration, InsightDirection.FLAT)]

        return insights

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            self.symbols.append(security.symbol)

        for security in changes.removed_securities:
            symbol = security.symbol
            if symbol in self.symbols:
                self.symbols.remove(symbol)
```

Data Point Attributes

The US Regulatory Alerts dataset provides `RegalyticsRegulatoryArticle` and `RegalyticsRegulatoryArticles` objects.

RegalyticsRegulatoryArticle

`RegalyticsRegulatoryArticle` objects have the following attributes:

RegalyticsRegulatoryArticles

`RegalyticsRegulatoryArticles` objects have the following attributes:

Datasets

Securities and Exchange Commission

The mission of the U.S. Securities and Exchange Commission is to protect investors, maintain fair, orderly, and efficient markets, and facilitate capital formation. The SEC oversees the key participants in the securities world, including securities exchanges, securities brokers and dealers, investment advisors, and mutual funds. The SEC is concerned primarily with promoting the disclosure of important market-related information, maintaining fair dealing, and protecting against fraud.

US SEC Filings

Securities and Exchange Commission

US SEC Filings

Introduction

The US SEC Filings dataset provides the quarterly financial earning reports that the United States Securities and Exchange Commission (SEC) requires from publicly traded companies in the US. The data covers 15,000 US Equities, starts in January 1998, and is delivered on a daily frequency. The data is sourced from the SEC's Electronic Data Gathering, Analysis, and Retrieval (EDGAR) system. QuantConnect downloads and formats the Quarterly Financial Reports (10-Q) and Annual Financial Report (8-K) filings of companies into a format for easy consumption by LEAN.

For more information about the US SEC Filings dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

The mission of the U.S. Securities and Exchange Commission is to protect investors, maintain fair, orderly, and efficient markets, and facilitate capital formation. The SEC oversees the key participants in the securities world, including securities exchanges, securities brokers and dealers, investment advisors, and mutual funds. The SEC is concerned primarily with promoting the disclosure of important market-related information, maintaining fair dealing, and protecting against fraud.

Getting Started

The following snippet demonstrates how to request data from the US SEC Filings dataset:

```py
self.aapl = self.add_equity("AAPL", Resolution.MINUTE).symbol
self.report_8k_symbol = self.add_data(SECReport8K, self.aapl).symbol
self.report_10k_symbol = self.add_data(SECReport10K, self.aapl).symbol
self.report_10q_symbol = self.add_data(SECReport10Q, self.aapl).symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1998
Asset Coverage	15,000 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add US SEC Filings data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```py
class SECReportAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2019, 8, 21)
        self.set_cash(100000)

        self.aapl = self.add_equity("AAPL", Resolution.MINUTE).symbol
        self.report_8k_symbol = self.add_data(SECReport8K, self.aapl).symbol
        self.report_10k_symbol = self.add_data(SECReport10K, self.aapl).symbol
        self.report_10q_symbol = self.add_data(SECReport10Q, self.aapl).symbol
```

Accessing Data

To get the current US SEC Filings data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.report_8k_symbol):
        data_point = slice[self.report_8k_symbol]
        self.log(f"{self.report_8k_symbol} report count at {slice.time}: {len(data_point.report.documents)}")

    if slice.contains_key(self.report_10k_symbol):
        data_point = slice[self.report_10k_symbol]
        self.log(f"{self.report_10k_symbol} report count at {slice.time}: {len(data_point.report.documents)}")

    if slice.ContainsKey(self.report_10q_symbol):
        data_point = slice[self.report_10q_symbol]
        self.log(f"{self.report_10q_symbol} report count at {slice.Time}: {len(data_point.report.documents)}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
PY
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.get(SECReport8K).items():
        self.log(f"{dataset_symbol} report count at {slice.time}: {len(data_point.report.documents)}")

    for dataset_symbol, data_point in slice.get(SECReport10K).items():
        self.log(f"{dataset_symbol} report count at {slice.time}: {len(data_point.report.documents)}")

    for dataset_symbol, data_point in slice.get(SECReport10Q).items():
        self.log(f"{dataset_symbol} report count at {slice.time}: {len(data_point.report.documents)}")
```

Historical Data

To get historical US SEC Filings data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrames
report_8k_history_df = self.history(self.report_8k_symbol, 100, Resolution.DAILY)
report_10k_history_df = self.history(self.report_10k_symbol, 100, Resolution.DAILY)
report_10q_history_df = self.history(self.report_10q_symbol, 100, Resolution.DAILY)
history_df = self.history([self.report_8k_symbol,
                           self.report_10k_symbol,
                           self.report_10q_symbol], 100, Resolution.DAILY)

# Dataset objects
report_8k_history_bars = self.history[SECReport8K](self.report_8k_symbol, 100, Resolution.DAILY)
report_10k_history_bars = self.history[SECReport10K](self.report_10k_symbol, 100, Resolution.DAILY)
report_10q_history_bars = self.history[SECReport10Q](self.report_10q_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
PY
self.remove_security(self.report_8k_symbol)
self.remove_security(self.report_10k_symbol)
self.remove_security(self.report_10q_symbol)
```

If you subscribe to US SEC Filings data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The US SEC Filings dataset enables you to create strategies using information from SEC reports. Examples include the following strategies:

- Extracting information about corporate earnings from the documents for further analysis
- Applying sentiment analysis to the text content of the documents (for example, keyword scoring and ranking)

Classic Algorithm Example

The following example algorithm creates a dynamic universe of the 10 most liquid US Equities. It then buys the securities that have an 8K report with more than 20,000 characters and forms an equal-weighted portfolio. Instead of trading based on how long the report is, you could use sentiment analysis by scoring keywords.

PY

```
from AlgorithmImports import *

class SECReport8KAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True

Datasets

Smart Insider

Smart Insider was founded by Michael Tindale in 2016 with the goal of forming the most progressive insider data vendor in the field. Smart Insider provides access to buyback intention and transactions for quantitative researchers. In addition to their Corporate Buybacks dataset, Smart Insider provides data on stock trades made by US politicians and thousands of high net worth individuals around the globe.

Corporate Buybacks

Smart Insider

Corporate Buybacks

Introduction

The Corporate Buybacks dataset by Smart Insider tracks US Equities share buyback programs. The data covers 3,000 US Equities, starts in May 2015, and is delivered on a second frequency. This dataset is created by analyzing daily buyback announcements and by using secondary data sources to ensure records are accurate and complete.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Corporate Buybacks dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Smart Insider was founded by Michael Tindale in 2016 with the goal of forming the most progressive insider data vendor in the field. Smart Insider provides access to buyback intention and transactions for quantitative researchers. In addition to their Corporate Buybacks dataset, Smart Insider provides data on stock trades made by US politicians and thousands of high net worth individuals around the globe.

Getting Started

The following snippet demonstrates how to request data from the Corporate Buybacks dataset:

```
self.aapl = self.add_equity("AAPL", Resolution.MINUTE).symbol
self.intention_symbol = self.add_data(SmartInsiderIntention, self.aapl).symbol
self.transaction_symbol = self.add_data(SmartInsiderTransaction, self.aapl).symbol

self.intention_universe = self.add_universe(SmartInsiderIntentionUniverse, self.intention_selection)
self.transaction_universe = self.add_universe(SmartInsiderTransactionUniverse, self.transaction_selection)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	May 2015
Asset Coverage	3,000 US Equities
Data Density	Sparse
Resolution	Second
Timezone	New York

Requesting Data

To add Corporate Buybacks data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
class CorporateBuybacksDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2016, 1, 1)
