To create an automatic indicator for `MesaAdaptiveMovingAverage` , call the `mama` helper method from the `QCAlgorithm` class. The `mama` method creates a `MesaAdaptiveMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class MesaAdaptiveMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._mama = self.mama(self._symbol, 0.5, 0.05)

    def on_data(self, slice: Slice) -> None:

        if self._mama.is_ready:
            # The current value of self._mama is represented by self._mama.current.value
            self.plot("MesaAdaptiveMovingAverage", "mama", self._mama.current.value)
            # Plot all attributes of self._mama
            self.plot("MesaAdaptiveMovingAverage", "fama", self._mama.fama.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `MesaAdaptiveMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class MesaAdaptiveMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._mesaadaptivemovingaverage = MesaAdaptiveMovingAverage(0.5, 0.05)

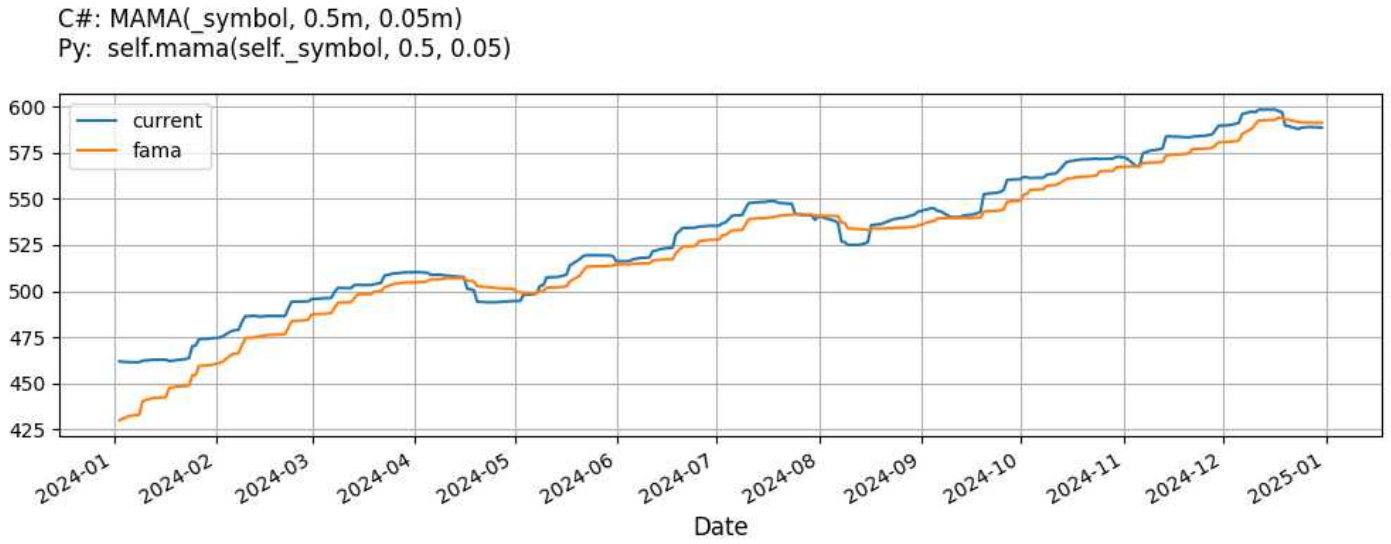
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._mesaadaptivemovingaverage.update(bar)

        if self._mesaadaptivemovingaverage.is_ready:
            # The current value of self._mesaadaptivemovingaverage is represented by self._mesaadaptivemovingaverage.current.value
            self.plot("MesaAdaptiveMovingAverage", "mesaadaptivemovingaverage", self._mesaadaptivemovingaverage.current.value)
            # Plot all attributes of self._mesaadaptivemovingaverage
            self.plot("MesaAdaptiveMovingAverage", "fama", self._mesaadaptivemovingaverage.fama.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `MesaAdaptiveMovingAverage` indicator properties:



Indicator History

To get the historical data of the `MesaAdaptiveMovingAverage` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class MesaAdaptiveMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._mama = self.mama(self._symbol, 0.5, 0.05)

        indicator_history = self.indicator_history(self._mama, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._mama, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._mama, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)

        # Access all attributes of indicator_history
        indicator_history_df = indicator_history.data_frame
        fama = indicator_history_df["fama"]
```

Mid Point

Introduction

This indicator computes the MidPoint (MIDPOINT) The MidPoint is calculated using the following formula: MIDPOINT = (Highest Value + Lowest Value) / 2

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MIDPOINT Indicator

To create an automatic indicator for `MidPoint` , call the `midpoint` helper method from the `QCAlgorithm` class. The `midpoint` method creates a `MidPoint` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class MidPointAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._midpoint = self.midpoint(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._midpoint.is_ready:
            # The current value of self._midpoint is represented by self._midpoint.current.value
            self.plot("MidPoint", "midpoint", self._midpoint.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `MidPoint` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class MidPointAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._midpoint = MidPoint(20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._midpoint.update(bar.end_time, bar.close)

        if self._midpoint.is_ready:
            # The current value of self._midpoint is represented by self._midpoint.current.value
            self.plot("MidPoint", "midpoint", self._midpoint.current.value)
```

Supported Indicators

Mid Price

Introduction

This indicator computes the MidPrice (MIDPRICE). The MidPrice is calculated using the following formula: MIDPRICE = (Highest High + Lowest Low) / 2

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MIDPRICE Indicator

To create an automatic indicator for `MidPrice` , call the `midprice` helper method from the `QCAlgorithm` class. The `midprice` method creates a `MidPrice` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class MidPriceAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._midprice = self.midprice(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._midprice.is_ready:
            # The current value of self._midprice is represented by self._midprice.current.value
            self.plot("MidPrice", "midprice", self._midprice.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `MidPrice` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class MidPriceAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._midprice = MidPrice(20)

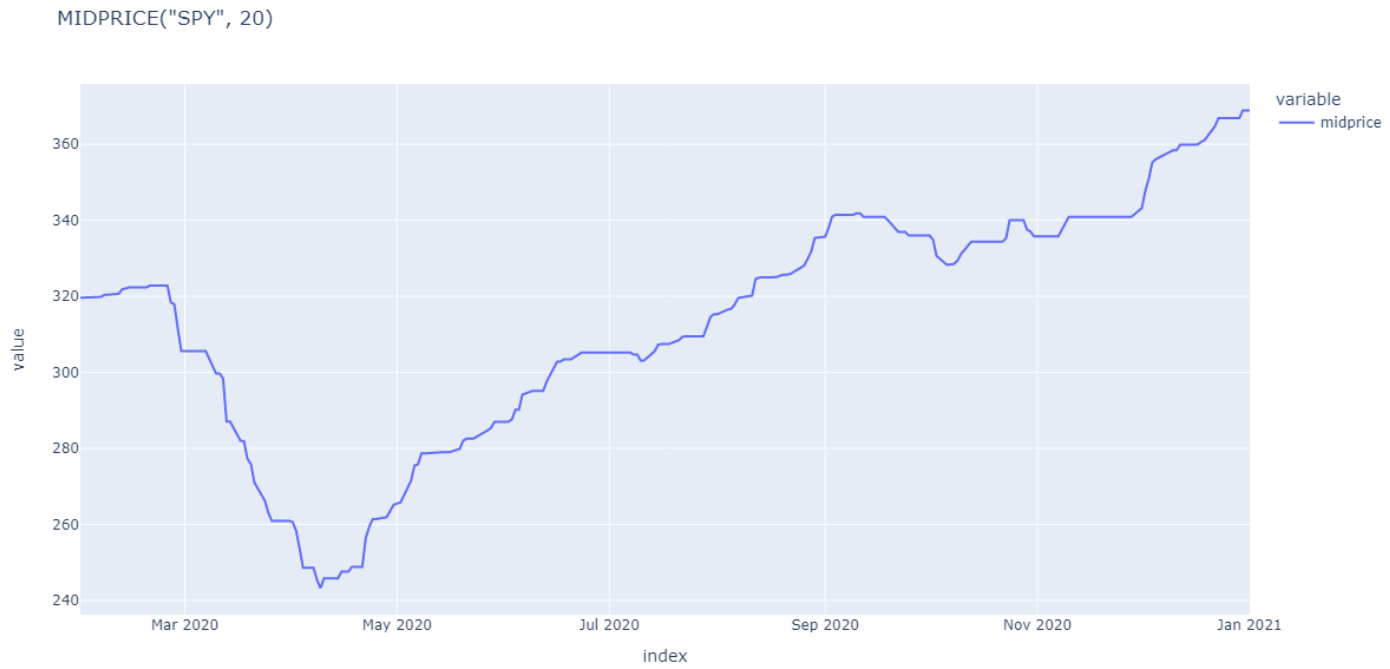
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._midprice.update(bar)

        if self._midprice.is_ready:
            # The current value of self._midprice is represented by self._midprice.current.value
            self.plot("MidPrice", "midprice", self._midprice.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `MidPrice` indicator properties:



Indicator History

To get the historical data of the `MidPrice` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

Supported Indicators

Minimum

Introduction

This indicator represents an indicator capable of tracking the minimum value and how many periods ago it occurred

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MIN Indicator

To create an automatic indicator for `Minimum` , call the `min` helper method from the `QCAlgorithm` class. The `min` method creates a `Minimum` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class MinimumAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._min = self.min(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._min.is_ready:
            # The current value of self._min is represented by self._min.current.value
            self.plot("Minimum", "min", self._min.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Minimum` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class MinimumAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._minimum = Minimum(20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._minimum.update(bar.end_time, bar.close)

        if self._minimum.is_ready:
            # The current value of self._minimum is represented by self._minimum.current.value
            self.plot("Minimum", "minimum", self._minimum.current.value)
```

For more information about this indicator, see its reference .

Momentum

Introduction

This indicator computes the n-period change in a value using the following: value_0 - value_n

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MOM Indicator

To create an automatic indicator for `Momentum` , call the `mom` helper method from the `QCAlgorithm` class. The `mom` method creates a `Momentum` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class MomentumAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._mom = self.mom(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._mom.is_ready:
            # The current value of self._mom is represented by self._mom.current.value
            self.plot("Momentum", "mom", self._mom.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Momentum` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class MomentumAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._momentum = Momentum(20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._momentum.update(bar.end_time, bar.close)

        if self._momentum.is_ready:
            # The current value of self._momentum is represented by self._momentum.current.value
            self.plot("Momentum", "momentum", self._momentum.current.value)
```

For more information about this indicator, see its reference .

Visualization

Money Flow Index

Introduction

The Money Flow Index (MFI) is an oscillator that uses both price and volume to measure buying and selling pressure Typical Price = (High + Low + Close)/3 Money Flow = Typical Price x Volume Positive Money Flow = Sum of the money flows of all days where the typical price is greater than the previous day's typical price Negative Money Flow = Sum of the money flows of all days where the typical price is less than the previous day's typical price Money Flow Ratio = (14-period Positive Money Flow)/(14-period Negative Money Flow) Money Flow Index = 100 x Positive Money Flow / (Positive Money Flow + Negative Money Flow)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MFI Indicator

To create an automatic indicator for `MoneyFlowIndex` , call the `mfi` helper method from the `QCAlgorithm` class. The `mfi` method creates a `MoneyFlowIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class MoneyFlowIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._mfi = self.mfi(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._mfi.is_ready:
            # The current value of self._mfi is represented by self._mfi.current.value
            self.plot("MoneyFlowIndex", "mfi", self._mfi.current.value)
            # Plot all attributes of self._mfi
            self.plot("MoneyFlowIndex", "positive_money_flow", self._mfi.positive_money_flow.current.value)
            self.plot("MoneyFlowIndex", "negative_money_flow", self._mfi.negative_money_flow.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `MoneyFlowIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class MoneyFlowIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._moneyflowindex = MoneyFlowIndex(20)

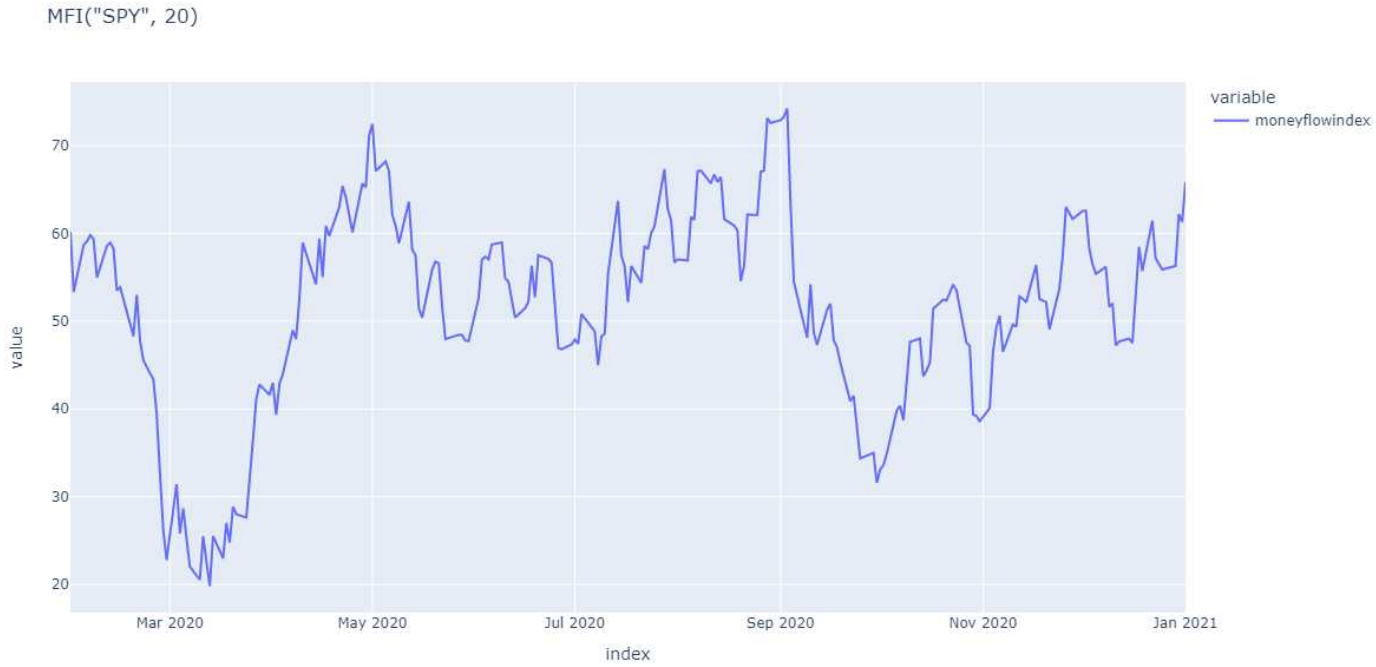
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._moneyflowindex.update(bar)

        if self._moneyflowindex.is_ready:
            # The current value of self._moneyflowindex is represented by self._moneyflowindex.current.value
            self.plot("MoneyFlowIndex", "moneyflowindex", self._moneyflowindex.current.value)
            # Plot all attributes of self._moneyflowindex
            self.plot("MoneyFlowIndex", "positive_money_flow", self._moneyflowindex.positive_money_flow.current.value)
            self.plot("MoneyFlowIndex", "negative_money_flow", self._moneyflowindex.negative_money_flow.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `MoneyFlowIndex` indicator properties:



Indicator History

To get the historical data of the `MoneyFlowIndex` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
PY
class MoneyFlowIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._mfi = self.mfi(self._symbol, 20)

        indicator_history = self.indicator_history(self._mfi, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._mfi, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._mfi, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)

        # Access all attributes of indicator_history
        indicator_history_df = indicator_history.data_frame
        positive_money_flow = indicator_history_df["positivemoneyflow"]
        negative_money_flow = indicator_history_df["negativemoneyflow"]
```

Supported Indicators

Moving Average Convergence Divergence

Introduction

This indicator creates two moving averages defined on a base indicator and produces the difference between the fast and slow averages.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MACD Indicator

To create an automatic indicator for `MovingAverageConvergenceDivergence` , call the `macd` helper method from the `QCAlgorithm` class. The `macd` method creates a `MovingAverageConvergenceDivergence` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class MovingAverageConvergenceDivergenceAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._macd = self.macd(self._symbol, 12, 26, 9, MovingAverageType.EXPONENTIAL)

    def on_data(self, slice: Slice) -> None:

        if self._macd.is_ready:
            # The current value of self._macd is represented by self._macd.current.value
            self.plot("MovingAverageConvergenceDivergence", "macd", self._macd.current.value)
            # Plot all attributes of self._macd
            self.plot("MovingAverageConvergenceDivergence", "fast", self._macd.fast.current.value)
            self.plot("MovingAverageConvergenceDivergence", "slow", self._macd.slow.current.value)
            self.plot("MovingAverageConvergenceDivergence", "signal", self._macd.signal.current.value)
            self.plot("MovingAverageConvergenceDivergence", "histogram", self._macd.histogram.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `MovingAverageConvergenceDivergence` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class MovingAverageConvergenceDivergenceAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._movingaverageconvergencedivergence = MovingAverageConvergenceDivergence(12, 26, 9, MovingAverageType.EXPONENTIAL)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._movingaverageconvergencedivergence.update(bar.end_time, bar.close)

        if self._movingaverageconvergencedivergence.is_ready:
            # The current value of self._movingaverageconvergencedivergence is represented by
self._movingaverageconvergencedivergence.current.value
            self.plot("MovingAverageConvergenceDivergence", "movingaverageconvergencedivergence",
self._movingaverageconvergencedivergence.current.value)
            # Plot all attributes of self._movingaverageconvergencedivergence
            self.plot("MovingAverageConvergenceDivergence", "fast", self._movingaverageconvergencedivergence.fast.current.value)
            self.plot("MovingAverageConvergenceDivergence", "slow", self._movingaverageconvergencedivergence.slow.current.value)
            self.plot("MovingAverageConvergenceDivergence", "signal", self._movingaverageconvergencedivergence.signal.current.value)
            self.plot("MovingAverageConvergenceDivergence", "histogram",
self._movingaverageconvergencedivergence.histogram.current.value)
```

For more information about this indicator, see its reference .

Supported Indicators

New Highs New Lows

Introduction

The NewHighsNewLows is a New Highs / New Lows indicator that accepts IBaseDataBar data as its input. This type is more of a shim/typedef to reduce the need to refer to things as NewHighsNewLows<IBaseDataBar>

To view the implementation of this indicator, see the LEAN GitHub repository .

Using NHNL Indicator

To create an automatic indicator for `NewHighsNewLows` , call the `nhnl` helper method from the `QCAlgorithm` class. The `nhnl` method creates a `NewHighsNewLows` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class NewHighsNewLowsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._nhnl = self.nhnl([self._symbol, self._reference], 2)

    def on_data(self, slice: Slice) -> None:

        if self._nhnl.is_ready:
            # The current value of self._nhnl is represented by self._nhnl.current.value
            self.plot("NewHighsNewLows", "nhnl", self._nhnl.current.value)
            # Plot all attributes of self._nhnl
            self.plot("NewHighsNewLows", "difference", self._nhnl.difference.current.value)
            self.plot("NewHighsNewLows", "ratio", self._nhnl.ratio.current.value)
```

To create an automatic indicator for `NewHighsNewLows` using universe constituents, call the `nhnl` helper method from the `QCAlgorithm` class. The `nhnl` method creates a `NewHighsNewLows` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In this case, you should call the helper method in the `on_securities_changed` method.

```
PY
class NewHighsNewLowsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024,1,1)
        self.set_end_date(2024,12,31)
        self.universe_settings.resolution = Resolution.DAILY
        self.universe_settings.schedule.on(self.date_rules.month_start())
        self._universe = self.add_universe(self.universe.etf('SPY'))

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        self._nhnl = self.nhnl(list(self._universe.selected), 2)

    def on_data(self, slice: Slice) -> None:

        if self._nhnl.is_ready:
            # The current value of self._nhnl is represented by self._nhnl.current.value
            self.plot("NewHighsNewLows", "nhnl", self._nhnl.current.value)
            # Plot all attributes of self._nhnl
            self.plot("NewHighsNewLows", "difference", self._nhnl.difference.current.value)
            self.plot("NewHighsNewLows", "ratio", self._nhnl.ratio.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `NewHighsNewLows` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```py
class NewHighsNewLowsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._newhighsnewlows = NewHighsNewLows("NHNL", 2)
        self._newhighsnewlows.add(self._symbol);
        self._newhighsnewlows.add(self._reference);

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._newhighsnewlows.update(bar)
        bar = slice.bars.get(self._reference)
        if bar:
            self._newhighsnewlows.update(bar)

        if self._newhighsnewlows.is_ready:
            # The current value of self._newhighsnewlows is represented by self._newhighsnewlows.current.value
            self.plot("NewHighsNewLows", "newhighsnewlows", self._newhighsnewlows.current.value)
            # Plot all attributes of self._newhighsnewlows
            self.plot("NewHighsNewLows", "difference", self._newhighsnewlows.difference.current.value)
            self.plot("NewHighsNewLows", "ratio", self._newhighsnewlows.ratio.current.value)
```

For more information about this indicator, see its reference .

Normalized Average True Range

Introduction

This indicator computes the Normalized Average True Range (NATR). The Normalized Average True Range is calculated with the following formula: NATR = (ATR(period) / Close) * 100

To view the implementation of this indicator, see the LEAN GitHub repository .

Using NATR Indicator

To create an automatic indicator for `NormalizedAverageTrueRange` , call the `natr` helper method from the `QCAlgorithm` class. The `natr` method creates a `NormalizedAverageTrueRange` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class NormalizedAverageTrueRangeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._natr = self.natr(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._natr.is_ready:
            # The current value of self._natr is represented by self._natr.current.value
            self.plot("NormalizedAverageTrueRange", "natr", self._natr.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `NormalizedAverageTrueRange` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class NormalizedAverageTrueRangeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._normalizedaveragetruerange = NormalizedAverageTrueRange(20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._normalizedaveragetruerange.update(bar)

        if self._normalizedaveragetruerange.is_ready:
            # The current value of self._normalizedaveragetruerange is represented by self._normalizedaveragetruerange.current.value
            self.plot("NormalizedAverageTrueRange", "normalizedaveragetruerange", self._normalizedaveragetruerange.current.value)
```

For more information about this indicator, see its reference .

Supported Indicators

On Balance Volume

Introduction

This indicator computes the On Balance Volume (OBV). The On Balance Volume is calculated by determining the price of the current close price and previous close price. If the current close price is equivalent to the previous price the OBV remains the same, If the current close price is higher the volume of that day is added to the OBV, while a lower close price will result in negative value.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using OBV Indicator

To create an automatic indicator for `OnBalanceVolume` , call the `obv` helper method from the `QCAlgorithm` class. The `obv` method creates a `OnBalanceVolume` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class OnBalanceVolumeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._obv = self.obv(self._symbol)

    def on_data(self, slice: Slice) -> None:

        if self._obv.is_ready:
            # The current value of self._obv is represented by self._obv.current.value
            self.plot("OnBalanceVolume", "obv", self._obv.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `OnBalanceVolume` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class OnBalanceVolumeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._onbalancevolume = OnBalanceVolume()

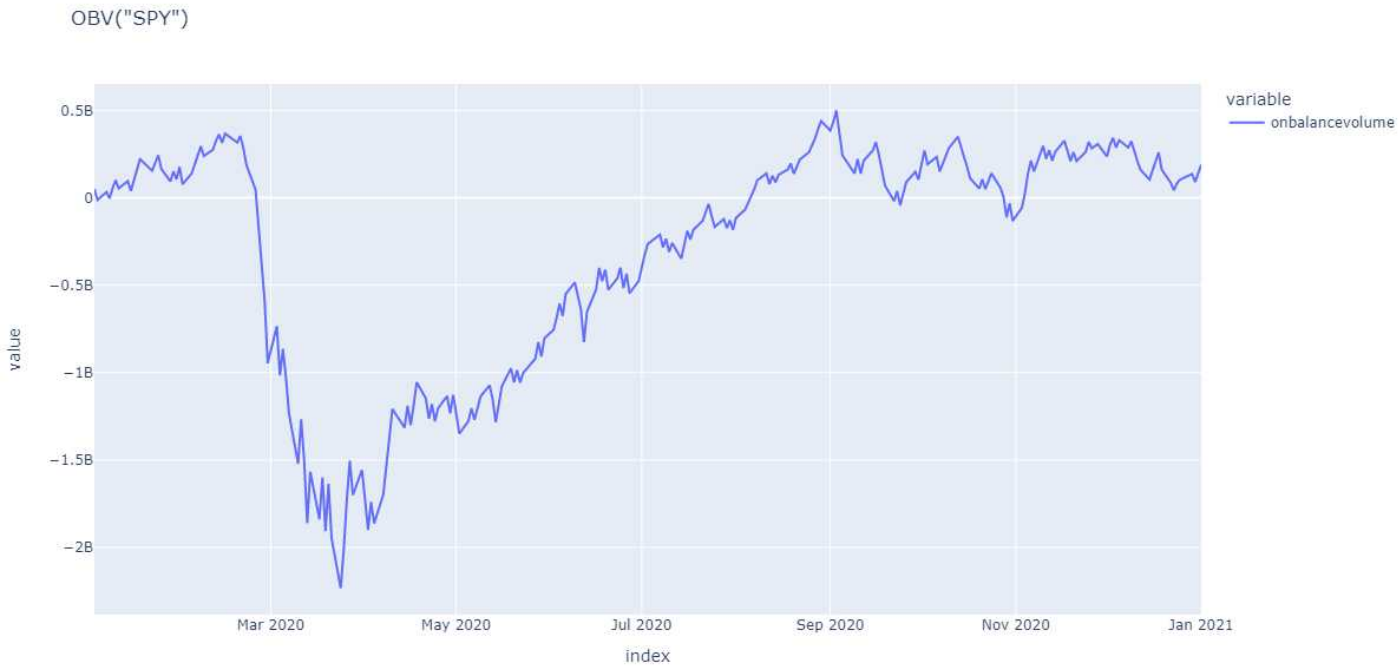
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._onbalancevolume.update(bar)

        if self._onbalancevolume.is_ready:
            # The current value of self._onbalancevolume is represented by self._onbalancevolume.current.value
            self.plot("OnBalanceVolume", "onbalancevolume", self._onbalancevolume.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `OnBalanceVolume` indicator properties:



Indicator History

To get the historical data of the `OnBalanceVolume` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class OnBalanceVolumeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._obv = self.obv(self._symbol)

        indicator_history = self.indicator_history(self._obv, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._obv, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._obv, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Parabolic Stop And Reverse

Introduction

Parabolic SAR Indicator Based on TA-Lib implementation

To view the implementation of this indicator, see the LEAN GitHub repository .

Using PSAR Indicator

To create an automatic indicator for `ParabolicStopAndReverse` , call the `psar` helper method from the `QCAlgorithm` class. The `psar` method creates a `ParabolicStopAndReverse` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class ParabolicStopAndReverseAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._psar = self.psar(self._symbol, 0.02, 0.02, 0.2)

    def on_data(self, slice: Slice) -> None:

        if self._psar.is_ready:
            # The current value of self._psar is represented by self._psar.current.value
            self.plot("ParabolicStopAndReverse", "psar", self._psar.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ParabolicStopAndReverse` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class ParabolicStopAndReverseAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._parabolicstopandreverse = ParabolicStopAndReverse(0.02, 0.02, 0.2)

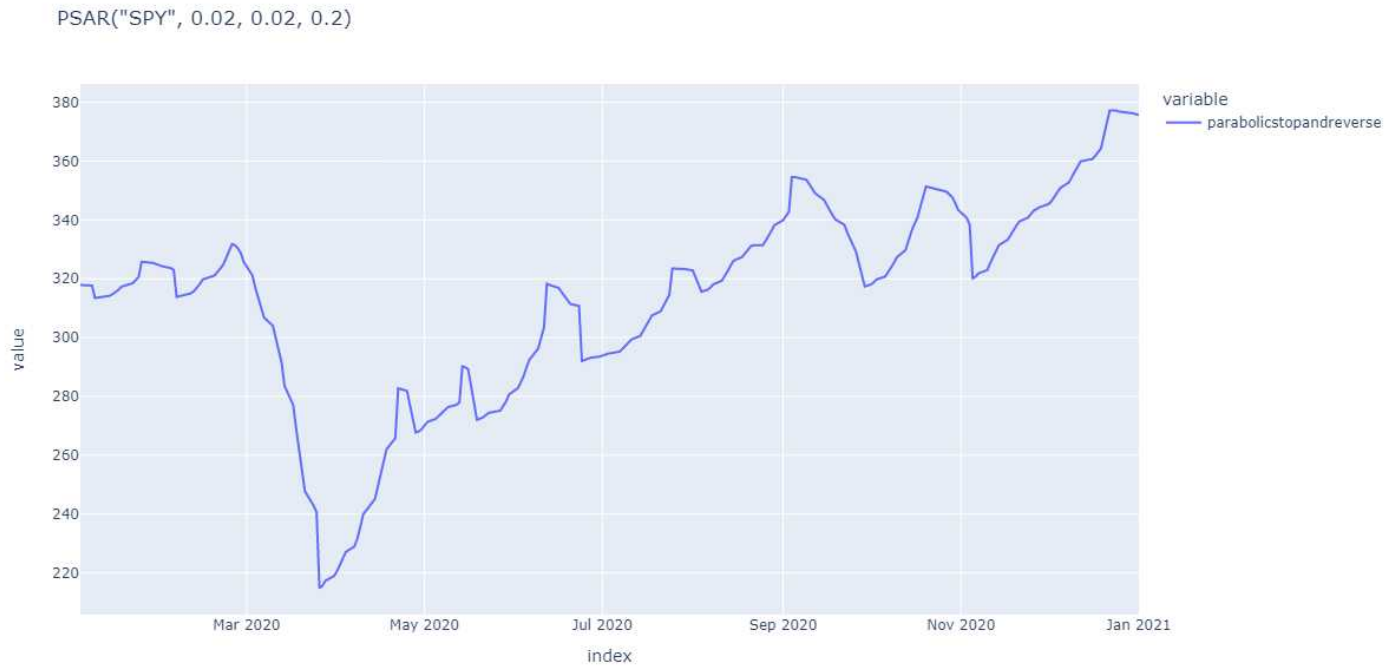
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._parabolicstopandreverse.update(bar)

        if self._parabolicstopandreverse.is_ready:
            # The current value of self._parabolicstopandreverse is represented by self._parabolicstopandreverse.current.value
            self.plot("ParabolicStopAndReverse", "parabolicstopandreverse", self._parabolicstopandreverse.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `ParabolicStopAndReverse` indicator properties:



Indicator History

To get the historical data of the `ParabolicStopAndReverse` indicator, call the `self.indicator_history` method. Parabolic Stop And Reverse Extended

Introduction

Parabolic SAR Extended Indicator Based on TA-Lib implementation

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SAREXT Indicator

To create an automatic indicator for `ParabolicStopAndReverseExtended` , call the `sarext` helper method from the `QCAlgorithm` class. The `sarext` method creates a `ParabolicStopAndReverseExtended` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class ParabolicStopAndReverseExtendedAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._sarext = self.sarext(self._symbol, 0.0, 0.0, 0.02, 0.02, 0.2, 0.02, 0.02, 0.2)

    def on_data(self, slice: Slice) -> None:

        if self._sarext.is_ready:
            # The current value of self._sarext is represented by self._sarext.current.value
            self.plot("ParabolicStopAndReverseExtended", "sarext", self._sarext.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ParabolicStopAndReverseExtended` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class ParabolicStopAndReverseExtendedAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._parabolicstopandreverseextended = ParabolicStopAndReverseExtended(0.0, 0.0, 0.02, 0.02, 0.2, 0.02, 0.02, 0.2)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._parabolicstopandreverseextended.update(bar)

        if self._parabolicstopandreverseextended.is_ready:
            # The current value of self._parabolicstopandreverseextended is represented by
self._parabolicstopandreverseextended.current.value
            self.plot("ParabolicStopAndReverseExtended", "parabolicstopandreverseextended",
self._parabolicstopandreverseextended.current.value)
```

For more information about this indicator, see its reference .

Percentage Price Oscillator

Introduction

This indicator computes the Percentage Price Oscillator (PPO) The Percentage Price Oscillator is calculated using the following formula: PPO[i] = 100 * (FastMA[i] - SlowMA[i]) / SlowMA[i]

To view the implementation of this indicator, see the LEAN GitHub repository .

Using PPO Indicator

To create an automatic indicator for `PercentagePriceOscillator` , call the `ppo` helper method from the `QCAlgorithm` class. The `ppo` method creates a `PercentagePriceOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class PercentagePriceOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._ppo = self.ppo(self._symbol, 10, 20, MovingAverageType.SIMPLE)

    def on_data(self, slice: Slice) -> None:

        if self._ppo.is_ready:
            # The current value of self._ppo is represented by self._ppo.current.value
            self.plot("PercentagePriceOscillator", "ppo", self._ppo.current.value)
            # Plot all attributes of self._ppo
            self.plot("PercentagePriceOscillator", "fast", self._ppo.fast.current.value)
            self.plot("PercentagePriceOscillator", "slow", self._ppo.slow.current.value)
            self.plot("PercentagePriceOscillator", "signal", self._ppo.signal.current.value)
            self.plot("PercentagePriceOscillator", "histogram", self._ppo.histogram.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `PercentagePriceOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

Premier Stochastic Oscillator

Introduction

Premier Stochastic Oscillator (PSO) Indicator implementation. This indicator combines a stochastic oscillator with exponential moving averages to provide a normalized output between -1 and 1, which can be useful for identifying trends and potential reversal points in the market.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using PSO Indicator

To create an automatic indicator for `PremierStochasticOscillator` , call the `pso` helper method from the `QCAlgorithm` class. The `pso` method creates a `PremierStochasticOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class PremierStochasticOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._pso = self.pso(self._symbol, 14, 3)

    def on_data(self, slice: Slice) -> None:

        if self._pso.is_ready:
            # The current value of self._pso is represented by self._pso.current.value
            self.plot("PremierStochasticOscillator", "pso", self._pso.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `PremierStochasticOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class PremierStochasticOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._premierstochasticoscillator = PremierStochasticOscillator(14, 3)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._premierstochasticoscillator.update(bar)

        if self._premierstochasticoscillator.is_ready:
            # The current value of self._premierstochasticoscillator is represented by self._premierstochasticoscillator.current.value
            self.plot("PremierStochasticOscillator", "premierstochasticoscillator", self._premierstochasticoscillator.current.value)
```

For more information about this indicator, see its reference .

Supported Indicators

Rate Of Change

Introduction

This indicator computes the n-period rate of change in a value using the following: (value_0 - value_n) / value_n

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ROC Indicator

To create an automatic indicator for `RateOfChange` , call the `roc` helper method from the `QCAlgorithm` class. The `roc` method creates a `RateOfChange` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class RateOfChangeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._roc = self.roc(self._symbol, 10)

    def on_data(self, slice: Slice) -> None:

        if self._roc.is_ready:
            # The current value of self._roc is represented by self._roc.current.value
            self.plot("RateOfChange", "roc", self._roc.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `RateOfChange` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class RateOfChangeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._rateofchange = RateOfChange(10)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._rateofchange.update(bar.end_time, bar.close)

        if self._rateofchange.is_ready:
            # The current value of self._rateofchange is represented by self._rateofchange.current.value
            self.plot("RateOfChange", "rateofchange", self._rateofchange.current.value)
```

For more information about this indicator, see its reference .

The following plot shows values for some of the `RateOfChange` indicator properties:

Indicator History

To get the historical data of the `RateOfChange` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class RateOfChangeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._roc = self.roc(self._symbol, 10)

        indicator_history = self.indicator_history(self._roc, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._roc, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._roc, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Supported Indicators

Rate Of Change Percent

Introduction

This indicator computes the n-period percentage rate of change in a value using the following: 100 * (value_0 - value_n) / value_n

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ROCP Indicator

To create an automatic indicator for `RateOfChangePercent` , call the `rocp` helper method from the `QCAlgorithm` class. The `rocp` method creates a `RateOfChangePercent` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class RateOfChangePercentAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._rocp = self.rocp(self._symbol, 10)

    def on_data(self, slice: Slice) -> None:

        if self._rocp.is_ready:
            # The current value of self._rocp is represented by self._rocp.current.value
            self.plot("RateOfChangePercent", "rocp", self._rocp.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `RateOfChangePercent` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class RateOfChangePercentAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._rateofchangepercent = RateOfChangePercent(10)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._rateofchangepercent.update(bar.end_time, bar.close)

        if self._rateofchangepercent.is_ready:
            # The current value of self._rateofchangepercent is represented by self._rateofchangepercent.current.value
            self.plot("RateOfChangePercent", "rateofchangepercent", self._rateofchangepercent.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `RateOfChangePercent` indicator properties:

Indicator History

To get the historical data of the `RateOfChangePercent` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class RateOfChangePercentAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._rocp = self.rocp(self._symbol, 10)

        indicator_history = self.indicator_history(self._rocp, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._rocp, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._rocp, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)

Rate Of Change Ratio

Introduction

This indicator computes the Rate Of Change Ratio (ROCR). The Rate Of Change Ratio is calculated with the following formula: ROCR = price / prevPrice

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ROCR Indicator

To create an automatic indicator for `RateOfChangeRatio` , call the `rocr` helper method from the `QCAlgorithm` class. The `rocr` method creates a `RateOfChangeRatio` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class RateOfChangeRatioAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._rocr = self.rocr(self._symbol, 10)

    def on_data(self, slice: Slice) -> None:

        if self._rocr.is_ready:
            # The current value of self._rocr is represented by self._rocr.current.value
            self.plot("RateOfChangeRatio", "rocr", self._rocr.current.value)
```

PY

For more information about this method, see the QCAlgorithm class .

You can manually create a `RateOfChangeRatio` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class RateOfChangeRatioAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._rateofchangeratio = RateOfChangeRatio(10)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._rateofchangeratio.update(bar.end_time, bar.close)

        if self._rateofchangeratio.is_ready:
            # The current value of self._rateofchangeratio is represented by self._rateofchangeratio.current.value
            self.plot("RateOfChangeRatio", "rateofchangeratio", self._rateofchangeratio.current.value)
```

PY

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `RateOfChangeRatio` indicator properties:

Indicator History

To get the historical data of the `RateOfChangeRatio` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

Supported Indicators

Regression Channel

Introduction

The Regression Channel indicator extends the with the inclusion of two (upper and lower) channel lines that are distanced from the linear regression line by a user defined number of standard deviations. Reference: http://www.onlinetradingconcepts.com/TechnicalAnalysis/LinRegChannel.html

To view the implementation of this indicator, see the LEAN GitHub repository .

Using RC Indicator

To create an automatic indicator for `RegressionChannel` , call the `rc` helper method from the `QCAlgorithm` class. The `rc` method creates a `RegressionChannel` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class RegressionChannelAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._rc = self.rc(self._symbol, 20, 2)

    def on_data(self, slice: Slice) -> None:

        if self._rc.is_ready:
            # The current value of self._rc is represented by self._rc.current.value
            self.plot("RegressionChannel", "rc", self._rc.current.value)
            # Plot all attributes of self._rc
            self.plot("RegressionChannel", "linear_regression", self._rc.linear_regression.current.value)
            self.plot("RegressionChannel", "upper_channel", self._rc.upper_channel.current.value)
            self.plot("RegressionChannel", "lower_channel", self._rc.lower_channel.current.value)
            self.plot("RegressionChannel", "intercept", self._rc.intercept.current.value)
            self.plot("RegressionChannel", "slope", self._rc.slope.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `RegressionChannel` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class RegressionChannelAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._regressionchannel = RegressionChannel(20, 2)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._regressionchannel.update(bar.end_time, bar.close)

        if self._regressionchannel.is_ready:
            # The current value of self._regressionchannel is represented by self._regressionchannel.current.value
            self.plot("RegressionChannel", "regressionchannel", self._regressionchannel.current.value)
            # Plot all attributes of self._regressionchannel
            self.plot("RegressionChannel", "linear_regression", self._regressionchannel.linear_regression.current.value)
            self.plot("RegressionChannel", "upper_channel", self._regressionchannel.upper_channel.current.value)
            self.plot("RegressionChannel", "lower_channel", self._regressionchannel.lower_channel.current.value)
            self.plot("RegressionChannel", "intercept", self._regressionchannel.intercept.current.value)
            self.plot("RegressionChannel", "slope", self._regressionchannel.slope.current.value)
```

For more information about this indicator, see its reference .

Relative Daily Volume

Introduction

The Relative Daily Volume indicator is an indicator that compares current cumulative volume to the cumulative volume for a given time of day, measured as a ratio. Current volume from open to current time of day / Average over the past x days from open to current time of day

To view the implementation of this indicator, see the LEAN GitHub repository .

Using RDV Indicator

To create an automatic indicator for `RelativeDailyVolume` , call the `rdv` helper method from the `QCAlgorithm` class. The `rdv` method creates a `RelativeDailyVolume` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class RelativeDailyVolumeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._rdv = self.rdv(self._symbol, 2)

    def on_data(self, slice: Slice) -> None:

        if self._rdv.is_ready:
            # The current value of self._rdv is represented by self._rdv.current.value
            self.plot("RelativeDailyVolume", "rdv", self._rdv.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `RelativeDailyVolume` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY

Supported Indicators

Relative Moving Average

Introduction

This indicator represents the relative moving average indicator (RMA). RMA = SMA(3 x Period) - SMA(2 x Period) + SMA(1 x Period) per formula: https://www.hybrid-solutions.com/plugins/client-vtl-plugins/free/rma.html

To view the implementation of this indicator, see the LEAN GitHub repository .

Using RMA Indicator

To create an automatic indicator for `RelativeMovingAverage` , call the `rma` helper method from the `QCAlgorithm` class. The `rma` method creates a `RelativeMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class RelativeMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._rma = self.rma(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._rma.is_ready:
            # The current value of self._rma is represented by self._rma.current.value
            self.plot("RelativeMovingAverage", "rma", self._rma.current.value)
            # Plot all attributes of self._rma
            self.plot("RelativeMovingAverage", "short_average", self._rma.short_average.current.value)
            self.plot("RelativeMovingAverage", "medium_average", self._rma.medium_average.current.value)
            self.plot("RelativeMovingAverage", "long_average", self._rma.long_average.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `RelativeMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

Relative Strength Index

Introduction

This indicator represents the Relative Strength Index (RSI) developed by K. Welles Wilder. You can optionally specified a different moving average type to be used in the computation

To view the implementation of this indicator, see the LEAN GitHub repository .

Using RSI Indicator

To create an automatic indicator for `RelativeStrengthIndex` , call the `rsi` helper method from the `QCAlgorithm` class. The `rsi` method creates a `RelativeStrengthIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class RelativeStrengthIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._rsi = self.rsi(self._symbol, 14)

    def on_data(self, slice: Slice) -> None:

        if self._rsi.is_ready:
            # The current value of self._rsi is represented by self._rsi.current.value
            self.plot("RelativeStrengthIndex", "rsi", self._rsi.current.value)
            # Plot all attributes of self._rsi
            self.plot("RelativeStrengthIndex", "average_loss", self._rsi.average_loss.current.value)
            self.plot("RelativeStrengthIndex", "average_gain", self._rsi.average_gain.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `RelativeStrengthIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

Relative Vigor Index

Introduction

The Relative Vigor Index (RVI) compares the ratio of the closing price of a security to its trading range. For illustration, let: a = Close−Open b = Close−Open of One Bar Prior to a c = Close−Open of One Bar Prior to b d = Close−Open of One Bar Prior to c e = High−Low of Bar a f = High−Low of Bar b g = High−Low of Bar c h = High−Low of Bar d Then let (a+2*(b+c)+d)/6 be NUM and (e+2*(f+g)+h)/6 be DENOM. RVI = SMA(NUM)/SMA(DENOM) for a specified period. https://www.investopedia.com/terms/r/relative_vigor_index.asp

To view the implementation of this indicator, see the LEAN GitHub repository .

Using RVI Indicator

To create an automatic indicator for `RelativeVigorIndex` , call the `rvi` helper method from the `QCAlgorithm` class. The `rvi` method creates a `RelativeVigorIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class RelativeVigorIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._rvi = self.rvi(self._symbol, 20, MovingAverageType.SIMPLE)

    def on_data(self, slice: Slice) -> None:

        if self._rvi.is_ready:
            # The current value of self._rvi is represented by self._rvi.current.value
            self.plot("RelativeVigorIndex", "rvi", self._rvi.current.value)
            # Plot all attributes of self._rvi
            self.plot("RelativeVigorIndex", "signal", self._rvi.signal.current.value)
```

PY

For more information about this method, see the QCAlgorithm class .

You can manually create a `RelativeVigorIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class RelativeVigorIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._relativevigorindex = RelativeVigorIndex(20, MovingAverageType.SIMPLE)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._relativevigorindex.update(bar)

        if self._relativevigorindex.is_ready:
            # The current value of self._relativevigorindex is represented by self._relativevigorindex.current.value
            self.plot("RelativeVigorIndex", "relativevigorindex", self._relativevigorindex.current.value)
            # Plot all attributes of self._relativevigorindex
            self.plot("RelativeVigorIndex", "signal", self._relativevigorindex.signal.current.value)
```

PY

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `RelativeVigorIndex` indicator properties:

Indicator History

To get the historical data of the `RelativeVigorIndex` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class RelativeVigorIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._rvi = self.rvi(self._symbol, 20, MovingAverageType.SIMPLE)

        indicator_history = self.indicator_history(self._rvi, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._rvi, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._rvi, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)

        # Access all attributes of indicator_history
        indicator_history_df = indicator_history.data_frame
        signal = indicator_history_df["signal"]
```

Rho

Introduction

Option Rho indicator that calculate the rho of an option

To view the implementation of this indicator, see the LEAN GitHub repository .

Using R Indicator

To create an automatic indicator for `Rho` , call the `r` helper method from the `QCAlgorithm` class. The `r` method creates a `Rho` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class RhoAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 20)

        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._option = SymbolRepresentation.parse_option_ticker_osi("SPY 240920C00564000");
        self._mirror_option = SymbolRepresentation.parse_option_ticker_osi("SPY 240920P00564000");
        self.add_option_contract(self._option, Resolution.DAILY);
        self.add_option_contract(self._mirror_option, Resolution.DAILY);

        self._r = self.r(self._option, self._mirror_option)

    def on_data(self, slice: Slice) -> None:
        if self._r.is_ready:
            # The current value of self._r is represented by self._r.current.value
            self.plot("Rho", "r", self._r.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Rho` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class RhoAlgorithm(QCAlgorithm):

Rogers Satchell Volatility

Introduction

This indicator computes the Rogers-Satchell Volatility It is an estimator for measuring the volatility of securities with an average return not equal to zero.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using RSV Indicator

To create an automatic indicator for `RogersSatchellVolatility` , call the `rsv` helper method from the `QCAlgorithm` class. The `rsv` method creates a `RogersSatchellVolatility` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class RogersSatchellVolatilityAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._rsv = self.rsv(self._symbol, 30)

    def on_data(self, slice: Slice) -> None:

        if self._rsv.is_ready:
            # The current value of self._rsv is represented by self._rsv.current.value
            self.plot("RogersSatchellVolatility", "rsv", self._rsv.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `RogersSatchellVolatility` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class RogersSatchellVolatilityAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._rogerssatchellvolatility = RogersSatchellVolatility(30)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._rogerssatchellvolatility.update(bar)

        if self._rogerssatchellvolatility.is_ready:
            # The current value of self._rogerssatchellvolatility is represented by self._rogerssatchellvolatility.current.value
            self.plot("RogersSatchellVolatility", "rogerssatchellvolatility", self._rogerssatchellvolatility.current.value)
```

For more information about this indicator, see its reference .

Simple Moving Average

Introduction

This indicator represents the traditional simple moving average indicator (SMA)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SMA Indicator

To create an automatic indicator for `SimpleMovingAverage` , call the `sma` helper method from the `QCAlgorithm` class. The `sma` method creates a `SimpleMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class SimpleMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._sma = self.sma(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._sma.is_ready:
            # The current value of self._sma is represented by self._sma.current.value
            self.plot("SimpleMovingAverage", "sma", self._sma.current.value)
            # Plot all attributes of self._sma
            self.plot("SimpleMovingAverage", "rolling_sum", self._sma.rolling_sum.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `SimpleMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class SimpleMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._simplemovingaverage = SimpleMovingAverage(20)

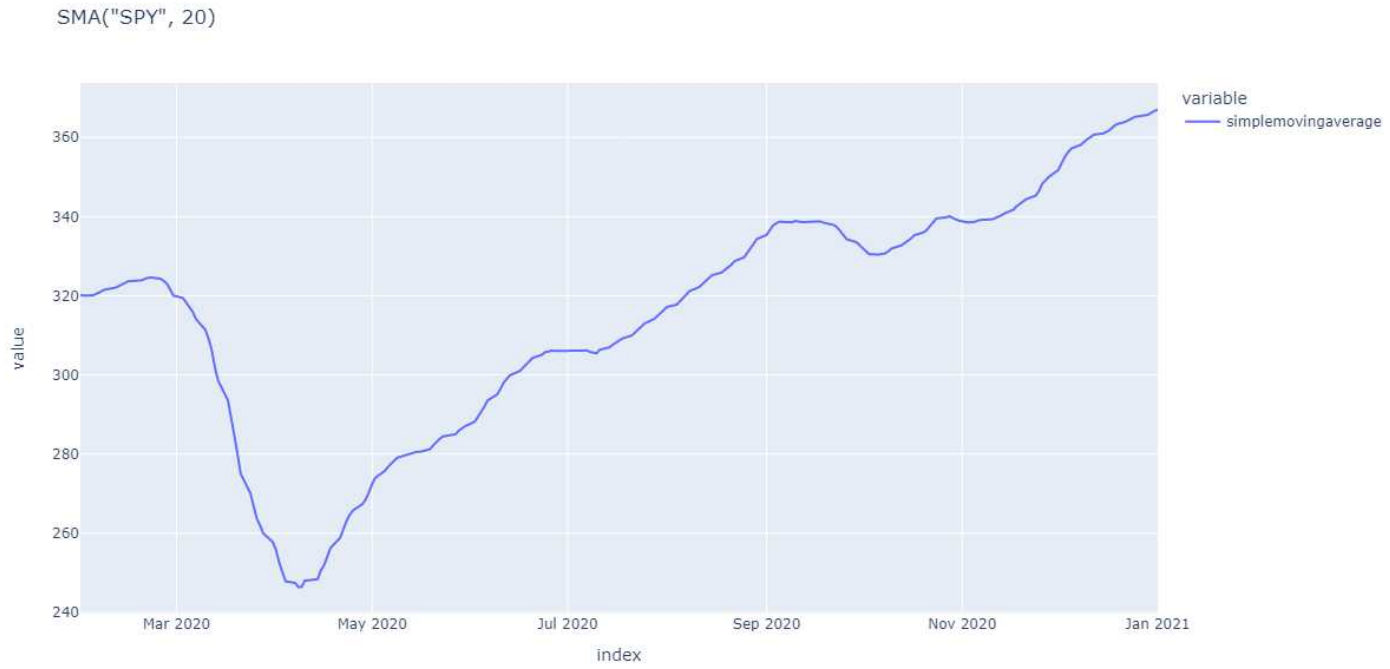
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._simplemovingaverage.update(bar.end_time, bar.close)

        if self._simplemovingaverage.is_ready:
            # The current value of self._simplemovingaverage is represented by self._simplemovingaverage.current.value
            self.plot("SimpleMovingAverage", "simplemovingaverage", self._simplemovingaverage.current.value)
            # Plot all attributes of self._simplemovingaverage
            self.plot("SimpleMovingAverage", "rolling_sum", self._simplemovingaverage.rolling_sum.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `SimpleMovingAverage` indicator properties:



Indicator History

To get the historical data of the `SimpleMovingAverage` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
class SimpleMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol

Smoothed On Balance Volume

Introduction

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SOBV Indicator

To create an automatic indicator for `SmoothedOnBalanceVolume` , call the `sobv` helper method from the `QCAlgorithm` class. The `sobv` method creates a `SmoothedOnBalanceVolume` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class SmoothedOnBalanceVolumeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._sobv = self.sobv(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._sobv.is_ready:
            # The current value of self._sobv is represented by self._sobv.current.value
            self.plot("SmoothedOnBalanceVolume", "sobv", self._sobv.current.value)
            # Plot all attributes of self._sobv
            self.plot("SmoothedOnBalanceVolume", "on_balance_volume", self._sobv.on_balance_volume.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `SmoothedOnBalanceVolume` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class SmoothedOnBalanceVolumeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._smoothedonbalancevolume = SmoothedOnBalanceVolume(20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._smoothedonbalancevolume.update(bar)

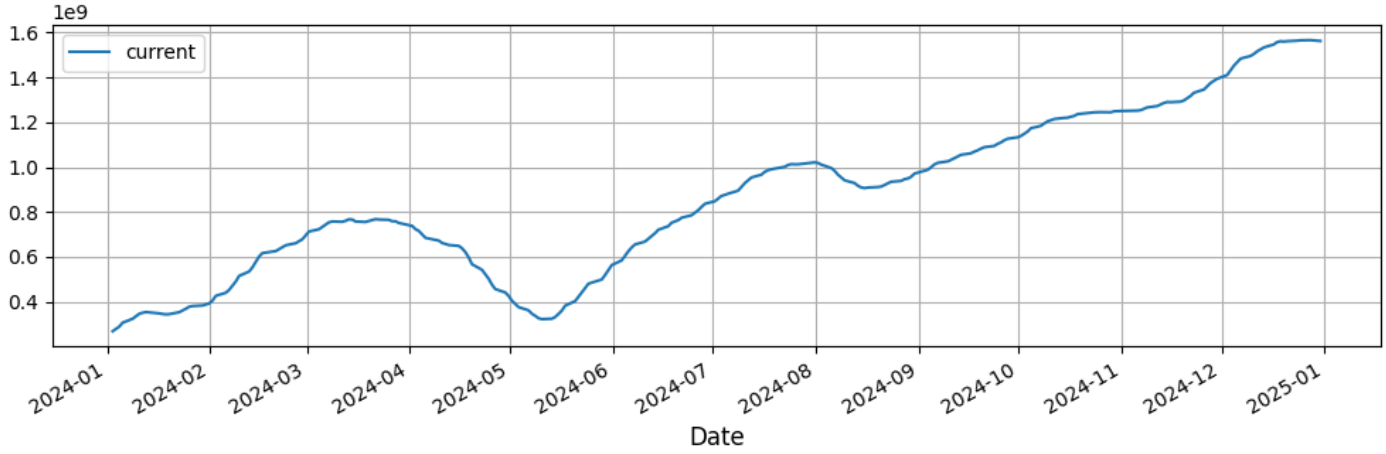
        if self._smoothedonbalancevolume.is_ready:
            # The current value of self._smoothedonbalancevolume is represented by self._smoothedonbalancevolume.current.value
            self.plot("SmoothedOnBalanceVolume", "smoothedonbalancevolume", self._smoothedonbalancevolume.current.value)
            # Plot all attributes of self._smoothedonbalancevolume
            self.plot("SmoothedOnBalanceVolume", "on_balance_volume", self._smoothedonbalancevolume.on_balance_volume.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `SmoothedOnBalanceVolume` indicator properties:

C#: SOBV(_symbol, 20)
Py: self.sobv(self._symbol, 20)



Indicator History

To get the historical data of the `SmoothedOnBalanceVolume` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class SmoothedOnBalanceVolumeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._sobv = self.sobv(self._symbol, 20)

        indicator_history = self.indicator_history(self._sobv, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._sobv, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._sobv, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)

        # Access all attributes of indicator_history
        indicator_history_df = indicator_history.data_frame
        on_balance_volume = indicator_history_df["onbalancevolume"]
```

Supported Indicators

Sortino Ratio

Introduction

Calculation of the Sortino Ratio, a modification of the . Reference: https://www.cmegroup.com/education/files/rr-sortino-a-sharper-ratio.pdf Formula: S(x) = (R - T) / TDD Where: S(x) - Sortino ratio of x R - the average period return T - the target or required rate of return for the investment strategy under consideration. In Sortino's early work, T was originally known as the minimum acceptable return, or MAR. In his more recent work, MAR is now referred to as the Desired Target Return. TDD - the target downside deviation.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SORTINO Indicator

To create an automatic indicator for `SortinoRatio` , call the `sortino` helper method from the `QCAlgorithm` class. The `sortino` method creates a `SortinoRatio` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class SortinoRatioAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._sortino = self.sortino(self._symbol, 22)

    def on_data(self, slice: Slice) -> None:

        if self._sortino.is_ready:
            # The current value of self._sortino is represented by self._sortino.current.value
            self.plot("SortinoRatio", "sortino", self._sortino.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `SortinoRatio` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class SortinoRatioAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._sortinoratio = SortinoRatio(22)

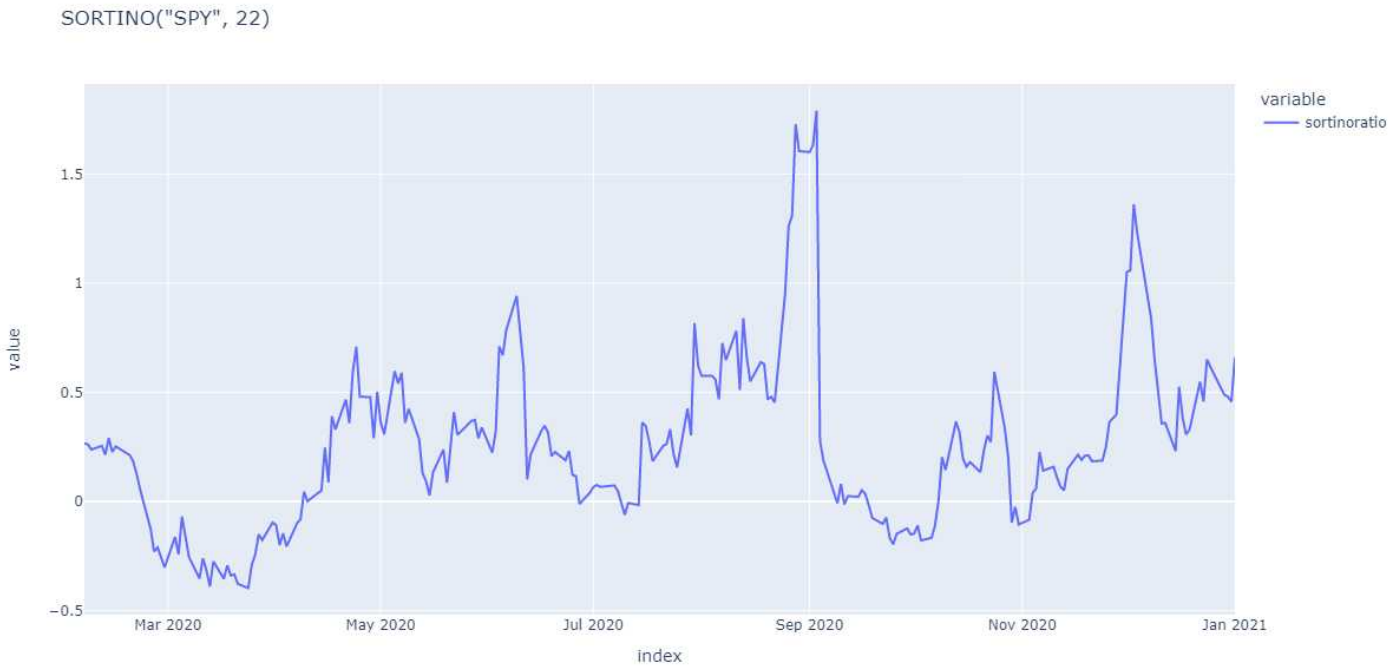
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._sortinoratio.update(bar.end_time, bar.close)

        if self._sortinoratio.is_ready:
            # The current value of self._sortinoratio is represented by self._sortinoratio.current.value
            self.plot("SortinoRatio", "sortinoratio", self._sortinoratio.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `SortinoRatio` indicator properties:



Indicator History

To get the historical data of the `SortinoRatio` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
class SortinoRatioAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._sortino = self.sortino(self._symbol, 22)

        indicator_history = self.indicator_history(self._sortino, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._sortino, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._sortino, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Supported Indicators

Squeeze Momentum

Introduction

The SqueezeMomentum indicator calculates whether the market is in a "squeeze" condition, determined by comparing Bollinger Bands to Keltner Channels. When the Bollinger Bands are inside the Keltner Channels, the indicator returns 1 (squeeze on). Otherwise, it returns -1 (squeeze off).

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SM Indicator

To create an automatic indicator for `SqueezeMomentum` , call the `sm` helper method from the `QCAlgorithm` class. The `sm` method creates a `SqueezeMomentum` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class SqueezeMomentumAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._sm = self.sm(self._symbol, 20, 2, 20, 1.5)

    def on_data(self, slice: Slice) -> None:

        if self._sm.is_ready:
            # The current value of self._sm is represented by self._sm.current.value
            self.plot("SqueezeMomentum", "sm", self._sm.current.value)
            # Plot all attributes of self._sm
            self.plot("SqueezeMomentum", "bollinger_bands", self._sm.bollinger_bands.current.value)
            self.plot("SqueezeMomentum", "keltner_channels", self._sm.keltner_channels.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `SqueezeMomentum` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class SqueezeMomentumAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._squeezemomentum = SqueezeMomentum(20, 2, 20, 1.5)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._squeezemomentum.update(bar)

        if self._squeezemomentum.is_ready:
            # The current value of self._squeezemomentum is represented by self._squeezemomentum.current.value
            self.plot("SqueezeMomentum", "squeezemomentum", self._squeezemomentum.current.value)
            # Plot all attributes of self._squeezemomentum
            self.plot("SqueezeMomentum", "bollinger_bands", self._squeezemomentum.bollinger_bands.current.value)
            self.plot("SqueezeMomentum", "keltner_channels", self._squeezemomentum.keltner_channels.current.value)
```

For more information about this indicator, see its reference .

Visualization

Standard Deviation

Introduction

This indicator computes the n-period population standard deviation.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using STD Indicator

To create an automatic indicator for `StandardDeviation` , call the `std` helper method from the `QCAlgorithm` class. The `std` method creates a `StandardDeviation` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class StandardDeviationAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._std = self.std(self._symbol, 22)

    def on_data(self, slice: Slice) -> None:

        if self._std.is_ready:
            # The current value of self._std is represented by self._std.current.value
            self.plot("StandardDeviation", "std", self._std.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `StandardDeviation` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class StandardDeviationAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._standarddeviation = StandardDeviation(22)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._standarddeviation.update(bar.end_time, bar.close)

        if self._standarddeviation.is_ready:
            # The current value of self._standarddeviation is represented by self._standarddeviation.current.value
            self.plot("StandardDeviation", "standarddeviation", self._standarddeviation.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `StandardDeviation` indicator properties:

        time_period_indicator_history = self.indicator_history(self._std, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Supported Indicators

Stochastic

Introduction

This indicator computes the Slow Stochastics %K and %D. The Fast Stochastic %K is is computed by (Current Close Price - Lowest Price of given Period) / (Highest Price of given Period - Lowest Price of given Period) multiplied by 100. Once the Fast Stochastic %K is calculated the Slow Stochastic %K is calculated by the average/smoothed price of of the Fast %K with the given period. The Slow Stochastic %D is then derived from the Slow Stochastic %K with the given period.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using STO Indicator

To create an automatic indicator for `Stochastic` , call the `sto` helper method from the `QCAlgorithm` class. The `sto` method creates a `Stochastic` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class StochasticAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._sto = self.sto(self._symbol, 20, 10, 20)

    def on_data(self, slice: Slice) -> None:

        if self._sto.is_ready:
            # The current value of self._sto is represented by self._sto.current.value
            self.plot("Stochastic", "sto", self._sto.current.value)
            # Plot all attributes of self._sto
            self.plot("Stochastic", "fast_stoch", self._sto.fast_stoch.current.value)
            self.plot("Stochastic", "stoch_k", self._sto.stoch_k.current.value)
            self.plot("Stochastic", "stoch_d", self._sto.stoch_d.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Stochastic` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class StochasticAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._stochastic = Stochastic(20, 10, 20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._stochastic.update(bar)

        if self._stochastic.is_ready:
            # The current value of self._stochastic is represented by self._stochastic.current.value
            self.plot("Stochastic", "stochastic", self._stochastic.current.value)
            # Plot all attributes of self._stochastic
            self.plot("Stochastic", "fast_stoch", self._stochastic.fast_stoch.current.value)
            self.plot("Stochastic", "stoch_k", self._stochastic.stoch_k.current.value)
            self.plot("Stochastic", "stoch_d", self._stochastic.stoch_d.current.value)
```

Stochastic Relative Strength Index

Introduction

Stochastic RSI, or simply StochRSI, is a technical analysis indicator used to determine whether an asset is overbought or oversold, as well as to identify current market trends. As the name suggests, the StochRSI is a derivative of the standard Relative Strength Index (RSI) and, as such, is considered an indicator of an indicator. It is a type of oscillator, meaning that it fluctuates above and below a center line.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SRSI Indicator

To create an automatic indicator for `StochasticRelativeStrengthIndex` , call the `srsi` helper method from the `QCAlgorithm` class. The `srsi` method creates a `StochasticRelativeStrengthIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class StochasticRelativeStrengthIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._srsi = self.srsi(self._symbol, 14, 14, 3, 3)

    def on_data(self, slice: Slice) -> None:

        if self._srsi.is_ready:
            # The current value of self._srsi is represented by self._srsi.current.value
            self.plot("StochasticRelativeStrengthIndex", "srsi", self._srsi.current.value)
            # Plot all attributes of self._srsi
            self.plot("StochasticRelativeStrengthIndex", "k", self._srsi.k.current.value)
            self.plot("StochasticRelativeStrengthIndex", "d", self._srsi.d.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `StochasticRelativeStrengthIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class StochasticRelativeStrengthIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._stochasticrelativestrengthindex = StochasticRelativeStrengthIndex(14, 14, 3, 3)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._stochasticrelativestrengthindex.update(bar.end_time, bar.close)

        if self._stochasticrelativestrengthindex.is_ready:
            # The current value of self._stochasticrelativestrengthindex is represented by
self._stochasticrelativestrengthindex.current.value
            self.plot("StochasticRelativeStrengthIndex", "stochasticrelativestrengthindex",
self._stochasticrelativestrengthindex.current.value)
            # Plot all attributes of self._stochasticrelativestrengthindex
            self.plot("StochasticRelativeStrengthIndex", "k", self._stochasticrelativestrengthindex.k.current.value)
            self.plot("StochasticRelativeStrengthIndex", "d", self._stochasticrelativestrengthindex.d.current.value)
```

For more information about this indicator, see its reference .

Visualization

Indicator History

To get the historical data of the `StochasticRelativeStrengthIndex` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class StochasticRelativeStrengthIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._srsi = self.srsi(self._symbol, 14, 14, 3, 3)

        indicator_history = self.indicator_history(self._srsi, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._srsi, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._srsi, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)

        # Access all attributes of indicator_history
        indicator_history_df = indicator_history.data_frame
        k = indicator_history_df["k"]
        d = indicator_history_df["d"]
```

Supported Indicators

Sum

Introduction

This indicator represents an indicator capable of tracking the sum for the given period

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SUM Indicator

To create an automatic indicator for `Sum` , call the `sum` helper method from the `QCAlgorithm` class. The `sum` method creates a `Sum` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class SumAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._sum = self.sum(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._sum.is_ready:
            # The current value of self._sum is represented by self._sum.current.value
            self.plot("Sum", "sum", self._sum.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Sum` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class SumAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._sum = Sum(20)

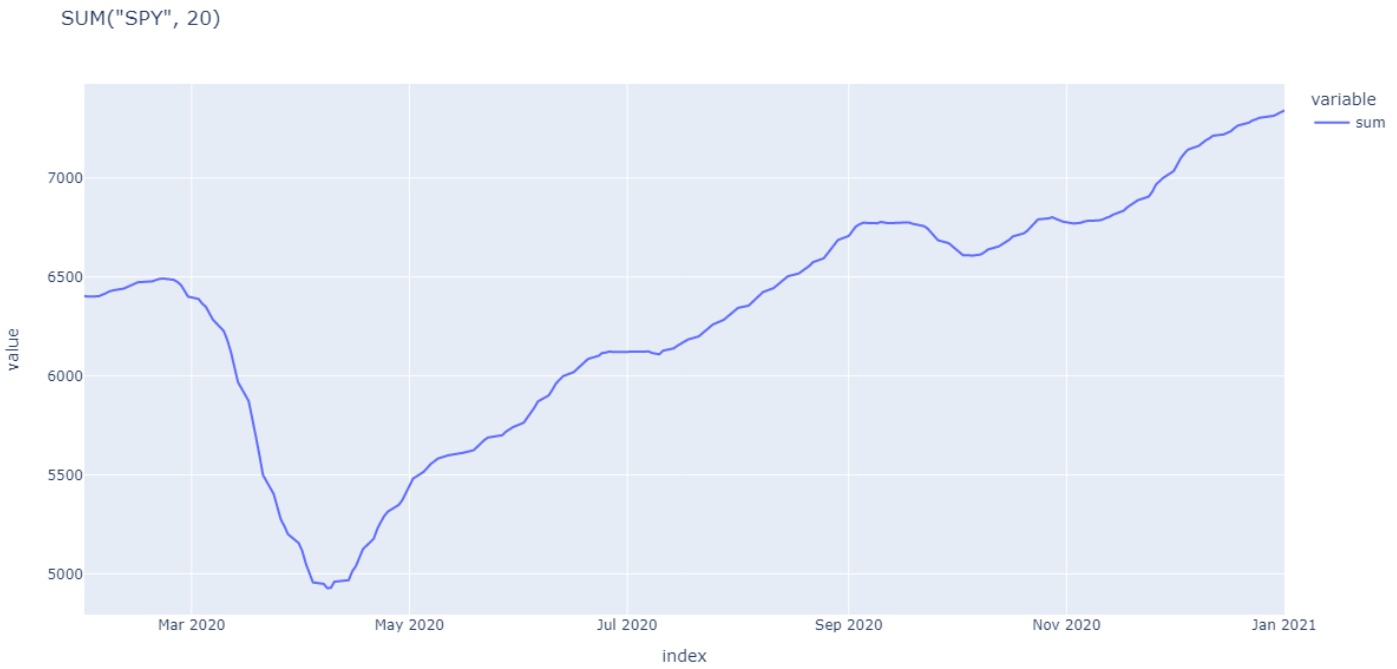
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._sum.update(bar.end_time, bar.close)

        if self._sum.is_ready:
            # The current value of self._sum is represented by self._sum.current.value
            self.plot("Sum", "sum", self._sum.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `Sum` indicator properties:



Indicator History

To get the historical data of the `Sum` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
PY
class SumAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._sum = self.sum(self._symbol, 20)

        indicator_history = self.indicator_history(self._sum, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._sum, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._sum, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Supported Indicators

Super Trend

Introduction

Super trend indicator. Formula can be found here via the excel file: https://tradingtuitions.com/supertrend-indicator-excel-sheet-with-realtime-buy-sell-signals/

To view the implementation of this indicator, see the LEAN GitHub repository .

Using STR Indicator

To create an automatic indicator for `SuperTrend` , call the `str` helper method from the `QCAlgorithm` class. The `str` method creates a `SuperTrend` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class SuperTrendAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._str = self.str(self._symbol, 20, 2, MovingAverageType.WILDERS)

    def on_data(self, slice: Slice) -> None:

        if self._str.is_ready:
            # The current value of self._str is represented by self._str.current.value
            self.plot("SuperTrend", "str", self._str.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `SuperTrend` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class SuperTrendAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._supertrend = SuperTrend(20, 2, MovingAverageType.WILDERS)

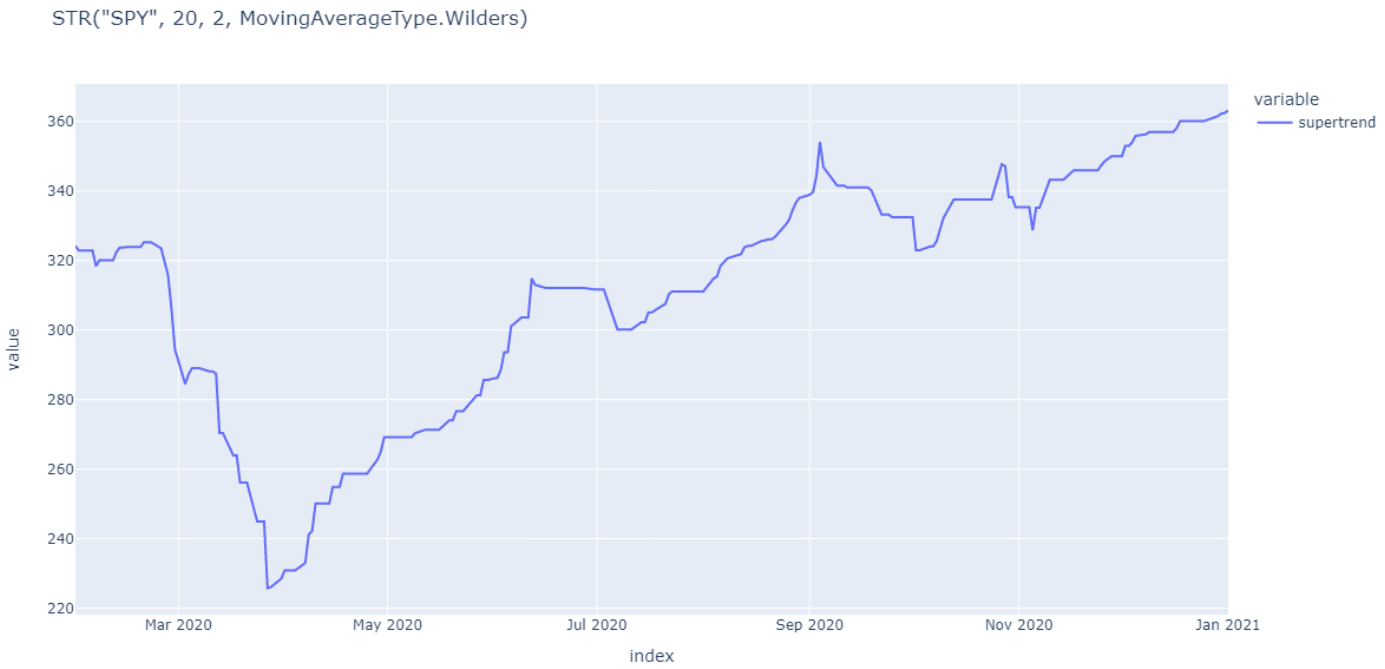
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._supertrend.update(bar)

        if self._supertrend.is_ready:
            # The current value of self._supertrend is represented by self._supertrend.current.value
            self.plot("SuperTrend", "supertrend", self._supertrend.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `SuperTrend` indicator properties:



Indicator History

To get the historical data of the `SuperTrend` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
class SuperTrendAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._str = self.str(self._symbol, 20, 2, MovingAverageType.WILDERS)

        indicator_history = self.indicator_history(self._str, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._str, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._str, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),

Swiss Army Knife

Introduction

Swiss Army Knife indicator by John Ehlers

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SWISS Indicator

To create an automatic indicator for `SwissArmyKnife` , call the `swiss` helper method from the `QCAlgorithm` class. The `swiss` method creates a `SwissArmyKnife` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class SwissArmyKnifeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._swiss = self.swiss(self._symbol, 20, 0.2, SwissArmyKnifeTool.GAUSS)

    def on_data(self, slice: Slice) -> None:

        if self._swiss.is_ready:
            # The current value of self._swiss is represented by self._swiss.current.value
            self.plot("SwissArmyKnife", "swiss", self._swiss.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `SwissArmyKnife` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class SwissArmyKnifeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._swissarmyknife = SwissArmyKnife(20, 0.2, SwissArmyKnifeTool.GAUSS)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._swissarmyknife.update(bar.end_time, bar.close)

        if self._swissarmyknife.is_ready:
            # The current value of self._swissarmyknife is represented by self._swissarmyknife.current.value
            self.plot("SwissArmyKnife", "swissarmyknife", self._swissarmyknife.current.value)
```

For more information about this indicator, see its reference .

T3 Moving Average

Introduction

This indicator computes the T3 Moving Average (T3). The T3 Moving Average is calculated with the following formula: EMA1(x, Period) = EMA(x, Period) EMA2(x, Period) = EMA(EMA1(x, Period),Period) GD(x, Period, volumeFactor) = (EMA1(x, Period)*(1+volumeFactor)) - (EMA2(x, Period)* volumeFactor) T3 = GD(GD(GD(t, Period, volumeFactor), Period, volumeFactor), Period, volumeFactor);

To view the implementation of this indicator, see the LEAN GitHub repository .

Using T3 Indicator

To create an automatic indicator for `T3MovingAverage` , call the `t_3` helper method from the `QCAlgorithm` class. The `t_3` method creates a `T3MovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class T3MovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._t_3 = self.t_3(self._symbol, 30, 0.7)

    def on_data(self, slice: Slice) -> None:

        if self._t_3.is_ready:
            # The current value of self._t_3 is represented by self._t_3.current.value
            self.plot("T3MovingAverage", "t_3", self._t_3.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `T3MovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class T3MovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._t3movingaverage = T3MovingAverage(30, 0.7)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._t3movingaverage.update(bar.end_time, bar.close)

        if self._t3movingaverage.is_ready:
            # The current value of self._t3movingaverage is represented by self._t3movingaverage.current.value
            self.plot("T3MovingAverage", "t3movingaverage", self._t3movingaverage.current.value)
```

For more information about this indicator, see its reference .

Resolution.MINUTE)
```

Supported Indicators

Target Downside Deviation

Introduction

This indicator computes the n-period target downside deviation. The target downside deviation is defined as the root-mean-square, or RMS, of the deviations of the realized return's underperformance from the target return where all returns above the target return are treated as underperformance of 0. Reference: https://www.cmegroup.com/education/files/rr-sortino-a-sharper-ratio.pdf

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TDD Indicator

To create an automatic indicator for `TargetDownsideDeviation` , call the `tdd` helper method from the `QCAlgorithm` class. The `tdd` method creates a `TargetDownsideDeviation` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class TargetDownsideDeviationAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._tdd = self.tdd(self._symbol, 50)

    def on_data(self, slice: Slice) -> None:

        if self._tdd.is_ready:
            # The current value of self._tdd is represented by self._tdd.current.value
            self.plot("TargetDownsideDeviation", "tdd", self._tdd.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `TargetDownsideDeviation` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class TargetDownsideDeviationAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._targetdownsidedeviation = IndicatorExtensions.of(TargetDownsideDeviation(50), RateOfChange(1))

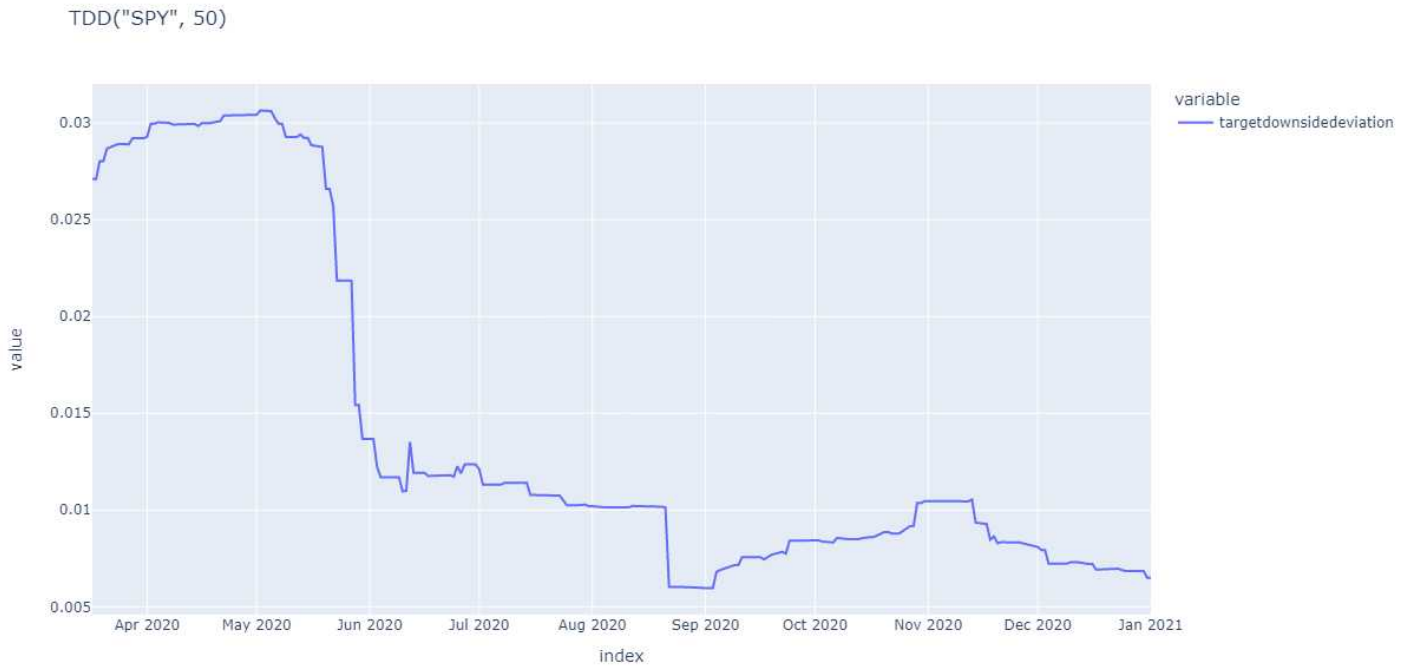
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._targetdownsidedeviation.update(bar.end_time, bar.close)

        if self._targetdownsidedeviation.is_ready:
            # The current value of self._targetdownsidedeviation is represented by self._targetdownsidedeviation.current.value
            self.plot("TargetDownsideDeviation", "targetdownsidedeviation", self._targetdownsidedeviation.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `TargetDownsideDeviation` indicator properties:



Indicator History

To get the historical data of the `TargetDownsideDeviation` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class TargetDownsideDeviationAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._tdd = self.tdd(self._symbol, 50)

        indicator_history = self.indicator_history(self._tdd, self._symbol, 100, Resolution.MINUTE)

Time Series Forecast

Introduction

This indicator represents an indicator capable of predicting new values given previous data from a window. source

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TSF Indicator

To create an automatic indicator for `TimeSeriesForecast` , call the `tsf` helper method from the `QCAlgorithm` class. The `tsf` method creates a `TimeSeriesForecast` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class TimeSeriesForecastAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._tsf = self.tsf(self._symbol, 3)

    def on_data(self, slice: Slice) -> None:

        if self._tsf.is_ready:
            # The current value of self._tsf is represented by self._tsf.current.value
            self.plot("TimeSeriesForecast", "tsf", self._tsf.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `TimeSeriesForecast` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class TimeSeriesForecastAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._timeseriesforecast = TimeSeriesForecast(3)

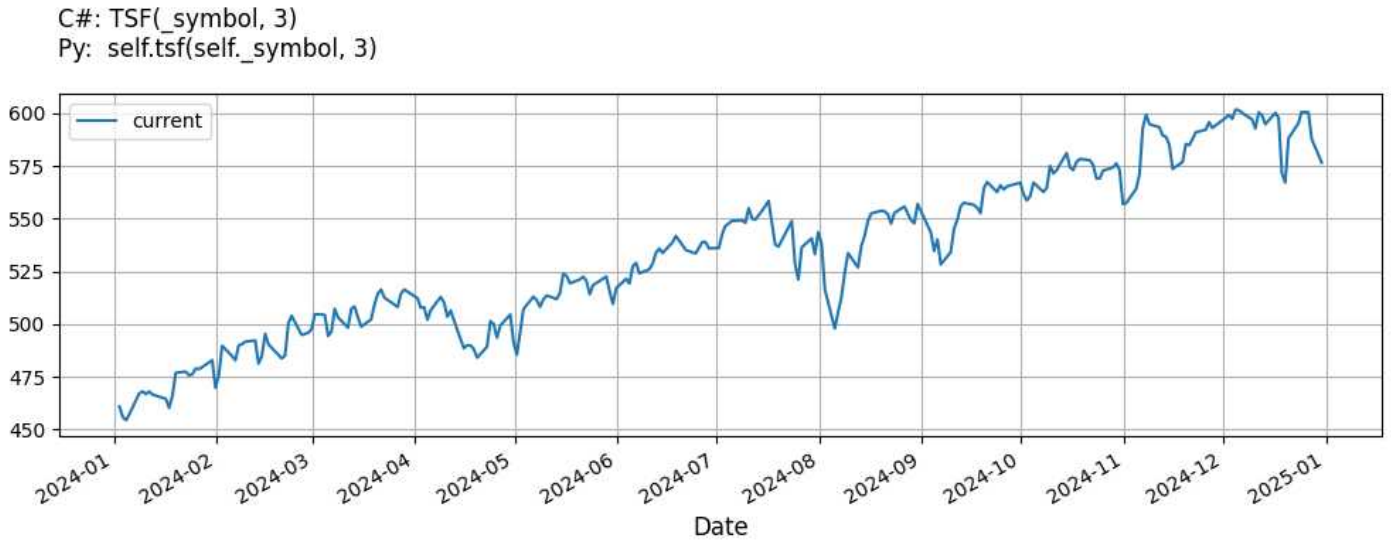
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._timeseriesforecast.update(bar.end_time, bar.close)

        if self._timeseriesforecast.is_ready:
            # The current value of self._timeseriesforecast is represented by self._timeseriesforecast.current.value
            self.plot("TimeSeriesForecast", "timeseriesforecast", self._timeseriesforecast.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `TimeSeriesForecast` indicator properties:



Indicator History

To get the historical data of the `TimeSeriesForecast` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class TimeSeriesForecastAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._tsf = self.tsf(self._symbol, 3)

        indicator_history = self.indicator_history(self._tsf, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._tsf, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._tsf, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Supported Indicators

Tom Demark Sequential

Introduction

This indicator represents the Tom Demark Sequential indicator, which is used to identify potential trend exhaustion points. This implementation tracks both the setup and countdown phases, and can be extended to handle bullish and bearish setups, as well as qualifiers such as Perfect Setups and Countdown completions. - **Setup Phase**: Detects a trend by counting 9 consecutive bars where the close is less than (Buy Setup) or greater than (Sell Setup) the close 4 bars earlier. - **TDST Support/Resistance**: After a valid 9-bar setup completes, the indicator records the **lowest low** (for Sell Setup) or **highest high** (for Buy Setup) among the 9 bars. These are referred to as Support Price(for Buy Setup) and Resistance Price (for Sell Setup), and serve as critical thresholds that validate the continuation of the countdown phase. - **Countdown Phase**: Once a valid setup is completed, the indicator attempts to count 13 qualifying bars (not necessarily consecutive) where the close is less than (Buy Countdown) or greater than (Sell Countdown) the low/high 2 bars earlier. During this phase, the TDST Support/Resistance levels are checked — if the price breaks these levels, the countdown phase is reset, as the trend reversal condition is considered invalidated.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TDS Indicator

To create an automatic indicator for `TomDemarkSequential` , call the `tds` helper method from the `QCAlgorithm` class. The `tds` method creates a `TomDemarkSequential` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class TomDemarkSequentialAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._tds = self.tds(self._symbol)

    def on_data(self, slice: Slice) -> None:

        if self._tds.is_ready:
            # The current value of self._tds is represented by self._tds.current.value
            self.plot("TomDemarkSequential", "tds", self._tds.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `TomDemarkSequential` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class TomDemarkSequentialAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._tomdemarksequential = TomDemarkSequential()

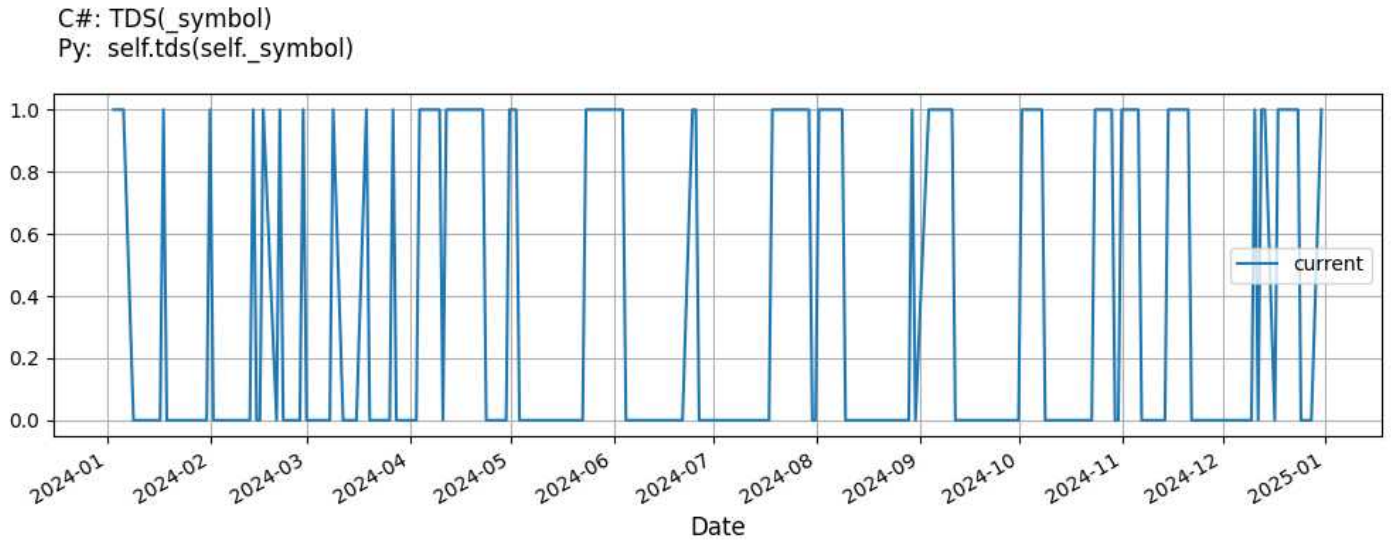
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._tomdemarksequential.update(bar)

        if self._tomdemarksequential.is_ready:
            # The current value of self._tomdemarksequential is represented by self._tomdemarksequential.current.value
            self.plot("TomDemarkSequential", "tomdemarksequential", self._tomdemarksequential.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `TomDemarkSequential` indicator properties:



Indicator History

To get the historical data of the `TomDemarkSequential` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class TomDemarkSequentialAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._tds = self.tds(self._symbol)

Supported Indicators

Triangular Moving Average

Introduction

This indicator computes the Triangular Moving Average (TRIMA). The Triangular Moving Average is calculated with the following formula: (1) When the period is even, TRIMA(x,period)=SMA(SMA(x,period/2),(period/2)+1) (2) When the period is odd, TRIMA(x,period)=SMA(SMA(x,(period+1)/2),(period+1)/2)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TRIMA Indicator

To create an automatic indicator for `TriangularMovingAverage` , call the `trima` helper method from the `QCAlgorithm` class. The `trima` method creates a `TriangularMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class TriangularMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._trima = self.trima(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._trima.is_ready:
            # The current value of self._trima is represented by self._trima.current.value
            self.plot("TriangularMovingAverage", "trima", self._trima.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `TriangularMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class TriangularMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._triangularmovingaverage = TriangularMovingAverage(20)

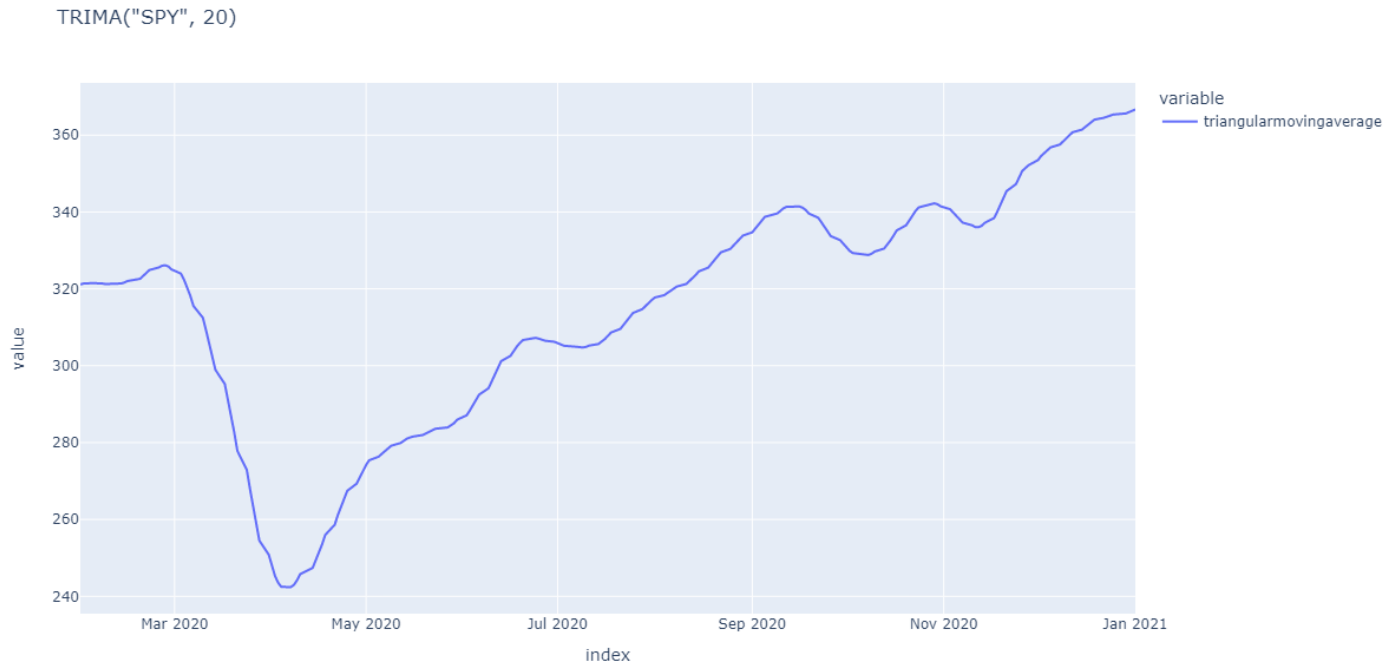
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._triangularmovingaverage.update(bar.end_time, bar.close)

        if self._triangularmovingaverage.is_ready:
            # The current value of self._triangularmovingaverage is represented by self._triangularmovingaverage.current.value
            self.plot("TriangularMovingAverage", "triangularmovingaverage", self._triangularmovingaverage.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `TriangularMovingAverage` indicator properties:



Indicator History

To get the historical data of the `TriangularMovingAverage` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
class TriangularMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._trima = self.trima(self._symbol, 20)

        indicator_history = self.indicator_history(self._trima, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._trima, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._trima, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),

Supported Indicators

Triple Exponential Moving Average

Introduction

This indicator computes the Triple Exponential Moving Average (TEMA). The Triple Exponential Moving Average is calculated with the following formula: EMA1 = EMA(t,period) EMA2 = EMA(EMA(t,period),period) EMA3 = EMA(EMA(EMA(t,period),period),period) TEMA = 3 * EMA1 - 3 * EMA2 + EMA3

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TEMA Indicator

To create an automatic indicator for `TripleExponentialMovingAverage` , call the `tema` helper method from the `QCAlgorithm` class. The `tema` method creates a `TripleExponentialMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class TripleExponentialMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._tema = self.tema(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._tema.is_ready:
            # The current value of self._tema is represented by self._tema.current.value
            self.plot("TripleExponentialMovingAverage", "tema", self._tema.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `TripleExponentialMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class TripleExponentialMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._tripleexponentialmovingaverage = TripleExponentialMovingAverage(20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._tripleexponentialmovingaverage.update(bar.end_time, bar.close)

        if self._tripleexponentialmovingaverage.is_ready:
            # The current value of self._tripleexponentialmovingaverage is represented by
self._tripleexponentialmovingaverage.current.value
            self.plot("TripleExponentialMovingAverage", "tripleexponentialmovingaverage",
self._tripleexponentialmovingaverage.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `TripleExponentialMovingAverage` indicator properties:

Indicator History

To get the historical data of the `TripleExponentialMovingAverage` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class TripleExponentialMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol

Supported Indicators

Trix

Introduction

This indicator computes the TRIX (1-period ROC of a Triple EMA) The TRIX is calculated as explained here: http://stockcharts.com/school/doku.php?id=chart_school:technical_indicators:trix

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TRIX Indicator

To create an automatic indicator for `Trix` , call the `trix` helper method from the `QCAlgorithm` class. The `trix` method creates a `Trix` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class TrixAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._trix = self.trix(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._trix.is_ready:
            # The current value of self._trix is represented by self._trix.current.value
            self.plot("Trix", "trix", self._trix.current.value)
```

PY

For more information about this method, see the QCAlgorithm class .

You can manually create a `Trix` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class TrixAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._trix = Trix(20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._trix.update(bar.end_time, bar.close)

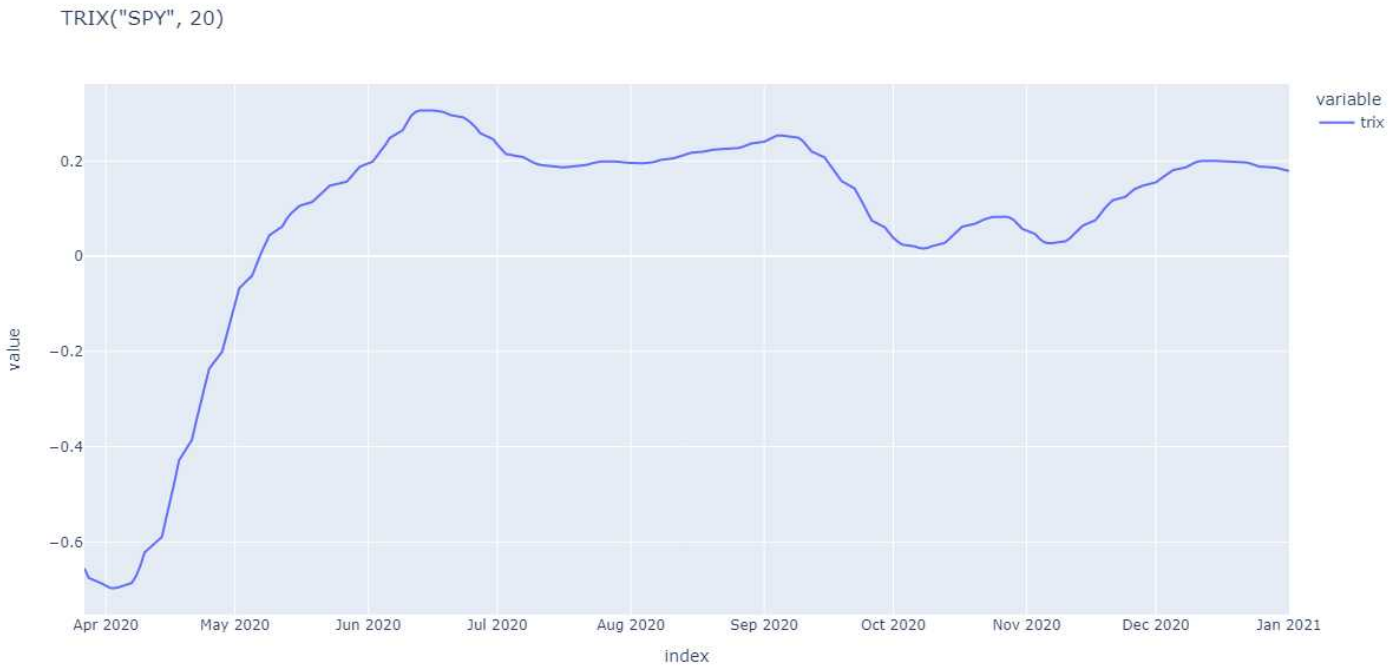
        if self._trix.is_ready:
            # The current value of self._trix is represented by self._trix.current.value
            self.plot("Trix", "trix", self._trix.current.value)
```

PY

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `Trix` indicator properties:



Indicator History

To get the historical data of the `Trix` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class TrixAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._trix = self.trix(self._symbol, 20)

        indicator_history = self.indicator_history(self._trix, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._trix, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._trix, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),

Supported Indicators

True Range

Introduction

This indicator computes the True Range (TR). The True Range is the greatest of the following values: value1 = distance from today's high to today's low. value2 = distance from yesterday's close to today's high. value3 = distance from yesterday's close to today's low.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TR Indicator

To create an automatic indicator for `TrueRange` , call the `tr` helper method from the `QCAlgorithm` class. The `tr` method creates a `TrueRange` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class TrueRangeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._tr = self.tr(self._symbol)

    def on_data(self, slice: Slice) -> None:

        if self._tr.is_ready:
            # The current value of self._tr is represented by self._tr.current.value
            self.plot("TrueRange", "tr", self._tr.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `TrueRange` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class TrueRangeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._truerange = TrueRange()

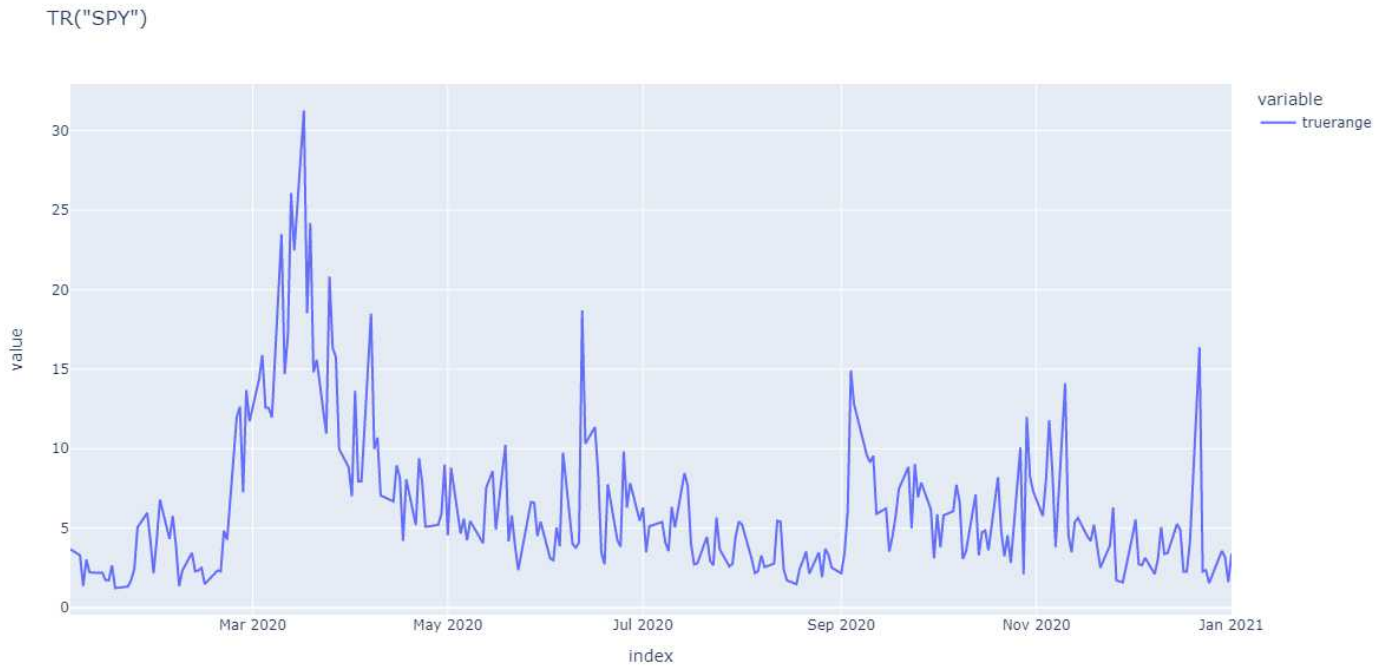
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._truerange.update(bar)

        if self._truerange.is_ready:
            # The current value of self._truerange is represented by self._truerange.current.value
            self.plot("TrueRange", "truerange", self._truerange.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `TrueRange` indicator properties:



Indicator History

To get the historical data of the `TrueRange` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class TrueRangeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol

Supported Indicators

True Strength Index

Introduction

This indicator computes the True Strength Index (TSI). The True Strength Index is calculated as explained here: https://school.stockcharts.com/doku.php?id=technical_indicators:True_strength_index Briefly, the calculation has three steps: 1. Smooth the momentum and the absolute momentum by getting an EMA of them (typically of period 25) 2. Double smooth the momentum and the absolute momentum by getting an EMA of their EMA (typically of period 13) 3. The TSI formula itself: divide the double-smoothed momentum over the double-smoothed absolute momentum and multiply by 100 The signal is typically a 7-to-12-EMA of the TSI.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TSI Indicator

To create an automatic indicator for `TrueStrengthIndex` , call the `tsi` helper method from the `QCAlgorithm` class. The `tsi` method creates a `TrueStrengthIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class TrueStrengthIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._tsi = self.tsi(self._symbol, 25, 13, 7, MovingAverageType.EXPONENTIAL)

    def on_data(self, slice: Slice) -> None:

        if self._tsi.is_ready:
            # The current value of self._tsi is represented by self._tsi.current.value
            self.plot("TrueStrengthIndex", "tsi", self._tsi.current.value)
            # Plot all attributes of self._tsi
            self.plot("TrueStrengthIndex", "signal", self._tsi.signal.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `TrueStrengthIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class TrueStrengthIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._truestrengthindex = TrueStrengthIndex(25, 13, 7, MovingAverageType.EXPONENTIAL)

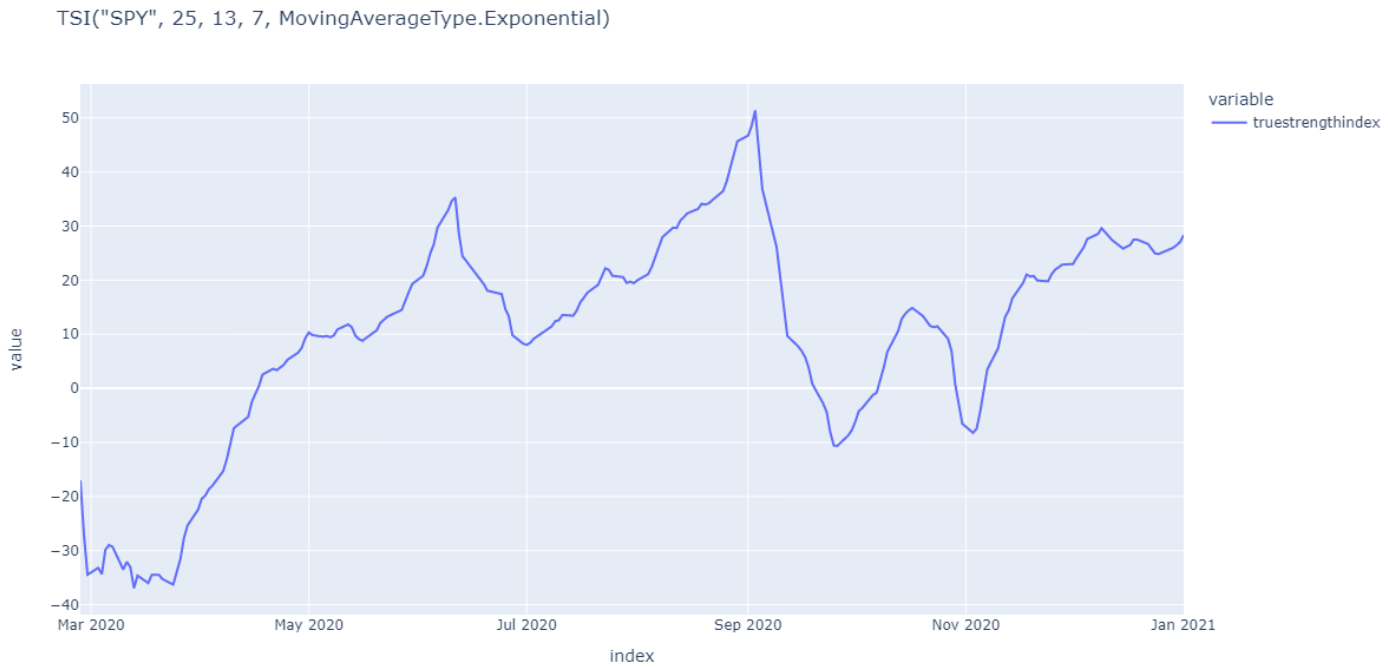
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._truestrengthindex.update(bar.end_time, bar.close)

        if self._truestrengthindex.is_ready:
            # The current value of self._truestrengthindex is represented by self._truestrengthindex.current.value
            self.plot("TrueStrengthIndex", "truestrengthindex", self._truestrengthindex.current.value)
            # Plot all attributes of self._truestrengthindex
            self.plot("TrueStrengthIndex", "signal", self._truestrengthindex.signal.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `TrueStrengthIndex` indicator properties:



Indicator History

To get the historical data of the `TrueStrengthIndex` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class TrueStrengthIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._tsi = self.tsi(self._symbol, 25, 13, 7, MovingAverageType.EXPONENTIAL)

        indicator_history = self.indicator_history(self._tsi, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._tsi, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._tsi, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)

        # Access all attributes of indicator_history
        indicator_history_df = indicator_history.data_frame
        signal = indicator_history_df["signal"]
```

Ultimate Oscillator

Introduction

This indicator computes the Ultimate Oscillator (ULTOSC) The Ultimate Oscillator is calculated as explained here: http://stockcharts.com/school/doku.php?id=chart_school:technical_indicators:ultimate_oscillator

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ULTOSC Indicator

To create an automatic indicator for `UltimateOscillator` , call the `ultosc` helper method from the `QCAlgorithm` class. The `ultosc` method creates a `UltimateOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class UltimateOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._ultosc = self.ultosc(self._symbol, 5, 10, 20)

    def on_data(self, slice: Slice) -> None:

        if self._ultosc.is_ready:
            # The current value of self._ultosc is represented by self._ultosc.current.value
            self.plot("UltimateOscillator", "ultosc", self._ultosc.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `UltimateOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class UltimateOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._ultimateoscillator = UltimateOscillator(5, 10, 20)

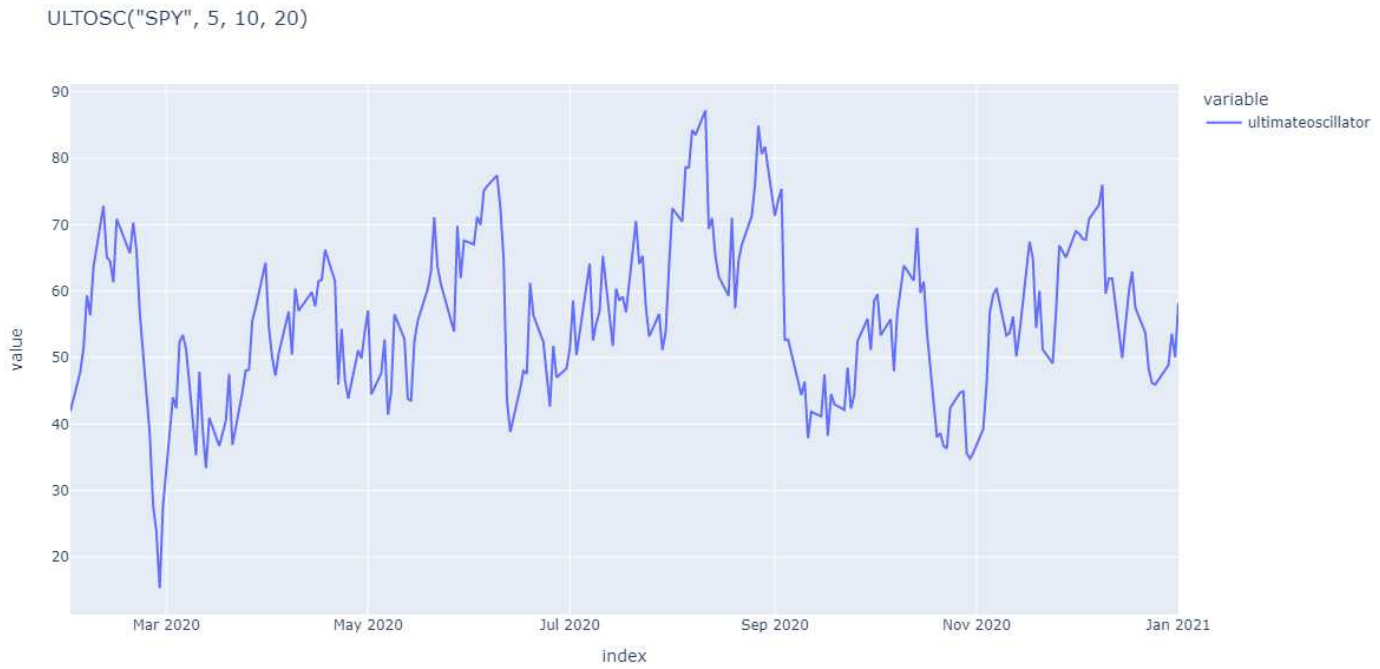
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._ultimateoscillator.update(bar)

        if self._ultimateoscillator.is_ready:
            # The current value of self._ultimateoscillator is represented by self._ultimateoscillator.current.value
            self.plot("UltimateOscillator", "ultimateoscillator", self._ultimateoscillator.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `UltimateOscillator` indicator properties:



Indicator History

To get the historical data of the `UltimateOscillator` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class UltimateOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._ultosc = self.ultosc(self._symbol, 5, 10, 20)

        indicator_history = self.indicator_history(self._ultosc, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._ultosc, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._ultosc, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Supported Indicators

Value At Risk

Introduction

This indicator computes 1-day VaR for a specified confidence level and lookback period

To view the implementation of this indicator, see the LEAN GitHub repository .

Using VAR Indicator

To create an automatic indicator for `ValueAtRisk` , call the `var` helper method from the `QCAlgorithm` class. The `var` method creates a `ValueAtRisk` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class ValueAtRiskAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._var = self.var(self._symbol, 252, 0.95)

    def on_data(self, slice: Slice) -> None:

        if self._var.is_ready:
            # The current value of self._var is represented by self._var.current.value
            self.plot("ValueAtRisk", "var", self._var.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ValueAtRisk` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class ValueAtRiskAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._valueatrisk = ValueAtRisk(252, 0.95)

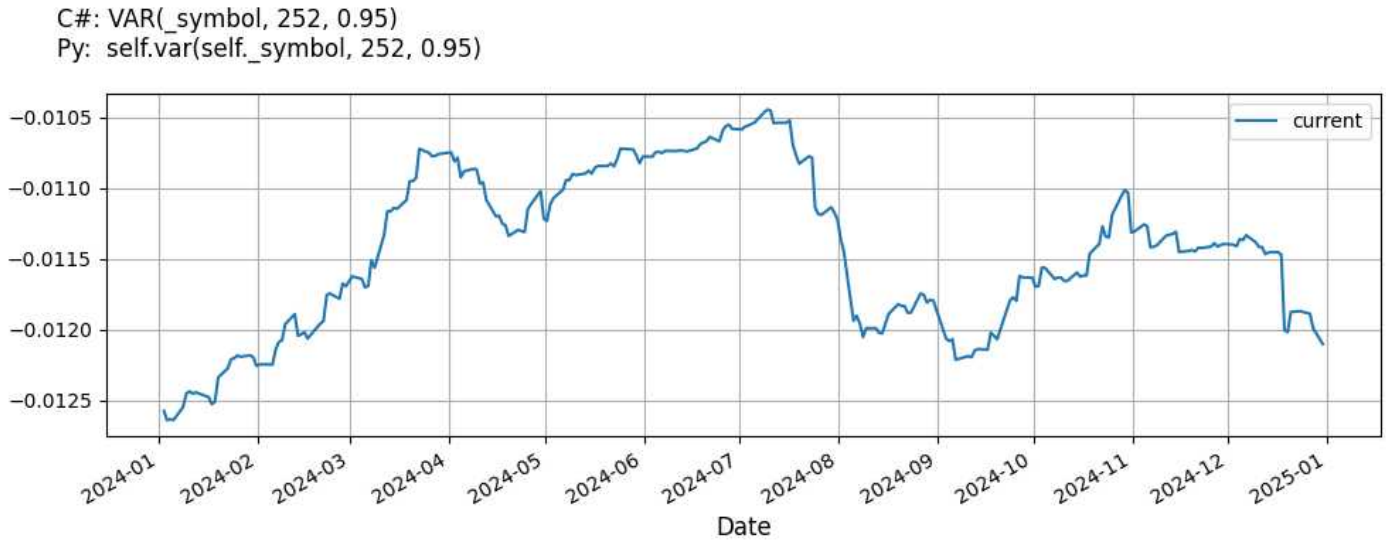
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._valueatrisk.update(bar.end_time, bar.close)

        if self._valueatrisk.is_ready:
            # The current value of self._valueatrisk is represented by self._valueatrisk.current.value
            self.plot("ValueAtRisk", "valueatrisk", self._valueatrisk.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `ValueAtRisk` indicator properties:



Indicator History

To get the historical data of the `ValueAtRisk` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
PY
class ValueAtRiskAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._var = self.var(self._symbol, 252, 0.95)

        indicator_history = self.indicator_history(self._var, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._var, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._var, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Supported Indicators

Variable Index Dynamic Average

Introduction

This indicator computes the n-period adaptive weighted moving average indicator. VIDYAi = Pricei x F x ABS(CMOi) + VIDYAi-1 x (1 - F x ABS(CMOi)) where: VIDYAi - is the value of the current period. Pricei - is the source price of the period being calculated. F = 2/(Period_EMA+1) - is a smoothing factor. ABS(CMOi) - is the absolute current value of CMO. VIDYAi-1 - is the value of the period immediately preceding the period being calculated.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using VIDYA Indicator

To create an automatic indicator for `VariableIndexDynamicAverage` , call the `vidya` helper method from the `QCAlgorithm` class. The `vidya` method creates a `VariableIndexDynamicAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class VariableIndexDynamicAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._vidya = self.vidya(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._vidya.is_ready:
            # The current value of self._vidya is represented by self._vidya.current.value
            self.plot("VariableIndexDynamicAverage", "vidya", self._vidya.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `VariableIndexDynamicAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class VariableIndexDynamicAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._variableindexdynamicaverage = VariableIndexDynamicAverage(20)

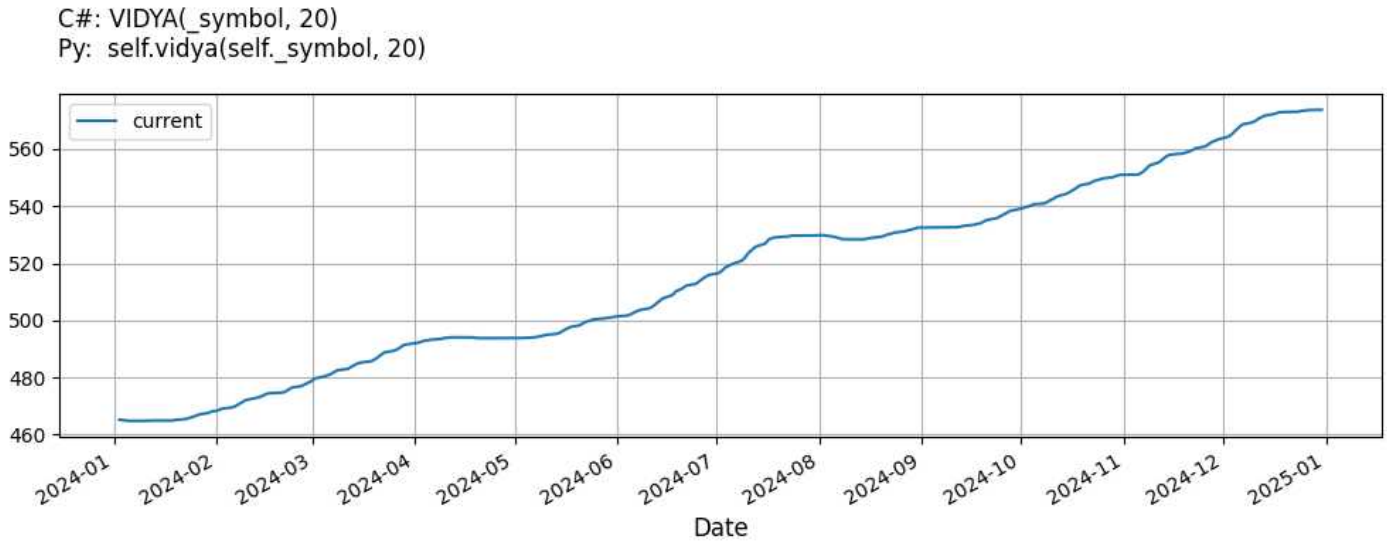
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._variableindexdynamicaverage.update(bar.end_time, bar.close)

        if self._variableindexdynamicaverage.is_ready:
            # The current value of self._variableindexdynamicaverage is represented by self._variableindexdynamicaverage.current.value
            self.plot("VariableIndexDynamicAverage", "variableindexdynamicaverage", self._variableindexdynamicaverage.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `VariableIndexDynamicAverage` indicator properties:



Indicator History

To get the historical data of the `VariableIndexDynamicAverage` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class VariableIndexDynamicAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._vidya = self.vidya(self._symbol, 20)

        indicator_history = self.indicator_history(self._vidya, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._vidya, self._symbol, timedelta(days=10), Resolution.MINUTE)

Supported Indicators

Variance

Introduction

This indicator computes the n-period population variance.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using V Indicator

To create an automatic indicator for `Variance` , call the `v` helper method from the `QCAlgorithm` class. The `v` method creates a `Variance` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class VarianceAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._v = self.v(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._v.is_ready:
            # The current value of self._v is represented by self._v.current.value
            self.plot("Variance", "v", self._v.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Variance` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class VarianceAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._variance = Variance(20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._variance.update(bar.end_time, bar.close)

        if self._variance.is_ready:
            # The current value of self._variance is represented by self._variance.current.value
            self.plot("Variance", "variance", self._variance.current.value)
```

For more information about this indicator, see its reference .

Volume Weighted Average Price Indicator

Introduction

Volume Weighted Average Price (VWAP) Indicator: It is calculated by adding up the dollars traded for every transaction (price multiplied by number of shares traded) and then dividing by the total shares traded for the day.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using VWAP Indicator

To create an automatic indicator for `VolumeWeightedAveragePriceIndicator` , call the `vwap` helper method from the `QCAlgorithm` class. The `vwap` method creates a `VolumeWeightedAveragePriceIndicator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class VolumeWeightedAveragePriceIndicatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._vwap = self.vwap(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._vwap.is_ready:
            # The current value of self._vwap is represented by self._vwap.current.value
            self.plot("VolumeWeightedAveragePriceIndicator", "vwap", self._vwap.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `VolumeWeightedAveragePriceIndicator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class VolumeWeightedAveragePriceIndicatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._volumeweightedaveragepriceindicator = VolumeWeightedAveragePriceIndicator(20)

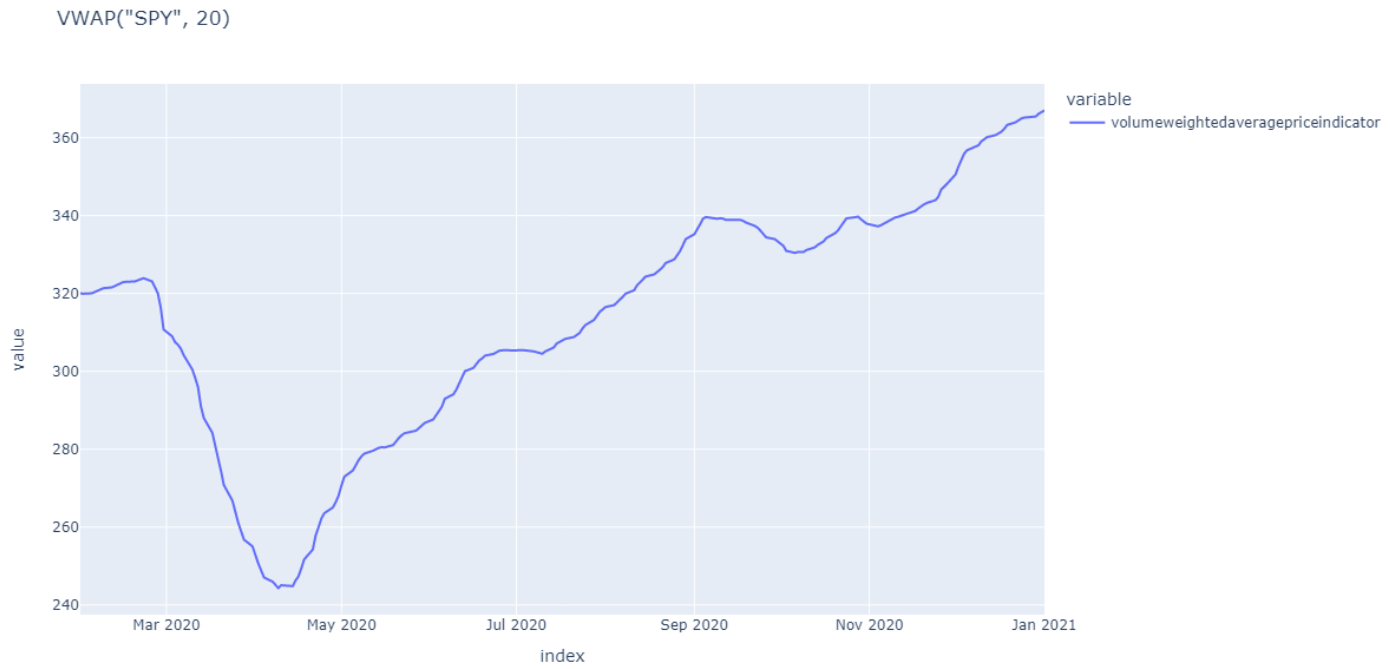
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._volumeweightedaveragepriceindicator.update(bar)

        if self._volumeweightedaveragepriceindicator.is_ready:
            # The current value of self._volumeweightedaveragepriceindicator is represented by
self._volumeweightedaveragepriceindicator.current.value
            self.plot("VolumeWeightedAveragePriceIndicator", "volumeweightedaveragepriceindicator",
self._volumeweightedaveragepriceindicator.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `VolumeWeightedAveragePriceIndicator` indicator properties:



Indicator History

To get the historical data of the `VolumeWeightedAveragePriceIndicator` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
class VolumeWeightedAveragePriceIndicatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._vwap = self.vwap(self._symbol, 20)

        indicator_history = self.indicator_history(self._vwap, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._vwap, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._vwap, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),

Supported Indicators

Volume Weighted Moving Average

Introduction

This indicator computes the Volume Weighted Moving Average (VWMA) It is a technical analysis indicator used by traders to determine the average price of an asset over a given period of time, taking into account both price and volume.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using VWMA Indicator

To create an automatic indicator for `VolumeWeightedMovingAverage` , call the `vwma` helper method from the `QCAlgorithm` class. The `vwma` method creates a `VolumeWeightedMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class VolumeWeightedMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._vwma = self.vwma(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._vwma.is_ready:
            # The current value of self._vwma is represented by self._vwma.current.value
            self.plot("VolumeWeightedMovingAverage", "vwma", self._vwma.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `VolumeWeightedMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class VolumeWeightedMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._volumeweightedmovingaverage = VolumeWeightedMovingAverage(20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._volumeweightedmovingaverage.update(bar)

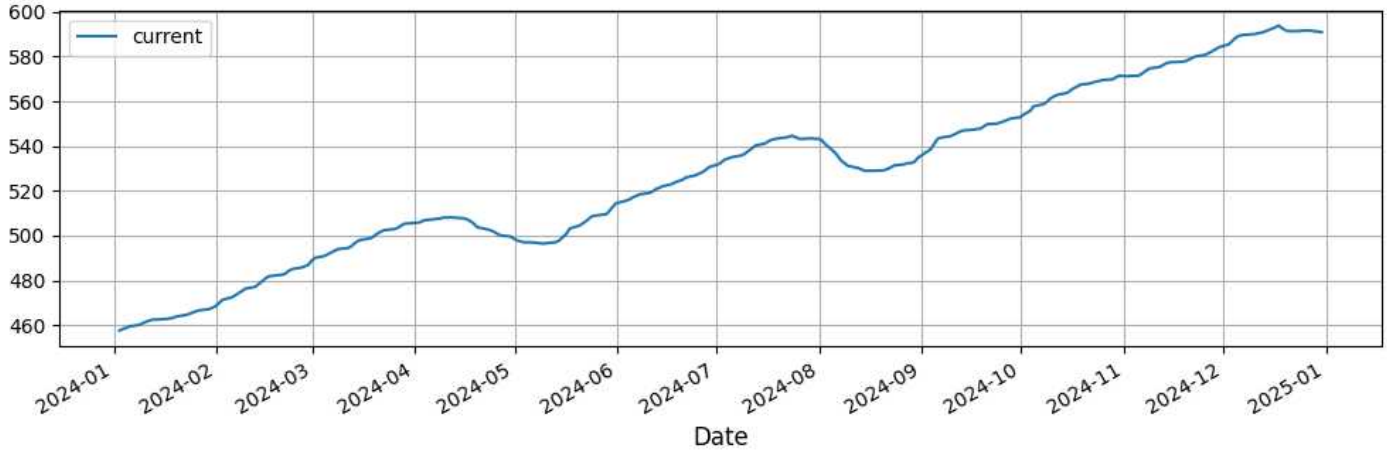
        if self._volumeweightedmovingaverage.is_ready:
            # The current value of self._volumeweightedmovingaverage is represented by self._volumeweightedmovingaverage.current.value
            self.plot("VolumeWeightedMovingAverage", "volumeweightedmovingaverage", self._volumeweightedmovingaverage.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `VolumeWeightedMovingAverage` indicator properties:

C#: VWMA(_symbol, 20)
Py: self.vwma(self._symbol, 20)



Indicator History

To get the historical data of the `VolumeWeightedMovingAverage` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class VolumeWeightedMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._vwma = self.vwma(self._symbol, 20)

        indicator_history = self.indicator_history(self._vwma, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._vwma, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._vwma, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Supported Indicators

Vortex

Introduction

This indicator represents the Vortex Indicator, which identifies the start and continuation of market trends. It includes components that capture positive (upward) and negative (downward) trend movements. This indicator compares the ranges within the current period to previous periods to calculate upward and downward movement trends.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using VTX Indicator

To create an automatic indicator for `Vortex` , call the `vtx` helper method from the `QCAlgorithm` class. The `vtx` method creates a `Vortex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class VortexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._vtx = self.vtx(self._symbol, 14)

    def on_data(self, slice: Slice) -> None:

        if self._vtx.is_ready:
            # The current value of self._vtx is represented by self._vtx.current.value
            self.plot("Vortex", "vtx", self._vtx.current.value)
            # Plot all attributes of self._vtx
            self.plot("Vortex", "plus_vortex", self._vtx.plus_vortex.current.value)
            self.plot("Vortex", "minus_vortex", self._vtx.minus_vortex.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Vortex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class VortexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._vortex = Vortex(14)

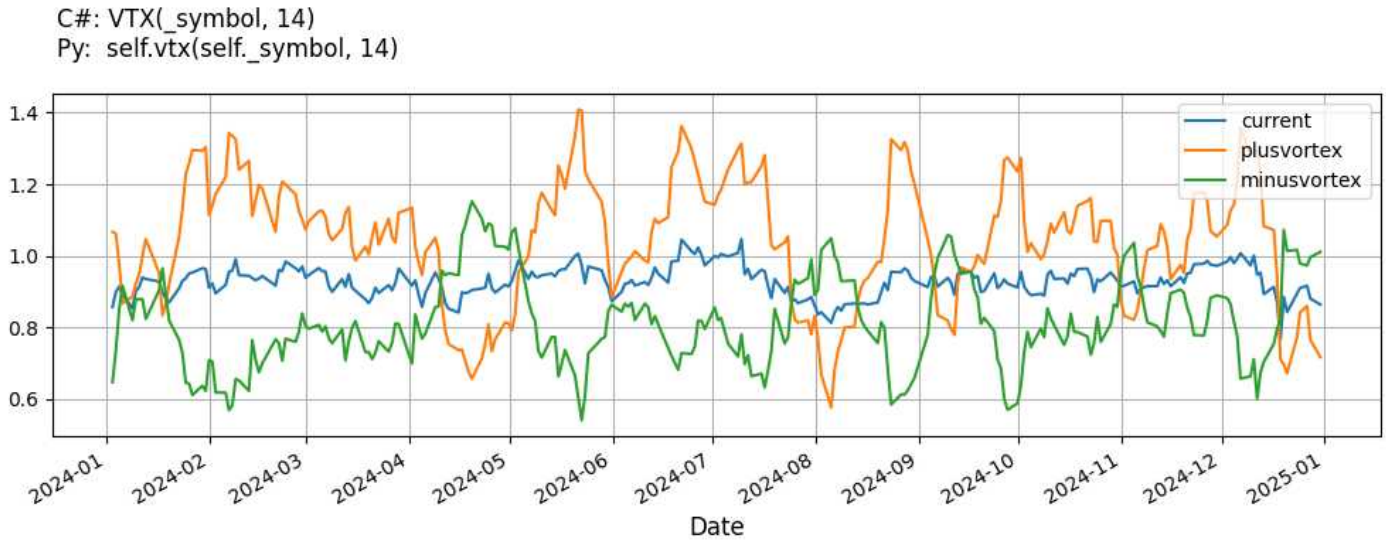
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._vortex.update(bar)

        if self._vortex.is_ready:
            # The current value of self._vortex is represented by self._vortex.current.value
            self.plot("Vortex", "vortex", self._vortex.current.value)
            # Plot all attributes of self._vortex
            self.plot("Vortex", "plus_vortex", self._vortex.plus_vortex.current.value)
            self.plot("Vortex", "minus_vortex", self._vortex.minus_vortex.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `Vortex` indicator properties:



Indicator History

To get the historical data of the `Vortex` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class VortexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._vtx = self.vtx(self._symbol, 14)

        indicator_history = self.indicator_history(self._vtx, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._vtx, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._vtx, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)

        # Access all attributes of indicator_history
        indicator_history_df = indicator_history.data_frame
        plus_vortex = indicator_history_df["plusvortex"]
        minus_vortex = indicator_history_df["minusvortex"]

Supported Indicators

Wilder Accumulative Swing Index

Introduction

This indicator calculates the Accumulative Swing Index (ASI) as defined by Welles Wilder in his book 'New Concepts in Technical Trading Systems'. $ASI_t = ASI_{t-1} + SI_t$ Where: ASI_{t-1} The for the previous period. SI_t The calculated for the current period.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ASI Indicator

To create an automatic indicator for `WilderAccumulativeSwingIndex` , call the `asi` helper method from the `QCAlgorithm` class. The `asi` method creates a `WilderAccumulativeSwingIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class WilderAccumulativeSwingIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._asi = self.asi(self._symbol, 20, Resolution.DAILY)

    def on_data(self, slice: Slice) -> None:

        if self._asi.is_ready:
            # The current value of self._asi is represented by self._asi.current.value
            self.plot("WilderAccumulativeSwingIndex", "asi", self._asi.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `WilderAccumulativeSwingIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class WilderAccumulativeSwingIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._wilderaccumulativeswingindex = WilderAccumulativeSwingIndex(20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._wilderaccumulativeswingindex.update(bar)

        if self._wilderaccumulativeswingindex.is_ready:
            # The current value of self._wilderaccumulativeswingindex is represented by self._wilderaccumulativeswingindex.current.value
            self.plot("WilderAccumulativeSwingIndex", "wilderaccumulativeswingindex", self._wilderaccumulativeswingindex.current.value)
```

For more information about this indicator, see its reference .

Visualization

Supported Indicators

Wilder Swing Index

Introduction

This indicator calculates the Swing Index (SI) as defined by Welles Wilder in his book 'New Concepts in Technical Trading Systems'. $SI_t = 50 * (N / R) * (K / T)$ Where: N Equals: $C_t - C_{t-1} + 0.5 * (C_t - O_t) + 0.25 * (C_{t-1} - O_{t-1})$ *See* R Found by selecting the expression with the largest value and then using the corresponding formula. Expression => Formula $|H_t - C_{t-1}|$ => $|H_t - C_t| - 0.5 * |L_t - C_{t-1}| + 0.25 * |C_{t-1} - O_{t-1}|$ $|L_t - C_{t-1}|$ => $|L_t - C_t| - 0.5 * |H_t - C_{t-1}| + 0.25 * |C_{t-1} - O_{t-1}|$ $|H_t - L_t|$ => $|H_t - L_{t-1}| + 0.25 * |C_{t-1} - O_{t-1}|$ *See* K Found by selecting the larger of the two expressions: $|H_t - C_{t-1}|$, $|L_t - C_{t-1}|$ *See* T The limit move, or the maximum change in price during the time period for the bar. Passed as limitMove via the constructor. *See*

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SI Indicator

To create an automatic indicator for `WilderSwingIndex` , call the `si` helper method from the `QCAlgorithm` class. The `si` method creates a `WilderSwingIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class WilderSwingIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._si = self.si(self._symbol, 20, Resolution.DAILY)

    def on_data(self, slice: Slice) -> None:

        if self._si.is_ready:
            # The current value of self._si is represented by self._si.current.value
            self.plot("WilderSwingIndex", "si", self._si.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `WilderSwingIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class WilderSwingIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._wilderswingindex = WilderSwingIndex(20)

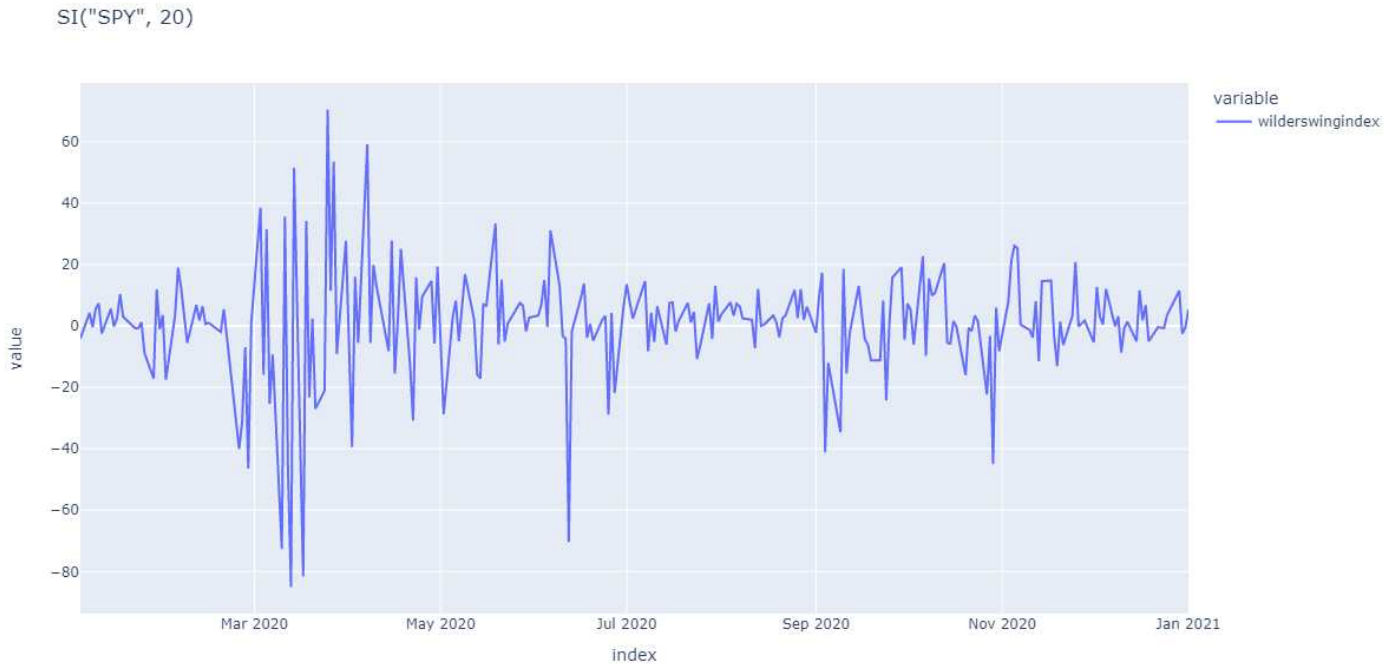
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._wilderswingindex.update(bar)

        if self._wilderswingindex.is_ready:
            # The current value of self._wilderswingindex is represented by self._wilderswingindex.current.value
            self.plot("WilderSwingIndex", "wilderswingindex", self._wilderswingindex.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `WilderSwingIndex` indicator properties:



Indicator History

To get the historical data of the `WilderSwingIndex` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class WilderSwingIndexAlgorithm(QCAlgorithm):

        time_period_indicator_history = self.indicator_history(self._si, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Supported Indicators

Williams Percent R

Introduction

Williams %R, or just %R, is the current closing price in relation to the high and low of the past N days (for a given N). The value of this indicator fluctuates between -100 and 0. The symbol is said to be oversold when the oscillator is below -80%, and overbought when the oscillator is above -20%.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using WILR Indicator

To create an automatic indicator for `WilliamsPercentR` , call the `wilr` helper method from the `QCAlgorithm` class. The `wilr` method creates a `WilliamsPercentR` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class WilliamsPercentRAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._wilr = self.wilr(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._wilr.is_ready:
            # The current value of self._wilr is represented by self._wilr.current.value
            self.plot("WilliamsPercentR", "wilr", self._wilr.current.value)
            # Plot all attributes of self._wilr
            self.plot("WilliamsPercentR", "maximum", self._wilr.maximum.current.value)
            self.plot("WilliamsPercentR", "minimum", self._wilr.minimum.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `WilliamsPercentR` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY

Supported Indicators

Zero Lag Exponential Moving Average

Introduction

This indicator represents the zero lag moving average indicator (ZLEMA) ie a technical indicator that aims is to eliminate the inherent lag associated to all trend following indicators which average a price over time.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ZLEMA Indicator

To create an automatic indicator for `ZeroLagExponentialMovingAverage` , call the `zlema` helper method from the `QCAlgorithm` class. The `zlema` method creates a `ZeroLagExponentialMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class ZeroLagExponentialMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._zlema = self.zlema(self._symbol, 10)

    def on_data(self, slice: Slice) -> None:

        if self._zlema.is_ready:
            # The current value of self._zlema is represented by self._zlema.current.value
            self.plot("ZeroLagExponentialMovingAverage", "zlema", self._zlema.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ZeroLagExponentialMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class ZeroLagExponentialMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._zerolagexponentialmovingaverage = ZeroLagExponentialMovingAverage(10)

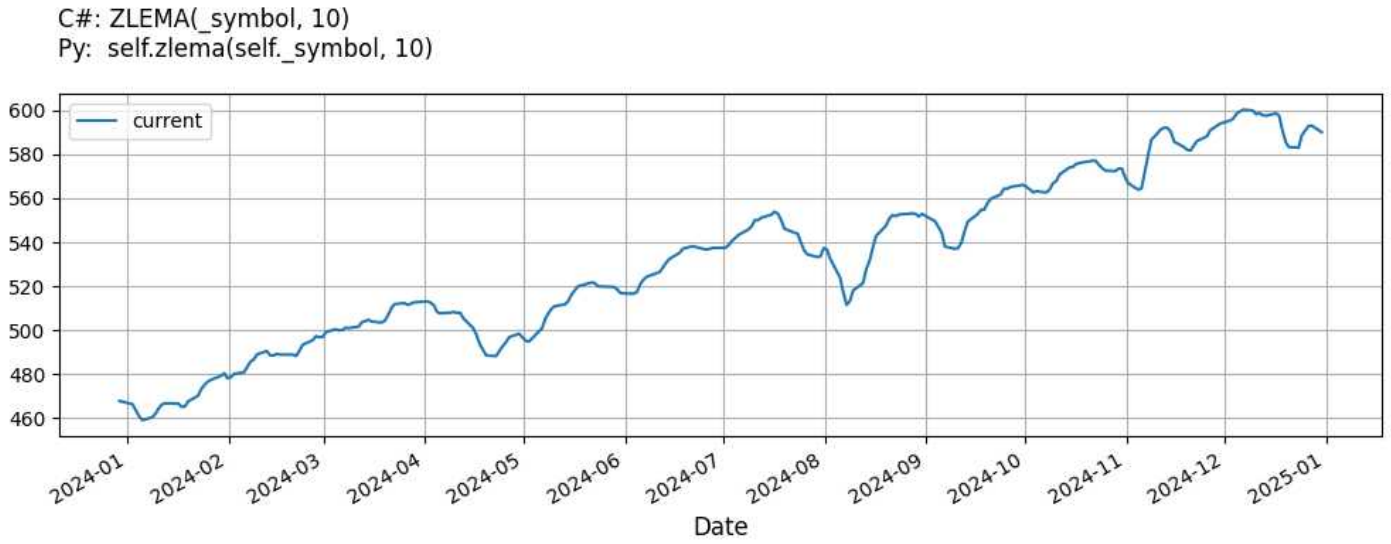
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._zerolagexponentialmovingaverage.update(bar.end_time, bar.close)

        if self._zerolagexponentialmovingaverage.is_ready:
            # The current value of self._zerolagexponentialmovingaverage is represented by
self._zerolagexponentialmovingaverage.current.value
            self.plot("ZeroLagExponentialMovingAverage", "zerolagexponentialmovingaverage",
self._zerolagexponentialmovingaverage.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `ZeroLagExponentialMovingAverage` indicator properties:



Indicator History

To get the historical data of the `ZeroLagExponentialMovingAverage` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class ZeroLagExponentialMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._zlema = self.zlema(self._symbol, 10)

        indicator_history = self.indicator_history(self._zlema, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._zlema, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._zlema, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Supported Indicators

Zig Zag

Introduction

The ZigZag indicator identifies significant turning points in price movements, filtering out noise using a sensitivity threshold and a minimum trend length. It alternates between high and low pivots to determine market trends.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ZZ Indicator

To create an automatic indicator for `ZigZag` , call the `zz` helper method from the `QCAlgorithm` class. The `zz` method creates a `ZigZag` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class ZigZagAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._zz = self.zz(self._symbol, 0.05, 1)

    def on_data(self, slice: Slice) -> None:

        if self._zz.is_ready:
            # The current value of self._zz is represented by self._zz.current.value
            self.plot("ZigZag", "zz", self._zz.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ZigZag` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class ZigZagAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._zigzag = ZigZag(0.05, 1)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._zigzag.update(bar)

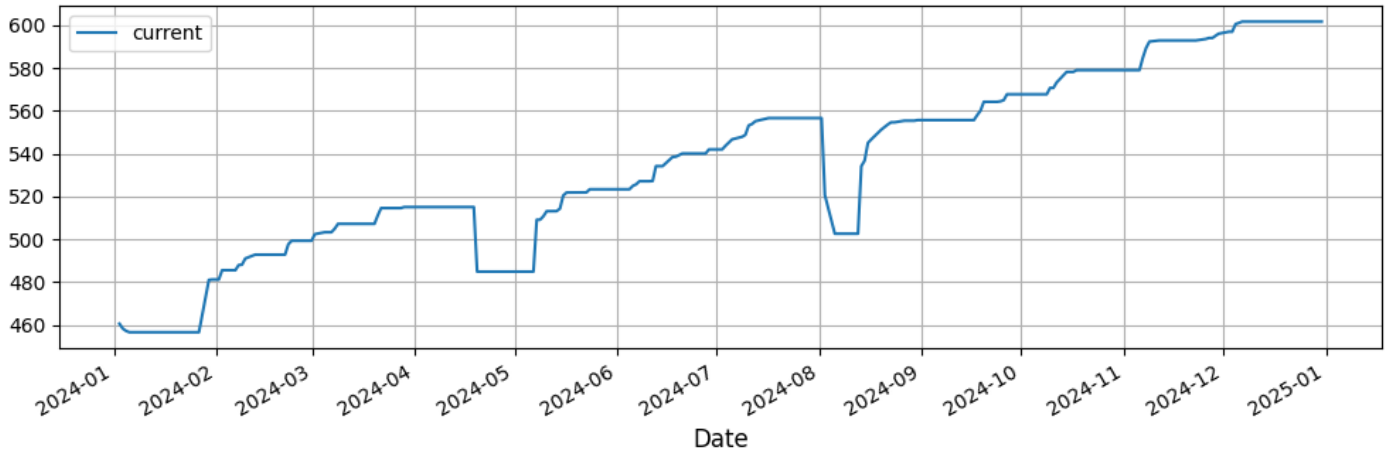
        if self._zigzag.is_ready:
            # The current value of self._zigzag is represented by self._zigzag.current.value
            self.plot("ZigZag", "zigzag", self._zigzag.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `ZigZag` indicator properties:

C#: ZZ(_symbol, 0.05m, 1)
Py: self.zz(self._symbol, 0.05, 1)



Indicator History

To get the historical data of the `ZigZag` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class ZigZagAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._zz = self.zz(self._symbol, 0.05, 1)

        indicator_history = self.indicator_history(self._zz, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._zz, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._zz, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Indicators

Key Concepts

Introduction

Indicators translate a stream of data points into a numerical value you can use to detect trading opportunities. LEAN provides more than 100 pre-built technical indicators and candlestick patterns you can use in your algorithms. To view a list of all the indicators, see the Supported Indicators . One simple indicator to learn is the Identity indicator, which just returns the value of the asset.

```
pep = self.identity("PEP") # Pepsi ticker
```
PY

Design Philosophy

Technical indicators take in a stream of data points, `Bar` objects, or `TradeBar` objects and produce a continuous value. Candlestick patterns take in a stream of `Bar` or `TradeBar` objects and produce a value that's either 0, 1, or -1 to signify the presence of the pattern.

You can configure technical indicators and candlestick patterns to receive manual or automatic updates. With manual indicators, you update the indicator with whatever data you want and whenever you want. With automatic indicators, the algorithm automatically uses the security data to update the indicator value.

LEAN's indicators are implemented "on-line". This means as data pipes through, it updates the internal state of the indicator. Other platforms perform indicator math on an array of values in bulk which can be very inefficient when working on large volumes of data. You need to warm up your indicators and prime them with data to get them ready.

Indicator Types

You can classify an indicator as either a data point, bar, or TradeBar indicator. Their classification depends on the type of data they receive.

Data Point Indicators

Data point indicators use `IndicatorDataPoint` objects to compute their value. Some examples of data point indicators include the following:

- SimpleMovingAverage
- ExponentialMovingAverage
- Momentum

Bar Indicators

Bar indicators use `QuoteBar` or `TradeBar` objects to compute their value. Since Forex and CFD securities don't have `TradeBar` data, they use bar indicators. Candlestick patterns are examples of bar indicators. Some other examples of bar indicators include the following:

- WilliamsPercentR
- Stochastics
- AverageTrueRange

TradeBar Indicators

`TradeBar` indicators use `TradeBar` objects to compute their value. Some `TradeBar` indicators use the volume property of the `TradeBar` to compute their value. Some examples of `TradeBar` indicators include the following:

- Beta
- AdvanceDeclineVolumeRatio
- VolumeWeightedAveragePriceIndicator

Naming Convention

The class name to create a manual indicator is the indicator name spelled in pascal case. For example, to create a manual simple moving average indicator , use the `SimpleMovingAverage` class.

The method to create an automatic indicator is usually named after the acronym of the indicator name. For example, to create an automatic simple moving average indicator , use the `sma` method.

To view the class name and shortcut method of each indicator, see the Supported Indicators .

Create Indicators

There are two ways to create indicators. You can create indicators with the indicator constructor or use a helper method in the `QCAlgorithm` class. If you use the helper method, the indicator automatically updates as your algorithm receives new data.

```
PY
def initialize(self) -> None:
    # Create a manual indicator with the indicator constructor
    self.manual_bb = BollingerBands(20, 2)
    # Create an automatic indicator with the helper method
    self._symbol = self.add_crypto("BTCUSD").Symbol
    self.auto_bb = self.bb(self._symbol, 20, 2, Resolution.DAILY)
```

Set Historical Values Window Size

Indicators have a built-in `RollingWindow` that stores their historical values. The default window size is 2. To change the window size, set the `Window.Size` member.

```
PY
# Increase the Size to 10 for Bollinger Band
self.manual_bb.window.size = 10
self.auto_bb.window.size = 10

# Increase the Size to 20 for the middle band
self.manual_bb.middle_band.window.size = 20
self.auto_bb.middle_band.window.size = 20
```

When you decrease the size, it removes the oldest values that no longer fit in the `RollingWindow` . When you explicitly increase the `size` member, it doesn't automatically add any new elements to the `RollingWindow` . However, if you set the value of an index in the `RollingWindow` and the index doesn't currently exist, it fills the empty indices with `None` . For example, the following code increases the `size` to 10, sets the 10th element to the indicator current value, and sets the 6th-9th elements to `None` :

```
PY
self.manual_bb.window[9] = self.manual_bb.current
self.auto_bb.window[9] = self.auto_bb.current
```

Check Readiness

Indicators aren't always ready when you first create them. The length of time it takes to trust the indicator values depends on the indicator period. To know if an indicator is ready to use, use the `is_ready` property.

```
PY
if not self.auto_bb.is_ready:
    return
```

To get the number of samples the indicator has processed, use the `samples` property.

```
PY
samples = self.auto_bb.samples
```

The `RollingWindow` objects that store the historical values may not be full when the indicator is ready to use. To check if the `Window` is full, use its `is_ready` flag.

```
PY
if not self.auto_bb.window.is_ready:
    return
```

Track Update Events

When an indicator receives a new data point and updates its state, it triggers an update event. To be notified of update events, attach an event handler to the indicator object. The event handler receives 2 arguments: the indicator object and the latest `IndicatorDataPoint` it produced.

```py
# After you create the indicator, attach an event handler
self.auto_bb.updated += self.update_event_handler

# Define the event handler within the same class
def update_event_handler(self, indicator: object, indicator_data_point: IndicatorDataPoint) -> None:
    if indicator.is_ready:
        self.plot("Indicator", "Value", indicator_data_point.value)
```

Get Current Values

To access the indicator value, use the `current.value` property. Some indicators have one output and some indicators have multiple outputs. The `SimpleMovingAverage` indicator only has one output, the average price over the last n periods, so the `current.value` property returns this value. The `BollingerBand` indicator has multiple outputs because it has a simple moving average, an upper band, and a lower band. For indicators that have multiple outputs, refer to the Supported Indicators to see how to access the output values.

```py
sma = self.sma.current.value

current_price = self.auto_bb.current.value
bb_upper_band = self.auto_bb.upper_band.current.value
bb_lower_band = self.auto_bb.lower_band.current.value
```

You can implicitly cast indicators to the decimal version of their `current.value` property.

```py
if self.sma.current.value > self.auto_bb.upper_band.current.value:
    self.set_holdings(self._symbol, -0.1)
```

Get Historical Values

To access historical indicator values, you can use the indicator's built-in `RollingWindow` or you can call the `indicator_history` method to request values over a specific period of time.

Get Trailing Values

To access trailing indicator values, use reverse list access semantics with positive and negative indexing. The current (most recent) indicator value is at index 0, the previous value is at index 1 or the `previous` property, and so on until the length of the window. By default, the window length is 2. If you index the window with a number that's greater than the maximum index of the window, you get a `None` value and the window length grows to support the new index.

```py
current_bb = self.auto_bb.current # self.auto_bb[0]
previous_bb = self.auto_bb.previous # or self.auto_bb[1]
oldest_bb = self.auto_bb.window[-1]
none_value = self.auto_bb.window[100]

previous_upper_band = self.auto_bb.upper_band.previous
oldest_upper_band = self.auto_bb.upper_band.window[-1]
```

To access all of an indicator's historical values in the window, iterate through the indicator object.

```py
for value in self.auto_bb:
    self.log(f'{value}')
```

Request Historical Values

The `indicator_history` method also provides historical indicator values. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
# Get historical indicator values.
history = self.indicator_history(self.sma, self._symbol, timedelta(30))

# Organize the historical values into a DataFrame.
df = history.data_frame

# Iterate through the historical values.
for indicator_data_point in history:
    t = indicator_data_point.end_time
    value = indicator_data_point.value
```

To make the `indicator_history` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```
history = self.indicator_history(self.sma, self._symbol, timedelta(30), selector=Field.VOLUME)
```

Some indicators require the prices of two assets to compute their value (for example, Beta). In this case, pass a list of the `Symbol` objects to the method.

```
self._spy = self.add_equity("SPY").symbol
self._aapl = self.add_equity('AAPL').symbol
self._beta = Beta("", self._aapl, self._spy, 21)
history = self.indicator_history(self._beta, [self._spy, self._aapl], 10, Resolution.DAILY)
```

If the indicator is an Option indicator with an underlying Equity, the `indicator_history` uses the `SCALED_RAW` data normalization mode when requesting historical prices.

Reset Indicators

To reset indicators, call the `reset` method.

```
self.auto_bb.reset()
```

The process to warm up your indicator depends on if it's a manual or automatic indicator .

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your indicators when splits and dividends occur. If a split or dividend occurs, the data in your indicators becomes invalid because it doesn't account for the price adjustments that the split or dividend causes. To replace your indicator history with the newly-adjusted prices, call the `reset` method and then warm up the indicator with `SCALED_RAW` data from a history request .

```
# In OnData
if data.splits.contains_key(self._symbol) or data.dividends.contains_key(self._symbol):
    # Reset the indicator
    self._sma.reset()

    # Warm up the indicator
    trade_bars = self.history[TradeBar](self._symbol, self._sma.warm_up_period, Resolution.DAILY,
data_normalization_mode=DataNormalizationMode.SCALED_RAW)
    for trade_bar in trade_bars:
        self._sma.update(trade_bar.end_time, trade_bar.close)
```

Common Design Patterns

The location in your algorithm where you create and manage indicators depends on the type of universe you use.

One Asset In a Static Universe

If you only have one security in your algorithm, you can create indicators for it during initialization .

```
def initialize(self):
    self._symbol = self.add_equity("SPY").symbol
    self.settings.automatic_indicator_warm_up = True
    self._sma = self.sma(self._symbol, 20, Resolution.DAILY)
```

Multiple Assets or a Dynamic Universe

If your algorithm has multiple assets or a dynamic universe of assets, add custom members to the `Security` objects as you receive them in `on_securities_changed`.

```
def on_securities_changed(self, changes: SecurityChanges) -> None:
    for security in changes.added_securities:
        # Create an indicator
        security.indicator = self.sma(security.Symbol, 10)

        # Warm up the indicator
        self.warm_up_indicator(security.symbol, security.indicator)

    for security in changes.removed_securities:
        self.deregister_indicator(security.indicator)
```

Differences From Third-Party Indicators

The values of our indicators can sometimes produce different results than the indicators on other platforms. There can be several reasons for these discrepancies.

Price Differences

If you find differences in indicator values, compare the prices that are fed into the indicator on each platform. If the input data is slightly different, the indicator values will be different. To test if it's a difference in price data, feed in the data from the third-party platform into our indicators. We validate the indicators against third-party sources and when the values are the same, the indicator values are similar too.

Timestamp Differences

We timestamp our data to the time when the period ends. Many other platforms timestamp to the beginning of the candle.

Implementation Differences

Some indicators can have slightly different default arguments for their implementation. A common difference across platforms is to use a different `MovingAverageType` for the indicators. To view the default arguments for all our indicators, see Supported Indicators. To view the full implementation of our indicators, see the LEAN GitHub repository.

Warm Up Period Differences

Some platforms use all of the historical data to warm up their indicators while LEAN indicators have a fixed number of bars they need to warm up. As a result, indicators with long memory like the Exponential Moving Average can have slightly different values across platforms.

Risk Free Interest Rate Differences

Some indicators, like Sharpe ratios and Sortino ratios, are a function of the risk free interest rate. LEAN provides several different ways to define the interest rate, which can lead to different indicator values compared to other platforms.

RegressionChannelAlgorithm.py Python TalibIndicatorsAlgorithm.py Python

Indicators

Manual Indicators

Introduction

Manual indicators are indicators that don't automatically update from the underlying security data. Manual updates let you customize how you update the indicator, such as using a custom field or using Renko Bars . It's not always necessary to create manual indicators though. Automatic indicators are easier to create and update.

Naming Convention

The class name to create a manual indicator is the indicator name spelled in pascal case. For example, to create a manual simple moving average indicator , use the `SimpleMovingAverage` class.

Create Manual Indicators

To create manual indicators, instantiate an indicator with its constructor. To view all of the available indicators and their constructors, see Supported Indicators .

```py
# Create an indicator
self.delay = Delay(20)

# Create a candlestick pattern
self.two_crows = TwoCrows()
```

You can track indicators by their name. To name a manual indicator, pass a string as the first argument to the constructor.

```py
# Name an indicator
self.delay = Delay("AAPL Past Price", 20)
self.log(self.delay.name)

# Name a candlestick pattern
self.two_crows = TwoCrows("Two Crows Pattern")
self.log(self.two_crows.name)
```

If you don't name an indicator, it's given a default name. For example, the default name for a `Delay` indicator is "Delay(period)".

Manual Updates

With manual updates, you control what data you use to update the indicator. For instance, you can use the 3:30 PM price in your daily moving average instead of the daily closing price or you can use the maximum temperature of the past 10 cloudy days.

To update an indicator, call the `update` method. The `update` method expects one of the following arguments:

- Time/decimal pair
- `IndicatorDataPoint`
- `QuoteBar`
- `TradeBar`
- Custom data bar

To view what data type you should use to update an indicator, see Supported Indicators .

You can update indicators at any point in your algorithm, but the most common places are during the `on_data` event handler or during a consolidation event handler.

```
def initialize(self) -> None:
    self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol

    self._rsi = RelativeStrengthIndex(10, MovingAverageType.SIMPLE)
    self.ad = AccumulationDistribution()

    self.consolidator = TradeBarConsolidator(timedelta(3))   # 10 x 3 daily trade bars to warm up the RSI.
    self.consolidator = QuoteBarConsolidator(timedelta(3))   # 10 x 3 daily quote bars to warm up the RSI.
    self.consolidator = RenkoBarConsolidator(1)     # Renko consolidator that emits a bar when the price moves $1
    # Update the AD indicator with the consolidated bar
    self.consolidator.data_consolidated += self.on_data_consolidated
    self.subscription_manager.add_consolidator(self._symbol, self.consolidator)

def on_data_consolidated(self, sender, bar):
    self.ad.update(bar)

def on_data(self, slice: Slice) -> None:
    # Update the RSI indicator value with the new input close price every day
    if slice.bars.contains_key(self._symbol):
        bar = slice.bars[self._symbol]
        self.rsi.update(bar.end_time, bar.close)
```

Automatic Updates

With automatic updates, your indicators automatically update with the security data on a schedule you set. To configure automatic updates, create a consolidator and then call the `register_indicator` method. If you register an indicator for automatic updates, don't call the indicator's `update` method or else the indicator will receive double updates.

```
# Create a security subscription
self._symbol = self.add_equity("SPY", Resolution.MINUTE).symbol

# Create a manual indicator
self.indicator = RelativeStrengthIndex(10, MovingAverageType.SIMPLE)

# Create a consolidator
consolidator = TradeBarConsolidator(3)            # 10 x 3 min trade bars to warm up the RSI.
consolidator = QuoteBarConsolidator(4)            # 10 x 4 min quote bars to warm up the RSI
consolidator = RenkoConsolidator(1)               # Renko consolidator that emits a bar when the price moves $1
consolidator = IdentityDataConsolidator[TradeBar]()   # Identity consolidator that passes through each TradeBar data point

# Register the indicator to update with the consolidated data
self.register_indicator(self._symbol, self.indicator, consolidator)
```

Data point indicators use only a single price data in their calculations. By default, those indicators use the closing price. For assets with `TradeBar` data, that price is the `TradeBar` close price. For assets with `QuoteBar` data, that price is the mid-price of the bid closing price and the ask closing price. To create an indicator with the other fields like the `Open` , `High` , `Low` , or `Close` , provide a `selector` argument to the `register_indicator` method.

```
self.register_indicator(self._symbol, self.indicator, consolidator, Field.HIGH)
```

The `Field` class has the following `selector` properties:

To stop automatically updating an indicator, pass the indicator to the `deregister_indicator` property method.

```
self.deregister_indicator(self.indicator)
# Alias:
# self.unregister_indicator(self.indicator)
```

Warm Up Indicators

Indicators use historical data to compute their value. Before you start trading with an indicator, warm it up. There are several ways to warm-up manual indicators.

Manual Indicator Warm-up

If you have access to the `QCAlgorithm` object, you can manually warmup indicators with a history request .

```
# Create a manual indicator.
self._sma = SimpleMovingAverage(20)
# Get 20 bars of daily data.
history = algorithm.history[TradeBar](self._symbol, 20, Resolution.DAILY)
# Manually warm up the indicator with the historical close prices.
for bar in history:
    self._sma.update(bar.end_time, bar.close)
```

PY

Warm-up Helper Method

If an indicator inherits (implements) the `IIndicatorWarmUpPeriodProvider` interface, you can warm it up with the `warm_up_indicator` method.

```
# Warm up the indicator using the warm-up helper.
self._sma = SimpleMovingAverage(20)
algorithm.warm_up_indicator(self._symbol, self._sma)
```

PY

To warm up the indicator with a resolution that's different from the security resolution, pass a resolution or `timedelta` argument to the `warm_up_indicator` method. The resolution you provide should be greater than or equal to the security resolution. For example, if the security has minute resolution data, you should warm up the indicator with data that spans at least one minute.

```
# Warm-up with daily bars.
algorithm.warm_up_indicator(self._symbol, self._sma, Resolution.DAILY)

# Warm-up with 3-day bars.
algorithm.warm_up_indicator(self._symbol, self._sma, timedelta(days=3))
```

PY

The `warm_up_indicator` method uses the default `value` of the historical data to warm up the indicator. In most cases, this is the closing price. To warm up the indicator with an alternative price field, pass a `Field` argument to the method.

```
# Warm up the indicator using daily high prices instead of close prices.
algorithm.warm_up_indicator(self._symbol, self._sma, Resolution.DAILY, Field.HIGH)
```

PY

Some indicators require the prices of two assets to compute their value (for example, Beta). In this case, pass a list of the `Symbol` objects to the method.

```
# Use the warm-up helper for an indicator that needs the data of 2 assets.
self._spy = self.add_equity("SPY").symbol
self._aapl = self.add_equity('AAPL').symbol
self._beta = Beta("", self._aapl, self._spy, 21)
self.warm_up_indicator([self._aapl, self._spy], self._beta, Resolution.DAILY)
```

PY

Algorithm Warm-up

If you create indicators at the beginning of your algorithm, you can set an algorithm warm-up period to warm up the indicators. When you set an algorithm warm-up period, the engine pumps data in and automatically updates all the indicators from before the start date of the algorithm. To ensure that all the indicators are ready after the algorithm warm-up period, choose a lookback period that contains sufficient data.

```
# In the initialize() method, request data and construct the indicators you need.
self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
self._sma = SimpleMovingAverage(20)
self.set_warm_up(20)

# In the on_data event handler, update your indicators.
# Use the self.is_warming_up flag to skip some code execution.
self._sma.update(data[self._symbol]) # Delete this line if you registered the indicator for automatic updates.
if self.is_warming_up:
    return
```

PY

Timing Considerations

In some cases, you might create and warm up the indicator during its sampling period. For example, say the security resolution is minute, the

indicator resolution is daily, and you create and warm-up the indicator at noon without using the `set_warm_up` method. In this example, the history request that gathers data to warm up the indicator won't contain any data from the current day. Furthermore, if you set up a consolidator to update the indicator, the consolidator also won't aggregate any data from before noon. It doesn't cause issues if the indicator only uses the close price to calculate the indicator value (like the simple moving average indicator) because the first consolidated bar that updates the indicator will have the correct close price. However, if the indicator uses more than just the close price to calculate its value (like the True Range indicator), the open, high, and low values of the first consolidated bar may be incorrect, causing the initial indicator values to be incorrect.

Liquidity Considerations

When LEAN makes a history request to warm up an indicator, it may not return enough data to warm up the indicator. After warming up an indicator, check for readiness , reset it , and increase the lookback period for a new history request if necessary.

```py
# In Initialize
symbol = self.add_equity("SPY").symbol
self._sma = SimpleMovingAverage(20)
self.warm_up_indicator(symbol, self._sma, Resolution.DAILY)
if not self._sma.is_ready:
    # The history request didn't return enough data to warm up the indicator.
    # Reset it, and increase the lookback period and try again.
    self._sma.reset()
    self.indicator_history(self._sma, symbol, 40, Resolution.DAILY)
```

Delay Indicator

The `Delay` indicator delays its input by a specified number of bars. It is mainly used to combine indicators, enabling you to set a delay without using built-in rolling windows . For example, you can create a displaced moving average by applying a `Delay` to a `SimpleMovingAverage` .

```py
# Create a 20-bar Delay indicator
self._delay = Delay(20)

# Create a displaced SMA by combining Delay with SMA
sma = SimpleMovingAverage(10)
displaced_sma = IndicatorExtensions.of(Delay(5), sma)
```

For a full example of using the `Delay` indicator to create a displaced SMA ribbon strategy, see Combining Indicators Examples .

For more information about this indicator, see the class reference and implementation .

Examples

The following examples demonstrate some common practices for using manual indicators.

Example 1: Universe Selection

The following algorithm selects the stocks within 5% of the 1-year maximum price among the top 100 liquid stocks. To do so, we make use of Maximum indicator to do so. Then, we hold the stocks with price > EMA > SMA , which indicates an upward accelerating trend.

PY

```
class ManualIndicatorAlgorithm(QCAlgorithm):
    maximum_by_symbol = {}

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Select a popularity-based universe with indicators in a Selection function.
        self._universe = self.add_universe(self.selection)

        # Set a scheduled event to rebalance daily on the daily indicator signals.
        self.schedule.on(
            self.date_rules.every_day(),
            self.time_rules.at(9, 31),
            self.rebalance
        )

    def selection(self, fundamentals: list[Fundamental]) -> list[Symbol]:
        selected = []

        # Initially filtered for the top 100 liquid stocks first.
        filtered = sorted(fundamentals, key=lambda f: f.dollar_volume, reverse=True)[:100]

        for f in filtered:
            if f.symbol not in self.maximum_by_symbol:
                self.maximum_by_symbol[f.symbol] = Maximum(252)
                # Warm up the Maximum indicator to its readiness to use immediately.
                history = self.history[TradeBar](f.symbol, 252, Resolution.DAILY)
                for bar in history:
                    self.maximum_by_symbol[f.symbol].update(bar.end_time, bar.close)
            else:
                # Update the indicator with the last known adjusted price daily.
                self.maximum_by_symbol[f.symbol].update(f.end_time, f.adjusted_price)

            # Select to trade if the current price is within 5% of the maximum price of the last year.
            # Close to the maximum price provides evidence of high popularity for the fund to support the trend.
            if f.adjusted_price >= self.maximum_by_symbol[f.symbol].current.value * 0.95:
                selected.append(f.symbol)

        return selected

    def rebalance(self) -> None:
        def to_buy(symbol):
            security = self.securities[symbol]
            # Buy the stocks whose prices are above the EMA and the EMA is above the SMA, meaning their trend is upward accelerating.
            return security.price > security.ema.current.value > security.sma.current.value

        symbols_to_buy = [symbol for symbol in self._universe.selected if to_buy(symbol)]

        # Equally invest in the selected stocks to dissipate the capital risk evenly.
        count = len(symbols_to_buy)
        if count > 0:
            targets = [PortfolioTarget(symbol, 1 / count) for symbol in symbols_to_buy]
            # Liquidate the positions that are not on an upward trend or are not popular anymore.
            self.set_holdings(targets, liquidate_existing_holdings=True)

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for added in changes.added_securities:
            symbol = added.symbol
            # Create an EMA and an SMA manual indicator for trade signal generation.
            added.ema = ExponentialMovingAverage(20)
            added.sma = SimpleMovingAverage(20)

            # Warm up the indicators to ensure their readiness to use them immediately.
            self.warm_up_indicator(symbol, added.ema, Resolution.DAILY)
            self.warm_up_indicator(symbol, added.sma, Resolution.DAILY)

            # Subscribe to the indicators to update daily price data for updated trade signal generation.
            self.register_indicator(symbol, added.ema, Resolution.DAILY)
            self.register_indicator(symbol, added.sma, Resolution.DAILY)

        for removed in changes.removed_securities:
            # Cancel data subscription to release computation resources when leaving the universe.
            self.deregister_indicator(removed.ema)
            self.deregister_indicator(removed.sma)
```

Indicators

Automatic Indicators

Introduction

Automatic indicators are indicators that automatically update from the underlying security data. Automatic indicators do everything that manual indicators do, but with automatic updates registered for you.

Naming Convention

The method to create an automatic indicator is usually named after the acronym of the indicator name. For example, to create an automatic simple moving average indicator , use the `sma` method.

Create Automatic Indicators

To create automatic indicators, call the indicator helper method from the `QCAlgorithm` class. The indicator helper methods create an indicator object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. To view the helper method for each indicator, see Supported Indicators . In most cases, you should call the helper method in the `initialize` method.

The indicator resolution must be greater than or equal to the resolution of the security subscription. For instance, if your security subscription is for minute resolution data, the indicator resolution should be minute, hour, or daily resolution.

```
PY
# In Initialize()
symbol = self.add_equity("SPY").symbol

#  - Create an indicator
self._sma = self.sma(symbol, 20, Resolution.DAILY)

#  - Create a candlestick pattern
patterns = CandlestickPatterns(self)
self.two_crows = patterns.two_crows(self._symbol)
```

When you create an indicator with a helper method, the indicator is given a default name. You can track indicators by their name. The default name for the `SimpleMovingAverage` indicator is " sma (period , ticker _ resolution)". For example, in the preceding code snippet, the `SimpleMovingAverage` indicator is named " sma (20,SPY_day)". To get the name of an indicator, inspect its `name` property.

```
PY
self.log(self.sma.name)
self.log(self.two_crows.name)
```

Alternative Price Fields

Data point indicators use only a single price data in their calculations. By default, those indicators use the closing price. For assets with `TradeBar` data, that price is the `TradeBar` close price. For assets with `QuoteBar` data, that price is the mid-price of the bid closing price and the ask closing price. To create an indicator with the other fields like the `OPEN` , `HIGH` , `LOW` , or `CLOSE` , provide a `selector` argument to the indicator helper method.

```
PY
# Define a 10-period daily RSI indicator with shortcut helper method
# Select the Open price to update the indicator
self._rsi = self.rsi("SPY", 10,  MovingAverageType.SIMPLE, Resolution.DAILY, Field.OPEN)
```

The `Field` class has the following `selector` properties:

Warm Up Indicators

Indicators compute their value based on historical data. Before you start trading with an indicator, warm it up. There are several ways to warm-up automatic indicators.

Algorithm Warm-up

You can set an algorithm warm-up period to warm up the indicators. When you set an algorithm warm-up period, the engine pumps data in and automatically updates all the indicators from before the start date. To ensure that all the indicators are ready after the algorithm warm-up period, choose a look-back period that contains sufficient data.

```
# In Initialize
symbol = self.add_equity("SPY").symbol
self._sma = self.sma(symbol, 20, Resolution.DAILY)
self.set_warm_up(20, Resolution.DAILY)

# In OnData
if self.is_warming_up:
    return
```

PY

Manual Indicator Warm-up

You can manually warm up indicators with a history request .

```
# In Initialize
symbol = self.add_equity("SPY").symbol
self._sma = self.sma(symbol, 20, Resolution.DAILY)

history = self.history(symbol, 20, Resolution.DAILY)
if not history.empty:
    for time, row in history.loc[symbol].iterrows():
        self._sma.update(time, row.close)
```

PY

Warm-up Helper Method

If an indicator inherits the `IIndicatorWarmUpPeriodProvider` class, you can warm it up with the `warm_up_indicator` method.

```
self._sma = self.sma(self._symbol, 20)
self.warm_up_indicator(self._symbol, self._sma)
```

PY

To warm up the indicator with a resolution that's different from the security resolution, pass a resolution or `timedelta` argument to the `warm_up_indicator` method. The resolution you provide should be greater than or equal to the security resolution. For example, if the security has minute resolution data, you should warm up the indicator with data that spans at least one minute. If the indicator resolution is different from the security resolution, provide the indicator resolution as the argument to properly warm up the indicator.

```
# Warm up with daily bars
self.warm_up_indicator(self._symbol, self._sma, Resolution.DAILY)

# Warm up with 3-day bars
self.warm_up_indicator(self._symbol, self._sma, timedelta(days=3))
```

PY

The `warm_up_indicator` method uses the default `value` of the historical data to warm up the indicator. In most cases, this is the closing price. To warm up the indicator with a different data field, pass a `Field` argument to the method.

```
self.warm_up_indicator(self._symbol, self._sma, Resolution.DAILY, Field.HIGH)
```

PY

Some indicators require the prices of two assets to compute their value (for example, Beta). In this case, pass a list of the `Symbol` objects to the method.

```
self._spy = self.add_equity("SPY").symbol
self._aapl = self.add_equity('AAPL').symbol
self._beta = self.B(self._aapl, self._spy, 21, Resolution.DAILY)
self.warm_up_indicator([self._aapl, self._spy], self._beta, Resolution.DAILY)
```

PY

Automatic Indicator Warm-up

You can set the `self.settings.automatic_indicator_warm_up` property to true before you create most indicators to automatically warm them up.

This technique doesn't work for all indicators.

```py
# In Initialize
symbol = self.add_equity("SPY").symbol
self.settings.automatic_indicator_warm_up = True
self._sma = self.sma(symbol, 20, Resolution.DAILY)
```

The `automatic_indicator_warm_up` settings does not account for built-in `RollingWindow` that stores their historical values , use the `warm_up_indicator` or the `indicator_history` method instead.

Timing Considerations

In some cases, you might create and warm up the indicator during its sampling period. For example, say the security resolution is minute, the indicator resolution is daily, and you create and warm-up the indicator at noon without using the `set_warm_up` method. In this example, the history request that gathers data to warm up the indicator won't contain any data from the current day. Furthermore, if you set up a consolidator to update the indicator, the consolidator also won't aggregate any data from before noon. It doesn't cause issues if the indicator only uses the close price to calculate the indicator value (like the simple moving average indicator) because the first consolidated bar that updates the indicator will have the correct close price. However, if the indicator uses more than just the close price to calculate its value (like the True Range indicator), the open, high, and low values of the first consolidated bar may be incorrect, causing the initial indicator values to be incorrect.

Liquidity Considerations

When LEAN makes a history request to warm up an indicator, it may not return enough data to warm up the indicator. After warming up an indicator, check for readiness , reset it , and increase the lookback period for a new history request if necessary.

```py
# In Initialize
symbol = self.add_equity("SPY").symbol
self.settings.automatic_indicator_warm_up = True
self._sma = self.sma(symbol, 20, Resolution.DAILY)
if not self._sma.is_ready:
    # The history request didn't return enough data to warm up the indicator.
    # Reset it, and increase the lookback period and try again.
    self._sma.reset()
    self.indicator_history(self._sma, symbol, 40, Resolution.DAILY)
```

Deregister Indicators

To stop the automatic updates of an indicator, pass the indicator to the `deregister_indicator` property method.

```py
self.deregister_indicator(self._sma)
# Alias:
# self.unregister_indicator(self._sma)
```

Common Mistakes

Avoid the following common mistakes when you use automatic indicators.

Using Indicator Values Before the Indicator Is Warmed Up

Indicators can provide inaccurate output values before they are warmed up. To avoid issues, always check the `is_ready` flag before you use indicator output values.

```py
# is_ready signals whether the indicator values are accurate and ready to use.
if self.indicator.is_ready:
    value = self.indicator.current.value
```

Manually Registering an Automatic Indicator for Updates

If you create an automatic indicator and then register it for automatics updates or call the `update` method, the indicator receives multiple input values during each update cycle. To avoid issues, create automatic indicators but don't register them for automatic updates or call the `update` method.

```
# Automatic indicator short-cuts create the indicator and register it for data updates.
self.indicator = self.sma(self._symbol, 5)

# Don't register the automatic indicators for data. They automatically get data.
# self.register_indicator(self._symbol, self.indicator, Resolution.DAILY)
```

Examples

The following examples demonstrate some common practices for using automatic indicators.

Example 1: Trade With Automatic Indicators in a Dynamic Universe

The following algorithm selects a universe of the 20 most liquid US Equities each day. At the start of each trading session, it then forms an equal-weighted portfolio of the stocks that have price > EMA > SMA , which indicates an upward accelerating trend. As assets enter the universe, it creates automatic indicators for them. As assets leave the universe, it deregisters the indicators.

```
class AutomaticIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Add a universe of the 20 most liquid stocks to trade trends more efficiently.
        self._universe = self.add_universe(self.universe.top(20))

        # Set a Scheduled Event to rebalance at the start of each day with the daily indicator signals.
        self.schedule.on(self.date_rules.every_day(), self.time_rules.at(9, 31), self._rebalance)

    def _rebalance(self) -> None:
        # Buy the stocks where price is above EMA and EMA is above SMA, meaning its trend is upward and accelerating.
        securities = [self.securities[symbol] for symbol in self._universe.selected]
        symbols_to_buy = [
            security.symbol for security in securities
            if security.price > security.ema.current.value > security.sma.current.value
        ]

        # Equally invest in the selected stocks to evenly distribute the capital risk.
        count = len(symbols_to_buy)
        if count:
            targets = [PortfolioTarget(symbol, 1 / count) for symbol in symbols_to_buy]
            # Liquidate the positions that are no longer popular or in an uptrend.
            self.set_holdings(targets, liquidate_existing_holdings=True)

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            symbol = security.symbol
            # Create EMA & SMA indicators to generate trade signals. Use duck typing to save the indicator instances.
            security.ema = self.ema(symbol, 20, Resolution.DAILY)
            security.sma = self.sma(symbol, 20, Resolution.DAILY)

            # Warm up the indicators so they are ready to use immediately.
            self.warm_up_indicator(symbol, security.ema, Resolution.DAILY)
            self.warm_up_indicator(symbol, security.sma, Resolution.DAILY)

        for security in changes.removed_securities:
            # Stop updating the indicators of assets that leave the universe to release computation resources.
            self.deregister_indicator(security.ema)
            self.deregister_indicator(security.sma)
```

Indicators

Plotting Indicators

Introduction

LEAN provides helper methods to make it simple to create indicator plots.

Plot Update Events

To plot all of the values of some indicators, in the `initialize` method, call the `plot_indicator` method. The method plots each indicator value as the indicator updates. The method accepts up to four indicators.

```
PY
symbol = self.add_equity("SPY")
sma_short = self.sma(symbol, 10)
sma_long = self.sma(symbol, 20)
self.plot_indicator("<chartName>", sma_short, sma_long)
```

Plot Current Values

To plot the current value of indicators, call the `plot` method. The method accepts up to four indicators.

```
PY
# In Initialize
symbol = self.add_equity("SPY")
sma_short = self.sma(symbol, 10)
sma_long = self.sma(symbol, 20)

# In OnData
self.plot("<chartName>", sma_short, sma_long)
```

View Charts

The following table describes where you can access your charts, depending on how to deploy your algorithms:

Location	Algorithm Lab Algorithms	CLI Cloud Algorithms	CLI Local Algorithms
Backtest results page	✓	✓	
Live results page	✓	✓	
/backtests/read endpoint	✓	✓	
/live/read endpoint	✓	✓	
ReadBacktest method	✓	✓	
ReadLiveAlgorithm method	✓	✓	
Local JSON file in your <projectName> / backtests / <timestamp> or <projectName> / live / <timestamp> directory		✓	✓

Chart Limits

Not all indicators share the same base type(T), so you may not be able to plot them together since some indicators require points while others require `TradeBars` .

```
# Plot indicators that extend the "Indicator" type
self.plot_indicators("All Indicator Values", sma, rsi)
self.plot("Current Indicator Values", sma, rsi);

# Plot indicators that extend the "TradeBarIndicator" type
self.plot_indicators("All Indicator Values", atr, aroon)
self.plot("Current Indicator Values", atr, aroon);
```

If your indicator plots are complex, call the `plot` method with one indicator and plot its `current.value` property. For more information about plotting, see Charting .

Examples

The following examples demonstrate some common practices for plotting indicators.

Example 1: SMA Ribbon

The following algorithm trades simple moving average (SMA) crossings, which involves five SMA indicators to form an SMA ribbon. To visualize the ribbon, it plots each indicator with a different color.

```
class PlottingIndicatorAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Add SPY data to update indicators and trade.
        self._spy = self.add_equity("SPY", Resolution.DAILY).symbol

        # Create a chart to plot the ribbon. To better visualize the plot, use different colors per series.
        chart = Chart("Ribbon")
        chart.add_series(Series("Price", SeriesType.CANDLE, "$"))
        chart.add_series(Series("SMA10", SeriesType.LINE, "$", Color.VIOLET))
        chart.add_series(Series("SMA20", SeriesType.LINE, "$", Color.BLUE))
        chart.add_series(Series("SMA30", SeriesType.LINE, "$", Color.GREEN))
        chart.add_series(Series("SMA40", SeriesType.LINE, "$", Color.YELLOW))
        chart.add_series(Series("SMA50", SeriesType.LINE, "$", Color.RED))

        # Create 5 SMA indicators to create the SMA ribbon.
        self._smas = {n: self._create_sma(n) for n in [10, 20, 30, 40, 50]}

    def _create_sma(self, n: int) -> SimpleMovingAverage:
        sma = self.sma(self._spy, n, Resolution.DAILY)
        # Plot the indicator value to create the ribbon when the indicator updates.
        sma.updated += lambda sender, point: self.plot("Ribbon", f"SMA{n}", point.value)
        # Warm up the indicator so it's ready to use immediately.
        self.warm_up_indicator(self._spy, sma)
        return sma

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._spy)
        if bar:
            # Plot the candlestick when you get the daily bar.
            self.plot("Ribbon", "Price", bar.open, bar.high, bar.low, bar.close)

            # Follow strong upward trend.
            if self._is_uptrend(bar.close, self._smas):
                self.set_holdings(self._spy, 1)
            # Follow strong downward trend.
            elif self._is_downtrend(bar.close, self._smas):
                self.set_holdings(self._spy, -1)
            # Liquidate positions if the trend is less deterministic.
            else:
                self.liquidate()

    def _is_uptrend(self, price: float, smas: List[SimpleMovingAverage]) -> bool:
        # Uptrend occurs when price is above all SMAs and shorter SMAs are above longer SMAs.
        smas_list = [x[1].current.value for x in sorted(smas.items(), key=lambda x: x[0])]
        return all([smas_list[i] < smas_list[i-1] for i in range(1, len(smas_list))]) and price > smas_list[0]

    def _is_downtrend(self, price: float, smas: List[SimpleMovingAverage]) -> bool:
        # Downtrend occurs when price is below all SMAs and shorter SMAs are below longer SMAs.
        smas_list = [x[1].current.value for x in sorted(smas.items(), key=lambda x: x[0])]
        return all([smas_list[i] > smas_list[i-1] for i in range(1, len(smas_list))]) and price < smas_list[0]
```

Indicators

Combining Indicators

Introduction

Indicator extensions let you chain indications together like Lego blocks to create unique combinations. When you chain indicators together, the `current.value` property output of one indicator is the input of the following indicator. To chain indicators together with values other than the `current.value` property, create a custom indicator .

Addition

The `plus` extension sums the `current.value` property of two indicators or sums the `current.value` property of an indicator and a fixed value.

```
PY
# Sum the output of two indicators
min_ = self.min("SPY", 21)
std = self.std("SPY", 21)
min_plus_std = IndicatorExtensions.plus(min_, std)

# Sum the output of an indicator and a fixed value
min_plus_value = IndicatorExtensions.plus(min_, 10)
```

If you pass an indicator to the `plus` extension, you can name the composite indicator.

```
PY
named_indicator = IndicatorExtensions.plus(min_, std, "Buy Zone")
```

Subtraction

The `minus` extension subtracts the `current.value` property of two indicators or subtracts a fixed value from the `current.value` property of an indicator.

```
PY
# Subtract the output of two indicators
sma_short = self.sma("SPY", 14)
sma_long = self.sma("SPY", 21)
sma_difference = IndicatorExtensions.minus(sma_short, sma_long)

# Subtract a fixed value from the output of an indicator
sma_minus_value = IndicatorExtensions.minus(sma_short, 10)
```

If you pass an indicator to the `minus` extension, you can name the composite indicator.

```
PY
named_indicator = IndicatorExtensions.minus(sma_short, sma_long, "SMA Difference")
```

Multiplication

The `times` extension multiplies the `current.value` property of two indicators or multiplies a fixed value and the `current.value` property of an indicator.

```
PY
# Multiply the output of two indicators
ema_short = self.ema("SPY", 14)
ema_long = self.ema("SPY", 21)
ema_product = IndicatorExtensions.times(ema_short, ema_long)

# Multiply the output of an indicator and a fixed value
ema_times_value = IndicatorExtensions.times(ema_short, 1.5)
```

If you pass an indicator to the `times property` extension, you can name the composite indicator.

```
named_indicator = IndicatorExtensions.times(ema_short, ema_long, "EMA Product")
```

Division

The `over` extension divides the `current.value` property of an indicator by the `current.value` property of another indicator or a fixed value.

```
# Divide the output of two indicators
rsi_short = self.rsi("SPY", 14)
rsi_long = self.rsi("SPY", 21)
rsi_division = rsi_short.over(rsi_long)

# Divide the output of an indicator by a fixed value
rsi_half = IndicatorExtensions.over(rsi_short, 2)
```

If you pass an indicator to the `over` extension, you can name the composite indicator.

```
named_indicator = IndicatorExtensions.over(rsi_short, rsi_long, "RSI Division")
```

Weighted Average

The `weighted_by` extension calculates the average `current.value` property of an indicator over a lookback period, weighted by another indicator over the same lookback period. The value of the calculation is

$$\frac{\textbf{x} \cdot \textbf{y}}{ \sum\limits_{i=1}^{n} y_{i} }$$

where $\textbf{x}$ is a vector that contains the historical values of the first indicator,$\textbf{y}$ is a vector that contains the historical values of the second indicator, and n is the lookback period.

```
sma_short = self.sma("SPY", 14)
sma_long = self.sma("SPY", 21)
weighted_sma = IndicatorExtensions.weighted_by(sma_short, sma_long, 3)
```

Custom Chains

The `of` extension feeds an indicator's `current.value` property into the input of another indicator. The first argument of the `IndicatorExtensions.Of` method must be a manual indicator with no automatic updates. If you pass an indicator that has automatic updates as the argument, that first indicator is updated twice. The first update is from the security data and the second update is from the `IndicatorExtensions` class.

```
rsi = self.rsi("SPY", 14)
rsi_sma = IndicatorExtensions.of(SimpleMovingAverage(10), rsi) # 10-period SMA of the 14-period RSI
```

If you pass a manual indicator as the second argument, to update the indicator chain, update the second indicator. If you call the `update` method of the entire indicator chain, it won't update the chain properly.

Simple Moving Average

The `sma` extension calculates the simple moving average of an indicator's `current.value` property.

```
rsi = self.rsi("SPY", 14) # Create a RSI indicator
rsi_sma = IndicatorExtensions.SMA(rsi, 3) # Create an indicator to calculate the 3-period SMA of the RSI indicator
```

Exponential Moving Average

The `ema` extension calculates the exponential moving average of an indicator's `current.value` property.

```
rsi = self.rsi("SPY", 14) # Create a RSI indicator
rsi_ema = IndicatorExtensions.ema(rsi, 3) # Create an indicator to calculate the 3-period EMA of the RSI indicator
```

The `ema` extension can also accept a smoothing parameter that sets the percentage of data from the previous value that's carried into the next value.

```
rsi_ema = IndicatorExtensions.ema(rsi, 3, 0.1) # 10% smoothing factor
```

Maximum

The `max` extension calculates an indicator's maximum `current.value` property over a lookback window.

```
ema = self.ema("SPY", 14) # Create an EMA indicator
ema_max = IndicatorExtensions.max(ema, 10) # Create an indicator to calculate the maximum EMA over the last 10 periods
```

Minimum

The `min` extension calculates an indicator's minimum `current.value` property over a lookback window.

```
ema = self.ema("SPY", 14) # Create an EMA indicator
ema_min = IndicatorExtensions.min(ema, 10) # Create an indicator to calculate the minimum EMA over the last 10 periods
```

Examples

The following examples demonstrate some common practices for combining indicators.

Example 1: Volatility

The following algorithm trades a volatility strategy. By comparing SMA and the current value of the standard deviation of the return, we can estimate the current volatility regime is above or below average to trade the price volatility through strangle.

```
class CombiningIndicatorsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Request daily SPY data to feed the indicators and generate trade signals.
        # Use Raw data normalization mode to compare the strike price fairly.
        self.spy = self.add_equity("SPY", data_normalization_mode=DataNormalizationMode.RAW).symbol

        # Request option data to trade.
        option = self.add_option(self.spy)
        self._option = option.symbol
        # Filter for 7-day expiring options with $5 apart from the current price to trade volatility using strangle.
        option.set_filter(lambda universe: universe.strangle(7, 5, -5))

        # Create a return indicator to get the daily return of SPY.
        ret = self.roc(self.spy, 1, Resolution.DAILY)
        # Create an SD indicator to measure the 252-day SD of return to measure SPY's volatility.
        self._sd = IndicatorExtensions.of(StandardDeviation(252), ret)
        # Create a 20-day SMA indicator of the SD indicator to compare the average volatility.
        self._sma = IndicatorExtensions.of(SimpleMovingAverage(20), self._sd)

        # Warm up for immediate usage of indicators.
        self.set_warm_up(400, Resolution.DAILY)

    def on_data(self, slice: Slice) -> None:
        if self.is_warming_up:
            return
        chain = slice.option_chains.get(self._option)
        if not self.portfolio.invested and chain:
            # Create a strangle strategy to trade the volatility forecast.
            sorted_strike = sorted([x.strike for x in chain])
            otm_call_strike = sorted_strike[-1]
            otm_put_strike = sorted_strike[0]
            expiry = list(chain)[0].expiry
            strangle = OptionStrategies.strangle(self._option, otm_call_strike, otm_put_strike, expiry)

            # If the current STD is above its SMA, we estimate the volatility will remain high due to volatility clustering.
            # Thus, we long the strangle to earn from the price displacement from the current level.
            if self._sd.current.value > self._sma.current.value:
                self.buy(strangle, 2)
            # If the current STD is below its SMA, we estimate the volatility will remain lower due to volatility clustering.
            # Thus, we short the strangle to earn from the price staying at the current level.
            elif self._sd.current.value < self._sma.current.value:
                self.sell(strangle, 2)

        elif self.portfolio[self.spy].invested:
            # Liquidate any assigned underlying positions.
            self.liquidate(self.spy)
```

Example 2: Displaced SMA Ribbon

The following algorithm trades trends indicated by SMA crossings. We use the `IndicatorExtensions.of` method to create a Delay indicator on SMA indicator.

PY

```
class DisplacedMovingAverageRibbon(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Request daily SPY data for feeding indicator and trading.
        self.spy = self.add_equity("SPY", Resolution.DAILY).symbol

        # Create 6 15-day SMA indicators, with a 5-day delay between each indicator.
        count = 6
        offset = 5
        period = 15
        self.ribbon = []
        # Define our sma as the base of the ribbon.
        self.sma = SimpleMovingAverage(period)

        for x in range(count):
            # Define our offset to the zero SMA. These various offsets will create our 'displaced' ribbon.
            delay = Delay(offset*(x+1))
            # Using Delay indicator to create displaced SMA indicators.
            delayed_sma = IndicatorExtensions.of(delay, self.sma)
            # Register our new 'delayed_sma' for automatic updates on a daily resolution.
            self.register_indicator(self.spy, delayed_sma, Resolution.DAILY)
            self.ribbon.append(delayed_sma)

        # Plot indicators each time they update using the PlotIndicator function.
        for i in self.ribbon:
            self.plot_indicator("Ribbon", i)

    def on_data(self, data: Slice) -> None:
        # Trade only on updated data with ready-to-use indicators.
        if data[self.spy] is None: return
        if not all(x.is_ready for x in self.ribbon): return
        self.plot("Ribbon", "Price", data[self.spy].price)

        values = [x.current.value for x in self.ribbon]
        holding = self.portfolio[self.spy]
        # Buy SPY if the trend is upward.
        if (holding.quantity <= 0 and self.is_ascending(values)):
            self.set_holdings(self.spy, 1.0)
        # Liquidate if the trend is downwards.
        elif (holding.quantity > 0 and self.is_descending(values)):
            self.liquidate(self.spy)

    # Returns true if the SMA values are in ascending order, indicating an upward trend
    def is_ascending(self, values: List[float]) -> None:
        last = None
        for val in values:
            if last is None:
                last = val
                continue
            if last < val:
                return False
            last = val
        return True

    # Returns true if the SMA values are in descending order, indicating a downward trend
    def is_descending(self, values: List[float]) -> None:
        last = None
        for val in values:
            if last is None:
                last = val
                continue
            if last > val:
                return False
            last = val
        return True
```

Indicators

Custom Indicators

Introduction

LEAN supports over 100 pre-built indicators, but a custom indicator is an indicator you define. It receives input, performs some calculation, and sets its output value. Custom indicators are helpful when you want to achieve any of the following results:

- Use an indicator that LEAN doesn't currently implement
- Combine built-in indicators beyond the logic of Indicator Extensions
- Create your own unique indicator for trading

Define Indicators

Custom indicators must implement the `PythonIndicator` class. The indicator must have an `update` method and `name` , `time` , and `value` attributes. The `update` method must accept an `IndicatorDataPoint` , `QuoteBar` , or `TradeBar` and return a boolean that represents if the indicator is ready. The `time` attribute represents the last time you updated the indicator and the `value` attribute represents the current indicator value. The following definition provides an example of a custom simple moving average indicator.

```py
class CustomSimpleMovingAverage(PythonIndicator):
    def __init__(self, name, period):
        self.name = name
        self.warm_up_period = period
        self.time = datetime.min
        self.value = 0
        self.queue = deque(maxlen=period)

    def update(self, input: BaseData) -> bool:
        self.queue.appendleft(input.value)
        count = len(self.queue)
        self.time = input.time
        self.value = sum(self.queue) / count
        # Set the current attribute if you will update the indicator manually
        self.current = IndicatorDataPoint(input.end_time, self.value)
        # Call on_update to trigger an event (cannot be used in automatic updates)
        self.on_updated(self.current)
        return count == self.queue.maxlen

    # Define is_ready property if you will update the indicator manually
    @property
    def is_ready(self) -> bool:
        return len(self.queue) == self.queue.maxlen
```

The following definition provides an example of a custom money flow index indicator.

```py
class CustomMoneyFlowIndex(PythonIndicator):
    def __init__(self, name, period):
        super().__init__()
        self.name = name
        self.value = 0
        self.previous_typical_price = 0
        self.negative_money_flow = deque(maxlen=period)
        self.positive_money_flow = deque(maxlen=period)

    def update(self, input):
        if not isinstance(input, TradeBar):
            raise TypeError('CustomMoneyFlowIndex.update: input must be a TradeBar')

        typical_price = (input.high + input.low + input.close) / 3
        money_flow = typical_price * input.volume

        # We need to avoid double rounding errors
        if abs(self.previous_typical_price / typical_price - 1) < 1e-10:
            self.previous_typical_price = typical_price

        self.negative_money_flow.appendleft(money_flow if typical_price < self.previous_typical_price else 0)
        self.positive_money_flow.appendleft(money_flow if typical_price > self.previous_typical_price else 0)
        self.previous_typical_price = typical_price

        positive_money_flow_sum = sum(self.positive_money_flow)
        total_money_flow = positive_money_flow_sum + sum(self.negative_money_flow)

        self.value = 100
        if total_money_flow != 0:
            self.value *= positive_money_flow_sum / total_money_flow

        # Set the current attribute if you will update the indicator manually
        self.current = IndicatorDataPoint(input.end_time, self.value)

        # Call on_update to trigger an event (cannot be used in automatic updates)
        self.on_updated(self.current)

        return len(self.positive_money_flow) == self.positive_money_flow.maxlen

    # Define is_ready property if you will update the indicator manually
    @property
    def is_ready(self) -> bool:
        len(self.positive_money_flow) == self.positive_money_flow.maxlen
```

Create Indicators

You must define a custom indicator before you can create an instance of it.

To create a custom indicator, call the indicator constructor.

```py
self.custom_sma = CustomSimpleMovingAverage("My SMA", 10)
```

Updates

The process to update custom indicators is the same process you use to update manual indicators. If you update your custom indicator manually , you must set the `current` attribute, define the `is_ready` property, and call the `on_updated` method in the `update` method to trigger update events . When you register your custom indicator for automatic updates , these attributes are set automatically.

Warm Up Indicators

The process to warm up custom indicators is the same process you use to warm up manual indicators .

Examples

The following examples demonstrate some common practices for implementing custom indicators.

Example 1: Multiple Symbol Custom Indicator

The following algorithm implements a custom Cointegration price divergence indicator involving 2 symbols: GOOGL & GOOG. It trades the arbitrage between 2 cointegrated stocks on their price convergence after deviating more than 2 standard deviations.

```py
from sklearn.linear_model import LinearRegression
from statsmodels.tsa.stattools import adfuller

class CustomIndicatorsAlgorithm(QCAlgorithm):
```

```
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Request 2 classes of Google stock data to feed the indicators to generate trade signals and trade.
        goog1 = self.add_equity("GOOGL").symbol
        goog2 = self.add_equity("GOOG").symbol

        # Create a custom money flow index to generate a trade signal.
        self.cointegration = Cointegration(self, goog1, goog2, 252, self.date_rules.month_start())
        # Add a handler to trade on updates.
        self.cointegration.updated += self.on_updated
        # Register the indicator to update automatically with daily data.
        self.register_indicator(goog1, self.cointegration, Resolution.DAILY)
        self.register_indicator(goog2, self.cointegration, Resolution.DAILY)

        # Warm up for immediate usage of indicators.
        self.warm_up_indicator(goog1, self.cointegration, Resolution.DAILY)
        self.warm_up_indicator(goog2, self.cointegration, Resolution.DAILY)

    def on_updated(self, sender: object, point: IndicatorDataPoint) -> None:
        if sender.is_ready:
            holding = self.portfolio[self.cointegration.symbol1]

            # If the residual is lower than -2x SD, it means class A price is much higher than what it should be compared to class C.
            # We sell class A and buy class C to bet on their price convergence.
            if point.value < -2 and not holding.is_short:
                self.set_holdings(self.cointegration.symbol1, -0.5)
                self.set_holdings(self.cointegration.symbol2, 0.5 * self.cointegration.ratio)
            # If the residual is higher than the threshold, it means class A price is much lower than what it should be compared to class
C.
            # We buy class A and sell class C to bet on their price convergence.
            elif point.value > 2 and not holding.is_long:
                self.set_holdings(self.cointegration.symbol1, 0.5)
                self.set_holdings(self.cointegration.symbol2, -0.5 * self.cointegration.ratio)
            # Close positions of the price are converged.
            elif (holding.is_short and point.value > 0) or (holding.is_long and point.value < 0):
                self.liquidate()

class Cointegration(PythonIndicator):
    # The standard deviation of the residuals is such that the returned indicator value is relative to the SD.
    _residual_sd = 1e10
    # Store the coefficient and intercept of the cointegrated series for calculating the spread of a new data point.
    _coefficients = [0, 0]
    _windows = {}

    @property
    def ratio(self) -> float:
        return self._coefficients[0]

    @property
    def is_ready(self) -> bool:
        return all(window.is_ready for window in self._windows.values()) and all(x != 0 for x in self._coefficients)

        self.symbol2 = symbol2
        self.value = 0

        # Use rolling windows to save the price data for cointegration analysis.
        self._windows[symbol1] = RollingWindow(period)
        self._windows[symbol2] = RollingWindow(period)

        # Adjust the cointegration factor between the 2 classes' price series.
        algorithm.schedule.on(
            recalibrating_date_rule,
            algorithm.time_rules.at(23, 59),
            self.calculate_cointegration
        )

        self.warm_up_period = period

    def update(self, input: BaseData) -> bool:
        # Update the rolling windows for cointegration analysis.
        window = self._windows.get(input.symbol)
        if not window:
            raise Exception(f"{input.Symbol} is not part of the Cointegration relation.")
        window.add(IndicatorDataPoint(input.symbol, input.end_time, input.value))

        if not all(x == 0 for x in self._coefficients):
            # Calculate the updated cointegrated series spread only if all symbol data points are updated.
            if all(window[0].end_time == input.end_time for window in self._windows.values()):
                self.value = (self._coefficients[0] * self._windows[self.symbol2][0].value + self._coefficients[1] -
self._windows[self.symbol1][0].value) / self._residual_sd

        return self.is_ready

    def calculate_cointegration(self) -> None:
        # Lag direction is unimportant; it is just a sign flip in the linear regression, so we don't need to flip the window order.
        y = np.array([x.value for x in self._windows[self.symbol1]]).reshape(-1, 1)
        x = np.array([x.value for x in self._windows[self.symbol2]]).reshape(-1, 1)
```

```
        # Perform Linear Regression on both price series to investigate their relationship.
        lr = LinearRegression().fit(x, y)
        slope = float(lr.coef_[0])
        intercept = float(lr.intercept_)

        # Calculate the residuals series to check if it is stationary, meaning if the 2 price series move together.
        residuals = y - (intercept + slope * x)

        # Check if the residuals are stationary using the augmented Dickey-Fuller test.
        # This means no unit root exists for the difference series, and the residuals are stationary.
        critical = -1.941 + -0.2686 / self.warm_up_period + -3.365 / self.warm_up_period**2 + 31.223 / self.warm_up_period**3
        adf_reject = adfuller(residuals)[0] <= -3.45
        if adf_reject:
            # If cointegrated, update the positional sizing ratio and the spread threshold of the trade trigger.
            self._coefficients = [slope, intercept]
            self._residual_sd = float(np.std(residuals))
        else:
            self._coefficients = [0, 0]
            self._residual_sd = 100000000          # An arbitrarily large number that the class A price will never reach.
```

Example 2: Custom Money Flow Index

The following algorithm implements a custom Money Flow Index indicator, and updates it manually. We estimate the supply-demand balance of SPY and trade using the average money flow direction.

```py
from collections import deque

class CustomIndicatorsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Request daily SPY data to feed the indicators to generate trade signals and trade.
        self.spy = self.add_equity("SPY").symbol

        # Create a custom money flow index to generate a trade signal.
        self.custom_mfi = CustomMoneyFlowIndex(20)

        # Warm up for immediate usage of indicators.
        self.set_warm_up(20, Resolution.DAILY)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self.spy)
        if not bar:
            return
        # Update the custom MFI with the updated trade bar to obtain the updated trade signal.
        self.custom_mfi.update(bar)
        # Don't trade until warm-up is done.
        if self.is_warming_up:
            return
        # Buy if the positive money flow is above negative, indicating demand is greater than supply, driving up the price.
        if self.custom_mfi.current.value > 50:
            self.set_holdings(self.spy, 1)
        # Sell if the positive money flow is below negative, indicating demand is less than supply, driving down the price.
        else:
            self.set_holdings(self.spy, -1)

class CustomMoneyFlowIndex(PythonIndicator):
    def __init__(self, period: int) -> None:
        super().__init__()
        self.value = 0
        self.previous_typical_price = 0
        self.negative_money_flow = deque(maxlen=period)
        self.positive_money_flow = deque(maxlen=period)

    def update(self, input: BaseData) -> bool:
        if not isinstance(input, TradeBar):
            raise TypeError('CustomMoneyFlowIndex.update: input must be a TradeBar')

        # Estimate the money flow by averaging the price multiplied by volume.
        typical_price = (input.high + input.low + input.close) / 3
        money_flow = typical_price * input.volume

        # We need to avoid double-rounding errors.
        if abs(self.previous_typical_price / typical_price - 1) < 1e-10:
            self.previous_typical_price = typical_price

        # Add the period money flow to calculate the aggregated money flow.
        self.negative_money_flow.appendleft(money_flow if typical_price < self.previous_typical_price else 0)
        self.positive_money_flow.appendleft(money_flow if typical_price > self.previous_typical_price else 0)
        self.previous_typical_price = typical_price

        positive_money_flow_sum = sum(self.positive_money_flow)
        total_money_flow = positive_money_flow_sum + sum(self.negative_money_flow)

        # Set the value to be the positive money flow ratio.
        self.value = 100
        if total_money_flow != 0:

Example 3: Custom Annualized Volatility Indicator

The following algorithm implements a custom annualized log-return volatility indicator using a rolling window of close prices. It screens a dynamic Equity universe for overbought stocks whose annualized volatility exceeds 100% and enters short positions via limit orders using an equal-weight allocation, exiting when the Connors Relative Strength Index reverts below the exit threshold.

Indicators

Indicator Universes

Introduction

An indicator universe uses technical indicators to determine the constituents of the universe. Imagine a universe that only contains assets above their 10-day simple moving average. You can incorporate indicators into any of the types of universes in the Universes chapter . To create an indicator universe, define a helper class that contains the indicators and then define a universe that updates the indicators and selects assets.

Define SymbolData Objects

To make it easy to create and update indicators for each security in the universe, move the indicator logic into a class. In the universe definition, you can create an instance of this class for each security in the universe. The indicators you create in this class should be manual indicators so you can ensure they only update during universe selection.

```py
class SymbolData(object):
    def __init__(self, symbol):
        self._symbol = symbol
        self.tolerance = 1.01
        self.fast = ExponentialMovingAverage(100)
        self.slow = ExponentialMovingAverage(300)
        self.is_uptrend = False
        self.scale = 0

    def update(self, time, value):
        if self.fast.update(time, value) and self.slow.update(time, value):
            fast = self.fast.current.value
            slow = self.slow.current.value
            self.is_uptrend = fast > slow * self.tolerance

        if self.is_uptrend:
            self.scale = (fast - slow) / ((fast + slow) / 2.0)
```

You need to use a `SymbolData` class instead of assigning the indicators to the `Fundamental` object because you can't create custom attributes on `Fundamental` objects like you can with `Security` objects.

Define the Universe

You need to define SymbolData objects before you define the universe that selects securities.

When your universe function receives an object that contains all the possible securities, create a `SymbolData` object for each new security and update the remaining `SymbolData` objects with their daily price or some other data point. For example, the following universe definition selects US Equities that have the greatest difference between two moving averages.

```
class EmaCrossUniverseSelectionAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        '''Initialise the data and resolution required, as well as the cash and start-end dates for your algorithm. All algorithms must
initialized.'''

        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.universe_settings.asynchronous = True
        self.universe_settings.resolution = Resolution.DAILY
        self.universe_settings.leverage = 2

        self.count = 10
        self.averages = { }

        # this add universe method accepts two parameters:
        # - fundamental selection function: accepts an IEnumerable<Fundamental> and returns an IEnumerable<Symbol>
        self.add_universe(self.fundamental_selection_function)

    # sort the data by daily dollar volume and take the top 'NumberOfSymbols'
    def fundamental_selection_function(self, fundamental: List[Fundamental]) -> List[Symbol]:

        # We are going to use a dictionary to refer the object that will keep the moving averages
        for f in fundamental:
            if f.symbol not in self.averages:
                self.averages[f.symbol] = SymbolData(f.symbol)

            # Updates the SymbolData object with current EOD price
            avg = self.averages[f.symbol]
            avg.update(f.end_time, f.adjusted_price)

        # Filter the values of the dict: we only want up-trending securities
        values = list(filter(lambda x: x.is_uptrend, self.averages.values()))

        # Sorts the values of the dict: we want those with greater difference between the moving averages
        values.sort(key=lambda x: x.scale, reverse=True)

        for x in values[:self.count]:
            self.log('symbol: ' + str(x.symbol.value) + '  scale: ' + str(x.scale))

        # we need to return only the symbol objects
        return [ x.symbol for x in values[:self.count] ]
```

Examples

The following examples demonstrate some common practices for using indicator universes.

Example 1: Universe Selection

The following algorithm selects the stocks within 5% of the 1-year maximum price among the top 100 liquid stocks. To do so, we make use of Maximum indicator to do so. Then, we hold the stocks with price > EMA > SMA , which indicates an upward accelerating trend.

```py
class ManualIndicatorAlgorithm(QCAlgorithm):
    maximum_by_symbol = {}

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Select a popularity-based universe with indicators in a Selection function.
        self._universe = self.add_universe(self.selection)

        # Set a scheduled event to rebalance daily on the daily indicator signals.
        self.schedule.on(
            self.date_rules.every_day(),
            self.time_rules.at(9, 31),
            self.rebalance
        )

    def selection(self, fundamentals: list[Fundamental]) -> list[Symbol]:
        selected = []

        # Initially filtered for the top 100 liquid stocks first.
        filtered = sorted(fundamentals, key=lambda f: f.dollar_volume, reverse=True)[:100]

        for f in filtered:
            if f.symbol not in self.maximum_by_symbol:
                self.maximum_by_symbol[f.symbol] = Maximum(252)
                # Warm up the Maximum indicator to its readiness to use immediately.
                history = self.history[TradeBar](f.symbol, 252, Resolution.DAILY)
                for bar in history:
                    self.maximum_by_symbol[f.symbol].update(bar.end_time, bar.close)
            else:
                # Update the indicator with the last known adjusted price daily.
                self.maximum_by_symbol[f.symbol].update(f.end_time, f.adjusted_price)

            # Select to trade if the current price is within 5% of the maximum price of the last year.
            # Close to the maximum price provides evidence of high popularity for the fund to support the trend.
            if f.adjusted_price >= self.maximum_by_symbol[f.symbol].current.value * 0.95:
                selected.append(f.symbol)

        return selected

    def rebalance(self) -> None:
        def to_buy(symbol):
            security = self.securities[symbol]
            # Buy the stocks whose prices are above the EMA and the EMA is above the SMA, meaning their trend is upward accelerating.
            return security.price > security.ema.current.value > security.sma.current.value

        symbols_to_buy = [symbol for symbol in self._universe.selected if to_buy(symbol)]

        # Equally invest in the selected stocks to dissipate the capital risk evenly.
        count = len(symbols_to_buy)
        if count > 0:
            targets = [PortfolioTarget(symbol, 1 / count) for symbol in symbols_to_buy]
            # Liquidate the positions that are not on an upward trend or are not popular anymore.
            self.set_holdings(targets, liquidate_existing_holdings=True)

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for added in changes.added_securities:
            symbol = added.symbol
            # Create an EMA and an SMA manual indicator for trade signal generation.
            added.ema = ExponentialMovingAverage(20)
            added.sma = SimpleMovingAverage(20)

            # Warm up the indicators to ensure their readiness to use them immediately.
            self.warm_up_indicator(symbol, added.ema, Resolution.DAILY)
            self.warm_up_indicator(symbol, added.sma, Resolution.DAILY)

            # Subscribe to the indicators to update daily price data for updated trade signal generation.
            self.register_indicator(symbol, added.ema, Resolution.DAILY)
            self.register_indicator(symbol, added.sma, Resolution.DAILY)

        for removed in changes.removed_securities:
            # Cancel data subscription to release computation resources when leaving the universe.
            self.deregister_indicator(removed.ema)
            self.deregister_indicator(removed.sma)
```

Example 2: Reset Indicators on Corporate Actions

The following example shows how to select a universe of US Equities based on their price and SMA indicator. The `SelectionData` class keeps track of the SMA indicator for each stock in the universe dataset. When a split or dividend occurs for a stock, the data in its indicator becomes invalid because it doesn't account for the price adjustments that the split or dividend causes. The `SelectionData` class resets and warms up the indicator with the `SCALED_RAW` data normalization mode , which gives you accurate indicator values to use in your universe selection after each corporate action.

```py
class EquityIndicatorUniverseSelectionAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.settings.seed_initial_prices = True
        # Add a universe of US Equities based on an indicator.
        self._selection_data_by_symbol = {}
        self._universe = self.add_universe(self._select_assets)
        # Add a warm-up period to warm up the indicators in the universe selection.
        self.set_warm_up(timedelta(60))

    def _select_assets(self, fundamentals):
        # Update the indicator of all stocks in the universe dataset and
        # get the subset of stocks that have their indicator ready.
        ready_stocks = [
            f for f in fundamentals
            if self._selection_data_by_symbol.setdefault(f.symbol, SelectionData(self, f)).update(f)
        ]
        # As assests leave the Fundamental dataset, delete their SelectionData object.
        for symbol in self._selection_data_by_symbol.keys() - {f.symbol for f in fundamentals}:
            del self._selection_data_by_symbol[symbol]
        # During warm-up, keep the universe empty.
        if self.is_warming_up:
            return []
        # Select a subset of the stocks based on the indicator.
        # Example: 10 stocks furthest above their SMA.
        factor_by_symbol = {
            f.symbol: f.price / self._selection_data_by_symbol[f.symbol].indicator.current.value
            for f in ready_stocks
        }
        return sorted(
            {k: v for k, v in factor_by_symbol.items() if v > 0},

Rolling Window

Introduction

A `RollingWindow` is an array of a fixed-size that holds trailing data. It's more efficient to use `RollingWindow` objects to hold periods of data than to make multiple historical data requests . With a `RollingWindow` , you just update the latest data point while a `history` call fetches all of the data over the period you request. `RollingWindow` objects operate on a first-in, first-out process to allow for reverse list access semantics with positive and negative indexing. Index 0 refers to the most recent item in the window and the largest index refers to the last item in the window. Index -1 refers to the latest item as well.

Create Rolling Windows

To create rolling windows, instantiate the `RollingWindow` object with a maximum size.

```
PY
self._close_price_window = RollingWindow(4)
self._trade_bar_window = RollingWindow(2)
self._quote_bar_window = RollingWindow(2)
self._tuple_window = RollingWindow(2)
```

You can define the rolling window type with `RollingWindow[T]` , where `T` is the native or C# type of elements in the window.

```
PY
self._close_price_window = RollingWindow[float](4)
self._trade_bar_window = RollingWindow[TradeBar](2)
self._quote_bar_window = RollingWindow[QuoteBar](2)
```

The typeless version, `RollingWindow(int)` , allows for Python types. For example, `tuple` .

Add Data

To add data to a `RollingWindow` , call the `add` method.

```
PY
self._close_price_window.add(data["SPY"].close)
self._trade_bar_window.add(data["SPY"])
self._quote_bar_window.add(data["EURUSD"])
self._tuple_window.add((1, 2))
```

To update the data at a specific index, set the value for that index. If the index doesn't currently exist, it increases the size and fills the empty indices with a default value (zero or `None`).

```
PY
self._close_price_window[0] = data["SPY"].close
self._trade_bar_window[0] = data["SPY"]
self._quote_bar_window[0] = data["EURUSD"]
self._tuple_window[0] = (1, 2)
```

Warm Up

To warm up a `RollingWindow` , make a history request and then iterate through the result to add the data to the `RollingWindow` .

```
class WarmUpRollingWindowAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        spy = self.add_equity("SPY", Resolution.DAILY).symbol
        history_trade_bar = self.history[TradeBar](spy, 10, Resolution.DAILY)
        history_quote_bar = self.history[QuoteBar](spy, 10, Resolution.MINUTE)

        # Warm up the close price and trade bar rolling windows with the previous 10-day trade bar data
        close_price_window = RollingWindow(10)
        trade_bar_window = RollingWindow(10)
        for trade_bar in history_trade_bar:
            close_price_window.add(trade_bar.close)
            trade_bar_window.add(trade_bar)

        # Warm up the quote bar rolling window with the previous 10-minute quote bar data
        quote_bar_window = RollingWindow(10)
        for quote_bar in history_quote_bar:
            quote_bar_window.add(quote_bar)
```

Check Readiness

To check if a `RollingWindow` is full, use its `is_ready` flag.

```
if not self._close_price_window.is_ready:
    return
```

Adjust Size

To adjust the `RollingWindow` size, set the `size` property.

```
self._close_price_window.size = 3
self._trade_bar_window.size = 3
self._quote_bar_window.size = 3
self._tuple_window.size = 3
```

When you decrease the size, it removes the oldest values that no longer fit in the `RollingWindow` . When you explicitly increase the `size` member, it doesn't automatically add any new elements to the `RollingWindow` . However, if you set the value of an index in the `RollingWindow` and the index doesn't currently exist, it fills the empty indices with a default value (zero or `None`). For example, the following code increases the `size` to 10, sets the 10th element to 3, and sets the 4th-9th elements to the default value:

```
self._close_price_window[9] = 3
```

Access Data

`RollingWindow` objects operate on a first-in, first-out process to allow for reverse list access semantics with positive and negative indexing. Index 0 refers to the most recent item in the window and the largest index refers to the last item in the window. Index -1 refers to the latest item as well.

```
current_close = self._close_price_window[0]
previous_close = self._close_price_window[1]
oldest_close = self._close_price_window[self._close_price_window.count-1]
oldest_close = self._close_price_window[-1]   # Negative indexing
```

To get the item that was most recently removed from the `RollingWindow` , use the `most_recently_removed` property.

```
removed_close = self._close_price_window.most_recently_removed
```

Combine with Indicators

The `window` property of the indicators is a built-in `RollingWindow` that stores historical values. It holds a collection of `IndicatorDataPoint` objects, enabling quick access to the most recent historical indicator values for analysis, calculations, or comparisons in trading and financial strategies. Its

default size 2, but you can adjust its size. To warm up the indicator and its `RollingWindow`, call the `indicator_history` method with the window size as an argument.

```
class IndicatorRollingWindowAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        spy = self.add_equity("SPY").symbol
        qqq = self.add_equity("QQQ").symbol

        # Manual SMA indicator example.
        self._sma = SimpleMovingAverage(20)
        # Automatic Beta indicator example.
        self._beta = self.b(spy, qqq, 20)

        # Adjust the window size to 5 to access the previous 5 indicator data points.
        self._sma.window.size = 5
        self._beta.window.size = 5

        # Warm up the indicator and window for immediate usage.
        self.indicator_history(self._sma, spy, self._sma.window.size, Resolution.DAILY)
        # For indicators using 2+ symbols, use an iterable symbol list.
        self.indicator_history(self._beta, [spy, qqq], self._beta.window.size, Resolution.DAILY)
```

Combine with Consolidators

To store a history of consolidated bars, in the consolidation handler, add the consolidated bar to the `RollingWindow`.

```
self._consolidator.data_consolidated += self._on_data_consolidated

# Define consolidator handler function as a class method
def _on_data_consolidated(self, sender, consolidated_bar):
    self._trade_bar_window.add(consolidated_bar)
```

Market Session

The `Session` property of a `Security` object contains the open, high, low, close, volume, and open interest of trading sessions. The `Session` object is a `RollingWindow` object with size of zero by default. To enable market session tracking, set the size of the `Session` object to 2, so the previous session data is at index 1.

```
session = self.securities[self._symbol].session
session.size = 2
today_open = session.open
today_high = session.high
today_low = session.low
today_cumulative_volume = session.volume
if session.is_ready:
    yesterday_close = session[1].close
```

Increase the size of the `Session` object to store more session data. You can use cached data in the `Session` property instead of requesting historical daily data.

```
equity = self.add_equity("SPY")
# Increase the session lookback to 252 from default (0)
equity.session.size = 252
# Get all closing prices in the session history
closes = [x.close for x in session][::-1]
```

Cast to Other Types

You can cast a `RollingWindow` to a list or a DataFrame. If you cast it to a list, reverse the list so the most recent element is at the last index of the list. This is the order the elements would be in if you added the elements to the list with the `Add` method. To cast a `RollingWindow` to a DataFrame, the `RollingWindow` must contain `Slice`, `Tick`, `QuoteBar`, or `TradeBar` objects. If the `RollingWindow` contains ticks, the ticks must have unique timestamps.

```
closes = list(self._close_price_window)[::-1]  # Make sure to reverse the list.

tick_df = self.pandas_converter.get_data_frame[Tick](list(self._tick_window)[::-1])
trade_bar_df = self.pandas_converter.get_data_frame[TradeBar](list(self._trade_bar_window)[::-1])
quote_bar_df = self.pandas_converter.get_data_frame[QuoteBar](list(self._quote_bar_window)[::-1])
```

Delete Data

To remove all of the elements from a `RollingWindow` , call the `reset` method.

```
self._close_price_window.reset()
```

Examples

The following examples demonstrate some common practices for rolling windows.

Example 1: Price Actions

The following algorithm saves the trailing 3 `TradeBar` objects into a `RollingWindow` . When it identifies a volume contraction breakout price action pattern on the SPY, it buys to ride on the capital inflow. To exit positions, it places a 2% take profit and 1% stop loss order in the `on_order_event` method.

```py
class RollingWindowAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Add SPY data for signal generation and trading.
        self.spy = self.add_equity("SPY", Resolution.MINUTE).symbol

        # Set up a rolling window to hold the last 3 trade bars for price action detection as the trade signal.
        self.windows = RollingWindow(3)
        # Warm up the rolling window.
        history = self.history[TradeBar](self.spy, 3, Resolution.MINUTE)
        for bar in history:
            self.windows.add(bar)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self.spy)
        if bar:
            # Trade the price action if the previous bars fulfill a contraction breakout.
            if self.contraction_action and self.breakout(bar.close):
                self.set_holdings(self.spy, 0.5)

            # Add the current bar to the window.
            self.windows.add(bar)

    def contraction_action(self) -> None:
        # We trade contraction type price action, where the buying preesure is increasing.
        # 1. The last 3 bars are green.
        # 2. The price is increasing in trend.
        # 3. The trading volume is increasing as well.
        # 4. The range of the bars are decreasing.
        return (
            self.windows[2].close > self.windows[2].open and
            self.windows[1].close > self.windows[1].open and
            self.windows[0].close > self.windows[0].open and
            self.windows[0].close > self.windows[1].close > self.windows[2].close and
            self.windows[0].volume > self.windows[1].volume > self.windows[2].volume and
            self.windows[2].close - self.windows[2].open > self.windows[1].close - self.windows[1].open > self.windows[0].close -
self.windows[0].open
        )

    def breakout(self, current_close: float) -> None:
        # Trade breakout from contraction: the breakout should be much greater than the contracted range of the last bar.
        return current_close - self.windows[0].close > (self.windows[0].close - self.windows[0].open) * 2

    def on_order_event(self, order_event: OrderEvent) -> None:
        if order_event.status == OrderStatus.FILLED:
            if order_event.ticket.order_type == OrderType.MARKET:
                # Stop loss order at 1%.
                stop_price = order_event.fill_price * (0.99 if order_event.fill_quantity > 0 else 1.01)
                self.stop_market_order(self.spy, -self.portfolio[self.spy].quantity, stop_price)
                # Take profit order at 2%.
                take_profit_price = order_event.fill_price * (1.02 if order_event.fill_quantity > 0 else 0.98)
                self.limit_order(self.spy, -self.portfolio[self.spy].quantity, take_profit_price)
            elif order_event.ticket.order_type == OrderType.STOP_MARKET or order_event.ticket.order_type == OrderType.LIMIT:
                # Cancel open orders if stop loss or take profit order fills.
                self.transactions.cancel_open_orders()
```

Example 2: Bid-Ask Spread

The following algorithm trades the microeconomy of SPY's supply-demand relationship. It buys when the current bid-ask spread is less than average spread over the last 20 QuoteBar objects, indicating demand is approaching supply. When the spread is greater than the average, it shorts SPY. To save the last spread values, it uses a `RollingWindow` .

```py
class RollingWindowAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1);
        self.set_end_date(2024, 12, 31)

        # Add SPY data for signal generation and trading.
        self.spy = self.add_equity("SPY", Resolution.MINUTE).symbol

        # Set up a rolling window to hold the last 20 bar's bid-ask spread for trade signal generation.
        self.windows = RollingWindow(20)
        # Warm up for the rolling window with quote data.
        history = self.history[QuoteBar](self.spy, 20, Resolution.MINUTE)
        for bar in history:
            self.windows.add(bar.ask.close - bar.bid.close)

    def on_data(self, slice: Slice) -> None:
        bar = slice.quote_bars.get(self.spy)
        if bar:
            # Update the window with the current bid-ask spread.
            spread = bar.ask.close - bar.bid.close
            self.windows.add(spread)

            # Buy if the current spread is smaller than average, indicating demand is approaching supply. Buy force will drive up price.
            if spread < np.mean(list(self.windows)):
                self.set_holdings(self.spy, -0.5)
            # Short if the current spread is larger than average, indicating supply is gradually overwhelming demand.
            elif spread > np.mean(list(self.windows)):
                self.set_holdings(self.spy, 0.5)
```

Example 3: EMA Acceleration

The following algorithm trades SPY based on the direction and acceleration of its exponential moving average (EMA). It buys when the EMA is increasing and accelerating upward, indicating a strong uptrend. It short sells when the EMA is decreasing and accelerating downward, indicating a strong downtrend. To compare the current EMA value to its previous values, the algorithm utilizes the EMA's internal `RollingWindow` .

```py
class RollingWindowAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Add SPY data for trading.
        self.spy = self.add_equity("SPY", Resolution.MINUTE).symbol

        # Set up an automatic EMA indicator for trade signal generation.
        self._ema = self.ema(self.spy, 20, Resolution.DAILY)
        # Extend the size of the EMA's internal rolling window so we can access its historical values.
        self._ema.window.size = 3
        # Warm-up the indicator and its internal rolling window
        self.indicator_history(self._ema, self.spy, self._ema.window.size)

        # Schedule an event to rebalance SPY position at daily market open.
        self.schedule.on(self.date_rules.every_day(self.spy), self.time_rules.after_market_open(self.spy, 0), self.rebalance)

    def rebalance(self) -> None:
        # Buy if the current EMA is increasing with acceleration, indicating strong uptrend.
        if (self._ema.window[1].value < self._ema.current.value and
            self._ema.window[0].value - self._ema.window[1].value > self._ema.window[1].value - self._ema.window[2].value):
            self.set_holdings(self.spy, 0.5)
        # Short if the current EMA is decreasing with acceleration, indicating strong downtrend.
        elif (self._ema.window[1].value > self._ema.current.value and
            self._ema.window[0].value - self._ema.window[1].value < self._ema.window[1].value - self._ema.window[2].value):
            self.set_holdings(self.spy, -0.5)
        # Liquidate if no strong trend indicated.
        elif self.portfolio.invested:
            self.liquidate(self.spy)
```

Example 4: Market Session as History

Using `Session` instead of history requests or rolling window to cache the last 252 OHLCV bars, the following algorithm buys SPY accordingly when the market opens above the 252-day max of closing prices.

```py
class MarketSessionAsDailyHistory(QCAlgorithm):
    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        equity = self.add_equity("SPY")

        # Increase the session lookback to 252 from default (0)
        # since our strategy break out the 252-day max of closing prices
        equity.session.size = 252
        # Warm up with daily data for speed
        self.set_warm_up(equity.session.size, Resolution.DAILY)

        self.schedule.on(self.date_rules.every_day("SPY"), self.time_rules.after_market_open("SPY", 1), self.trade_break_out)

    def trade_break_out(self):
        '''Break-out strategy. If the market opens above the 252-day max of closing prices,
        allocate all in SPY. Liquidate if it opens below the mean.
        '''
        session = self.securities["SPY"].session
        # The session is ready when the number of samples is greater than the size (252)
        if self.is_warming_up or not session.is_ready:
            return

        # Create a pandas Series of the closing prices of session
        # to use the max and mean methods
        closes = pd.Series([x.close for x in session][::-1])
        _open, _max, _mean = session.open, closes.max(), closes.mean()

        # Invest all in SPY if the open break out the 252-day max and liquidate below the mean
        if _open > _max:
            self.set_holdings("SPY", 1, tag=f'{_open=:.2f}, {_max=:.2f}')
        if _open < _mean:
            self.liquidate("SPY", tag=f'{_open=:.2f}, {_mean=:.2f}')
```

Object Store

Introduction

The Object Store is a file system that you can use in your algorithms to save, read, and delete data. The Object Store is organization-specific, so you can save or read data from the same Object Store in all of your organization's projects. The Object Store works like a key-value storage system where you can store regular strings, JSON encoded strings, XML encoded strings, and bytes. You can access the data you store in the Object Store from backtests, the Research Environment, and live algorithms.

Get All Stored Data

To get all of the keys and values in the Object Store, iterate through the `object_store` property.

```
for kvp in self.object_store:
    key = kvp.key
    value = kvp.value
```

To iterate through just the keys in the Object Store, iterate through the `keys` property.

```
for key in self.object_store.keys:
    continue
```

Create Sample Data

You need some data to store data in the Object Store.

Follow these steps to create some sample data:

1. Create a `string` .

   ```
   string_sample = "My string"
   ```

2. Create a `Bytes` object.

   ```
   bytes_sample = str.encode("My String")
   ```

Save Data

The Object Store saves objects under a key-value system. If you save objects in backtests, you can access them from the Research Environment. To avoid slowing down your backtests, save data once in the `on_end_of_algorithm` event handler. In live trading, you can save data more frequently like at the end of a `train` method or after universe selection.

If you run algorithms in QuantConnect Cloud, you need storage create permissions to save data in the Object Store.

If you don't have data to store, create some sample data .

You can save `Bytes` and `string` objects in the Object Store. To store data, you need to provide a key. If you provide a key that is already in the Object Store, it will overwrite the data at that location. To avoid overwriting objects from other projects in your organization, prefix the key with your project ID. You can find the project ID in the URL of your browser when you open a project. For example, the ID of the project at quantconnect.com/project/12345 is 12345.

Strings

To save a `string` object, call the `save` or `save_string` method.

```
save_successful = self.object_store.save(f"{self.project_id}/string_key", string_sample)
```

Bytes

To save a `Bytes` object (for example, zipped data), call the `save_bytes` method.

```
save_successful = self.object_store.save_bytes(f"{self.project_id}/bytes_key", bytes_sample)

zipped_data_sample = Compression.zip_bytes(bytes(string_sample, "utf-8"), "data")
zip_save_successful = self.object_store.save_bytes(f"{self.project_id}/bytesKey.zip", zipped_data_sample)
```

Read Data

Read data from the Object Store to import algorithm variables between deployments, import data from the Research Environment, or load trained machine learning models. To read data from the Object Store, you need to provide the key you used to store the object.

You can load `Bytes` and `string` objects from the Object Store.

Before you read data from the Object Store, check if the key exists.

```
if self.object_store.contains_key(key):
    # Read data
```

Strings

To read a `string` object, call the `read` or `read_string` method.

```
string_data = self.object_store.read(f"{self.project_id}/string_key")
```

Bytes

To read a `Bytes` object, call the `read_bytes` method.

```
byte_data = self.object_store.read_bytes(f"{self.project_id}/bytes_key")
```

Delete Data

Delete objects in the Object Store to remove objects that you no longer need. If you run algorithms in QuantConnect Cloud, you need storage delete permissions to delete data from the Object Store.

To delete objects from the Object Store, call the `delete` method. Before you delete data, check if the key exists. If you try to delete an object with a key that doesn't exist in the Object Store, the method raises an exception.

```
if self.object_store.contains_key(key):
    self.object_store.delete(key)
```

To delete all of the content in the Object Store, iterate through all the stored data.

```
for kvp in self.object_store:
    self.object_store.delete(kvp.key)
```

Cache Data

When you write to or read from the Object Store, the algorithm caches the data. The cache speeds up the algorithm execution because if you try to read the Object Store data again with the same key, it returns the cached data instead of downloading the data again. The cache speeds up

execution, but it can cause problems if you are trying to share data between two nodes under the same Object Store key. For example, consider the following scenario:

1. You open project A and save data under the key `123` .
2. You open project B and save new data under the same key `123` .
3. In project A, you read the Object Store data under the key `123` , expecting the data from project B, but you get the original data you saved in step #1 instead.

   You get the data from step 1 instead of step 2 because the cache contains the data from step 1.

To clear the cache, call the `Clear` method.

```
self.object_store.clear()
```

Get File Path

To get the file path for a specific key in the Object Store, call the `get_file_path` method. If the key you pass to the method doesn't already exist in the Object Store, it's added to the Object Store.

```
file_path = self.object_store.get_file_path(key)
```

Storage Quotas

If you run algorithms locally, you can store as much data as your hardware will allow. If you run algorithms in QuantConnect Cloud, you must stay within your storage quota . To find your storage quota programmatically, use the `max_size` attribute for storage size and `max_files` attribute for the maximum number of files.

```
max_size = self.object_store.max_size
max_files = self.object_store.max_files
```

If you need more storage space, edit your storage plan .

Example for DataFrames

Follow these steps to create a DataFrame, save it into the Object Store, and load it from the Object Store:

1. Get some historical data.

   ```
   spy = self.add_equity("SPY").symbol
   df = self.history(self.securities.keys, 360, Resolution.DAILY)
   ```

2. Get the file path for a specific key in the Object Store.

   ```
   file_path = self.object_store.get_file_path("df_to_csv")
   ```

3. Call the to_csv method to save the DataFrame in the Object Store as a CSV file.

   ```
   df.to_csv(file_path)   # File size: 32721 bytes
   ```

4. Call the read_csv method to load the CSV file from the Object Store.

   ```
   reread = pd.read_csv(file_path)
   ```

pandas supports saving and loading DataFrame objects in the following additional formats:

- XML

```
file_path = self.object_store.get_file_path("df_to_xml")
df.to_xml(file_path)   # File size: 87816 bytes
reread = pd.read_xml(file_path)
```

- JSON

```
file_path = self.object_store.get_file_path("df_to_json")
df.to_json(file_path)   # File size: 125250 bytes
reread = pd.read_json(file_path)
```

- Parquet

```
file_path = self.object_store.get_file_path("df_to_parquet")
df.to_parquet(file_path)   # File size: 23996 bytes
reread = pd.read_parquet(file_path)
```

- Pickle

```
file_path = self.object_store.get_file_path("df_to_pickle")
df.to_pickle(file_path)   # File size: 19868 bytes
reread = pd.read_pickle(file_path)
```

Example for Plotting

You can use the Object Store to plot data from your backtests and live algorithm in the Research Environment. The following example demonstrates how to plot a Simple Moving Average indicator that's generated during a backtest.

1. Create a algorithm, add a data subscription, and add a simple moving average indicator.

```
class ObjectStoreChartingAlgorithm(QCAlgorithm):
    def initialize(self):
        self.add_equity("SPY")

        self._content = ''
        self._sma = self.sma("SPY", 22)
```

   The algorithm will save `self._content` to the Object Store.

2. Save the indicator data as `string` in `self._content` .

```
def on_data(self, data: Slice):
    self.plot('SMA', 'Value', self._sma.current.value)
    self._content += f'{self._sma.current.end_time},{self._sma.current.value}\n'
```

3. In the OnEndOfAlgorithm method, save the indicator data to the Object Store.

```
def on_end_of_algorithm(self):
    self.object_store.save('sma_values_python', self._content)
```

4. Open the Research Environment and create a `QuantBook` .

```
qb = QuantBook()
```

5. Read the indicator data from the Object Store.

```
content = qb.object_store.read("sma_values_python")
```

The key you provide must be the same key you used to save the object.

6. Convert the data to a pandas object and create a chart.

```
data = {}
for line in content.split('\n'):
    csv = line.split(',')
    if len(csv) > 1:
        data[csv[0]] = float(csv[1])

series = pd.Series(data, index=data.keys())
series.plot()
```

```
class ObjectStoreChartingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.add_equity("SPY", Resolution.MINUTE)

        self._content = ''
        # Create SMA indicator for referencing.
        self._sma = self.sma("SPY", 22)

    def on_data(self, data: Slice) -> None:
        # Cache the indicator data point to save it.
        self._content += f'{self._sma.current.end_time},{self._sma.current.value}\n'

    def on_end_of_algorithm(self) -> None:
        # Save the indicator values to object store for logging.
        self.object_store.save('sma_values_python', self._content)
```

Example for Logging

You can use the Object Store to log order data from your backtests and live algorithms, then analyze it in the Research Environment. The following example demonstrates how to log orders from an Exponential Moving Average (EMA) cross strategy to a text file in the Object Store.

1. Create an algorithm, add a daily equity subscription, and create two EMA indicators.

```
class ObjectStoreLoggingAlgorithm(QCAlgorithm):
    def initialize(self):
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._ema_short = self.ema(self._symbol, 10)
        self._ema_long = self.ema(self._symbol, 30)
        # Add a header row.
        self._content = 'Time,Symbol,Price,Quantity,Tag\n'
```

The algorithm saves `self._content` to the Object Store at the end of the backtest.

2. In the `OnData` method, place market orders when the EMAs cross.

```
def on_data(self, data: Slice):
    if not self._ema_short.is_ready or not self._ema_long.is_ready:
        return

    ema_short = self._ema_short.current.value
    ema_long = self._ema_long.current.value
    if ema_short > ema_long and not self.portfolio[self._symbol].is_long:
        self.market_order(self._symbol, 100, tag=f'BUY: ema-short: {ema_short:.4f} > ema-long: {ema_long:.4f}')
    elif ema_short < ema_long and not self.portfolio[self._symbol].is_short:
        self.market_order(self._symbol, -100, tag=f'SELL: ema-short: {ema_short:.4f} < ema-long: {ema_long:.4f}')
```

3. In the `OnOrderEvent` method, log each fill to the content string.

```
def on_order_event(self, order_event: OrderEvent):
    if order_event.status != OrderStatus.FILLED:
        return

    self._content += (
        f'{order_event.utc_time.strftime("%Y-%m-%d")},'
        f'{order_event.symbol},'
        f'{order_event.fill_price},'
        f'{order_event.fill_quantity},'
        f'{order_event.ticket.tag}\n'
    )
```

4. In the OnEndOfAlgorithm method, save the content to the Object Store.

```
def on_end_of_algorithm(self):
    key = f'{self.project_id}-{self.algorithm_id}.txt'
    self.object_store.save(key, self._content)
    self.log(f'Saved order log to Object Store: {key}')
```

5. Open the Research Environment and create a `QuantBook` .

```
qb = QuantBook()
```

6. Read the data from the Object Store.

```
# Replace the key with the one from your backtest log.
content = qb.object_store.read("<project-id>-<algorithm-id>.txt")
```

   The key you provide must be the same key you used to save the object. Check the backtest log for the exact key.

7. Split the content into lines.

```
lines = content.strip().split('\n')
# Display the header.
print(lines[0])
```

8. Display the first few rows (head) and last few rows (tail).

```
# Show the first 5 data rows.
for line in lines[1:6]:
    print(line)

# Show the last 5 data rows.
for line in lines[-5:]:
    print(line)
```

9. Search for all rows tagged as "BUY".

```
# Filter lines that contain "BUY".
buy_orders = [line for line in lines[1:] if 'BUY' in line]
for line in buy_orders:
    print(line)
```

```
class ObjectStoreLoggingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 1, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        # Create short and long EMA indicators.
        self._ema_short = self.ema(self._symbol, 10)
        self._ema_long = self.ema(self._symbol, 30)
        # Add a header row.
        self._content = 'Time,Symbol,Price,Quantity,Tag\n'

    def on_data(self, data: Slice) -> None:
        if not self._ema_short.is_ready or not self._ema_long.is_ready:
            return

        # Place a market order when the EMAs cross.
        ema_short = self._ema_short.current.value
        ema_long = self._ema_long.current.value
        if ema_short > ema_long and not self.portfolio[self._symbol].is_long:
            self.market_order(self._symbol, 100, tag=f'BUY: ema-short: {ema_short:.4f} > ema-long: {ema_long:.4f}')
        elif ema_short < ema_long and not self.portfolio[self._symbol].is_short:
            self.market_order(self._symbol, -100, tag=f'SELL: ema-short: {ema_short:.4f} < ema-long: {ema_long:.4f}')

    def on_order_event(self, order_event: OrderEvent) -> None:
        if order_event.status != OrderStatus.FILLED:
            return

        # Log each fill as a row.
        self._content += (
            f'{order_event.utc_time.strftime("%Y-%m-%d")},'
            f'{order_event.symbol},'
            f'{order_event.fill_price},'
            f'{order_event.fill_quantity},'
            f'{order_event.ticket.tag}\n'
        )

    def on_end_of_algorithm(self) -> None:
        # Save the order log to the Object Store.
        key = f'{self.project_id}-{self.algorithm_id}.txt'
        self.object_store.save(key, self._content)
        self.log(f'Saved order log to Object Store: {key}')
```

Example of Custom Data

Follow these steps to use the Object Store as a data source for custom data :

1. Create a custom data class that defines a storage key and implements the `get_source` method.

```
class Bitstamp(PythonData):
    KEY = 'bitstampusd.csv'
    def get_source(self, config, date, isLiveMode):
        return SubscriptionDataSource(Bitstamp.KEY, SubscriptionTransportMedium.OBJECT_STORE)
```

2. Create an algorithm that downloads data from an external source and saves it to the Object Store .

```
class ObjectStoreCustomDataAlgorithm(QCAlgorithm):
    def initialize(self):
        if not self.object_store.contains_key(Bitstamp.KEY):
            url = "https://raw.githubusercontent.com/QuantConnect/Documentation/master/Resources/datasets/custom-
data/bitstampusd.csv"
            content = self.download(url)
            self.object_store.save(Bitstamp.KEY, content)
```

3. Call the `add_data` method to subscribe to the custom type .

```
class ObjectStoreCustomDataAlgorithm(QCAlgorithm):
    def initialize(self):
        self.custom_data_symbol = self.add_data(Bitstamp, "BTC").symbol
```

4. Implement the `Reader` method for the custom data class.

```
class Bitstamp(PythonData):
    def reader(self, config, line, date, isLiveMode):
        # Example Line Format:
        # Date      Open   High    Low     Close   Volume (BTC)    Volume (Currency)   Weighted Price
        # 2011-09-13 5.8    6.0     5.65    5.97    58.37138238,    346.0973893944      5.929230648356
        if not line[0].isdigit():
            return None

        coin = Bitstamp()
        coin.symbol = config.symbol
        data = line.split(',')

        # If value is zero, return None
        coin.value = float(data[4])
        if coin.value == 0:
            return None

        coin.time = datetime.strptime(data[0], "%Y-%m-%d")
        coin.end_time = coin.time + timedelta(1)
        coin["Open"] = float(data[1])
        coin["High"] = float(data[2])
        coin["Low"] = float(data[3])
        coin["Close"] = coin.value
        coin["VolumeBTC"] = float(data[5])
        coin["VolumeUSD"] = float(data[6])
        coin["WeightedPrice"] = float(data[7])
        return coin
```

5. To confirm your algorithm is receiving the custom data, request some historical data , then log and plot the data from the `Slice` object.

```
class ObjectStoreCustomDataAlgorithm(QCAlgorithm):
    def initialize(self):
        history = self.history(Bitstamp, self.custom_data_symbol, 200, Resolution.DAILY)
        self.debug(f"We got {len(history)} items from historical data request of {self.custom_data_symbol}.")
    def on_data(self, slice):
        data = slice.get(Bitstamp).get( self.custom_data_symbol)
        if not data:
            return

        self.log(f'{data.end_time}: Close: {data.close}')
        self.plot(self.custom_data_symbol, 'Price', data.close)
```

The following algorithm provides a full example of a sourcing custom data from the Object Store:

```
class ObjectStoreCustomDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2012, 9, 13)
        self.set_end_date(2021, 6, 20)
        self.set_cash(100000)

        # Load the custom data from ObjectStore.
        if not self.object_store.contains_key(Bitstamp.KEY):
            url = "https://raw.githubusercontent.com/QuantConnect/Documentation/master/Resources/datasets/custom-data/bitstampusd.csv"
            content = self.download(url)
            self.object_store.save(Bitstamp.KEY, content)

        # Request custom data for plotting.
        # Define the symbol and "type" of our generic data.
        self.custom_data_symbol = self.add_data(Bitstamp, "BTC").symbol

        # Example historical call.
        history = self.history(Bitstamp, self.custom_data_symbol, 200, Resolution.DAILY)
        self.debug(f"We got {len(history)} items from historical data request of {self.custom_data_symbol}.")

    def on_data(self, slice: Slice) -> None:
        # Plot on updated data.
        data = slice.get(Bitstamp).get(self.custom_data_symbol)
        if not data:
            return

        self.log(f'{data.end_time}: Close: {data.close}')
        self.plot(self.custom_data_symbol, 'Price', data.close)

class Bitstamp(PythonData):
    KEY = 'bitstampusd.csv'
    def get_source(self, config, date, isLiveMode):
        # Load data from object store.
        return SubscriptionDataSource(Bitstamp.KEY, SubscriptionTransportMedium.OBJECT_STORE)

    def reader(self, config, line, date, isLiveMode):
        # Example Line Format:
        # Date      Open   High    Low     Close   Volume (BTC)    Volume (Currency)   Weighted Price
        # 2011-09-13 5.8    6.0     5.65    5.97    58.37138238,    346.0973893944      5.929230648356
        if not line[0].isdigit():
            return None

        coin = Bitstamp()
        coin.symbol = config.symbol
        data = line.split(',')

        # If value is zero, return None
        coin.value = float(data[4])
        if coin.value == 0:
            return None

        coin.time = datetime.strptime(data[0], "%Y-%m-%d")
        coin.end_time = coin.time + timedelta(1)
        coin["Open"] = float(data[1])
        coin["High"] = float(data[2])
        coin["Low"] = float(data[3])
        coin["Close"] = coin.value
        coin["VolumeBTC"] = float(data[5])
        coin["VolumeUSD"] = float(data[6])
        coin["WeightedPrice"] = float(data[7])
        return coin
```

Preserve Insights Between Deployments

Follow these steps to use the Object Store to preserve the algorithm state across live deployments:

1. Create an algorithm that defines a storage key and adds insights to the Insight Manager .

```
class ObjectStoreChartingAlgorithm(QCAlgorithm):
    def initialize(self):
        self.insight_key = f"{self.project_id}/insights"
        self.set_universe_selection(ManualUniverseSelectionModel([ Symbol.create("SPY", SecurityType.EQUITY, Market.USA) ]))
        self.set_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(5), 0.025, None))
```

2. At the top of the algorithm file, add the following imports:

```
from Newtonsoft.Json import JsonConvert
from System.Collections.Generic import List
```

`Insight` objects are C# objects, so you need the preceding C# libraries to serialize and deserialize them.

3. In the on_end_of_algorithm event handler of the algorithm, get the Insight objects and save them in the Object Store as a JSON object.

```
def on_end_of_algorithm(self):
    insights = self.insights.get_insights(lambda x: x.is_active(self.utc_time))
    content = ','.join([JsonConvert.SerializeObject(x) for x in insights])
    self.object_store.save(self.insight_key, f'[{content}]')
```

4. At the bottom of the `initialize` method, read the Insight objects from the Object Store and add them to the Insight Manager .

```
if self.object_store.contains_key(self.insight_key):
    insights = JsonConvert.DeserializeObject[List[Insight]](
        self.object_store.read(self.insights_key)
    )
    self.insights.add_range(insights)
```

The following algorithm provides a full example of preserving the Insight state between deployments:

```
from Newtonsoft.Json import JsonConvert
from System.Collections.Generic import List

class ObjectStoreInsightsAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.universe_settings.resolution = Resolution.DAILY

        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        self.insights_key = f"{self.project_id}/insights"

        # Read the file with the insights
        if self.object_store.contains_key(self.insights_key):
            # Load cached JSON key value pair from object store, then add to algorithm insights.
            insights = JsonConvert.DeserializeObject[List[Insight]](
                self.object_store.read(self.insights_key)
            )
            self.log(f"Read {len(insights)} insight(s) from the Object Store")
            self.insights.add_range(insights)

            # Delete the key to reuse it
            self.object_store.delete(self.insights_key)

        self.set_universe_selection(ManualUniverseSelectionModel([ Symbol.create("SPY", SecurityType.EQUITY, Market.USA) ]))
        self.set_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(5), 0.025, None))
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel(Resolution.DAILY))

    def on_end_of_algorithm(self) -> None:
        # Get all active insights.
        insights = self.insights.get_insights(lambda x: x.is_active(self.utc_time))
        # If we want to save all insights (expired and active), we can use
        # insights = self.insights.get_insights(lambda x: True)
        self.log(f"Save {len(insights)} insight(s) to the Object Store.")
        content = ','.join([JsonConvert.SerializeObject(x) for x in insights])
        self.object_store.save(self.insights_key, f'[{content}]')
```

Live Trading Considerations

If you update the Object Store from outside of your live trading node and then try to read the new content from inside your live trading algorithm, you may not get the new content because the Object Store caches data to speed up execution. To ensure you get the latest value for a specific key in the Object Store, clear the cache and then read the data .

```
self.object_store.clear()
if self.object_store.contains_key(key):
    value = self.object_store.read(key)
```

Optimization

Optimization

Parameters

Introduction

Parameters are project variables that your algorithm uses to define the value of internal variables like indicator arguments or the length of lookback windows. Parameters are stored outside of your algorithm code, but we inject the values of the parameters into your algorithm when you run a backtest, deploy a live algorithm, or launch an optimization job. To use parameters, set some parameters in your project and then load them into your algorithm.

Set Parameters

The process to set parameter values depends on the environment you use to write algorithms. See the tutorial in one of the following environments:

- Cloud Platform
- Local Platform
- LEAN CLI

Get Parameters

To get a parameter value into your algorithm, call the `get_parameter` method of the algorithm class.

```py
# Get the parameter string-value with this matching key.
# Project parameters are useful for optimization or securing variables outside the source-code.
parameter_value = self.get_parameter("Parameter Name")
```

The `get_parameter` method returns a string by default. If you provide a default parameter value, the method returns the parameter value as the same data type as the default value. If there are no parameters in your project that match the name you pass to the method and you provide a default value to the method, it returns the default value. The following table describes the arguments the `get_parameter` method accepts:

Argument	Data Type	Description	Default Value
`name`	`str`	The name of the parameter to get	
`default_value`	`str/int/double`	The default value to return	`None`

The following example algorithm gets the values of parameters of each data type:

```py
# Example to get the values of parameters of each data type:
class ParameterizedAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # Get the parameter value and return an integer.
        int_parameter_value = self.get_parameter("int_parameter_name", 100)

        # Get the parameter value and return a double.
        float_parameter_value = self.get_parameter("float_parameter_name", 0.95)

        # Get the parameter value as a string.
        string_parameter_value = self.get_parameter("parameter_name", "default_string_value")

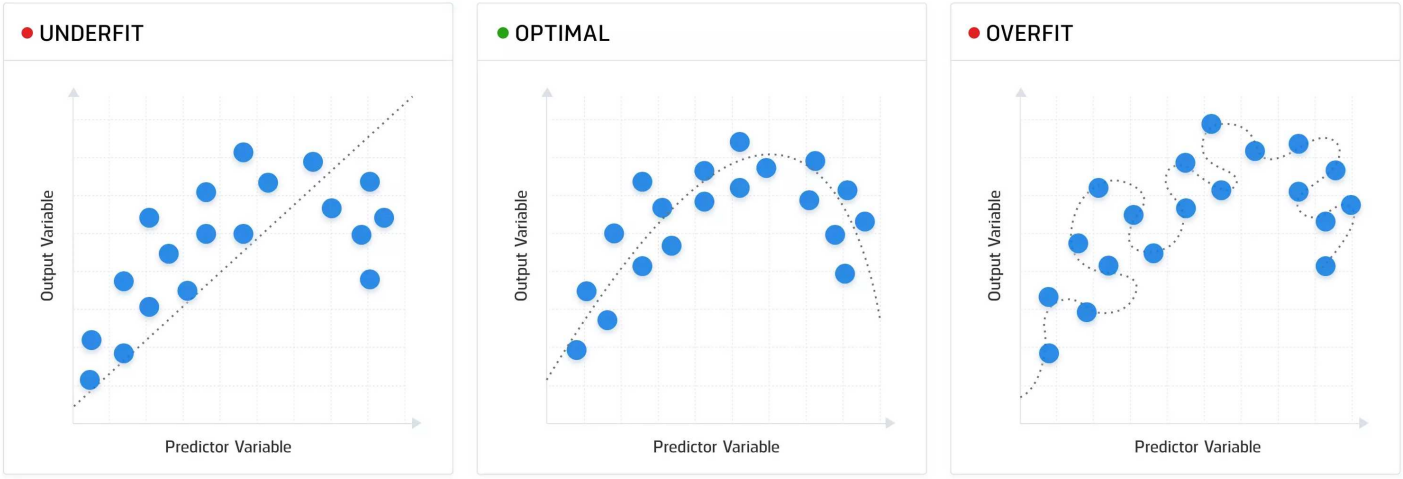
        # Cast the string to an integer.
        parameter_value = int(string_parameter_value)
```

The parameter values are sent to your algorithm when you deploy the algorithm, so it's not possible to change the parameter values while the

algorithm runs.

Overfitting

Overfitting occurs when a function is fit too closely fit to a limited set of training data. Overfitting can occur in your trading algorithms if you have many parameters or select parameters values that worked very well in the past but are sensitive to small changes in their values. In these cases, your algorithm will likely be fine-tuned to fit the detail and noise of the historical data to the extent that it negatively impacts the live performance of your algorithm. The following image shows examples of underfit, optimally-fit, and overfit functions:



An algorithm that is dynamic and generalizes to new data is more likely to survive across different market conditions and apply to other markets.

Look-Ahead Bias

Look-ahead bias occurs when an algorithm makes decisions using data that would not have yet been available. For instance, in optimization jobs, you optimize a set of parameters over a historical backtesting period. After the optimizer finds the optimal parameter values, the backtest period becomes part of the in-sample data. If you run a backtest over the same period using the optimal parameters, look-ahead bias has seeped into your research. In reality, it would not be possible to know the optimal parameters during the testing period until after the testing period is over. To avoid issues with look-ahead bias, optimize on older historical data and test the optimal parameter values on recent historical data. Alternatively, apply walk forward optimization to optimize the parameters on smaller batches of history.

Live Trading Considerations

To update parameters in live mode, add a Schedule Event that downloads a remote file and uses its contents to update the parameter values.

```py
def initialize(self):
    self.parameters = { }
    if self.live_mode:
        def download_parameters():
            content = self.download(url_to_remote_file)
            # Convert content to self.parameters

        self.schedule.on(self.date_rules.every_day(), self.time_rules.every(timedelta(minutes=1)), download_parameters)
```

Examples

The following examples demonstrate common practices for using optimization parameters.

Example 1: Bond Candidate Selection

The following algorithm holds a 60/40 stock-bond portfolio rebalancing monthly. To select the best bond ETF to act as a proxy to trade bonds, we create a list of bond tickers and grid search the best using each to backtest. Using a `bond-id` parameter, which is an integer ranging from 0 to the list size - 1 with a step size of 1, we can perform optimization to test each of them.

```py
class OptimizationParameterAlgorithm(QCAlgorithm):
    # A list of bond ETFs as candidates to trade as bond proxies.
    _bond_list = [
        "TLT", "IEF", "SHY", "VCSH", "VCLT"
    ]

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Get the bond candidate to be tested.
        bond_id = self.get_parameter("bond-id", 0)

        # Request SPY and the selected bond data for trading.
        self.spy = self.add_equity("SPY", Resolution.MINUTE).symbol
        self.bond = self.add_equity(self._bond_list[bond_id], Resolution.MINUTE).symbol

        # Rebalance for a stock-bond portfolio monthly.
        self.schedule.on(
            self.date_rules.month_start(self.spy),
            self.time_rules.after_market_open(self.spy, 1),
            self.rebalance
        )

    def rebalance(self) -> None:
        # Hold an all-weather stock-bond 60/40 portfolio.
        self.set_holdings(self.spy, 0.6)
        self.set_holdings(self.bond, 0.4)
```

Example 2: Test Different Period

This algorithm holds SPY for the whole day following the direction from the previous day. To test which period is the most effective for this momentum-following strategy, we can set an `offset` parameter and adjust the backtest period accordingly.

```py
from dateutil.relativedelta import relativedelta
class OptimizationParameterAlgorithm(QCAlgorithm):
    last_price = 0

    def initialize(self) -> None:
        # Get the number of months to offset the start date.
        offset = self.get_parameter("offset", 0)
        # Create a variable start date with offset to test which periods the algorithm performs better.
        start_date = datetime(2024, 1, 1)
        self.set_start_date(start_date + relativedelta(months=offset))
        # One-month fixed period test per backtest.
        self.set_end_date(self.start_date + relativedelta(months=1))

        # Request daily SPY data for trading.
        self.spy = self.add_equity("SPY", Resolution.DAILY).symbol

        self.set_warm_up(1)

    def on_data(self, slice: Slice) -> None:
        # Trade based on updated data.
        bar = slice.bars.get(self.spy)
        if bar:
            # Trade with riding on the last day's momentum.
            if self.last_price != 0 and bar.close > self.last_price and not self.portfolio[self.spy].is_long:
                self.set_holdings(self.spy, 0.5)
            elif self.last_price != 0 and bar.close < self.last_price and not self.portfolio[self.spy].is_short:
                self.set_holdings(self.spy, -0.5)

            self.last_price = bar.close
```

Example 3: Hyperparameter Tuning

The following example algorithm demonstrates an EMA cross strategy. To optimize for the best setup to attain the greatest Sharpe Ratio, the algorithm grid searches the best hyperparameters (the EMA periods) that do so.

```py
class ParameterizedAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2020, 1, 1)
        self.set_end_date(2024, 12, 31);
        self.set_cash(100000)
        # For warming up indicators.
        self.settings.automatic_indicator_warm_up = True

        # Request SPY data to feed the indicator and trade.
        self.spy = self.add_equity("SPY").symbol

        # Get and store the EMA settings to local parameters.
        fast_period = self.get_parameter("ema-fast", 50)
        slow_period = self.get_parameter("ema-slow", 200)

        # Set up the 2 EMA indicators for trade signal generation with the fast and slow periods from parameters.
        self._fast = self.ema("SPY", fast_period, Resolution.DAILY)
        self._slow = self.ema("SPY", slow_period, Resolution.DAILY)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self.spy)
        if bar:
            # Following the uptrend indicated by price up in nearer periods.
            if bar.close > self._fast.current.value > self._slow.current.value:
                self.set_holdings(self.spy, 0.5)
            # Following the downtrend indicated by price down in nearer periods.
            elif bar.close < self._fast.current.value < self._slow.current.value:
                self.set_holdings(self.spy, -0.5)
            # Liquidate if the trend is not strong.
            else:
                self.liquidate()
```

Optimization

Walk Forward Optimization

Introduction

Walk forward optimization is the practice of periodically adjusting the logic or parameters of a strategy to optimize some objective function over a trailing window of time. For example, say your strategy is to hold a long position when an asset is trading above its simple moving average (SMA) and to hold a short position when it's trading below the SMA. If your objective is to maximize returns, how many trailing data points should you use to compute the SMA?

Benefits

The parameter values that maximize your algorithm's performance are typically a function of the start and end dates of your training dataset. Market conditions change over time and a strategy that works well during one period may not perform as well during another. By continually adjusting the strategy parameters based on recent data, walk-forward optimization tailors your strategy to the latest market trends and patterns.

Optimization Frequency

There is a tradeoff when it comes to how often you optimize your algorithm's parameters. On one hand, if you frequently optimize your parameters, your parameters will be fit to the most recent, most meaningful market data. On the other hand, if you wait a long time between optimization sessions, your algorithm will run faster and you reduce the chance of overfitting. To define your optimization schedule, pass DateRules and TimeRules arguments to the train method.

```
// To define the optimization schedule, pass self.date_rules and self.time_rules arguments to the train method.
symbol = Symbol.create('SPY', SecurityType.EQUITY, Market.USA)
self.train(
    self.date_rules.month_start(symbol),
    self.time_rules.midnight,
    lambda: self._do_wfo(self._optimization_func, max, objective)
)
```

EMA Crossover Example

Follow these steps to implement walk forward optimization for an exponential moving average (EMA) crossover strategy:

1. Define the backtest dates and starting cash.

```
# Set the start date, end date, and starting cash.
def initialize(self):
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(100_000)
```

2. Enable the automatic indicator warm up setting .

```
# Set the automatic_indicator_warm_up property to true to enable automatic algorithm warm-up.
def initialize(self):
    # . . .
    self.settings.automatic_indicator_warm_up = True
```

3. Subscribe to an asset .

```
# Add daily SPY Equity data.
def initialize(self):
    # . . .
    self._security = self.add_equity("SPY", Resolution.DAILY)
    self._symbol = self._security.symbol
```

4. Add some members for the EMA indicators.

```py
# Initialize members for short and long EMA indicators.
def initialize(self):
    # . . .
    self._short_ema = None
    self._long_ema = None
```

5. Define the trading rules.

```py
# Define the trading logic.
def on_data(self, data):
    if self.is_warming_up:
        return

    # Case 1: Short EMA is above long EMA.
    if (self._short_ema > self._long_ema and
        not self._security.holdings.is_long):
        self.set_holdings(self._symbol, 1)
    # Case 2: Short EMA is below long EMA.
    elif (self._short_ema < self._long_ema and
            not self._security.holdings.is_short):
        self.set_holdings(self._symbol, 0)
```

6. Define a method that will adjust the algorithm's behavior, given a set of optimal parameters.

```py
# Define a method to adjust the algorithm's behavior based on the new optimal parameters.
def _update_algorithm_logic(self, optimal_parameters):
    # Remove the old indicators.
    if self._short_ema:
        self.deregister_indicator(self._short_ema)
    if self._long_ema:
        self.deregister_indicator(self._long_ema)
    # Create the new indicators.
    self._short_ema = self.ema(
        self._symbol, optimal_parameters['short_ema'], Resolution.DAILY
    )
    self._long_ema = self.ema(
        self._symbol, optimal_parameters['long_ema'], Resolution.DAILY
    )
```

7. Back in `initialize` method, generate all the possible combinations of parameter values.

```py
# In the initialize method, generate all possible combinations of parameter values.
import itertools

def initialize(self):
    # . . .
    self._parameter_sets = self._generate_parameter_sets(
        {
            'short_ema': (10, 50, 10),  # min, max, step
            'long_ema': (60, 200, 10)
        }
    )
    # . . .

def _generate_parameter_sets(self, search_space):
    # Create ranges for each parameter.
    ranges = {
        parameter_name: np.arange(min_, max_ + step_size, step_size)
        for parameter_name, (min_, max_, step_size) in search_space.items()
    }

    # Calculate the cartesian product and create a list of dictionaries for
    # the parameter sets.
    return [
        dict(zip(ranges.keys(), combination))
        for combination in list(itertools.product(*ranges.values()))
    ]
```

8. Define the objective function.

```py
# Define an objective function to optimize the algorithm's overall performance.
def initialize(self):
    # . . .
    objective = self._cumulative_return
    # . . .

def _cumulative_return(self, daily_returns):
    return (daily_returns + 1).cumprod()[-1] - 1
```

9. Define the optimization function.

```py
# Evaluate parameter sets with the objective function.
def _optimization_func(self, data, parameter_set, objective):
    p1 = parameter_set['short_ema']
    p2 = parameter_set['long_ema']
    short_ema = data['close'].ewm(p1, min_periods=p1).mean()
    long_ema = data['close'].ewm(p2, min_periods=p2).mean()
    exposure = (short_ema - long_ema).dropna().apply(np.sign)\
        .replace(0, pd.NA).ffill().shift(1)
    # ^ shift(1) because we enter the position on the next day.
    asset_daily_returns = data['open'].pct_change().shift(-1)
    # ^ shift(-1) because we want each entry to be the return from
    # the current day to the next day.
    strategy_daily_returns = (exposure * asset_daily_returns).dropna()
    return objective(strategy_daily_returns)
```

10. Schedule the optimization sessions.

```py
# Schedule the WFO process to run at the start of each month at midnight.
def initialize(self):
    # . . .
    self.train(
        self.date_rules.month_start(self._symbol),
        self.time_rules.midnight,
        lambda: self._do_wfo(self._optimization_func, max, objective)
    )
    # . . .

def _do_wfo(self, optimization_func, min_max, objective):
    # Get the historical data you need to calculate the scores.
    prices = self.history(
        self._symbol, timedelta(365), Resolution.DAILY
    ).loc[self._symbol]

    # Calculate the score of each parameter set.
    scores = [
        optimization_func(prices, parameter_set, objective)
        for parameter_set in self._parameter_sets
    ]

    # Find the parameter set that minimizes/maximizes the objective function.
    optimal_parameters = self._parameter_sets[scores.index(min_max(scores))]

    # Adjust the algorithm's logic.
    self._update_algorithm_logic(optimal_parameters)
```

11. Add a warm-up period .

    The warm-up period ensures that the algorithm calls the `_do_wfo` method at least one time before the algorithm starts trading.

```py
# Set the warm-up period.
def initialize(self):
    # . . .
    self.set_warm_up(timedelta(45))
```

The following algorithm combines the code snippets above into a single algorithm:

```py
# region imports
from AlgorithmImports import *
import itertools
# endregion

# Walk forward optimization with an EMA crossover strategy on SPY.
class WalkForwardOptimizationEmaAlgorithm(QCAlgorithm):
    def initialize(self):
```

```
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100_000)
        self.settings.automatic_indicator_warm_up = True
        self._security = self.add_equity("SPY", Resolution.DAILY)
        self._symbol = self._security.symbol
        self._short_ema = None
        self._long_ema = None
        # Generate all possible combinations of parameter values.
        self._parameter_sets = self._generate_parameter_sets(
            {
                'short_ema': (10, 50, 10),  # min, max, step
                'long_ema': (60, 200, 10)
            }
        )
        # Schedule the WFO process to run at the start of each month.
        objective = self._cumulative_return
        self.train(
            self.date_rules.month_start(self._symbol),
            self.time_rules.midnight,
            lambda: self._do_wfo(self._optimization_func, max, objective)
        )
        self.set_warm_up(timedelta(45))

    def on_data(self, data):
        if self.is_warming_up:
            return
        # Case 1: Short EMA is above long EMA.
        if (self._short_ema > self._long_ema and
            not self._security.holdings.is_long):
            self.set_holdings(self._symbol, 1)
        # Case 2: Short EMA is below long EMA.
        elif (self._short_ema < self._long_ema and
                not self._security.holdings.is_short):
            self.set_holdings(self._symbol, 0)

    def _update_algorithm_logic(self, optimal_parameters):
        # Remove the old indicators.
        if self._short_ema:
            self.deregister_indicator(self._short_ema)
        if self._long_ema:
            self.deregister_indicator(self._long_ema)
        # Create the new indicators.
        self._short_ema = self.ema(
            self._symbol, int(optimal_parameters['short_ema']), Resolution.DAILY
        )
        self._long_ema = self.ema(
            self._symbol, int(optimal_parameters['long_ema']), Resolution.DAILY
        )

    def _generate_parameter_sets(self, search_space):
        # Create ranges for each parameter.
        ranges = {
            parameter_name: np.arange(min_, max_ + step_size, step_size)
            for parameter_name, (min_, max_, step_size) in search_space.items()
        }
        # Calculate the cartesian product.
        return [
            dict(zip(ranges.keys(), combination))
            for combination in list(itertools.product(*ranges.values()))
        ]

    def _cumulative_return(self, daily_returns):
        return (daily_returns + 1).cumprod()[-1] - 1

    def _optimization_func(self, data, parameter_set, objective):
        p1 = parameter_set['short_ema']
        p2 = parameter_set['long_ema']
        short_ema = data['close'].ewm(p1, min_periods=int(p1)).mean()
        long_ema = data['close'].ewm(p2, min_periods=int(p2)).mean()
        exposure = (short_ema - long_ema).dropna().apply(np.sign)\
            .replace(0, pd.NA).ffill().shift(1)
        asset_daily_returns = data['open'].pct_change().shift(-1)
        strategy_daily_returns = (exposure * asset_daily_returns).dropna()
        return objective(strategy_daily_returns)

    def _do_wfo(self, optimization_func, min_max, objective):
        # Get the historical data to calculate the scores.
        prices = self.history(
            self._symbol, timedelta(365), Resolution.DAILY
        ).loc[self._symbol]
        # Calculate the score of each parameter set.
        scores = [
            optimization_func(prices, parameter_set, objective)
            for parameter_set in self._parameter_sets
        ]
        # Find the parameter set that maximizes the objective function.
        optimal_parameters = self._parameter_sets[scores.index(min_max(scores))]
        # Adjust the algorithm's logic.
        self._update_algorithm_logic(optimal_parameters)
```

Ideas

The following list provides some ideas on how you could use walk forward optimization:

1. Find the range of PE ratios that mazimize your algorithm's performance, and then use that range in your fundamental universe filter.
2. Experiment with asset universe diversity and counts.
3. Take 10 fundamental factors (PE, market cap, etc...). For each optimization session, step through and picks one factor at a time, using it as a ranking factor for the universe. Find the factor that leads to the greatest return over the lookback window and use it as the sole factor for the following month.

Machine Learning

Machine Learning

Key Concepts

Introduction

Machine learning is a field of study that combines statistics and computer science to build intelligent systems that predict outcomes. You can use machine learning techniques in your trading strategies.

Supported Libraries

LEAN supports several machine learning libraries. You can import these packages and use them in your algorithms.

Name	Version	Language	Import Statement	Examp

Add New Libraries

To request a new library, contact us . We will add the library to the queue for review and deployment. Since the libraries run on our servers, we need to ensure they are secure and won't cause harm. The process of adding new libraries takes 2-4 weeks to complete. View the list of libraries currently under review on the Issues list of the Lean GitHub repository .

Save Models

After you train a model, you can save it into the Object Store . In QuantConnect Cloud, we back up your Object Store data on QuantConnect servers. In local algorithms, your local machine saves the Object Store data. If you save models in live algorithms, save them at the end of the training method so you can access the trained model again if your algorithm stops executing. If you save models in backtests, save them during the `on_end_of_algorithm` event handler so that saving multiple times doesn't slow down your backtest.

If you train models outside of QuantConnect (for example, on your local machine), you can upload the model files to the Object Store with the LEAN CLI or the Cloud API . For library-specific upload instructions, see the Upload Models section in each Popular Libraries tutorial.

To view examples of storing library-specific models, see Popular Libraries .

Load Models

You can load machine learning models from the Object Store or a custom data file like pickle. If you load models from the Object Store, before you load the model into your algorithm, in the `initialize` method, check if the Object Store already contains the model. To avoid look-ahead bias in backtests, don't train your model on the same data you use to test the model.

Increase Backtest Speed

If your backtests are slow because they recalculate features and retrain models on every run, you can precompute your ML predictions in the Research Environment and save them to the Object Store . Your algorithm then streams in the precomputed predictions as a custom universe dataset, skipping all feature engineering and model inference at runtime. This pattern makes backtests significantly faster and lets you iterate on portfolio logic without rerunning the ML pipeline. For a full walkthrough, see Precomputed ML Predictions .

Library Errors

LEAN gracefully handles runtime errors that your code raises. It generally informs the location and cause of the error before the algorithm is terminated. FATAL ERROR EXCEPTION refers to a critical failure from third-party libraries, such as machine learning models, that LEAN doesn't handle.

Most QuantConnect members experience the invalid memory access error (SIGBUS) or division by zero error (SIGFPE) marked as "7 Killed" and "8 Killed" in the error message, respectively. The following sections explain some common errors and what causes them.

Memory Issues

You may experience the following memory issues:

- Out of Memory (OOM) : The process requires more memory (RAM or GPU memory) than is available, leading to a crash.
- Memory Leaks : If the program fails to properly release memoryy, it can eventually exhaust available resources.
- Invalid Memory Access : Bugs in custom C/C++ extensions, kernels, or libraries (for example, CUDA kernels for GPU acceleration) can cause misaligned memory access or invalid memory operations.

Numerical Instability

You may experience the following numerical instability errors:

- Division by Zero : This can occur due to input data with zeroes or during calculations, especially in custom loss functions or optimization algorithms.
- NaN or Infinity Values : These can arise due to data with NaN values, improper initialization, exploding gradients, or unstable mathematical operations.

Software Bugs

You may experience the following software bugs:

- Code Errors : Bugs in the implementation of the model, data preprocessing, or training loop can cause crashes.
- Library Incompatibility : Using incompatible versions of libraries (for example, TensorFlow or PyTorch) or dependencies can lead to fatal errors.

Machine Learning

Training Models

Introduction

Algorithms usually must process each timeslice within 10 minutes, but the `train` method allows you to increase this time to train machine learning models. The length of time you can train depends on your training quotas.

Train Models

To train models immediately, call the `train` method and pass in the name of your training method.

```
// Run an ML model training session and extend method call timeouts.
self.train(self.my_method)
```

Immediate training is most useful for training your model when you first deploy your strategy to production or when the model's performance begins to degrade.

Schedule Training Sessions

You can schedule model training sessions in a similar way to a Scheduled Event. To schedule a training session do this, pass in a DateRules and TimeRules argument to the `train` method.

```
# Set TrainingMethod to be executed at 8:00 am every Sunday
self.train(self.date_rules.every(DayOfWeek.SUNDAY), self.time_rules.at(8,0), self.my_training_method)
```

We recommend you schedule your training sessions for when the market is closed to get the best compute allocation. While the market is open, your CPU is occupied with processing incoming tick data and handling other LEAN events.

Training Quotas

Training resources are allocated with a leaky bucket algorithm where you can use a maximum of n-minutes in a single training session and the number of available minutes refills over time. This design gives you burst allocations when you need them and recharges the allowance to prepare for the next training.

Cloud Quotas

If you execute algorithms in QuantConnect Cloud, see Training Quotas for more information about the training quotas.

Local Quotas

If you execute algorithms locally, the following table shows the default settings for the leaky bucket algorithm:

Setting	Value
Capacity (minutes)	120
Time interval (minutes)	1440
Refill amount (minutes per time interval)	Capacity / 7

To allow virtually unlimited training for local algorithms, add the following key-value pairs to your Lean / Launcher / config.json file:

```
"scheduled-event-leaky-bucket-capacity" : 99999999,
"scheduled-event-leaky-bucket-time-interval-minutes" : 1,
"scheduled-event-leaky-bucket-refill-amount": 999999,
```

Check Model Readiness

In backtests, the `train` method is synchronous, so it blocks your algorithm execution while the model trains. In live trading, the `train` method is asynchronous, so ensure your model is trained before you continue the algorithm execution. Training occurs on a separate thread, so set a boolean flag to notify your algorithm of the model state. A semaphore is a thread-safe flag you can use to synchronize program operations across different threads.

```py
# Example of using a flag to signal the model is ready to use:
class SemaphoreTrainingAlgorithm(QCAlgorithm):

    model = None  # Model object
    model_is_training = False  # Model state flag

    def initialize(self) -> None:
        self.train(self.my_training_method)

    def my_training_method(self) -> None:
        self.model_is_training = True
        # Train the model here.
        self.model_is_training = False

    def on_data(self, slice: Slice) -> None:
        # Don't use the model while it is training.
        if self.model_is_training:
            return

        # Once training is complete, use the model.
        result = self.model.predict()
```

Examples

The following examples demonstrate some common practices for training the machine learning model.

Example 1: Scikit-Learn

The below algorithm makes use of `Scikit-Learn` library to predict the future price movement using the previous 5 OHLCV data. The model is trained using rolling 2-year data. To ensure the model applicable to the current market environment, we recalibrate the model on every Sunday.

```
from sklearn.svm import SVR
from sklearn.model_selection import GridSearchCV
import joblib

class ScikitLearnExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        self.set_cash(100000)
        # Request SPY data for model training, prediction and trading.
        self.symbol = self.add_equity("SPY", Resolution.DAILY).symbol

        # 2-year data to train the model.
        training_length = 252*2
        self.training_data = RollingWindow(training_length)
        # Warm up the training dataset to train the model immediately.
        history = self.history[TradeBar](self.symbol, training_length, Resolution.DAILY)
        for trade_bar in history:
            self.training_data.add(trade_bar)

        # Retrieve already trained model from object store to use immediately.
        if self.object_store.contains_key("sklearn_model"):
            file_name = self.object_store.get_file_path("sklearn_model")
            self.model = joblib.load(file_name)
        # Otherwise, grid serach with hyperparameter choices to create an optimal support vector regressor to predict price movement.
        else:
            param_grid = {'C': [.05, .1, .5, 1, 5, 10],
                          'epsilon': [0.001, 0.005, 0.01, 0.05, 0.1],
                          'gamma': ['auto', 'scale']}
            self.model = GridSearchCV(SVR(), param_grid, scoring='neg_mean_squared_error', cv=5)

        # Train the model to use the prediction right away.
        self.train(self.my_training_method)
        # Recalibrate the model weekly to ensure its accuracy on the updated domain.
        self.train(self.date_rules.every(DayOfWeek.SUNDAY), self.time_rules.at(8,0), self.my_training_method)

    def get_features_and_labels(self, n_steps=5) -> None:
        # Train and predict the return data, which is more normalized and stationary.
        training_df = self.pandas_converter.get_data_frame[TradeBar](list(self.training_data)[::-1])
        daily_pct_change = training_df.pct_change().dropna()

        # Stack the data for 5-day OHLCV data per each sample to train with.
        features = []
        labels = []
        for i in range(len(daily_pct_change)-n_steps):
            features.append(daily_pct_change.iloc[i:i+n_steps].values.flatten())
            labels.append(daily_pct_change['close'].iloc[i+n_steps])
        features = np.array(features)
        labels = np.array(labels)

        return features, labels

    def my_training_method(self) -> None:
        # Prepare the processed training data.
        features, labels = self.get_features_and_labels()
        # Recalibrate the model based on updated data.
        if isinstance(self.model, GridSearchCV):
            self.model = self.model.fit(features, labels).best_estimator_
        else:
            self.model = self.model.fit(features, labels)

    def on_data(self, slice: Slice) -> None:
        if self.symbol in slice.bars:
            self.training_data.add(slice.bars[self.symbol])

        # Get prediction by the updated features.
        features, _ = self.get_features_and_labels()
        prediction = self.model.predict(features[-1].reshape(1, -1))
        prediction = float(prediction)

        # If the predicted direction is going upward, buy SPY.
        if prediction > 0:
            self.set_holdings(self.symbol, 1)
        # If the predicted direction is going downward, sell SPY.
        elif prediction < 0:
            self.set_holdings(self.symbol, -1)

    def on_end_of_algorithm(self) -> None:
        # Store the model to object store to retrieve it in other instances in case the algorithm stops.
        model_key = "sklearn_model"
        file_name = self.object_store.get_file_path(model_key)
        joblib.dump(self.model, file_name)
        self.object_store.save(model_key)
```

Aesera

Introduction

This page explains how to build, train, deploy and store `Aesera` models.

To access Aesara, use the Legacy package environment. To set this environment, see the documentation in Cloud Platform or Local Platform .

Import Libraries

Import the `aesera` and `sklearn` libraries.

```
PY
from AlgorithmImports import *
import aesara
import aesara.tensor as at
from sklearn.model_selection import train_test_split
from sklearn.preprocessing import MinMaxScaler
import joblib
```

You need the `joblib` library to store models.

Create Subscriptions

In the `initialize` method, subscribe to some data so you can train the `sklearn` model and make predictions.

```
PY
# Add a security and save a reference to its Symbol.
self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
```

Build Models

In this example, build a logistic regression prediction model that uses the following features and labels:

Data Category	Description
Features	Normalized daily close price of the SPY over the last 5 days
Labels	Return direction of the SPY over the next day

The following image shows the time difference between the features and labels:

Follow the below steps to build the model:

1. Initialize variables.

```
# Declare Aesara's symbolic variables.
x = at.dmatrix("x")
y = at.dvector("y")

# Initialize a NumPy random number generator with a fixed seed for reproducibility.
rng = np.random.default_rng(100)

# Initialize the weight vector w randomly using shared so the model coefficients keep their values
# between training iterations (updates).
w = aesara.shared(rng.standard_normal(5), name="w")

# Initialize the bias term.
b = aesara.shared(0., name="b")
```

2. Construct the model graph.

```
# Construct the Aesara expression graph.
p_1 = 1 / (1 + at.exp(-at.dot(x, w) - b))           # Logistic transformation.
prediction = p_1 > 0.5                              # The prediction thresholded.
xent = y * at.log(p_1) - (1 - y) * at.log(1 - p_1)  # Cross-entropy log-loss function.
cost = xent.mean() + 0.01 * (w ** 2).sum()          # The cost to minimize (MSE).
gw, gb = at.grad(cost, [w, b])                      # Compute the gradient of the cost.
```

3. Compile the model.

```
# Define training and prediction functions with Aesara to optimize weights
# and biases during training and generate predictions.
self._train = aesara.function(
    inputs=[x, y],
    outputs=[prediction, xent],
    # Update weights and biases.
    updates=((w, w - 0.1 * gw), (b, b - 0.1 * gb)))
self.predict = aesara.function(inputs=[x], outputs=prediction)
```

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `initialize` method, make a history request .

```
# Fill a RollingWindow with 2 years of training data.
training_length = 252*2
self.training_data = RollingWindow(training_length)
history = self.history[TradeBar](self._symbol, training_length, Resolution.DAILY)
for trade_bar in history:
    self.training_data.add(trade_bar)
```

Define a Training Method

To train the model, define a method that fits the model with the training data.

```
# Prepare feature and label data for training.
def get_features_and_labels(self, n_steps=5):
    training_df = self.PandasConverter.GetDataFrame[TradeBar](list(self.training_data)[::-1])['close']

    features = []
    for i in range(1, n_steps + 1):
        close = training_df.shift(i)[n_steps:-1]
        close.name = f"close-{i}"
        features.append(close)
    features = pd.concat(features, axis=1)
    # Normalize using the 5 day interval.
    features = MinMaxScaler().fit_transform(features.T).T[4:]

    Y = training_df.pct_change().shift(-1)[n_steps*2-1:-1].reset_index(drop=True)
    labels = np.array([1 if y > 0 else 0 for y in Y])   # Binary class.

    return features, labels

def my_training_method(self):
    features, labels = self.get_features_and_labels()
    D = (features, labels)
    self._train(D[0], D[1])
```

Set Training Schedule

To train the model at the beginning of your algorithm, in the `initialize` method, call the `train` method.

```
# Train the model right now.
self.train(self.my_training_method)
```

To periodically re-train the model as your algorithm executes, in the `initialize` method, call the `train` method as a Scheduled Event .

```
# Train the model every Sunday at 8:00 AM.
self.train(self.date_rules.every(DayOfWeek.SUNDAY), self.time_rules.at(8, 0), self.my_training_method)
```

Update Training Data

To update the training data as the algorithm executes, in the `on_data` method, add the current `TradeBar` to the `RollingWindow` that holds the training data.

```
# Add the current bar to the training data to ensure the model trains with the most recent market data.
def on_data(self, slice: Slice) -> None:
    if self._symbol in slice.bars:
        self.training_data.add(slice.bars[self._symbol])
```

Predict Labels

To predict the labels of new data, in the `on_data` method, get the most recent set of features and then call the `predict` method.

```
# Get the feature set and make a prediction.
features, _ = self.get_features_and_labels()
prediction = self.predict(features[-1].reshape(1, -1))
prediction = float(prediction)
```

You can use the label prediction to place orders.

```
# Place orders based on the prediction.
if prediction == 1:
    self.set_holdings(self._symbol, 1)
elif prediction == 0:
    self.set_holdings(self._symbol, -1)
```

Save Models

Follow these steps to save `sklearn` models into the Object Store :

1. Set the key name you want to store the model under in the Object Store.

```
# Set the storage key to something representative.
model_key = f"{self.project_id}/model"
```

2. Call the `get_file_path` method with the key.

```
# Get the file path to save and access the model in the Object Store.
file_name = self.object_store.get_file_path(model_key)
```

   This method returns the file path where the model will be stored.

3. Call the `dump` method the file path.

```
# Serialize and save the model.
joblib.dump(self.predict, file_name)
```

   If you dump the model using the `joblib` module before you save the model, you don't need to retrain the model.

Upload Models

If you train models locally or in another environment, you can upload the model files to the Object Store so your algorithms can use them. Use the model key that matches the key your algorithm expects when it calls `object_store.get_file_path` .

Follow one of these approaches to upload your model files:

LEAN CLI

Run the `lean cloud object-store set` command to upload a local file to the Object Store.

```
$ lean cloud object-store set <projectId>/model <pathTo>/model
```

Replace `<projectId>` with your project Id and `<pathTo>` with the path to the local model file.

Cloud API

Use the Upload Object Store Files endpoint to upload a model file through the API.

Load Models

You can load and trade with pre-trained `sklearn` models that you saved in the Object Store. To load a `sklearn` model from the Object Store, in the `initialize` method, get the file path to the saved model and then call the `load` method.

```
# Load the trained Aesera model from the Object Store.
def initialize(self) -> None:
    model_key = f"{self.project_id}/model"
    if self.object_store.contains_key(model_key):
        file_name = self.object_store.get_file_path(model_key)
        self.model = joblib.load(file_name)
```

The `contains_key` method returns a boolean that represents if the `model_key` is in the Object Store. If the Object Store does not contain the `model_key` , save the model using the `model_key` before you proceed.

Examples

The following examples demonstrate some common practices for using `Aesera` library.

Example 1: Aesera

The below algorithm makes use of `Aesera` library to predict the future price movement using the previous 5 OHLCV data. The model is trained using rolling 2-year data. To ensure the model applicable to the current market environment, we recalibrate the model on every Sunday.

PY

```
import aesara
import aesara.tensor as at
from sklearn.model_selection import train_test_split
from sklearn.preprocessing import MinMaxScaler
import joblib

class AeseraExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Request SPY data for model training, prediction and trading.
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol

        # Use the session rolling window to cache 2-year daily data for training.
        training_length = 252*2
        self.securities[self._symbol].session.size = training_length
        self.set_warm_up(training_length, Resolution.DAILY)

        # Declare Aesara symbolic variables.
        x = at.dmatrix("x")
        y = at.dvector("y")

        # Initialize the weight vector w randomly using shared so the model coefficients keep
        # their values between training iterations (updates).
        rng = np.random.default_rng(100)
        w = aesara.shared(rng.standard_normal(5), name="w")
        # Initialize the bias term.
        b = aesara.shared(0., name="b")

        # Construct Aesara expression graph.
        p_1 = 1 / (1 + at.exp(-at.dot(x, w) - b))       # Probability that target = 1
        prediction = p_1 > 0.5                          # The prediction thresholded
        xent = y * at.log(p_1) - (1-y) * at.log(1-p_1)  # Cross-entropy log-loss function
        cost = xent.mean() + 0.01 * (w ** 2).sum()      # The cost to minimize
        gw, gb = at.grad(cost, [w, b])                  # Compute the gradient of the cost

        # Compile the model and train it later.
        self._train = aesara.function(
                inputs=[x, y],
                outputs=[prediction, xent],
                updates=((w, w - 0.1 * gw), (b, b - 0.1 * gb)))
        self.predict = aesara.function(inputs=[x], outputs=prediction)

    def on_warmup_finished(self) -> None:
        # Train the model to use the prediction right away.
        self.train(self.my_training_method)
        # Recalibrate the model weekly to ensure its accuracy on the updated domain.
        self.train(self.date_rules.every(DayOfWeek.SUNDAY), self.time_rules.at(8,0), self.my_training_method)

    def get_features_and_labels(self, n_steps=5) -> None:
        # Train and predict the return data, which is more normalized and stationary.
        training_df = self.pandas_converter.get_data_frame[TradeBar](list(self.securities[self._symbol].session)[::-1])['close']

        # Stack the data for 5-day OHLCV data per each sample to train with.
        features = []
        for i in range(1, n_steps + 1):
            close = training_df.shift(i)[n_steps:-1]
            close.name = f"close-{i}"
            features.append(close)
        features = pd.concat(features, axis=1)
        # Normalize using the 5 day interval.
        features = MinMaxScaler().fit_transform(features.T).T[4:]

        Y = training_df.pct_change().shift(-1)[n_steps*2-1:-1].reset_index(drop=True)
        # Train to predict the direction only.
        labels = np.array([1 if y > 0 else 0 for y in Y])   # binary class

        return features, labels

    def my_training_method(self) -> None:
        # Prepare the processed training data.
        features, labels = self.get_features_and_labels()
        D = (features, labels)
        # Recalibrate the model based on updated data.
        self._train(D[0], D[1])

        # Store the model to object store to retrieve it in other instances in case the algorithm stops.
        model_key = f"{self.project_id}/model_test_aesera"
        file_name = self.object_store.get_file_path(model_key)
        joblib.dump(self.predict, file_name)
        self.object_store.save(model_key)

    def on_data(self, slice: Slice) -> None:
        if self.is_warming_up or self._symbol not in slice.bars:
            return

        # Get prediction using the latest 5 OHLCV.
        features, _ = self.get_features_and_labels()
        prediction = self.predict(features[-1].reshape(1, -1))
        prediction = float(prediction)
```

```
        # If the predicted direction is going upward, buy SPY.
        if prediction == 1:
            self.set_holdings(self._symbol, 1)
        # If the predicted direction is going downward, sell SPY.
        elif prediction == 0:
            self.set_holdings(self._symbol, -1)
```

Popular Libraries

Copula

Introduction

This page explains how to build, train, deploy and store `Copula` models.

Import Libraries

Import the `copula` , `scipy` , and `sklearn` libraries.

```
PY
from AlgorithmImports import *
from copulas.bivariate import Bivariate
from scipy import stats
from sklearn.preprocessing import MinMaxScaler
import joblib
```

You need the `joblib` library to store models.

Create Subscriptions

In the `initialize` method, subscribe to some data so you can train the `copula` model and make predictions.

Since the algorithm is trading on options as speculation tools, to avoid insufficient buying power limited at the algorithm level, use `NullBuyingPowerModel` to bypass that.

```
PY
def initialize(self) -> None:
    # Request spx and ndx data for option pricing and selection.
    self.spx = self.add_index("SPX", Resolution.MINUTE).symbol
    self.ndx = self.add_index("NDX", Resolution.MINUTE).symbol

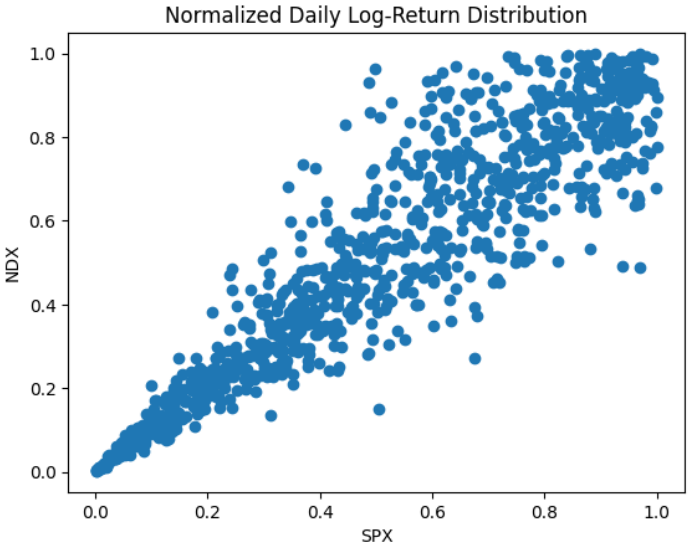
    self.set_security_initializer(self.custom_security_initializer)

def custom_security_initializer(self, security: Security) -> None:
    # Seed the last price for the initial filtering on option contracts using the price data.
    security.set_market_price(self.get_last_known_price(security))
    # Allow infinite margin to start the option positions.
    security.set_buying_power_model(NullBuyingPowerModel())
```

Build Models

In this example, build a copula model to estimate the log-return bivariate distribution of the paired securities, such that it can predict the correlated future price movement more accurately.

The following image shows the 1-year daily log-return bivariate distribution (normalized) of SPX and NDX indices as an example. As shown in the plot, although they exhibit a certain level of correlation, the tail is fat in both side, making normal distribution assumption unsuitable. In such case, we can make use of distributions from the extreme value theorem (Frank, Gumbel, or Clayton).



Follow the below steps to build the model:

1. Create a helper class to handle the copula trading.

```
class CopulaTrader:
    copula = None
    copula_name = None
    security1_scaler = MinMaxScaler()
    security2_scaler = MinMaxScaler()
    traded_pairs = []

    def __init__(self, algorithm: QCAlgorithm, security1: Symbol, security2: Symbol, alpha: float = 0.05, misprice_threshold: float
= 2.5) -> None:
        self._algorithm = algorithm
        # Interest rate and dividend yield providers to calculate fair option price later.
        self.interest_rate_provider = algorithm.risk_free_interest_rate_model
        self.security1_dividend_yield_provider = DividendYieldProvider(security1)
        self.security2_dividend_yield_provider = DividendYieldProvider(security2)
        # The significance level on KS test of the copula goodness-of-fit
        self.alpha = alpha
        # The threshold of the price divergence of a mispriced pair to have in order to start the positions.
        # Should at least over the transaction fee with some margin.
        self.misprice_threshold = misprice_threshold
```

2. Create a method to transform the raw data into daily log-return, such that the series is more stationary while capturing sufficient variance to accurately estimate the bivariate distribution.

```
class CopulaTrader:
    copula = None
    copula_name = None
    security1_scaler = MinMaxScaler()
    security2_scaler = MinMaxScaler()

    def _data_preparation(self, security1_prices: np.ndarray, security2_prices: np.ndarray) -> np.ndarray:
        # Calculate log price difference for fitting copulas, since the series has more stationary domain for prediction.
        security1_log_price = np.log(security1_prices)
        security2_log_price = np.log(security2_prices)
        security1_log_diff = np.diff(security1_log_price)
        security2_log_diff = np.diff(security2_log_price)
        # Scale to [0, 1] to fit the model.
        scaled_security1_data = self.security1_scaler.fit_transform(security1_log_diff.reshape(-1, 1))
        scaled_security2_data = self.security2_scaler.fit_transform(security2_log_diff.reshape(-1, 1))
        data = np.column_stack((scaled_security1_data, scaled_security2_data))
        return data
```

3. Create a method to fit the copula with the distribution yielding the best log-likelihood.

```
def _fit_bivariate_copula(self, data: np.ndarray) -> None:
    # Select the best-fitted bivariate copula by log-likelihood.
    self.copula = Bivariate.select_copula(data)
    self.copula_name = self.copula.copula_type
```

4. (Optional) Reconfirm it by a 2-sample KS test.

```py
def _fit_bivariate_copula(self, data: np.ndarray) -> None:
    # Continue from above

    # KS test to check if the actual data fits to the CDF of the copula good.
    samples = self.copula.sample(data.shape[0])
    p_value = self._ks2d2s(data[:, 0], samples[:, 0], data[:, 1], samples[:, 1])
    # Null hypothesis is the 2 datasets are having the same distribution, so if p < alpha, we reject the copula.
    if p_value < self.alpha:
        self.copula, self.copula_name = None, None
        self._algorithm.debug("No copula was fitted with statistically significant confidence.")
        return

    self._algorithm.debug(f"Best fitted copula distribution: {self.copula_name}, with tau: {self.copula.tau}")

def _ks2d2s(self, x1: np.ndarray, y1: np.ndarray, x2: np.ndarray, y2: np.ndarray) -> float:

    return p
```

5. Instantiate the helper class and fit the copula model.

```py
class CopulaTrader:
    def fit_bivariate_copula(self, security1_prices: np.ndarray, security2_prices: np.ndarray) -> None:
        training_data = self._data_preparation(security1_prices, security2_prices)
        self._fit_bivariate_copula(training_data)

class CopulaOptionTradingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # Set up the copula trading helper class.
        alpha = self.get_parameter("alpha", 0.05)
        misprice_threshold = self.get_parameter("misprice_threshold", 5)
        self.n_samples = self.get_parameter("n_samples", 1000)
        self.copula_trader = CopulaTrader(self, self.spx, self.ndx, alpha, misprice_threshold)

        # Fit the copula.
        # spx_prices & ndx_prices will be discussed later. They are 2 equal-size np array containing the raw price data of SPX and
NDX.
        self.copula_trader.fit_bivariate_copula(spx_prices, ndx_prices)
```

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `initialize` method, make a

history request .

```
def initialize(self) -> None:
    # Create a rolling window to save the spx and ndx price for fitting the copula on their relationship.
    # We use the recent 1 year to fit the model.
    self.windows = {self.spx: RollingWindow(252), self.ndx: RollingWindow(252)}
    # Warm up the rolling windows with historical data for its immediate use.
    for bar in self.history[TradeBar](self.spx, 252, Resolution.DAILY):
        self.windows[self.spx].add(bar.close)
    for bar in self.history[TradeBar](self.ndx, 252, Resolution.DAILY):
        self.windows[self.ndx].add(bar.close)
```

PY

Define a Training Method

To train the model, define a method that fits the model with the training data.

```
def fit_copula(self) -> None:
    # Obtain the historical price series of the spx and ndx for fitting the copula.
    # Note that we need to invert the rolling window series.
    spx_prices = np.array(list(self.windows[self.spx]))[::-1]
    ndx_prices = np.array(list(self.windows[self.ndx]))[::-1]
    # Fit the copula.
    self.copula_trader.fit_bivariate_copula(spx_prices, ndx_prices)
```

PY

Set Training Schedule

To train the model at the beginning of your algorithm, in the `initialize` method, call the `train` method.

```
# Fit the copula model for initial usage.
self.train(self.fit_copula)
```

PY

To periodically re-train the model as your algorithm executes, in the `initialize` method, call the `train` method as a Scheduled Event .

```
# Recalibrate the copula on every month to keep its accuracy updated.
self.train(self.date_rules.month_start(), self.time_rules.at(8,0), self.fit_copula)
```

PY

Update Training Data

To update the training data as the algorithm executes, make use of a consolidator to automatically update the rolling windows when a daily bar is consolidated through a consolidator handler.

```
def initialize(self) -> None:
    # Set a daily consolidator to update the rolling windows automatically.
    self.consolidate(self.spx, Resolution.DAILY, lambda bar: self.windows[bar.symbol].add(bar.close))
    self.consolidate(self.ndx, Resolution.DAILY, lambda bar: self.windows[bar.symbol].add(bar.close))
```

PY

Trading

In this example, we trade option mispricing arbitration using the copula model. More precisely, we are using the copula model to generate forward price series samples to price the options and do arbitration between options of the 2 correlated underlying. Since the copula can provide a distribution more accurately, we have an edge on the option pricing information.

Follow the below steps to trade the above logic:

1. Create a method to generate the forward price series samples of the 2 underlyings.

```py
class CopulaTrader:
    def _get_simulated_paths(self, current_security1_price: float, current_security2_price: float, expiry: datetime, current:
datetime, n_samples: int) -> tuple[float, float]:
        # Get the year till expiry.
        dtm = (expiry - current).total_seconds() / 60 / 60 / 24

        future_log_prices = np.log(np.array([[[current_security1_price, current_security2_price]] * n_samples]))
        # Convert to estimated trading days left.
        for _ in range(int(dtm / 252 * 365)):
            # The future price is simulated from N stochastic simulations.
            future_log_diff = self.copula.sample(n_samples)
            # Convert the daily log-difference into future price.
            security1_log_diff = self.security1_scaler.inverse_transform(future_log_diff[:, 0].reshape(-1, 1))
            security2_log_diff = self.security2_scaler.inverse_transform(future_log_diff[:, 1].reshape(-1, 1))
            log_diff = np.column_stack((security1_log_diff, security2_log_diff))
            future_log_prices = np.concatenate([future_log_prices, np.array([future_log_prices[-1, :, :] + log_diff])], axis=0)

        self.paths = np.exp(future_log_prices)
        # Return the ultimate price at the last iteration, convert back to price from log-price.
        return self.paths[-1], dtm
```

2. Create a method to price the options through averaging the payoff over all simulated paths.

```py
class CopulaTrader:
    def _calculate_fair_option_price(self, future_prices: np.ndarray, ttm: float, strike: float, right: OptionRight, interest_rate:
float, dividend_yield: float, security2: bool = False) -> float:
        select_col = 1 if security2 else 0
        future_prices = future_prices[:, select_col]

        # Average of option payoffs among simulation paths. Make use of vectorize calculation here instead of util method.
        option_prices = np.maximum(future_prices - strike, 0) if right == OptionRight.CALL else np.maximum(strike - future_prices,
0)
        # Adjust the continuous dividend payoff yield and interest rate.
        return np.exp((dividend_yield - interest_rate) * ttm) * np.mean(option_prices)
```

3. Create a method to calculate the probability of winning (price converges to our model).

   We use the ratio of paths that the underlyings ever reach the strikes of the options, since ATM options are most efficiently priced and equal among all option pricing engine.

```py
class CopulaTrader:
    def _ratio_reached(self, data: np.ndarray, point: np.ndarray) -> float:
        # Count how many paths ever reached the point.
        count = 0
        for i in range(data.shape[1]):
            if point[0] <= max(data[:, i, 0]) and point[1] <= max(data[:, i, 1]) and point[0] >= min(data[:, i, 0]) and point[1] >=
min(data[:, i, 1]):
                count += 1
        # Calculate the ratio of paths that the point has ever been reached.
        return count / data.shape[1]
```

4. Create a method to calculate the aboves and output the mispriced option pairs.

```py
class CopulaTrader:
    def scan_option_mispricing_combinations(self, security1_options: List[OptionContract], security2_options: List[OptionContract],
current_security1_price: float, current_security2_price: float,
        current: datetime, n_samples: int = 1000) -> List[tuple[OptionContract, OptionContract, float, float]]:
        # Get the simluated price series till the expiry. Note that you should use single expiry for all contracts for easier
handling and stable theta.
        future_prices, dtm = self._get_simulated_paths(current_security1_price, current_security2_price,
security1_options[0].expiry, current, n_samples)

        mispriced_pairs = []
        interest_rate = self.interest_rate_provider.get_interest_rate(current)
        security1_dividend_yield = self.security1_dividend_yield_provider.get_dividend_yield(current)
        security2_dividend_yield = self.security2_dividend_yield_provider.get_dividend_yield(current)

        # Separate call and put options to avoid mixed right pairs, in order to keep theta close to 0.
        for right in [OptionRight.CALL, OptionRight.PUT]:
            sorted_security1_options = sorted([contract for contract in security1_options if contract.right == right], key=lambda x:
x.strike)
            sorted_security2_options = sorted([contract for contract in security2_options if contract.right == right], key=lambda x:
x.strike)
            ttm = dtm / 365

            # Calculate the security1-security2 fair prices and spot any significant mispricing.
            for i, security1_option in enumerate(sorted_security1_options):
                for j, security2_option in enumerate(sorted_security2_options):
                    # Skip the pairs already being traded.
                    if (security1_option.symbol, security2_option.symbol) in [(y.symbol for y in x[0]) for x in self.traded_pairs]:
                        continue

                    # Calculate the probability of price converges. Since the ATM options are the most efficiently priced, we use
that as a proxy for our win rate.
                    # The probability will be based on the whether the simulated paths have ever reached the point (so it was ever
ATM).
                    prob = self._ratio_reached(self.paths, [security1_option.strike, security2_option.strike])

                    security1_price = self._calculate_fair_option_price(future_prices, ttm, security1_option.strike, right,
interest_rate, security1_dividend_yield, False)
                    security2_price = self._calculate_fair_option_price(future_prices, ttm, security2_option.strike, right,
interest_rate, security2_dividend_yield, True)
                    # Add to trade stacks only if the mispricing is opposite in direction and above profit threshold.
                    security1_price_divergence = security1_price - security1_option.ask_price
                    security2_price_divergence = security2_price - security2_option.bid_price
                    price_divergence1 = security1_price_divergence - security2_price_divergence
                    price_divergence2 = security1_price - security1_option.bid_price - security2_price + security2_option.ask_price
                    price_divergence = price_divergence1 if abs(price_divergence1) > abs(price_divergence2) else price_divergence1
                    if abs(price_divergence) > self.misprice_threshold and np.sign(security1_price_divergence) !=
np.sign(security2_price_divergence):
                        mispriced_pairs.append((security1_option, security2_option, price_divergence, prob))

        self._algorithm.debug(f"Found {len(mispriced_pairs)} mispriced option contract pairs.")

        return mispriced_pairs
```

5. Create a method to get the optimal position sizings for the top-expected-return trading opportunities.

```py
class CopulaTrader:
    def trade_options(self, mispriced_pairs: List[tuple[OptionContract, OptionContract, float, float]], fund: float,
contract_multiplier: int = 100) -> dict[OptionContract, float]:
        orders = {}
        total_pct = 0

        # Only trade on the top 10 expected return pairs.
        top_expected_ret = sorted(mispriced_pairs, key=lambda x: abs(x[2]) * x[3], reverse=True)[:10]
        for security1_option, security2_option, price_divergence, prob in top_expected_ret:
            # Calculate the order size of the mispricing pairs.
            contract1_price = security1_option.ask_price if price_divergence > 0 else security1_option.bid_price
            contract2_price = security2_option.ask_price if price_divergence < 0 else security2_option.bid_price
            security1_option_order_size, security2_option_order_size, order_pct = self._calculate_order_size(price_divergence, fund,
prob, contract1_price, contract2_price, contract_multiplier)
            # Only order those with positive Kelly sizing and keep the exposure to cash only.
            # Keep 5% buffer to avoid order errors.
            if order_pct and total_pct + order_pct <= 0.95:
                if security1_option not in orders:
                    orders[security1_option] = 0
                if security2_option not in orders:
                    orders[security2_option] = 0
            # Aggregate the overall order sizes between all pairs.
                orders[security1_option] += security1_option_order_size
                orders[security2_option] += security2_option_order_size
                total_pct += order_pct
                self.traded_pairs.append(((security1_option, security2_option), (security1_option_order_size,
security2_option_order_size)))

        return orders

    def _calculate_order_size(self, price_divergence: float, fund: float, prob_win: float, security1_option_price: float,
security2_option_price: float, contract_multiplier: int) -> tuple[float, float, float]:
        # The profit percentage is based on the option prices.
        capital = security1_option_price + security2_option_price
        profit_pct = abs(price_divergence) / capital
        # Assume no recovery at expiry if the price does not converges, while no extra loss will be paid.
        # To improve, you may use a continuous distribution to model the aggregated profit.
        # Keep at most 5% per trade, since option has leverage effect.
        order_pct = min(prob_win - (1 - prob_win) / profit_pct, 0.05)
        # The order size should be the shared by both side of the legs.
        order_size = order_pct * fund / capital // contract_multiplier
        order_pct = order_size * capital / fund
        # If the optimal order size is negative, do not place order.
        if order_pct < 0:
            return 0, 0, 0
        # If price divergence above 0, meaning security1 option is underpriced and the security2 option is overpriced, so we buy the
security1 option and sell the security2 option.
        if price_divergence > 0:
            return order_size, -order_size, order_pct
        # Vice versa otherwise.
        return -order_size, order_size, order_pct
```

6. Create a method to handle the portfolio and exit the positions when price converges.

```py
class CopulaTrader:
    def exit_trades(self, current: datetime) -> dict[OptionContract, float]:
        # Get the parameters for fair price calculation.
        interest_rate = self.interest_rate_provider.get_interest_rate(current)
        security1_dividend_yield = self.security1_dividend_yield_provider.get_dividend_yield(current)
        security2_dividend_yield = self.security2_dividend_yield_provider.get_dividend_yield(current)

        exit_positions = {}
        for ((contract1, contract2), (size1, size2)) in self.traded_pairs.copy():
            # Get the simluated price series till the expiry.
            future_prices = self.paths[-1]
            ttm = (contract1.expiry - current).total_seconds() / 60 / 60 / 24 / 365
            # Check if the price discrepancy converges (relatively).
            contract1_price = self._calculate_fair_option_price(future_prices, ttm, contract1.strike, contract1.right,
interest_rate, security1_dividend_yield, False)
            contract2_price = self._calculate_fair_option_price(future_prices, ttm, contract2.strike, contract2.right,
interest_rate, security2_dividend_yield, True)
            contract1.mid_price = (contract1.bid_price + contract1.ask_price) * 0.5
            contract2.mid_price = (contract2.bid_price + contract2.ask_price) * 0.5
            contract1_divergence = contract1_price - contract1.mid_price
            contract2_divergence = contract2_price - contract2.mid_price
            price_divergence = contract1_divergence - contract2_divergence

            # If so, place the opposite size to exit the positions.
            if (size1 > 0 and price_divergence <= 0) or (size1 < 0 and price_divergence >= 0):
                if contract1 not in exit_positions:
                    exit_positions[contract1] = 0
                if contract2 not in exit_positions:
                    exit_positions[contract2] = 0
                exit_positions[contract1] -= size1
                exit_positions[contract2] -= size2
                # Remove the record and allow the pair to be traded again.
                self.traded_pairs.remove(((contract1, contract2), (size1, size2)))

        return exit_positions
```

7. Create a method in the base algorithm to open trades. Schedule its run.

   To simply implementation, this example will only open trades after the previous positions are all expired, but you can change it to scan by some time interval.

```py
class CopulaOptionTradingAlgorithm(QCAlgorithm):
    def open_trades(self) -> None:

        # Check if copula was fitted
        if self.copula_trader.copula is None:
            return

        # Obtain the option chain of the spx and the ndx for trading.
        spx_options = self.option_chain(self.spx)
        ndx_options = self.option_chain(self.ndx)

        # Only use European options since the computation of averaging option payoff to price is more efficient.
        # Only include the ones within 5% of the current price, since they are more liquid and less susceptible from slippage.
        spx_price = self.securities[self.spx].price
        ndx_price = self.securities[self.ndx].price

        european_spx_options = [contract for contract in spx_options if contract.style == OptionStyle.EUROPEAN and spx_price * 1.05
> contract.strike > spx_price * 0.95]
        european_ndx_options = [contract for contract in ndx_options if contract.style == OptionStyle.EUROPEAN and ndx_price * 1.05
> contract.strike > ndx_price * 0.95]

        if len(european_spx_options) == 0 or len(european_ndx_options) == 0:
            return

        # Get the nearest expiry after 7 days to trade them. We use a single expiry to trade with more stable theta.
        spx_expiries = set(contract.expiry for contract in european_spx_options if contract.expiry > self.time + timedelta(7))
        ndx_expiries = set(contract.expiry for contract in european_ndx_options if contract.expiry > self.time + timedelta(7))
        common_expiries = spx_expiries.intersection(ndx_expiries)
        if len(common_expiries) == 0:
            return
        expiry = min(common_expiries)
        filtered_spx_options = [contract for contract in european_spx_options if contract.expiry == expiry]
        filtered_ndx_options = [contract for contract in european_ndx_options if contract.expiry == expiry]
        # Use simulations to price options by the fitted copula distributions to spot mispricing option pairs.
        mispriced_option_pairs = self.copula_trader.scan_option_mispricing_combinations(filtered_spx_options, filtered_ndx_options,
spx_price, ndx_price, self.time, self.n_samples)
        # Obtain the trading plan from the mispriced options, calculated using Kelly Criterion.
        trade_plan = self.copula_trader.trade_options(mispriced_option_pairs, self.portfolio.cash, 100)
        # Order both plans. Request the option contract data to trade it.
        for contract, size in trade_plan.items():
            symbol = self.add_option_contract(contract).symbol
            self.market_order(symbol, size)

        # Schedule the next option trades to be after the current selected expiry to simplify path calculation.
        next_trading_day = self.securities[self.spx].exchange.hours.get_next_trading_day(expiry)
        self.schedule.on(
            self.date_rules.on(next_trading_day),
            self.time_rules.after_market_open(self.spx, 1),
            self.open_trades
        )
```

8. Scan every N minutes to exit the positions if the price discrepancy between a pair is converged.

```py
class CopulaOptionTradingAlgorithm(QCAlgorithm):
    def on_data(self, slice: Slice) -> None:
        # Scan every 5 minutes to check price convergence.
        if slice.time.minute % 5 == 0:
            exit_plan = self.copula_trader.exit_trades(self.time)
            # Exit the paired positions when the price converges.
            for contract, size in exit_plan.items():
                self.market_order(contract.symbol, size)
```

Save Models

Follow these steps to save `copula` models into the Object Store :

1. Set the key name you want to store the model under in the Object Store.

```py
# Set the storage key to something representative.
model_key = f"{self.project_id}/copula"
```

2. Call the `get_file_path` method with the key.

```
# Get the file path to save and access the model in the Object Store.
file_name = self.object_store.get_file_path(model_key)
```

This method returns the file path where the model will be stored.

3. Call the `dump` method the file path.

```
# Serialize and save the model.
joblib.dump(self.predict, self.copula_trader.copula)
```

If you dump the model using the `joblib` module before you save the model, you don't need to retrain the model.

Upload Models

If you train models locally or in another environment, you can upload the model files to the Object Store so your algorithms can use them. Use the model key that matches the key your algorithm expects when it calls `object_store.get_file_path` .

Follow one of these approaches to upload your model files:

LEAN CLI

Run the `lean cloud object-store set` command to upload a local file to the Object Store.

```
$ lean cloud object-store set <projectId>/copula <pathTo>/copula
```

Replace `<projectId>` with your project Id and `<pathTo>` with the path to the local model file.

Cloud API

Use the Upload Object Store Files endpoint to upload a model file through the API.

Load Models

You can load and trade with pre-trained `copula` models that you saved in the Object Store. To load a `copula` model from the Object Store, in the `initialize` method, get the file path to the saved model and then call the `load` method.

```
# Load the trained Aesera model from the Object Store.
def initialize(self) -> None:
    model_key = f"{self.project_id}/copula"
    if self.object_store.contains_key(model_key):
        file_name = self.object_store.get_file_path(model_key)
        self.copula_trader.copula = joblib.load(file_name)
```

The `contains_key` method returns a boolean that represents if the `model_key` is in the Object Store. If the Object Store does not contain the `model_key` , save the model using the `model_key` before you proceed.

Examples

The below demonstrates the full algorithm of the above example.

```
from AlgorithmImports import *
from copulas.bivariate import Bivariate
from scipy import stats
from sklearn.preprocessing import MinMaxScaler

```

Popular Libraries

GPlearn

Introduction

This page explains how to build, train, deploy and store `GPlearn` models.

To access GPlearn, use the Legacy package environment. To set this environment, see the documentation in Cloud Platform or Local Platform .

Import Libraries

Import the `gplearn` and `joblib` libraries.

```
PY
from AlgorithmImports import *
from gplearn.genetic import SymbolicRegressor, SymbolicTransformer
import joblib
```

You need the `joblib` library to store models.

Create Subscriptions

In the `initialize` method, subscribe to some data so you can train the `GPLearn` model and make predictions.

```
PY
# Add a security and save a reference to its Symbol.
self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
```

Build Models

In this example, build a genetic programming feature transformation model and a genetic programming regression prediction model using the following features and labels:

Data Category	Description
Features	Daily percent change of the close price of the SPY over the last 5 days
Labels	Daily percent return of the SPY over the next day

The following image shows the time difference between the features and labels:

Follow these steps to create a method to build the model:

1. Declare a set of functions to use for feature engineering.

```
# Pick some functions for feature engineering to explore transformations of the data.
function_set = ['add', 'sub', 'mul', 'div',
                'sqrt', 'log', 'abs', 'neg', 'inv',
                'max', 'min']
```

2. Call the `SymbolicTransformer` constructor with the preceding set of functions and then save it as a class variable.

```
# Initialize a SymbolicTransformer with a function set for feature engineering.
self.gp_transformer = SymbolicTransformer(function_set=function_set)
```

3. Call the `SymbolicRegressor` constructor to instantiate the regression model.

```
# Instantiate the regression model to perform symbolic regression, which involves
# mathematical expressions to fit the data and identify patterns.
self.model = SymbolicRegressor()
```

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `initialize` method, make a history request .

```
# Fill a RollingWindow with 2 years of training data.
training_length = 252*2
self.training_data = RollingWindow(training_length)
history = self.history[TradeBar](self._symbol, training_length, Resolution.DAILY)
for trade_bar in history:
    self.training_data.add(trade_bar.close)
```

Define a Training Method

To train the model, define a method that fits the model with the training data.

```
# Prepare the feature and label data for training.
def get_features_and_labels(self, n_steps=5):
    training_df = list(self.training_data)[::-1]
    daily_pct_change = ((np.roll(training_df, -1) - training_df) / training_df)[:-1]

    features = []
    labels = []
    for i in range(len(daily_pct_change)-n_steps):
        features.append(daily_pct_change[i:i+n_steps])
        labels.append(daily_pct_change[i+n_steps])
    features = np.array(features)
    labels = np.array(labels)

    return features, labels

def my_training_method(self):
    features, labels = self.get_features_and_labels()

    # Perform feature engineering.
    self.gp_transformer.fit(features, labels)
    gp_features = self.gp_transformer.transform(features)
    new_features = np.hstack((features, gp_features))

    # Fit the regression model with transformed and raw features.
    self.model.fit(new_features, labels)
```

Set Training Schedule

To train the model at the beginning of your algorithm, in the `initialize` method, call the `train` method.

```
# Train the model right now.
self.train(self.my_training_method)
```

To periodically re-train the model as your algorithm executes, in the `initialize` method, call the `train` method as a Scheduled Event .

```
# Train the model every Sunday at 8:00 AM.
self.train(self.date_rules.every(DayOfWeek.SUNDAY), self.time_rules.at(8, 0), self.my_training_method)
```

Update Training Data

To update the training data as the algorithm executes, in the `on_data` method, add the current close price to the `RollingWindow` that holds the training data.

```
# Add the current close to the training data to ensure the model trains with the most recent market data.
def on_data(self, slice: Slice) -> None:
    if self._symbol in slice.bars:
        self.training_data.add(slice.bars[self._symbol].close)
```

Predict Labels

To predict the labels of new data, in the `on_data` method, get the most recent set of features and then call the `predict` method.

```
# Get the feature set.
features, _ = self.get_features_and_labels()

# Transform the features.
gp_features = self.gp_transformer.transform(features)
new_features = np.hstack((features, gp_features))

# Make a prediction.
prediction = self.model.predict(new_features)
prediction = float(prediction.flatten()[-1])
```

You can use the label prediction to place orders.

```
# Place orders based on the prediction.
if prediction > 0:
    self.set_holdings(self._symbol, 1)
elif prediction < 0:
    self.set_holdings(self._symbol, -1)
```

Save Models

Follow these steps to save `GPLearn` models into the Object Store :

1. Set the key names you want to store the models under in the Object Store.

   ```
   # Set the storage keys to something representative.
   transformer_model_key = f"{self.project_id}/transformer"
   regressor_model_key = f"{self.project_id}/regressor"
   ```

2. Call the `get_file_path` method with the keys.

   ```
   # Get the file paths to save and access the models in the Object Store.
   transformer_file_name = self.object_store.get_file_path(transformer_model_key)
   regressor_file_name = self.object_store.get_file_path(regressor_model_key)
   ```

   This method returns the file paths where the models will be stored.

3. Call the `dump` method the file paths.

```
# Serialize and save the models.
joblib.dump(self.gp_transformer, transformer_file_name)
joblib.dump(self.model, regressor_file_name)
```

If you dump the models using the `joblib` module before you save the models, you don't need to retrain the models.

Upload Models

If you train models locally or in another environment, you can upload the model files to the Object Store so your algorithms can use them. Use the model key that matches the key your algorithm expects when it calls `object_store.get_file_path` .

Follow one of these approaches to upload your model files:

LEAN CLI

Run the `lean cloud object-store set` command to upload a local file to the Object Store.

```
$ lean cloud object-store set <projectId>/transformer <pathTo>/transformer
```

```
$ lean cloud object-store set <projectId>/regressor <pathTo>/regressor
```

Replace `<projectId>` with your project Id and `<pathTo>` with the path to the local model file.

Cloud API

Use the Upload Object Store Files endpoint to upload a model file through the API.

Load Models

You can load and trade with pre-trained `GPLearn` models that you saved in the Object Store. To load a `GPLearn` model from the Object Store, in the `initialize` method, get the file path to the saved model and then call the `load` method.

```
# Load the GPLearn model from Object Store to use its saved state and update with new data if needed.
def initialize(self) -> None:
    transformer_model_key = f"{self.project_id}/transformer"
    regressor_model_key = f"{self.project_id}/regressor"
    if self.object_store.contains_key(transformer_model_key) and self.object_store.contains_key(regressor_model_key):
        transformer_file_name = self.object_store.get_file_path(transformer_model_key)
        regressor_file_name = self.object_store.get_file_path(regressor_model_key)
        self.gp_transformer = joblib.load(transformer_file_name)
        self.model = joblib.load(regressor_file_name)
```

The `contains_key` method returns a boolean that represents if `transformer_model_key` and `regressor_model_key` are in the Object Store. If the Object Store does not contain the keys, save the model using them before you proceed.

Examples

The following examples demonstrate some common practices for using `GPLearn` library.

Example 1: Genetic Learning

The below algorithm makes use of `GPLearn` library to predict the future price movement using the previous 5 OHLCV data. The model is trained using rolling 2-year data. To ensure the model applicable to the current market environment, we recalibrate the model on every Sunday.

```
from gplearn.genetic import SymbolicRegressor, SymbolicTransformer
import joblib

class GPLearnExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Request SPY data for model training, prediction and trading.
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
```

```
        # 2-year data to train the model.
        training_length = 252*2
        self.training_data = RollingWindow(training_length)
        # Warm up the training dataset to train the model immediately.
        history = self.history[TradeBar](self._symbol, training_length, Resolution.DAILY)
        for trade_bar in history:
            self.training_data.add(trade_bar.close)

        # Retrieve already trained model from object store to use immediately.
        transformer_model_key = f"{self.project_id}/Transformer"
        regressor_model_key = f"{self.project_id}/Regressor"
        if self.object_store.contains_key(transformer_model_key) and self.object_store.contains_key(regressor_model_key):
            transformer_file_name = self.object_store.get_file_path(transformer_model_key)
            regressor_file_name = self.object_store.get_file_path(regressor_model_key)

            self.gp_transformer = joblib.load(transformer_file_name)
            self.model = joblib.load(regressor_file_name)

        else:
            # Exhasting list of the non-linear transformation to apply on the variables.
            function_set = ['add', 'sub', 'mul', 'div',
                'sqrt', 'log', 'abs', 'neg', 'inv',
                'max', 'min']
            # Create and train the model to use the prediction right away.
            self.gp_transformer = SymbolicTransformer(function_set=function_set)
            self.model = SymbolicRegressor()
            self.train(self.my_training_method)

        # Recalibrate the model weekly to ensure its accuracy on the updated domain.
        self.train(self.date_rules.every(DayOfWeek.SUNDAY), self.time_rules.at(8,0), self.my_training_method)

    def get_features_and_labels(self, n_steps=5) -> tuple[list, list]:
        # Train and predict the return data, which is more normalized and stationary.
        training_df = list(self.training_data)[::-1]
        daily_pct_change = ((np.roll(training_df, -1) - training_df) / training_df)[:-1]

        # Stack the data for 5-day OHLCV data per each sample to train with.
        features = []
        labels = []
        for i in range(len(daily_pct_change)-n_steps):
            features.append(daily_pct_change[i:i+n_steps])
            labels.append(daily_pct_change[i+n_steps])
        features = np.array(features)
        labels = np.array(labels)

        return features, labels

    def my_training_method(self) -> None:
        # Prepare the processed training data.
        features, labels = self.get_features_and_labels()

        # Feature engineering
        self.gp_transformer.fit(features, labels)
        gp_features = self.gp_transformer.transform(features)
        new_features = np.hstack((features, gp_features))

        # Fit the regression model with transformed and raw features.
        self.model.fit(new_features, labels)

    def on_data(self, slice: Slice) -> None:
        features, _ = self.get_features_and_labels()

        # Get transformed features
        gp_features = self.gp_transformer.transform(features)
        new_features = np.hstack((features, gp_features))

        # Get prediction using the latest 5 OHLCV.
        prediction = self.model.predict(new_features)
        prediction = float(prediction.flatten()[-1])

        # If the predicted direction is going upward, buy SPY.
        if prediction > 0:
            self.set_holdings(self._symbol, 1)
        # If the predicted direction is going downward, sell SPY.
        elif prediction < 0:
            self.set_holdings(self._symbol, -1)

    def on_end_of_algorithm(self) -> None:
        # Store the model to object store to retrieve it in other instances in case the algorithm stops.
        transformer_model_key = f"{self.project_id}/Transformer"
        regressor_model_key = f"{self.project_id}/Regressor"
        transformer_file_name = self.object_store.get_file_path(transformer_model_key)
        regressor_file_name = self.object_store.get_file_path(regressor_model_key)
        joblib.dump(self.gp_transformer, transformer_file_name)
        joblib.dump(self.model, regressor_file_name)
        self.object_store.save(transformer_model_key)
        self.object_store.save(regressor_model_key)
```

Popular Libraries

Hmmlearn

Introduction

This page explains how to build, train, deploy and store `Hmmlearn` models.

Import Libraries

Import the `hmmlearn` and `joblib` libraries.

```
PY
from AlgorithmImports import *
from hmmlearn import hmm
import joblib
```

You need the `joblib` library to store models.

Create Subscriptions

In the `initialize` method, subscribe to some data so you can train the `hmmlearn` model and make predictions.

```
PY
# Add a security and save a reference to its Symbol.
self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
```

Build Models

In this example, assume the market has only 2 regimes and the market returns follow a Gaussian distribution. Therefore, create a 2-component Hidden Markov Model with Gaussian emissions, which is equivalent to a Gaussian mixture model with 2 means.

To build the model, call the `GaussianHMM` constructor with the number of components, a covariance type, and the number of iterations:

```
PY
# Initialize GaussianHMM with 2 states for capturing patterns, full covariance to model complex relationships, and
# 100 iterations for sufficient training.
self.model = hmm.GaussianHMM(n_components=2, covariance_type="full", n_iter=100)
```

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `initialize` method, make a history request .

```
PY
# Fill a RollingWindow with 2 years of historical closing prices.
training_length = 252*2
self.training_data = RollingWindow(training_length)
history = self.history[TradeBar](self._symbol, training_length, Resolution.DAILY)
for trade_bar in history:
    self.training_data.add(trade_bar.close)
```

Define a Training Method

To train the model, define a method that fits the model with the training data.

```
# Prepare feature and label data for training by processing the RollingWindow data into a time series.
def get_features(self):
    training_df = np.array(list(self.training_data)[::-1])
    daily_pct_change = (np.roll(training_df, 1) - training_df) / training_df

    return daily_pct_change[1:].reshape(-1, 1)

def my_training_method(self):
    features = self.get_features()
    self.model.fit(features)
```

Set Training Schedule

To train the model at the beginning of your algorithm, in the `initialize` method, call the `train` method.

```
# Train the model initially to provide a baseline for prediction and decision-making.
self.train(self.my_training_method)
```

To periodically re-train the model as your algorithm executes, in the `initialize` method, call the `train` method as a Scheduled Event .

```
# Train the model every Sunday at 8:00 AM.
self.train(self.date_rules.every(DayOfWeek.SUNDAY), self.time_rules.at(8, 0), self.my_training_method)
```

Update Training Data

To update the training data as the algorithm executes, in the `on_data` method, add the current close price to the `RollingWindow` that holds the training data.

```
# Add the latest bar to the training data to ensure the model is trained with the most recent market data.
def on_data(self, slice: Slice) -> None:
    if self._symbol in slice.bars:
        self.training_data.add(slice.bars[self._symbol].close)
```

Predict Labels

To predict the labels of new data, in the `on_data` method, get the most recent set of features and then call the `predict` method.

```
# Get the current feature set and make a prediction.
new_feature = self.get_features()
prediction = self.model.predict(new_feature)
prediction = float(prediction[-1])
```

You can use the label prediction to place orders.

```
# Place orders based on the forecasted market direction.
if prediction == 1:
    self.set_holdings(self._symbol, 1)
else:
    self.liquidate(self._symbol)
```

Save Models

Follow these steps to save `hmmlearn` models into the Object Store :

1. Set the key name you want to store the model under in the Object Store.

   ```
   # Set the key to store the model in the Object Store so you can use it later.
   model_key = f"{self.project_id}/model.hmm"
   ```

2. Call the `get_file_path` method with the key.

```
# Get the file path to correctly save and access the model in Object Store.
file_name = self.object_store.get_file_path(model_key)
```

This method returns the file path where the model will be stored.

3. Call the `dump` method the file path.

```
# Serialize the model and save it to the file.
joblib.dump(self.model, file_name)
```

If you dump the model using the `joblib` module before you save the model, you don't need to retrain the model.

Upload Models

If you train models locally or in another environment, you can upload the model files to the Object Store so your algorithms can use them. Use the model key that matches the key your algorithm expects when it calls `object_store.get_file_path` .

Follow one of these approaches to upload your model files:

LEAN CLI

Run the `lean cloud object-store set` command to upload a local file to the Object Store.

```
$ lean cloud object-store set <projectId>/model.hmm <pathTo>/model.hmm
```

Replace `<projectId>` with your project Id and `<pathTo>` with the path to the local model file.

Cloud API

Use the Upload Object Store Files endpoint to upload a model file through the API.

Load Models

You can load and trade with pre-trained `hmmlearn` models that you saved in the Object Store. To load a `hmmlearn` model from the Object Store, in the `initialize` method, get the file path to the saved model and then call the `load` method.

```
# Load the hmmlearn model from Object Store to use its saved state and update it with new data if needed.
def initialize(self) -> None:
    model_key = f"{self.project_id}/model.hmm"
    if self.object_store.contains_key(model_key):
        file_name = self.object_store.get_file_path(model_key)
        self.model = joblib.load(file_name)
```

The `contains_key` method returns a boolean that represents if the `model_key` is in the Object Store. If the Object Store does not contain the `model_key` , save the model using the `model_key` before you proceed.

Examples

The following examples demonstrate some common practices for using `Hmmlearn` library.

Example 1: Hidden Markov Model Regime Detection

The below algorithm makes use of `Hmmlearn` library to predict the future market regime through a hidden markov model using return data. If the regime is upward market, we hold SPY. Otherwise, we liquidate the portfolio. The model is trained using rolling 2-year data. To ensure the model applicable to the current market environment, we recalibrate the model on every Sunday.

PY

```
from hmmlearn import hmm
import joblib

class HmmlearnExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Request SPY data for model training, prediction and trading.
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol

        # Use the session rolling window to cache 2-year daily data for training.
        training_length = 252*2
        self.securities[self._symbol].session.size = training_length
        self.set_warm_up(training_length, Resolution.DAILY)

        # Retrieve already trained model from object store to use immediately.
        self._model_key = f"{self.project_id}/model.hmm"
        if self.object_store.contains_key(self._model_key):
            file_name = self.object_store.get_file_path(self._model_key)
            self.model = joblib.load(file_name)
        # Create a 2-regime model otherwise to predict different variance regime markets.
        else:
            self.model = hmm.GaussianHMM(n_components=2, covariance_type="full", n_iter=100)

    def on_warmup_finished(self) -> None:
        # Train the model to use the prediction right away.
        self.train(self.my_training_method)
        # Recalibrate the model weekly to ensure its accuracy on the updated domain.
        self.train(self.date_rules.every(DayOfWeek.SUNDAY), self.time_rules.at(8,0), self.my_training_method)

    def get_features(self) -> None:
        # Train and predict the return data, which is more normalized and stationary.
        training_df = np.array([x.close for x in self.securities[self._symbol].session][::-1])
        daily_pct_change = np.diff(training_df) / training_df[:-1]

        return daily_pct_change.reshape(-1, 1)

    def my_training_method(self) -> None:
        # Prepare the processed training data.
        features = self.get_features()
        # Recalibrate the model based on updated data.
        self.model.fit(features)

    def on_data(self, slice: Slice) -> None:
        if self.is_warming_up or self._symbol not in slice.bars:
            return

        # Get prediction by the updated features.
        new_feature = self.get_features()
        prediction = self.model.predict(new_feature)
        prediction = float(prediction[-1])

        # If the predicted direction is going upward, buy SPY.
        if prediction == 1:
            self.set_holdings(self._symbol, 1)
        # If the predicted direction is going downward, liquidate.
        else:
            self.liquidate(self._symbol)

    def on_end_of_algorithm(self) -> None:
        # Store the model to object store to retrieve it in other instances in case the algorithm stops.
        file_name = self.object_store.get_file_path(self._model_key)
        joblib.dump(self.model, file_name)
```

Popular Libraries

Keras

Introduction

This page explains how to build, train, deploy and store `Keras` models.

Import Libraries

Import the `keras` libraries.

```
PY
from AlgorithmImports import *
from tensorflow.keras.models import Sequential, load_model
from tensorflow.keras.layers import Dense, Flatten
from tensorflow.keras.optimizers import Adam
```

Create Subscriptions

In the `initialize` method, subscribe to some data so you can train the `keras` model and make predictions.

```
PY
# Add a security and save a reference to its Symbol.
self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
```

Build Models

In this example, build a neural-network regression model that uses the following features and labels:

Data Category	Description
Features	Daily percent change of the open, high, low, close, and volume of the SPY over the last 5 days
Labels	Daily percent return of the SPY over the next day

The following image shows the time difference between the features and labels:

Follow the below steps to build the model:

1. In the `initialize` method, create a `Sequential` object with several layers.

```
# Build a neural network with Dense layers for feature extraction, Flatten for reshaping, and a final
# Dense layer for prediction.
self.model = Sequential([Dense(10, input_shape=(5,5), activation='relu'),
                         Dense(10, activation='relu'),
                         Flatten(),
                         Dense(1)])
```

Set the `input_shape` of the first layer to `(5, 5)` because each sample contains the percent change of 5 factors (percent change of the open, high, low, close, and volume) over the previous 5 days. Call the `Flatten` constructor because the input is 2-dimensional but the output is just a single value.

2. Call the `compile` method with a loss function, an optimizer, and a list of metrics to monitor.

```
# Configure the model to use mean squared error loss, Adam optimizer, and track mean absolute error
# and mean squared error for performance evaluation.
self.model.compile(loss='mse',
                   optimizer=Adam(),
                   metrics=['mae', 'mse'])
```

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `initialize` method, make a history request .

```
# Fill a RollingWindow with 2 years of historical TradeBar objects.
training_length = 252*2
self.training_data = RollingWindow(training_length)
history = self.history[TradeBar](self._symbol, training_length, Resolution.DAILY)
for trade_bar in history:
    self.training_data.add(trade_bar)
```

Define a Training Method

To train the model, define a method that fits the model with the training data.

```
# Prepare feature and label data for training by processing the RollingWindow data into a time series.
def get_features_and_labels(self, n_steps=5):
    training_df = self.pandas_converter.get_data_frame[TradeBar](list(self.training_data)[::-1])
    daily_pct_change = training_df.pct_change().dropna()

    features = []
    labels = []
    for i in range(len(daily_pct_change)-n_steps):
        features.append(daily_pct_change.iloc[i:i+n_steps].values)
        labels.append(daily_pct_change['close'].iloc[i+n_steps])
    features = np.array(features)
    labels = np.array(labels)

    return features, labels

def my_training_method(self):
    features, labels = self.get_features_and_labels()
    self.model.fit(features, labels, epochs=5)
```

Set Training Schedule

To train the model at the beginning of your algorithm, in the `initialize` method, call the `train` method.

```
# Train the model initially to provide a baseline for prediction and decision-making.
self.train(self.my_training_method)
```

To periodically re-train the model as your algorithm executes, in the `initialize` method, call the `train` method as a Scheduled Event .

```
# Train the model every Sunday at 8:00 AM
self.train(self.date_rules.every(DayOfWeek.SUNDAY), self.time_rules.at(8, 0), self.my_training_method)
```

Update Training Data

To update the training data as the algorithm executes, in the `on_data` method, add the current `TradeBar` to the `RollingWindow` that holds the training data.

```
# Add the latest bar to training data to ensure the model is trained with the most recent market data.
def on_data(self, slice: Slice) -> None:
    if self._symbol in slice.bars:
        self.training_data.add(slice.bars[self._symbol])
```

Predict Labels

To predict the labels of new data, in the `on_data` method, get the most recent set of features and then call the `predict` method.

```
# Get the current feature set and make a prediction.
features, _ = self.get_features_and_labels()
features = features[-1].reshape(1, 5, 5)
prediction = float(self.model.predict(features)[-1])
```

You can use the label prediction to place orders.

```
# Place orders based on the forecasted market direction.
if prediction > 0:
    self.set_holdings(self._symbol, 1)
elif prediction < 0:
    self.set_holdings(self._symbol, -1)
```

Save Models

Follow these steps to save `keras` models into the Object Store :

1. Set the key name you want to store the model under in the Object Store.

   The key must end with a .keras extension for the native Keras format (recommended) or a .h5 extension.

   ```
   # Set the key to store the model in the Object Store so you can use it later.
   model_key = f"{self.project_id}/model.keras"
   ```

2. Call the `get_file_path` method with the key.

   ```
   # Get the file path to correctly save and access the model in Object Store.
   file_name = self.object_store.get_file_path(model_key)
   ```

   This method returns the file path where the model will be stored.

3. Call the `save` method with the file path.

   ```
   # Serialize the model and save it to the file.
   self.model.save(file_name)
   ```

Upload Models

If you train models locally or in another environment, you can upload the model files to the Object Store so your algorithms can use them. Use the model key that matches the key your algorithm expects when it calls `object_store.get_file_path` .

Follow one of these approaches to upload your model files:

LEAN CLI

Run the `lean cloud object-store set` command to upload a local file to the Object Store.

```
$ lean cloud object-store set <projectId>/model.keras <pathTo>/model.keras
```

Replace `<projectId>` with your project Id and `<pathTo>` with the path to the local model file.

Cloud API

Use the Upload Object Store Files endpoint to upload a model file through the API.

Load Models

You can load and trade with pre-trained `keras` models that you saved in the Object Store. To load a `keras` model from the Object Store, in the `initialize` method, get the file path to the saved model and then call the `load_model` method.

```
# Load the model from Object Store to use its saved state and update it with new data if needed.
def initialize(self) -> None:
    model_key = f"{self.project_id}/model.keras"
    if self.object_store.contains_key(model_key):
        file_name = self.object_store.get_file_path(model_key)
        self.model = load_model(file_name)
```

PY

The `contains_key` method returns a boolean that represents if the `model_key` is in the Object Store. If the Object Store does not contain the `model_key` , save the model using the `model_key` before you proceed.

Examples

The following examples demonstrate some common practices for using `Keras` library.

Example 1: Multi-layer Perceptron Model

The below algorithm makes use of `Keras` library to predict the future price movement using the previous 5 OHLCV data. The model is built with multi-layer perceptrons, ReLu activation function, and Adam optimization. It is trained using rolling 2-year data. To ensure the model applicable to the current market environment, we recalibrate the model on every Sunday.

PY

```
from tensorflow.keras.models import Sequential, load_model
from tensorflow.keras.layers import Dense, Flatten
from tensorflow.keras.optimizers import Adam

class KerasExampleAlgorithm(QCAlgorithm):
    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)  # Set Strategy Cash
        # Request SPY data for model training, prediction and trading.
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol

        # Retrieve already trained model from object store to use immediately.
        self._model_key = f"{self.project_id}/model.keras"
        if self.object_store.contains_key(self._model_key):
            file_name = self.object_store.get_file_path(self._model_key)
            self.model = load_model(file_name)

        # Create a MLP model otherwise to predict price movement.
        else:
            self.model = Sequential([Dense(10, input_shape=(5,5), activation='relu'),
                            Dense(10, activation='relu'),
                            Flatten(),
                            Dense(1)])
            self.model.compile(loss='mse',
                    optimizer=Adam(),
                    metrics=['mae', 'mse'])

        # Use the session rolling window to cache 2-year daily data for training.
        training_length = 252*2
        self.securities[self._symbol].session.size = training_length
        self.set_warm_up(training_length, Resolution.DAILY)

    def on_warmup_finished(self) -> None:
        # Train the model to use the prediction right away.
        self.train(self.my_training_method)
        # Recalibrate the model weekly to ensure its accuracy on the updated domain.
        self.train(self.date_rules.every(DayOfWeek.SUNDAY), self.time_rules.at(8, 0), self.my_training_method)

    def get_features_and_labels(self, n_steps=5) -> tuple[float, float]:
        # Train and predict the return data, which is more normalized and stationary.
        training_df = self.pandas_converter.get_data_frame[TradeBar](list(self.securities[self._symbol].session)[::-1])
        daily_pct_change = training_df.pct_change().dropna()

        # Stack the data for 5-day OHLCV data per each sample to train with.
        features = []
        labels = []
        for i in range(len(daily_pct_change)-n_steps):
            features.append(daily_pct_change.iloc[i:i+n_steps].values)
            labels.append(daily_pct_change['close'].iloc[i+n_steps])
        features = np.array(features)
        labels = np.array(labels)

        return features, labels

    def my_training_method(self) -> None:
        # Prepare the processed training data.
        features, labels = self.get_features_and_labels()
        # Recalibrate the model based on updated data.
        self.model.fit(features, labels, epochs=5)

    def on_data(self, slice: Slice) -> None:
        if self.is_warming_up or self._symbol not in slice.bars:
            return

        # Get prediction by the updated features.
        features, _ = self.get_features_and_labels()
        features = features[-1].reshape(1, 5, 5)
        prediction = float(self.model.predict(features)[-1])

        # If the predicted direction is going upward, buy SPY.
        if prediction > 0:
            self.set_holdings(self._symbol, 1)
        # If the predicted direction is going downward, sell SPY.
        elif prediction < 0:
            self.set_holdings(self._symbol, -1)

    def on_end_of_algorithm(self):
        # Store the model to object store to retrieve it in other instances in case the algorithm stops.
        file_name = self.object_store.get_file_path(self._model_key)
        self.model.save(file_name)
```

Popular Libraries

PyTorch

Introduction

This page explains how to build, train, deploy and store `PyTorch` models.

Import Libraries

Import the `torch` and `joblib` libraries.

```
PY
from AlgorithmImports import *
import torch
from torch import nn
import joblib
```

You need the `joblib` library to store models.

Create Subscriptions

In the `initialize` method, subscribe to some data so you can train the `torch` model and make predictions.

```
PY
# Add a security and save a reference to its Symbol.
self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
```

Build Models

In this example, build a neural-network regression model that uses the following features and labels:

Data Category	Description
Features	The last 5 closing prices.
Labels	The following day's closing price

The following image shows the time difference between the features and labels:

Follow these steps to create a method to build the model:

1. Define a subclass of `nn.Module` to be the model.

   In this example, use the ReLU activation function for each layer.

```
# Define a feed-forward neural network with two hidden layers for learning complex features, ReLU
# activations to introduce non-linearity, and a single regression output for predicting continuous values.
class NeuralNetwork(nn.Module):
    # Define the model structure.
    def __init__(self):
        super(NeuralNetwork, self).__init__()
        self.flatten = nn.Flatten()
        self.linear_relu_stack = nn.Sequential(
            nn.Linear(5, 5),   # input size, output size of the layer.
            nn.ReLU(),         # Relu non-linear transformation.
            nn.Linear(5, 5),
            nn.ReLU(),
            nn.Linear(5, 1),   # Output size = 1 for regression.
        )

    # Define the feed-forward prediction procedure.
    def forward(self, x):
        x = torch.from_numpy(x).float()
        result = self.linear_relu_stack(x)
        return result
```

2. Create an instance of the model and set its configuration to train on the GPU if it's available.

```
# Use GPU if it's available for faster computation. Otherwise, fallback to CPU.
device = 'cuda' if torch.cuda.is_available() else 'cpu'
# Initialize the model on the selected device.
self.model = NeuralNetwork().to(device)
```

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `initialize` method, make a history request .

```
# Fill a RollingWindow with 2 years of historical closing prices.
training_length = 252*2
self.training_data = RollingWindow(training_length)
history = self.history[TradeBar](self._symbol, training_length, Resolution.DAILY)
for trade_bar in history:
    self.training_data.add(trade_bar.close)
```

Define a Training Method

To train the model, define a method that fits the model with the training data.

```
# Prepare feature and label data for training by processing the RollingWindow data into a time series.
def get_features_and_labels(self, n_steps=5):
    close_prices = list(self.training_data)[::-1]

    features = []
    labels = []
    for i in range(len(close_prices)-n_steps):
        features.append(close_prices[i:i+n_steps])
        labels.append(close_prices[i+n_steps])
    features = np.array(features)
    labels = np.array(labels)

    return features, labels

def my_training_method(self):
    features, labels = self.get_features_and_labels()

    # Set the loss and optimization functions.
    # In this example, use the mean squared error as the loss function and stochastic gradient descent as the optimizer.
    loss_fn = nn.MSELoss()
    learning_rate = 0.001
    optimizer = torch.optim.SGD(self.model.parameters(), lr=learning_rate)

    # Loop through each epoch and train the model.
    epochs = 5
    for t in range(epochs):
        # Loop through each batch to train the model.
        for batch, (feature, label) in enumerate(zip(features, labels)):
            # Calculate the prediction and loss.
            pred = self.model(feature)
            real = torch.from_numpy(np.array(label).flatten()).float()
            loss = loss_fn(pred, real)

            # Perform backpropagation.
            optimizer.zero_grad()
            loss.backward()
            optimizer.step()
```

Set Training Schedule

To train the model at the beginning of your algorithm, in the `initialize` method, call the `train` method.

```
# Train the model initially to provide a baseline for prediction and decision-making.
self.train(self.my_training_method)
```

To periodically re-train the model as your algorithm executes, in the `initialize` method, call the `train` method as a Scheduled Event .

```
# Train the model every Sunday at 8:00 AM
self.train(self.date_rules.every(DayOfWeek.SUNDAY), self.time_rules.at(8, 0), self.my_training_method)
```

Update Training Data

To update the training data as the algorithm executes, in the `on_data` method, add the current `TradeBar` to the `RollingWindow` that holds the training data.

```
# Add the latest bar to training data to ensure the model is trained with the most recent market data.
def on_data(self, slice: Slice) -> None:
    if self._symbol in slice.Bars:
        self.training_data.add(slice.bars[self._symbol].close)
```

Predict Labels

To predict the labels of new data, in the `on_data` method, get the most recent set of features and pass it to the model.

```
# Get the current feature set and make a prediction.
features, _ = self.get_features_and_labels()
prediction = self.model(features[-1].reshape(1, -1))
prediction = float(prediction.detach().numpy()[-1])
```

You can use the label prediction to place orders.

```
# Place orders based on the forecasted market direction.
if prediction > slice.bars[self._symbol].price:
    self.set_holdings(self._symbol, 1)
elif prediction < slice.bars[self._symbol].price:
    self.set_holdings(self._symbol, -1)
```

Save Models

Follow these steps to save `PyTorch` models into the Object Store :

1. Set the key name of the model to be stored in the Object Store.

   ```
   # Set the key to store the model in the Object Store so you can use it later.
   model_key = f"{self.project_id}/model"
   ```

2. Call the `get_file_path` method with the key.

   ```
   # Get the file path to correctly save and access the model in Object Store.
   file_name = self.object_store.get_file_path(model_key)
   ```

   This method returns the file path where the model will be stored.

3. Call the `dump` method the file path.

   ```
   # Serialize the model and save it to the file.
   joblib.dump(self.model, file_name)
   ```

   If you dump the model using the `joblib` module before you save the model, you don't need to retrain the model.

Upload Models

If you train models locally or in another environment, you can upload the model files to the Object Store so your algorithms can use them. Use the model key that matches the key your algorithm expects when it calls `object_store.get_file_path` .

Follow one of these approaches to upload your model files:

LEAN CLI

Run the `lean cloud object-store set` command to upload a local file to the Object Store.

```
$ lean cloud object-store set <projectId>/model <pathTo>/model
```

Replace `<projectId>` with your project Id and `<pathTo>` with the path to the local model file.

Cloud API

Use the Upload Object Store Files endpoint to upload a model file through the API.

Load Models

You can load and trade with pre-trained `PyTorch` models that you saved in the Object Store. To load a `PyTorch` model from the Object Store, in the `initialize` method, get the file path to the saved model and then call the `load` method.

```
# Load the PyTorch model from Object Store to use its saved state and update it with new data if needed.
def initialize(self) -> None:
    model_key = f"{self.project_id}/model"
    if self.object_store.contains_key(model_key):
        file_name = self.object_store.get_file_path(model_key)
        self.model = joblib.load(file_name)
```

The `contains_key` method returns a boolean that represents if the `model_key` is in the Object Store. If the Object Store does not contain the `model_key` , save the model using the `model_key` before you proceed.

Examples

The following examples demonstrate some common practices for using `PyTorch` library.

Example 1: Multi-layer Perceptron Model

The below algorithm makes use of `PyTorch` library to predict the future price movement using the previous 5 OHLCV data. The model is built with multi-layer perceptrons, ReLu activation function, and stochastic gradient descent optimization. It is trained using rolling 2-year data. To ensure the model applicable to the current market environment, we recalibrate the model on every Sunday.

PY

```
import torch
from torch import nn
import joblib

class PyTorchExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Request SPY data for model training, prediction and trading.
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol

        # Use the session rolling window to cache 2-year daily data for training.
        training_length = 252*2
        self.securities[self._symbol].session.size = training_length
        self.set_warm_up(training_length, Resolution.DAILY)

        # Retrieve already trained model from object store to use immediately.
        self._model_key = f"{self.project_id}/pytorch-example-model"
        if self.live_mode and self.object_store.contains_key(self._model_key):

        return result
```

Popular Libraries

Scikit-Learn

Introduction

This page explains how to build, train, deploy and store `Scikit-Learn` models.

Import Libraries

Import the `sklearn` and `joblib` libraries.

```py
from AlgorithmImports import *
from sklearn.svm import SVR
from sklearn.model_selection import GridSearchCV
import joblib
```

You need the `joblib` library to store models.

Create Subscriptions

In the `initialize` method, subscribe to some data so you can train the `sklearn` model and make predictions.

```py
# Add a security and save a reference to its Symbol.
self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
```

Build Models

In this example, build a support vector regression prediction model that uses the following features and labels:

Data Category	Description
Features	Daily percent change of the open, high, low, close, and volume of the SPY over the last 5 days
Labels	Daily percent return of the SPY over the next day

The following image shows the time difference between the features and labels:

To build the model, call the `GridSearchCV` constructor with the SVR model, the parameter grid, a scoring method, the number of cross-validation folds:

```
# Define a grid of hyperparameters to search over and perform cross-validation.
aram_grid = {'C': [.05, .1, .5, 1, 5, 10],
             'epsilon': [0.001, 0.005, 0.01, 0.05, 0.1],
             'gamma': ['auto', 'scale']}
self.model = GridSearchCV(SVR(), param_grid, scoring='neg_mean_squared_error', cv=5)
```

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `initialize` method, make a history request .

```
# Fill a RollingWindow with 2 years of historical bars.
training_length = 252*2
self.training_data = RollingWindow(training_length)
history = self.history[TradeBar](self._symbol, training_length, Resolution.DAILY)
for trade_bar in history:
    self.training_data.add(trade_bar)
```

Define a Training Method

To train the model, define a method that fits the model with the training data.

```
# Prepare feature and label data for training by processing the RollingWindow data into a time series.
def get_features_and_labels(self, n_steps=5):
    training_df = self.pandas_converter.get_data_frame[TradeBar](list(self.training_data)[::-1])
    daily_pct_change = training_df.pct_change().dropna()

    features = []
    labels = []
    for i in range(len(daily_pct_change)-n_steps):
        features.append(daily_pct_change.iloc[i:i+n_steps].values.flatten())
        labels.append(daily_pct_change['close'].iloc[i+n_steps])
    features = np.array(features)
    labels = np.array(labels)

    return features, labels

def my_training_method(self):
    features, labels = self.get_features_and_labels()
    self.model = self.model.fit(features, labels).best_estimator_
```

Set Training Schedule

To train the model at the beginning of your algorithm, in the `initialize` method, call the `train` method.

```
# Train the model initially to provide a baseline for prediction and decision-making.
self.train(self.my_training_method)
```

To periodically re-train the model as your algorithm executes, in the `initialize` method, call the `train` method as a Scheduled Event .

```
# Train the model every Sunday at 8:00 AM
self.train(self.date_rules.every(DayOfWeek.SUNDAY), self.time_rules.at(8, 0), self.my_training_method)
```

Update Training Data

To update the training data as the algorithm executes, in the `on_data` method, add the current `TradeBar` to the `RollingWindow` that holds the training data.

```
# Add the latest bar to the training data to ensure the model is trained with the most recent market data.
def on_data(self, slice: Slice) -> None:
    if self._symbol in slice.bars:
        self.training_data.add(slice.bars[self._symbol])
```

Predict Labels

To predict the labels of new data, in the `on_data` method, get the most recent set of features and then call the `predict` method.

```
# Get the current feature set and make a prediction.
features, _ = self.get_features_and_labels()
prediction = self.model.predict(features[-1].reshape(1, -1))
prediction = float(prediction)
```

You can use the label prediction to place orders.

```
# Place orders based on the forecasted market direction.
if prediction > 0:
    self.SetHoldings(self._symbol, 1)
elif prediction < 0:
    self.SetHoldings(self._symbol, -1)
```

Save Models

Follow these steps to save `sklearn` models into the Object Store :

1. Set the key name you want to store the model under in the Object Store.

   ```
   # Set the key to store the model in the Object Store so you can use it later.
   model_key = f"{self.project_id}/model"
   ```

2. Call the `get_file_path` method with the key.

   ```
   # Get the file path to correctly save and access the model in Object Store.
   file_name = self.object_store.get_file_path(model_key)
   ```

   This method returns the file path where the model will be stored.

3. Call the `dump` method the file path.

   ```
   # Serialize the model and save it to the file.
   joblib.dump(self.model, file_name)
   ```

   If you dump the model using the `joblib` module before you save the model, you don't need to retrain the model.

Upload Models

If you train models locally or in another environment, you can upload the model files to the Object Store so your algorithms can use them. Use the model key that matches the key your algorithm expects when it calls `object_store.get_file_path` .

Follow one of these approaches to upload your model files:

LEAN CLI

Run the `lean cloud object-store set` command to upload a local file to the Object Store.

```
$ lean cloud object-store set <projectId>/model <pathTo>/model
```

Replace `<projectId>` with your project Id and `<pathTo>` with the path to the local model file.

Cloud API

Use the Upload Object Store Files endpoint to upload a model file through the API.

Load Models

You can load and trade with pre-trained `sklearn` models that you saved in the Object Store. To load a `sklearn` model from the Object Store, in the `initialize` method, get the file path to the saved model and then call the `load` method.

```
# Load the sklearn model from the Object Store to use its saved state and update it with new data if needed.
def initialize(self) -> None:
    model_key = f"{self.project_id}/model"
    if self.object_store.contains_key(model_key):
        file_name = self.object_store.get_file_path(model_key)
        self.model = joblib.load(file_name)
```

The `contains_key` method returns a boolean that represents if the `model_key` is in the Object Store. If the Object Store does not contain the `model_key` , save the model using the `model_key` before you proceed.

Examples

The following examples demonstrate some common practices for using Scikit-Learn library.

Example 1: Scikit-Learn

The below algorithm makes use of `Scikit-Learn` library to predict the future price movement using the previous 5 OHLCV data. The model is trained using rolling 2-year data. To ensure the model applicable to the current market environment, we recalibrate the model on every Sunday.

PY

```
from sklearn.svm import SVR
from sklearn.model_selection import GridSearchCV
import joblib

class ScikitLearnExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        self.set_cash(100000)
        # Request SPY data for model training, prediction and trading.
        self.symbol = self.add_equity("SPY", Resolution.DAILY).symbol

        # 2-year data to train the model.
        training_length = 252*2
        self.training_data = RollingWindow(training_length)
        # Warm up the training dataset to train the model immediately.
        history = self.history[TradeBar](self.symbol, training_length, Resolution.DAILY)
        for trade_bar in history:
            self.training_data.add(trade_bar)

        # Retrieve already trained model from object store to use immediately.
        if self.object_store.contains_key("sklearn_model"):
            file_name = self.object_store.get_file_path("sklearn_model")
            self.model = joblib.load(file_name)
        # Otherwise, grid serach with hyperparameter choices to create an optimal support vector regressor to predict price movement.
        else:
            param_grid = {'C': [.05, .1, .5, 1, 5, 10],
                          'epsilon': [0.001, 0.005, 0.01, 0.05, 0.1],
                          'gamma': ['auto', 'scale']}
            self.model = GridSearchCV(SVR(), param_grid, scoring='neg_mean_squared_error', cv=5)

        # Train the model to use the prediction right away.
        self.train(self.my_training_method)
        # Recalibrate the model weekly to ensure its accuracy on the updated domain.
        self.train(self.date_rules.every(DayOfWeek.SUNDAY), self.time_rules.at(8,0), self.my_training_method)

    def get_features_and_labels(self, n_steps=5) -> None:
        # Train and predict the return data, which is more normalized and stationary.
        training_df = self.pandas_converter.get_data_frame[TradeBar](list(self.training_data)[::-1])
        daily_pct_change = training_df.pct_change().dropna()

        # Stack the data for 5-day OHLCV data per each sample to train with.
        features = []
        labels = []
        for i in range(len(daily_pct_change)-n_steps):
            features.append(daily_pct_change.iloc[i:i+n_steps].values.flatten())
            labels.append(daily_pct_change['close'].iloc[i+n_steps])
        features = np.array(features)
        labels = np.array(labels)

        return features, labels

    def my_training_method(self) -> None:
        # Prepare the processed training data.
        features, labels = self.get_features_and_labels()
        # Recalibrate the model based on updated data.
        if isinstance(self.model, GridSearchCV):
            self.model = self.model.fit(features, labels).best_estimator_
        else:
            self.model = self.model.fit(features, labels)

    def on_data(self, slice: Slice) -> None:
        if self.symbol in slice.bars:
            self.training_data.add(slice.bars[self.symbol])

        # Get prediction by the updated features.
        features, _ = self.get_features_and_labels()
        prediction = self.model.predict(features[-1].reshape(1, -1))
        prediction = float(prediction)

        # If the predicted direction is going upward, buy SPY.
        if prediction > 0:
            self.set_holdings(self.symbol, 1)
        # If the predicted direction is going downward, sell SPY.
        elif prediction < 0:
            self.set_holdings(self.symbol, -1)

    def on_end_of_algorithm(self) -> None:
        # Store the model to object store to retrieve it in other instances in case the algorithm stops.
        model_key = "sklearn_model"
        file_name = self.object_store.get_file_path(model_key)
        joblib.dump(self.model, file_name)
        self.object_store.save(model_key)
```

Popular Libraries

Tensorflow

Introduction

This page explains how to build, train, deploy and store `Tensorflow` models.

Import Libraries

Import the `tensorflow` library.

```py
from AlgorithmImports import *
import tensorflow as tf
```

Create Subscriptions

In the `initialize` method, subscribe to some data so you can train the `tensorflow` model and make predictions.

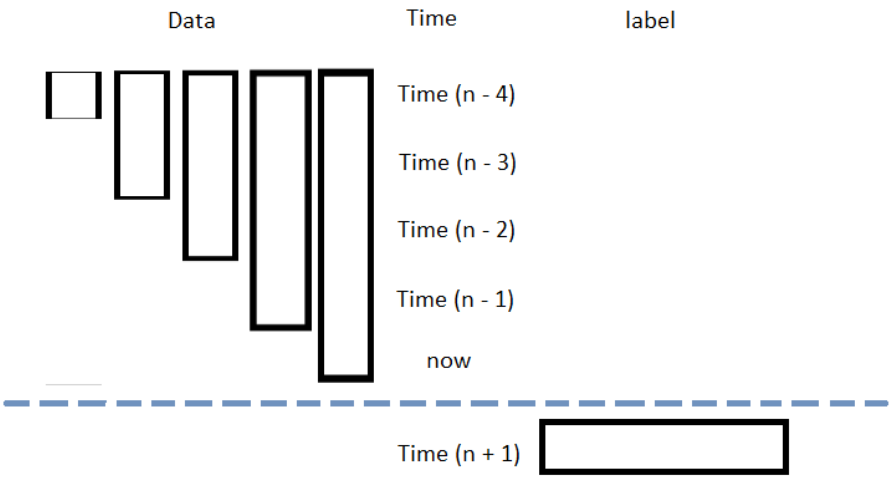
```py
# Add a security and save a reference to its Symbol.
self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
```

Build Models

In this example, build a neural-network regression prediction model that uses the following features and labels:

Data Category	Description
Features	The last 5 close price differencing compared to current price
Labels	The following day's price change

The following image shows the time difference between the features and labels:



Follow these steps to create a method to build the model:

1. Define some parameters, including the number of factors, neurons, and epochs.

```
# Set some hyperparameters:
num_factors = 5     # Set the number of input features.
num_neurons_1 = 10  # Set the neurons in each hidden layer to capture complexity.
num_neurons_2 = 10
num_neurons_3 = 5
self.epochs = 20    # Set the training epochs for sufficient learning.
self.learning_rate = 0.0001  # Set the learning rate for optimization control.
```

2. Create the model using built-in Keras API.

```
# Define the model with sequential layers: an input layer with ReLU activation to introduce non-linearity,
# two hidden layers for feature extraction, and an output layer for predictions.
self.model = tf.keras.Sequential([
    tf.keras.layers.Dense(num_neurons_1, activation=tf.nn.relu, input_shape=(num_factors,)),  # The input shape is required.
    tf.keras.layers.Dense(num_neurons_2, activation=tf.nn.relu),
    tf.keras.layers.Dense(num_neurons_3, activation=tf.nn.relu),
    tf.keras.layers.Dense(1)
])
```

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `initialize` method, make a history request .

```
# Fill a RollingWindow with 300 days of historical closing prices.
training_length = 300
self.training_data = RollingWindow(training_length)
history = self.history[TradeBar](self._symbol, training_length, Resolution.DAILY)
for trade_bar in history:
    self.training_data.add(trade_bar.close)
```

Define a Training Method

To train the model, define a method that fits the model with the training data.

```
# Prepare feature and label data for training by processing the RollingWindow data into a time series.
def get_features_and_labels(self, lookback=5):
    lookback_series = []

    data = pd.Series(list(self.training_data)[::-1])
    for i in range(1, lookback + 1):
        df = data.diff(i)[lookback:-1]
        df.name = f"close-{i}"
        lookback_series.append(df)

    X = pd.concat(lookback_series, axis=1).reset_index(drop=True).dropna()
    Y = data.diff(-1)[lookback:-1].reset_index(drop=True)
    return X.values, Y.values

def my_training_method(self):
    features, labels = self.get_features_and_labels()

    # Define the loss function. We use MSE in this example.
    def loss_mse(target_y, predicted_y):
        return tf.reduce_mean(tf.square(target_y - predicted_y))

    # Train the model.
    optimizer = tf.keras.optimizers.Adam(learning_rate=self.learning_rate)
    for i in range(self.epochs):
        with tf.GradientTape() as t:
            loss = loss_mse(labels, self.model(features))

        jac = t.gradient(loss, self.model.trainable_weights)
        optimizer.apply_gradients(zip(jac, self.model.trainable_weights))
```

Set Training Schedule

To train the model at the beginning of your algorithm, in the `initialize` method, call the `train` method.

```
# Train the model initially to provide a baseline for prediction and decision-making.
self.train(self.my_training_method)
```

To periodically re-train the model as your algorithm executes, in the `initialize` method, schedule some training sessions .

```
# Train the model every Sunday at 8:00 AM
self.train(self.date_rules.every(DayOfWeek.SUNDAY), self.time_rules.at(8, 0), self.my_training_method)
```

Update Training Data

To update the training data as the algorithm executes, in the `on_data` method, add the current close price to the `RollingWindow` that holds the training data.

```
# Add the latest closing price to the training data to ensure the model is trained with the most recent market data.
def on_data(self, slice: Slice) -> None:
    if self._symbol in slice.bars:
        self.training_data.add(slice.bars[self._symbol].close)
```

Predict Labels

To predict the labels of new data, in the `on_data` method, get the most recent set of features and then call the `run` method with new features.

```
# Get the current feature set and make a prediction.
new_features, __ = self.get_features_and_labels()
prediction = self.model(new_features)
prediction = float(prediction.numpy()[-1])
```

You can use the label prediction to place orders.

```
# Place orders based on the forecasted market direction.
if prediction > 0:
    self.SetHoldings(self._symbol, 1)
elif prediction < 0:
    self.SetHoldings(self._symbol, -1)
```

Save Models

Follow these steps to save `Tensorflow` models into the Object Store :

1. Set the key name of the model to be stored in the Object Store.

   ```
   # Set the key to store the model in the Object Store so you can use it later.
   model_key = f"{self.project_id}/model.keras"
   ```

   Note that the model has to have the suffix `.keras` .

2. Call the `get_file_path` method with the key.

   ```
   # Get the file path to correctly save and access the model in Object Store.
   file_name = self.object_store.get_file_path(model_key)
   ```

   This method returns the file path where the model will be stored.

3. Call the `save` method with the model and file path.

```
# Serialize the model and save it to the file.
model.save(file_name)
```

4. Save the model to the file path.

```
# Save the model to object store to capture model state for reusability.
self.object_store.save(model_key)
```

Upload Models

If you train models locally or in another environment, you can upload the model files to the Object Store so your algorithms can use them. Use the model key that matches the key your algorithm expects when it calls `object_store.get_file_path` .

Follow one of these approaches to upload your model files:

LEAN CLI

Run the `lean cloud object-store set` command to upload a local file to the Object Store.

```
$ lean cloud object-store set <projectId>/model.keras <pathTo>/model.keras
```

Replace `<projectId>` with your project Id and `<pathTo>` with the path to the local model file.

Cloud API

Use the Upload Object Store Files endpoint to upload a model file through the API.

Load Models

You can load and trade with pre-trained `tensorflow` models that you saved in the Object Store. To load a `tensorflow` model from the Object Store, in the `initialize` method, get the file path to the saved model and then recall the graph and weights of the model.

```
# Load the tensorflow model from the Object Store to use its saved state and update it with new data if needed.
def initialize(self) -> None:
    model_key = f"{self.project_id}/model.keras"
    if self.object_store.contains_key(model_key):
        file_name = self.object_store.get_file_path(model_key)
        self.model = tf.keras.models.load_model(file_name)
```

The `contains_key` method returns a boolean that represents if the `model.keras` is in the Object Store. If the Object Store doesn't contain the keys, save the model using them before you proceed.

Examples

The following examples demonstrate some common practices for using `Keras` library.

Example 1: Multi-layer Perceptron Model

The below algorithm makes use of `Keras` library to predict the future price movement using the previous 5 OHLCV data. The model is built with multi-layer perceptrons, ReLu activation function, and Adam optimization. It is trained using rolling 2-year data. To ensure the model applicable to the current market environment, we recalibrate the model on every Sunday.

PY

```
import tensorflow as tf

class TensorFlowAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Request SPY data for model training, prediction and trading.
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol

        # Hyperparameter to create the MLP model.
        num_factors = 5
        num_neurons_1 = 10
        num_neurons_2 = 10
        num_neurons_3 = 5
        self.epochs = 100
        self.learning_rate = 0.0001

        # Create the MLP model with ReLu activiation.
        self.model = tf.keras.Sequential([
            tf.keras.layers.Dense(num_neurons_1, activation=tf.nn.relu, input_shape=(num_factors,)),  # input shape required
            tf.keras.layers.Dense(num_neurons_2, activation=tf.nn.relu),
            tf.keras.layers.Dense(num_neurons_3, activation=tf.nn.relu),
            tf.keras.layers.Dense(1)
        ])

        # Use the session rolling window to cache 2-year daily data for training.
        training_length = 500
        self.securities[self._symbol].session.size = training_length
        self.set_warm_up(training_length, Resolution.DAILY)

    def on_warmup_finished(self) -> None:

        data = pd.Series([x.close for x in self.securities[self._symbol].session][::-1])
        for i in range(1, lookback + 1):
            df = data.diff(i)[lookback:-1]
            df.name = f"close-{i}"
            lookback_series.append(df)

        X = pd.concat(lookback_series, axis=1).reset_index(drop=True).dropna()
        Y = data.diff(-1)[lookback:-1].reset_index(drop=True)
        return X.values, Y.values

    def my_training_method(self) -> None:
        # Prepare the processed training data.
        features, labels = self.get_features_and_labels()

        # Define the loss function, we use MSE in this example
        def loss_mse(target_y, predicted_y):
            return tf.reduce_mean(tf.square(target_y - predicted_y))

        # Train the model with Adam optimization function.
        optimizer = tf.keras.optimizers.Adam(learning_rate=self.learning_rate)
        for i in range(self.epochs):
            with tf.GradientTape() as t:
                loss = loss_mse(labels, self.model(features))

            jac = t.gradient(loss, self.model.trainable_weights)
            optimizer.apply_gradients(zip(jac, self.model.trainable_weights))

    def on_data(self, data) -> None:
        if self.is_warming_up or not data.bars.contains_key(self._symbol):
            return

        # Get prediction by the updated features.
        new_features, __ = self.get_features_and_labels()
        prediction = float(self.model(new_features).numpy().flatten()[-1])

        # If the predicted direction is going upward, buy SPY, else sell.
        self.set_holdings(self._symbol, 1 if prediction > 0 else -1)
```

Popular Libraries

Tslearn

Introduction

This page explains how to build, train, deploy and store `Tslearn` models.

Import Libraries

Import the `tslearn` libraries.

```
PY
from AlgorithmImports import *
from tslearn.barycenters import softdtw_barycenter
from tslearn.clustering import TimeSeriesKMeans
```

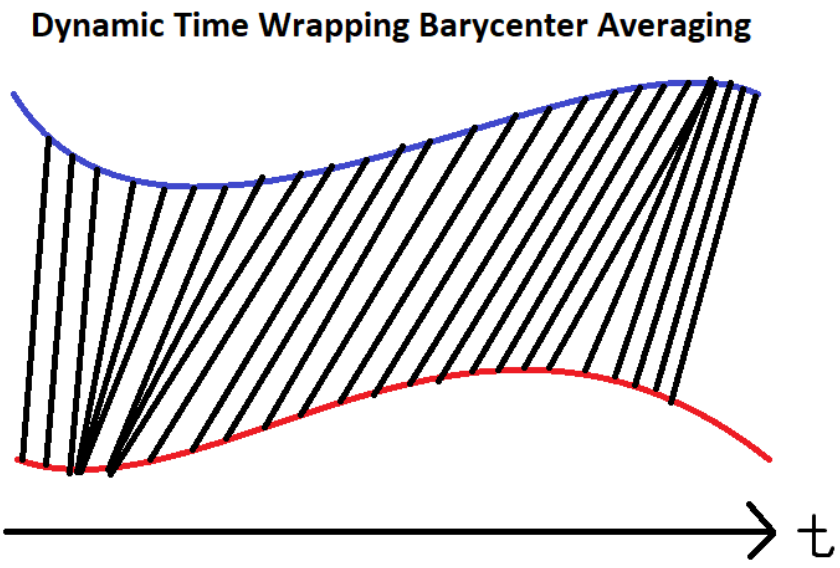
Create Subscriptions

In the `initialize` method, subscribe to some data so you can train the `tslearn` model.

```
PY
# Add securities and save a reference to their Symbol objects.
tickers = ["SPY", "QQQ", "DIA",
           "AAPL", "MSFT", "TSLA",
           "IEF", "TLT", "SHV", "SHY",
           "GLD", "IAU", "SLV",
           "USO", "XLE", "XOM"]
symbols = [self.add_equity(ticker, Resolution.DAILY).symbol for ticker in tickers]
```

Build Models

In this example, train a model that clusters the universe of Equities into distinct groups and then allocate an equal portion of the portfolio to each cluster. To cluster the securities, instead of using a real-time comparison, apply Dynamic Time Wrapping Barycenter Averaging (DBA) to their historical prices and then run a k-means clustering algorithm. DBA is a technique of averaging a few time-series into a single one without losing much of their information. Since not all time-series move efficiently like in ideal EMH assumption, this technique allows similarity analysis of different time-series with sticky lags. The following image shows a visualization of the process. For more information about the technical details, see Dynamic Time Warping in the tslearn documentation .



To perform DBA and then cluster the securities by k-means, create a TimeSeriesKMeans model:

```
# Create a model to cluster the time series into 6 groups using DTW for similarity measurement.
self.model = TimeSeriesKMeans(n_clusters=6, metric="dtw")
```

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `initialize` method, make a history request .

```
# Fill a RollingWindow with 2 years of historical closing prices.
training_length = 252
self.training_data = {}
history = self.history(self.symbols, training_length, Resolution.DAILY).unstack(0).close
for symbol in self.symbols:
    self.training_data[symbol] = RollingWindow(training_length)
    for close_price in history[symbol]:
        self.training_data[symbol].add(close_price)
```

Define a Training Method

To train the model, define a method that fits the model with the training data.

```
# Prepare feature and label data for training by processing the RollingWindow data into a time series.
def get_features(self):
    close_price = pd.DataFrame({symbol: list(data)[::-1] for symbol, data in self.training_data.items()})
    log_price = np.log(close_price)
    log_normal_price = (log_price - log_price.mean()) / log_price.std()

    return log_normal_price

def my_training_method(self):
    features = self.get_features()
    self.model.fit(features.T.values)
```

Set Training Schedule

To train the model at the beginning of your algorithm, in the `initialize` method, call the `train` method.

```
# Train the model initially to provide a baseline for prediction and decision-making.
self.train(self.my_training_method)
```

To periodically re-train the model as your algorithm executes, in the `initialize` method, call the `train` method as a Scheduled Event .

```
# Train the model every Sunday at 8:00 AM
self.train(self.date_rules.every(DayOfWeek.SUNDAY), self.time_rules.at(8, 0), self.my_training_method)
```

Update Training Data

To update the training data as the algorithm executes, in the `on_data` method, add the current `TradeBar` to the `RollingWindow` that holds the training data.

```
# Add the latest price to the training data to ensure the model is trained with the most recent market data.
def on_data(self, slice: Slice) -> None:
    for kvp in slice.bars:
        self.training_data[kvp.key].add(kvp.value.close)
```

Predict Labels

To predict the labels of new data, in the `on_data` method, get the most recent set of features and then call the `predict` method.

```
# Get the current feature set and make a prediction.
features = self.get_features()
self.labels = self.model.predict(features.T.values)
```

You can use the label prediction to place orders.

```
# Place orders based on the predicted clusters.
for i in set(self.labels):
    assets_in_cluster = features.columns[[n for n, k in enumerate(self.labels) if k == i]]
    size = 1/6/len(assets_in_cluster)
    self.set_holdings([PortfolioTarget(symbol, size) for symbol in assets_in_cluster])
```

Save Models

Follow these steps to save `tslearn` models into the Object Store :

1. Set the key name of the model to be stored in the Object Store.

   ```
   # Set the key to store the model in the Object Store for reuse across sessions.
   model_key = f"{self.project_id}/model.hdf5"
   ```

2. Call the `get_file_path` method with the key.

   ```
   # Get the file path to correctly save and access the model in Object Store.
   file_name = self.object_store.get_file_path(model_key)
   ```

   This method returns the file path where the model will be stored.

3. Delete the current file to avoid a `FileExistsError` error when you save the model.

   ```
   import os
   os.remove(file_name)
   ```

4. Call the `to_hdf5` method with the file path.

   ```
   # Serialize the model and save it to the file.
   self.model.to_hdf5(file_name)
   ```

Upload Models

If you train models locally or in another environment, you can upload the model files to the Object Store so your algorithms can use them. Use the model key that matches the key your algorithm expects when it calls `object_store.get_file_path` .

Follow one of these approaches to upload your model files:

LEAN CLI

Run the `lean cloud object-store set` command to upload a local file to the Object Store.

```
$ lean cloud object-store set <projectId>/model.hdf5 <pathTo>/model.hdf5
```

Replace `<projectId>` with your project Id and `<pathTo>` with the path to the local model file.

Cloud API

Use the Upload Object Store Files endpoint to upload a model file through the API.

Load Models

You can load and trade with pre-trained `tslearn` models that saved in Object Store. To load a `tslearn` model from the Object Store, in the `initialize` method, get the file path to the saved model and then call the `from_hdf5` method.

```
# Load the tslearn model from the Object Store to use its saved state and update it with new data if needed.
def initialize(self) -> None:
    model_key = f"{self.project_id}/model.hdf5"
    if self.object_store.contains_key(model_key):
        file_name = self.object_store.get_file_path(model_key)
        self.model = TimeSeriesKMeans.from_hdf5(file_name + ".hdf5")
```

The `contains_key` method returns a boolean that represents if the `model_key` is in the Object Store. If the Object Store does not contain the `model_key` , save the model using the `model_key` before you proceed.

Examples

The following examples demonstrate some common practices for using `Tslearn` library.

Example 1: Dynamic Time Wrapping (DTW) Clustering

The below algorithm makes use of `Tslearn` library to cluster stocks based on their recent year's price movement through DTW Barycenter Averaging. Then, we invest each cluster equally, while investing stocks within cluster equally as well. To ensure the model applicable to the current market environment, we recalibrate the model on every Sunday.

PY

```
from tslearn.barycenters import softdtw_barycenter
from tslearn.clustering import TimeSeriesKMeans
import joblib

class TslearnExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Request stocks data for model training, clustering and trading.
        tickers = ["SPY", "QQQ", "DIA",
                "AAPL", "MSFT", "TSLA",
                "IEF", "TLT", "SHV", "SHY",
                "GLD", "IAU", "SLV",
                "USO", "XLE", "XOM"]
        self.symbols = [self.add_equity(ticker, Resolution.DAILY).symbol for ticker in tickers]

        # 1-year data to train the model.
        self._training_length = 252

        # Create the DTW model to cluster the stocks.
        self.model = TimeSeriesKMeans(n_clusters=6,   # We have 6 main groups
                                      metric="dtw")

        # Train the model to use the prediction right away.
        self.train(self.my_training_method)
        # Recalibrate the model weekly to ensure its accuracy on the updated domain.
        self.train(self.date_rules.every(DayOfWeek.SUNDAY), self.time_rules.at(8,0), self.my_training_method)

    def get_features(self) -> None:
        # Get historical close prices and cluster the log-return data, which is more normalized and stationary.
        close_price = self.history(self.symbols, self._training_length, Resolution.DAILY).unstack(0).close.dropna(axis=1)
        log_price = np.log(close_price)
        log_normal_price = (log_price - log_price.mean()) / log_price.std()

        return log_normal_price

    def my_training_method(self) -> None:
        # Prepare the processed training data.
        features = self.get_features()
        # Recalibrate the model based on updated data.
        self.model.fit(features.T.values)

    def on_data(self, slice: Slice) -> None:
        if not hasattr(self.model, 'cluster_centers_'):
            return

        # Get prediction by the updated features.
        features = self.get_features()
        self.labels = self.model.predict(features.T.values)

        # Equally invest in each cluster, while investing each stocks within cluster equally to evenly dissipate capital risks at various
levels.
        for i in set(self.labels):
            assets_in_cluster = features.columns[[n for n, k in enumerate(self.labels) if k == i]]
            size = 1/6/len(assets_in_cluster)
            self.set_holdings([PortfolioTarget(symbol, size) for symbol in assets_in_cluster])

    def on_end_of_algorithm(self) -> None:
        # Store the model to object store to retrieve it in other instances in case the algorithm stops.
        model_key = f"{self.project_id}/model_test.hdf5"
        # If the model already exists, delete it so the `to_hdf5` method doesn't raise an error.
        if self.object_store.contains_key(model_key):
            self.object_store.delete(model_key)
        file_name = self.object_store.get_file_path(model_key)
        self.model.to_hdf5(file_name)
```

Popular Libraries

XGBoost

Introduction

This page explains how to build, train, deploy and store `XGBoost` models.

Import Libraries

Import the `XGBoost` and `joblib` libraries.

```
from AlgorithmImports import *
import xgboost as xgb
import joblib
```

You need the `joblib` library to store models.

Create Subscriptions

In the `initialize` method, subscribe to some data so you can train the `xgboost` model and make predictions.

```
# Add a security and save a reference to its Symbol.
self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
```

Build Models

In this example, build a gradient boost tree regression prediction model that uses the following features and labels:

Data Category	Description
Features	The last 5 closing prices
Labels	The following day's closing price

The following image shows the time difference between the features and labels:

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `initialize` method, make a history request .

```py
# Fill a RollingWindow with 2 years of historical closing prices.
training_length = 252*2
self.training_data = RollingWindow(training_length)
history = self.history[TradeBar](self._symbol, training_length, Resolution.DAILY)
for trade_bar in history:
    self.training_data.add(trade_bar.close)
```

Define a Training Method

To train the model, define a method that fits the model with the training data.

```py
# Prepare feature and label data for training by processing the RollingWindow data into a time series.
def get_features_and_labels(self, n_steps=5):
    # Create a list of close prices from the rolling window.
    close_prices = np.array(list(self.training_data)[::-1])
    df = (np.roll(close_prices, -1) - close_prices) * 0.5 + close_prices * 0.5
    df = df[:-1]

    features = []
    labels = []
    for i in range(len(df)-n_steps):
        features.append(df[i:i+n_steps])
        labels.append(df[i+n_steps])

    features = np.array(features)
    labels = np.array(labels)
    # Standardize the features and labels arrays.
    features = (features - features.mean()) / features.std()
    labels = (labels - labels.mean()) / labels.std()

    # Load the NumPy array into a DMatrix object.
    d_matrix = xgb.DMatrix(features, label=labels)

    return d_matrix

def my_training_method(self):
    # Instantiate the DMatrix object with the features and labels array.
    d_matrix = self.get_features_and_labels()
    # Define the parameters for the XGBoost model.
    params = {
        'booster': 'gbtree',
        'colsample_bynode': 0.8,
        'learning_rate': 0.1,
        'lambda': 0.1,
        'max_depth': 5,
        'num_parallel_tree': 100,
        'objective': 'reg:squarederror',
        'subsample': 0.8,
      }
    # Create the model and fit it with the training data.
    self.model = xgb.train(params, d_matrix, num_boost_round=10)
```

Set Training Schedule

To train the model at the beginning of your algorithm, in the `initialize` method, call the `train` method.

```py
# Train the model initially to provide a baseline for prediction and decision-making.
self.train(self.my_training_method)
```

To periodically re-train the model as your algorithm executes, in the `initialize` method, call the `train` method as a Scheduled Event .

```py
# Train the model every Sunday at 8:00 AM.
self.train(self.date_rules.every(DayOfWeek.SUNDAY), self.time_rules.at(8, 0), self.my_training_method)
```

Update Training Data

To update the training data as the algorithm executes, in the `on_data` method, add the current `TradeBar` to the `RollingWindow` that holds the training data.

```
# Add the latest price to the training data to ensure the model is trained with the most recent market data.
def on_data(self, slice: Slice) -> None:
    if self._symbol in slice.bars:
        # Update the training data with new most recent close price.
        self.training_data.add(slice.bars[self._symbol].close)
```

Predict Labels

To predict the labels of new data, in the `on_data` method, get the most recent set of features and then call the `predict` method.

```
# Get the current feature set and make a prediction.
new_d_matrix = self.get_features_and_labels(df)
prediction = self.model.predict(new_d_matrix)
prediction = prediction.flatten()
```

You can use the label prediction to place orders.

```
# Place orders based on the forecasted market direction.
if float(prediction[-1]) > float(prediction[-2]):
    self.set_holdings(self._symbol, 1)
else:
    self.set_holdings(self._symbol, -1)
```

Save Models

Follow these steps to save `xgboost` models into the Object Store :

1. Set the key name of the model to be stored in the Object Store.

   ```
   # Set the key to store the model in the Object Store so you can use it later.
   model_key = f"{self.project_id}/model"
   ```

2. Call the `get_file_path` method with the key.

   ```
   # Get the file path to correctly save and access the model in Object Store.
   file_name = self.object_store.get_file_path(model_key)
   ```

   This method returns the file path where the model will be stored.

3. Call the `dump` method the file path.

   ```
   # Serialize the model and save it to the file.
   joblib.dump(self.model, file_name)
   ```

   If you dump the model using the `joblib` module before you save the model, you don't need to retrain the model.

Upload Models

If you train models locally or in another environment, you can upload the model files to the Object Store so your algorithms can use them. Use the model key that matches the key your algorithm expects when it calls `object_store.get_file_path` .

Follow one of these approaches to upload your model files:

LEAN CLI

Run the `lean cloud object-store set` command to upload a local file to the Object Store.

```
$ lean cloud object-store set <projectId>/model <pathTo>/model
```

Replace `<projectId>` with your project Id and `<pathTo>` with the path to the local model file.

Cloud API

Use the Upload Object Store Files endpoint to upload a model file through the API.

Load Models

You can load and trade with pre-trained `xgboost` models that saved in Object Store. To load a `xgboost` model from the Object Store, in the `initialize` method, get the file path to the saved model and then call the `load` method.

```
PY
# Load the xgboost model from the Object Store to use its saved state and update it with new data if needed.
def initialize(self) -> None:
    model_key = f"{self.project_id}/model"
    if self.object_store.contains_key(model_key):
        file_name = self.object_store.get_file_path(model_key)
        self.model = joblib.load(file_name)
```

The `contains_key` method returns a boolean that represents if the `model_key` is in the Object Store. If the Object Store does not contain the `model_key` , save the model using the `model_key` before you proceed.

Examples

The following examples demonstrate some common practices for using `XGBoost` library.

Example 1: Gradient Boosting Model

The below algorithm makes use of `XGBoost` library to predict the future price movement using the previous 5 OHLCV data. The model is trained using rolling 2-year data. To ensure the model applicable to the current market environment, we recalibrate the model on every Sunday.

```
PY
import xgboost as xgb
import joblib

class XGBoostExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Request SPY data for model training, prediction and trading.
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol

        # Use the session rolling window to cache 2-year daily data for training.
        training_length = 252*2
        self.securities[self._symbol].session.size = training_length

Hugging Face

Hugging Face

Key Concepts

Introduction

Hugging Face is a leading company in natural language processing (NLP), providing powerful tools and pre-trained models that can significantly enhance your trading algorithms on QuantConnect. By integrating Hugging Face's models, you can easily leverage advanced NLP capabilities for tasks such as sentiment analysis, news classification, and market forecasting without defining and training the model yourself. Hugging Face provides an easy way to leverage the research of community members to increase the sophistication of your trading algorithms.

Supported Models

Hundreds of thousands of Hugging Face models are publicly available and ready to use. To view all of them, see the Model Hub on the Hugging Face website. The Model card tab of each model repository explains an overview of how the model works, its requirements, and a quick start guide.

QuantConnect Cloud caches some of the most popular models to speed up your development workflow. The following table shows the cached models:

To see the commit hash of the cached models, run the following algorithm in QC Cloud and then view the logs :

```py
# Scan and log all cached Hugging Face model revisions from the cache directory.
from huggingface_hub import scan_cache_dir

class HuggingFaceModelHashAlgorithm(QCAlgorithm):

    def initialize(self):
        cache_info = scan_cache_dir()
        cached_models_log = []
        for entry in cache_info.repos:
            revisions = [revision.commit_hash for revision in entry.revisions]
            cached_models_log.append(f'Repo: {entry.repo_id}. Revisions {str(revisions)}')
        self.quit('\n'.join(sorted(cached_models_log)))
```

Train Models

Hugging Face models are pre-trained, so you can quickly load them into your algorithms and use their output to inform your trading decisions. To customize the model for your specific use case, you can fine-tune the pre-trained model with your own training data.

Examples

Chronos-T5

Introduction

This page explains how to use Chronos-T5 in LEAN trading algorithms. The model repository provides the following description:

> Chronos is a family of **pretrained time series forecasting models** based on language model architectures. A time series is transformed into a sequence of tokens via scaling and quantization, and a language model is trained on these tokens using the cross-entropy loss. Once trained, probabilistic forecasts are obtained by sampling multiple future trajectories given the historical context. Chronos models have been trained on a large corpus of publicly available time series data, as well as synthetic data generated using Gaussian processes.
>
> For details on Chronos models, training data and procedures, and experimental results, please refer to the paper Chronos: Learning the Language of Time Series .

Use Cases

The Chronos-T5 model is a time series forecasting model. The following use cases explain how you might utilize it in trading algorithms:

- Forecast the future equity curves for a set of assets, then pass them to an optimizer to determine the weights that maximize the future Sharpe ratio of the portfolio.
- Forecast the future volatility of an asset to manage risk and opimize portfolio allocations.
- Train the model to forecast the impact of specific events on an asset and then adjust your holdings in response to the event. For example, you could train the model to forecast the impact of news , corporate actions , or financial reports .

Load Pre-Trained Model

Follow these steps to load the pre-trained Chronos-T5 model:

1. Add the following imports to the top of your code file:

```
PY
from chronos import ChronosPipeline
import torch
```

2. Call the `ChronosPipeline.from_pretrained` method with the model path.

   In QuantConnect Cloud, the path to the tiny model is amazon / chronos-t5-tiny .

```
PY
# Load the ChronosPipeline model.
self._pipeline = ChronosPipeline.from_pretrained(
    "amazon/chronos-t5-tiny",
    device_map="cuda" if torch.cuda.is_available() else "cpu",
    torch_dtype=torch.bfloat16,
)
```

3. (Optional) Set the seed to enable reproducibility.

```
PY
# Set the seed.
from transformers import set_seed
set_seed(1, True)
```

Fine-Tune Model

The Chronos-T5 model is pre-trained, so you don't need to fine-tune it. Fine-tuning the model just tailors it to your specific use case. Follow these steps to fine-tune it:

1. Add the following imports to the top of your code file:

```py
import torch
from ast import literal_eval
from pathlib import Path
from functools import partial
from transformers import Trainer, TrainingArguments, set_seed
from gluonts.dataset.pandas import PandasDataset
from gluonts.itertools import Filter
from chronos import ChronosConfig, ChronosPipeline
from chronos.scripts.training.train import ChronosDataset, has_enough_observations, load_model
from chronos.scripts.training import train
from logging import getLogger, INFO
```

2. In the `initialize` method, define the model and some of its settings.

   In QuantConnect Cloud, the path to the tiny model is amazon/chronos-t5-tiny .

```py
def initialize(self):
    # Configure the model parameters to optimize performance.
    self._prediction_length = 3*21  # Three months of trading days
    self._device_map = "cuda" if torch.cuda.is_available() else "cpu"
    self._optimizer = 'adamw_torch_fused' if torch.cuda.is_available() else 'adamw_torch'
    self._model_name = "amazon/chronos-t5-tiny"
    self._model_path = self.object_store.get_file_path(
        f"{self.project_id}/llm/fine-tune/{self._model_name.replace('/', '-')}/"
    )
```

3. Define the fine-tuning method.

```py
# Configure the fine-tuning method and initiate the training.
def _train_chronos(
        self, training_data,
        probability: Optional[str] = None,
        context_length: int = 512,
        prediction_length: int = 64,
        min_past: int = 64,
        max_steps: int = 200_000,

            model_type=model_type,
            context_length=context_length,
            prediction_length=prediction_length,
            num_samples=num_samples,
            temperature=temperature,
            top_k=top_k,
            top_p=top_p,
        )

        # Add extra items to model config so that it's saved in the ckpt.
        model.config.chronos_config = chronos_config.__dict__
        # Create a shuffled training dataset with the specified parameters.
        shuffled_train_dataset = ChronosDataset(
            datasets=train_datasets,
            probabilities=probability,
            tokenizer=chronos_config.create_tokenizer(),
            context_length=context_length,
            prediction_length=prediction_length,
            min_past=min_past,
            mode="training",
        ).shuffle(shuffle_buffer_length=shuffle_buffer_length)

        # Define the training arguments.
        training_args = TrainingArguments(
            output_dir=str(output_dir),
            per_device_train_batch_size=per_device_train_batch_size,
            learning_rate=learning_rate,
            lr_scheduler_type=lr_scheduler_type,
            warmup_ratio=warmup_ratio,
            optim=optim,
            logging_dir=str(output_dir / "train-logs"),
            logging_strategy="steps",
            logging_steps=log_steps,
            save_strategy="steps",
            save_steps=save_steps,
            report_to=["tensorboard"],
            max_steps=max_steps,
            gradient_accumulation_steps=gradient_accumulation_steps,
            dataloader_num_workers=dataloader_num_workers,
            tf32=tf32,  # remove this if not using Ampere GPUs (e.g., A100)
            torch_compile=torch_compile,
            ddp_find_unused_parameters=False,
            remove_unused_columns=False,
        )

        # Create a Trainer instance for training the model.
        trainer = Trainer(
            model=model,
            args=training_args,
            train_dataset=shuffled_train_dataset,
        )
        # Start the training process.
        trainer.train()
        # Save the trained model to the output directory.
        model.save_pretrained(output_dir)
        # Return the path to the output directory.
        return output_dir
```

4. Create DataFrame(s) that contain your training samples.

   Each DataFrame should have one column, named "target". The rows throughout the DataFrame should span a consistent time. If there is no

data for the time step (for example, the weekend price of an Equity asset), put NaN as the value for the time step. The following example demonstrates how to create DataFrames that contain one year of trailing prices for a set of Equities:

```
# Get historical equity curves.
history = self.history(symbols, timedelta(365), Resolution.DAILY)['close'].unstack(0)

# Gather the training data.
training_data_by_symbol = {}
for symbol in symbols:
    df = history[[symbol]].dropna()
    if df.shape[0] < 10: # Skip this asset if there is very little data.
        continue
    adjusted_df = df.reset_index()[['time', symbol]]
    adjusted_df = adjusted_df.rename(columns={str(symbol.id): 'target'})
    adjusted_df['time'] = pd.to_datetime(adjusted_df['time'])
    adjusted_df.set_index('time', inplace=True)
    adjusted_df = adjusted_df.resample('D').asfreq()
    training_data_by_symbol[symbol] = adjusted_df
```

For more information about history requests, see History Requests .

5. Call the fine-tuning method with the training data.

```
# Train the model with set parameters and save it to the output directory.
output_dir_path = self._train_chronos(
    list(training_data_by_symbol.values()),
    context_length=int(252/2), # 6 months
    prediction_length=self._prediction_length,
    optim=self._optimizer,
    model_id=self._model_name,
    output_dir=self._model_path,
    learning_rate=1e-5,
    # Requires Ampere GPUs (e.g., A100)
    tf32=False,
    max_steps=3
)
```

6. Load the fine-tuned model.

```
# Load the trained model from the output directory.
pipeline = ChronosPipeline.from_pretrained(
    output_dir_path,
    device_map=self._device_map,
    torch_dtype=torch.bfloat16,
)
```

Forecast Time Series

Follow these steps to forecast time series with Chronos-T5:

1. Get some historical data .

```
# Get historical closing prices.
history = self.history(symbols, timedelta(365), Resolution.DAILY)['close'].unstack(0)
```

2. Load the pre-trained or fine-tuned model.
3. Forecast the future time series.

```
# Generate forecasts for the assets using the trained pipeline.
all_forecasts = pipeline.predict(
    [
        torch.tensor(history[symbol].dropna())
        for symbol in symbols
    ],
    self._prediction_length
)
```

In this example, the model returns several future price paths for each asset.

4. Aggregate the future prices paths of each asset into a single price path for each asset.

   For example, take the median value of each time step in the future price paths.

```
# Create a DataFrame with median forecasts for each asset.
forecasts_df = pd.DataFrame(
    {
        symbol: np.quantile(
            all_forecasts[i].numpy(), 0.5, axis=0   # 0.5 = median
        )
        for i, symbol in enumerate(symbols)
    }
)
```

Examples

The following examples demonstrate usage of the Chronos-T5 model.

Example 1: Price Prediction

The following algorithm selects the most liquid assets at the beginning of each month. Once a quarter, it gets the trailing year of prices for all the assets in the universe and then forecasts the prices paths of all the assets over the upcoming quarter. It then uses the SciPy package to find the weights that maximize the future Sharpe ratio of the portfolio and rebalances the portfolio to those weights.

```
import torch
from chronos import ChronosPipeline
from scipy.optimize import minimize
from transformers import set_seed
# endregion

class HuggingFaceBaseModelDemo(QCAlgorithm):
    """
    This algorithm demonstrates how to use a pre-trained HuggingFace
    model. It uses the "amazon/chronos-t5-tiny" model to forecast the
    future equity curves of the 5 most liquid assets in the market,
    then it uses the SciPy package to find the portfolio weights
    that will maximize the future Sharpe ratio of the portfolio.
    The portfolio is rebalanced every 3 months.
    """

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100_000)

        self.settings.min_absolute_portfolio_target_percentage = 0

        # Enable reproducibility.
        set_seed(1, True)

        # Load the pre-trained model.
        self._pipeline = ChronosPipeline.from_pretrained(
            "amazon/chronos-t5-tiny",
            device_map="cuda" if torch.cuda.is_available() else "cpu",
            torch_dtype=torch.bfloat16,
        )

Popular Models

DistilBERT

Introduction

This page explains how to use DistilBERT in LEAN trading algorithms. The model repository provides the following description:

> The DistilBERT model was proposed in the blog post Smaller, faster, cheaper, lighter: Introducing DistilBERT, adistilled version of BERT , and the paper DistilBERT, adistilled version of BERT: smaller, faster, cheaper and lighter . DistilBERT is a small, fast, cheap and light Transformer model trained by distilling BERT base. It has 40% less parameters than bert-base-uncased, runs 60% faster while preserving over 95% of BERT's performances as measured on the GLUE language understanding benchmark. This model is a fine-tune checkpoint of DistilBERT-base-cased , fine-tuned using (a second step of) knowledge distillation on SQuAD v1.1 .

Use Cases

The DistilBERT model is a question answering model. The following use cases explain how you might utilize it in trading algorithms:

- Summarize the upcoming changes reported through regulatory articles in preparation of sentiment analysis.
- Extract relevant information from news feeds like Tiingo and Benzinga while reducing noise.
- Parse through US SEC Filings to find critical information about company performance, legal issues, or changes in management.

Load Pre-Trained Model

Follow these steps to load the pre-trained DistilBERT model:

1. Import the pipeline.

```
PY
from transformers import pipeline
```

2. Create a pipeline object with the DistilBERT model.

   In QuantConnect Cloud, the path is distilbert / distilbert-base-cased-distilled-squad .

```
PY
question_answerer = pipeline(
    "question-answering",
    model='distilbert/distilbert-base-cased-distilled-squad',
    local_files_only=True
)
```

Answer Questions

Follow these steps to answer questions with DistilBERT:

1. Load the model .
2. Define the context.

```
PY
context = """
Introduced on 2024-11-01.
The legislation introduces a flat corporate income tax rate, reducing the current graduated system
to 5.5% for taxable years starting from January 1, 2025, and further lowering it to 3.5% for years
beginning January 1, 2026. It establishes a bonus depreciation deduction for qualified property and
research expenditures, allowing immediate cost recovery. The bill also terminates various corporate
tax credits, exemptions, and deductions, including those related to motion picture production,
research and development, and historic structure rehabilitation, with most credits expiring after
June 30, 2025. Additionally, it repeals provisions for certain tax programs and credits, such as the
corporate tax apportionment program and various incentives for businesses. The changes aim to simplify
corporate taxation and reduce the number of available tax credits, with the new provisions effective
for income tax periods starting January 1, 2025, and franchise tax periods beginning January 1, 2026.
The legislation will take effect upon the governor's signature or after the designated period for
gubernatorial action.
"""
```

3. Create the question.

```py
question = "What do these changes accomplish?"
```

4. Pass the question and context to the pipeline.

```py
result = question_answerer(question=question, context=context)
```

The following dictionary is an example result:

```py
{
    'score': 0.19066356122493744,
    'start': 820,
    'end': 895,
    'answer': 'simplify corporate taxation and reduce the number of available tax credits'
}
```

FinBERT

Introduction

This page explains how to use FinBERT in LEAN trading algorithms. The model repository provides the following description:

> FinBERT is a pre-trained NLP model to analyze sentiment of financial text. It is built by further training the BERT language model in the finance domain, using a large financial corpus and thereby fine-tuning it for financial sentiment classification. Financial PhraseBank by Malo et al. (2014) is used for fine-tuning. For more details, please see the paper FinBERT: Financial Sentiment Analysis with Pre-trained Language Models and our related blog post on Medium.
>
> The model will give softmax outputs for three labels: positive, negative or neutral.

Use Cases

The FinBERT model is a sentiment analysis model. The following use cases explain how you might utilize it in trading algorithms:

- Analyze the sentiment of the latest news articles for specific companies , then form a long-short portfolio with assets that have the most postive and most negative news sentiment.
- Monitor the sentiment of regulatory alerts in a risk management model and liquidate holdings when sentiment is extremely negative.
- Generate sentences based on information from other datasets and then feed them into the model to determine the sentiment. For example, you could use the US Government Contracts dataset to create the string "The Department of State grants AAPL a contract for the purchase of mobile phones".

Load Pre-Trained Model

Follow these steps to load the pre-trained FinBERT model:

1. Import the model and tokenizer classes.

```
PY
from transformers import TFBertForSequenceClassification, BertTokenizer
```

2. Define the path were the model is stored.

   In QuantConnect Cloud, the path is ProsusAI / finbert .

```
PY
model_path = "ProsusAI/finbert"
```

3. Create a TFBertForSequenceClassification model.

```
PY
self._model = TFBertForSequenceClassification.from_pretrained(model_path, local_files_only=True)
```

4. Create a BertTokenizer object.

```
PY
self._tokenizer = BertTokenizer.from_pretrained(model_path, local_files_only=True)
```

5. (Optional) Set the seed to enable reproducibility.

```
PY
from transformers import set_seed
set_seed(1, True)
```

Fine-Tune Model

The FinBERT model is pre-trained, so you don't need to fine-tune it. Fine-tuning the model just tailors it to your specific use case. Follow these steps to fine-tune it:

1. Import the `Dataset` class.

```py
from datasets import Dataset
```

2. Load the pre-trained model .
3. Compile the model with an optimizer and loss function.

```py
model.compile(
    optimizer=tf.keras.optimizers.Adam(learning_rate=3e-5),
    loss=tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
)
```

   You only need to compile the model once. TensorFlow offers many other optimizer and loss classes you can use.

4. Create a DataFrame that contains your training samples.

   The DataFrame should have two columns, named "text" and "label". The label must be an integer that represents the sentiment class. By default, the FinBERT model has three classes. Class zero represents negative sentiment, class one represents neutral sentiment, and class two represents positive sentiment.

```py
samples = pd.DataFrame(columns=['text', 'label'])
# Add rows to the DataFrame...
```

5. Convert the samples DataFrame to a `tf.data.Dataset` object.

```py
dataset = Dataset.from_pandas(samples)
```

6. Tokenize the text in each training sample.

```py
dataset = dataset.map(
    lambda sample: self._tokenizer(sample['text'], padding='max_length', truncation=True)
)
```

7. Call the model's prepare_tf_dataset method.

```py
dataset = model.prepare_tf_dataset(dataset, shuffle=True, tokenizer=self._tokenizer)
```

8. Call the model's fit method.

```py
model.fit(dataset, epochs=2)
```

Analyze Sentiment

Follow these steps to analyze the sentiment of some text with FinBERT:

1. Load the model .
2. (Optional) Fine-tune the model .
3. Get the text you want the model to analyze.

   The model can analyze a single sentence or a list of sentences.

```
content = "AAPL stock price spikes after record-breaking sales figures."
```

4. Tokenize the text(s).

```
inputs = self._tokenizer(content, padding=True, truncation=True, return_tensors='tf')
```

For more information about how to tokenize, see the PreTrainedTokenizer.__call__ reference on the Hugging Face website.

5. Perform dictionary unpacking on the preceding result and pass it to the model as input.

```
outputs = self._model(**inputs)
```

6. Apply softmax to the outputs to get probabilities of each sentiment class.

```
scores = tf.nn.softmax(outputs.logits, axis=-1).numpy()
```

The result of the preceding operation is a two dimensional numpy array. Each element in the two dimensional array is a list that contains the probability that the sentiment of the corresponding sentence is negative, neutral, or postiive, respectively. For example, you may get the following result if you use a single sentence as input. The result shows that the input is more positive than negative, but is likely neutral.

```
array([[0.21346861, 0.46771246, 0.318819]])
```

Examples

The following examples demonstrate usage of the FinBERT model.

Example 1: 10-day Sentiment Score

The following algorithm selects a volatile asset at the beginning of each month. It gets the Tiingo News articles that were released for the asset over the previous 10 days and then feeds them into the pre-trained FinBERT model. It then aggregates the sentiment scores of all the news releases. If the aggregated sentiment score is positive, it enters a long position for the month. If it's negative, it enters a short position for the month.

```
import tensorflow as tf
from transformers import TFBertForSequenceClassification, BertTokenizer, set_seed
from pathlib import Path

class FinbertBaseModelAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100_000)

        self.universe_settings.resolution = Resolution.DAILY
        self.universe_settings.schedule.on(self.date_rules.month_start("SPY"))
        self._universe = self.add_universe(
            lambda fundamental: [
                self.history(
                    [f.symbol for f in sorted(fundamental, key=lambda f: f.dollar_volume)[-10:]],
                    timedelta(365), Resolution.DAILY
                )['close'].unstack(0).pct_change().iloc[1:].std().idxmax()
            ]
        )

        set_seed(1, True)

        # Load the tokenizer and the model
        model_path = "ProsusAI/finbert"
        self._tokenizer = BertTokenizer.from_pretrained(model_path, local_files_only=True)
        self._model = TFBertForSequenceClassification.from_pretrained(model_path, local_files_only=True)

        self._last_rebalance_time = datetime.min
        self.set_warm_up(30, Resolution.DAILY)

    def on_warmup_finished(self):
        self._trade()
```

```
        self.schedule.on(self.date_rules.month_start("SPY", 1), self.time_rules.midnight, self._trade)

    def on_securities_changed(self, changes):
        for security in changes.removed_securities:

        # Generate exponentially increasing weights
        weights = np.exp(np.linspace(0, 1, n))

        # Normalize weights to sum to 1
        weights /= weights.sum()

        # Apply weights to sentiment scores
        weighted_scores = sentiment_scores * weights[:, np.newaxis]

        # Aggregate weighted scores by summing them
        aggregated_scores = weighted_scores.sum(axis=0)

        return aggregated_scores
```

Example 2: 30-day Sentiment Score With Fine Tuning

The following algorithm selects a volatile asset at the beginning of each month. It gets the Tiingo News articles that were released for the asset over the previous 30 days to generate the training set. The label is the market return that occurs from the current news release to the next news release. The algorithm then fine-tunes the model, calculates the sentiment, and rebalances the portfolio.

```
PY
import tensorflow as tf
from transformers import TFBertForSequenceClassification, BertTokenizer, set_seed

Popular Models

Sentiment Analysis

Introduction

This page explains how to use Hugging Face sentiment analysis models in LEAN trading algorithms. These models classify financial text into sentiment categories like positive, negative, and neutral. The following models are available:

- ahmedrachid/FinancialBERT-Sentiment-Analysis — A BERT model fine-tuned on financial data for sentiment analysis, classifying text as positive, negative, or neutral.
- bardsai/finance-sentiment-fr-base — A French-language financial sentiment classification model.
- cardiffnlp/twitter-roberta-base-sentiment-latest — A RoBERTa model fine-tuned on tweets for sentiment analysis.
- mrm8488/distilroberta-finetuned-financial-news-sentiment-analysis — A DistilRoBERTa model fine-tuned on financial news for sentiment classification.
- nickmuchi/deberta-v3-base-finetuned-finance-text-classification — A DeBERTa model fine-tuned for financial text classification.
- nickmuchi/distilroberta-finetuned-financial-text-classification — A DistilRoBERTa model fine-tuned for financial text classification.
- nickmuchi/sec-bert-finetuned-finance-classification — A SEC-BERT model fine-tuned for financial document classification.
- StephanAkkerman/FinTwitBERT-sentiment — A BERT model fine-tuned on financial tweets for sentiment classification.

All of these models accept text input and return classification labels with confidence scores. You can use them with the Hugging Face `transformers` library to analyze the sentiment of financial news and social media posts, then use the results to inform trading decisions.

Examples

The following examples demonstrate usage of Hugging Face sentiment analysis models.

Example 1: News Sentiment Trading

The following algorithm selects the most volatile asset at the beginning of each month. It gets the Tiingo News articles that were released for the asset over the previous 10 days and then feeds them into a sentiment analysis model. It aggregates the sentiment scores of all the news releases. If the aggregated sentiment is positive, it enters a long position for the month. If it's negative, it enters a short position. You can replace the model name with any of the sentiment analysis models listed on the introduction page.

PY

```
from transformers import pipeline, set_seed

class SentimentAnalysisModelAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)

Fill-Mask

Introduction

This page explains how to use Hugging Face fill-mask models in LEAN trading algorithms. Fill-mask models predict the most likely word to fill a masked position in a sentence. You can use them to extract text embeddings and build feature vectors from financial text. The following models are available:

- google-bert/bert-base-uncased — The original BERT base model (uncased), widely used for natural language understanding tasks.
- distilbert/distilbert-base-uncased — A distilled version of BERT that is 60% faster while retaining 97% of BERT's language understanding.
- FacebookAI/roberta-base — A robustly optimized BERT pretraining approach by Facebook AI.
- microsoft/deberta-base — A DeBERTa model by Microsoft that uses disentangled attention for improved language understanding.

These models are useful for extracting text embeddings from financial news. You can feed these embeddings into a downstream classifier or use cosine similarity to measure the semantic similarity between documents.

Examples

The following examples demonstrate usage of Hugging Face fill-mask models for feature extraction.

Example 1: Embedding-Based News Similarity

The following algorithm selects a volatile asset at the beginning of each month. It uses a fill-mask model to extract embeddings from Tiingo News articles. It then compares the average embedding of recent news to a reference "bullish" and "bearish" embedding. If the recent news is more similar to the bullish reference, it enters a long position. You can replace the model name with any of the fill-mask models listed on the introduction page.

```py
import torch
import numpy as np
from transformers import AutoTokenizer, AutoModel, set_seed

class FillMaskEmbeddingAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100_000)

        self.universe_settings.resolution = Resolution.DAILY
        self.universe_settings.schedule.on(self.date_rules.month_start("SPY"))
        self._universe = self.add_universe(
            lambda fundamental: [
                self.history(
                    [f.symbol for f in sorted(
                        fundamental, key=lambda f: f.dollar_volume
                    )[-10:]],
                    timedelta(365), Resolution.DAILY
                )['close'].unstack(0).pct_change().iloc[1:].std().idxmax()
            ]
        )

        set_seed(1, True)

Text Generation

Introduction

This page explains how to use Hugging Face text generation models in LEAN trading algorithms. These models generate text given an input prompt, which you can use for tasks like summarizing financial data or generating structured analysis. The following models are available:

- openai-community/gpt2 — The GPT-2 language model by OpenAI, a lightweight model suitable for text generation tasks.
- google/gemma-7b — A 7B parameter model from Google's Gemma family, offering strong text generation capabilities. Requires a GPU node.
- deepseek-ai/DeepSeek-R1-Distill-Llama-70B — A 70B parameter reasoning model distilled from DeepSeek-R1 into a Llama architecture. Requires a GPU node with significant memory.

Text generation models can analyze market context and generate structured outputs. You can prompt them to classify market conditions or extract trading signals from financial text. Note that larger models like Gemma-7B and DeepSeek-70B require GPU nodes with sufficient memory.

Examples

The following examples demonstrate usage of Hugging Face text generation models.

Example 1: GPT-2 Market Condition Classifier

The following algorithm uses GPT-2 to classify market conditions based on recent price data. At the beginning of each month, it calculates trailing returns, volatility, and momentum for the universe of the 5 most liquid assets. It then prompts GPT-2 to complete a structured market analysis template and parses the generated text to determine position sizing.

```py
from transformers import pipeline, set_seed

class GPT2MarketAnalysisAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100_000)

        self.settings.min_absolute_portfolio_target_percentage = 0

        set_seed(1, True)

        # Load the text generation pipeline with GPT-2.
        self._generator = pipeline(
            "text-generation",
            model="openai-community/gpt2"
        )

        # Define the universe.
        spy = Symbol.create("SPY", SecurityType.EQUITY, Market.USA)
        self.universe_settings.schedule.on(self.date_rules.month_start(spy))
        self.universe_settings.resolution = Resolution.DAILY
        self._universe = self.add_universe(
            self.universe.top(
                self.get_parameter('universe_size', 5)
            )
        )

        self._last_rebalance = datetime.min
        self.schedule.on(
            self.date_rules.month_start(spy, 1),
            self.time_rules.midnight,
            self._trade
        )
        self.set_warm_up(timedelta(31))

    def _trade(self):
        if self.is_warming_up:
            return
        if self.time - self._last_rebalance < timedelta(25):
            return
        self._last_rebalance = self.time

        symbols = list(self._universe.selected)
        if not symbols:
            return
```

```

            return
        weights = {s: v / total for s, v in scores.items()}

        # Rebalance.
        self.set_holdings(
            [
                PortfolioTarget(symbol, weight)
                for symbol, weight in weights.items()
            ],
            True
        )
```

Popular Models

Chronos-Bolt

Introduction

This page explains how to use Chronos-Bolt in LEAN trading algorithms. The model repository provides the following description:

> Chronos-Bolt models are a family of **lightweight, efficient time series forecasting models** . They are a follow-up to the original Chronos models, designed for faster inference and lower computational cost. Chronos-Bolt uses a T5-based encoder-decoder architecture where the encoder processes the historical context and the decoder directly generates quantile forecasts. Unlike the original Chronos models, Chronos-Bolt does not use tokenization, resulting in significantly faster inference. For details, refer to the paper Chronos: Learning the Language of Time Series .

Examples

The following examples demonstrate usage of the Chronos-Bolt model.

Example 1: Price Prediction

The following algorithm selects the most liquid assets at the beginning of each month. Once a quarter, it gets the trailing year of prices for all the assets in the universe and then forecasts the price paths over the upcoming quarter using Chronos-Bolt. It then uses the SciPy package to find the weights that maximize the future Sharpe ratio of the portfolio and rebalances the portfolio to those weights. Chronos-Bolt is a faster variant of Chronos-T5 that directly generates quantile forecasts.

```py
import torch
import numpy as np
from scipy.optimize import minimize
from chronos import ChronosBoltPipeline
from transformers import set_seed
# endregion

class ChronosBoltAlgorithm(QCAlgorithm):
    """
    This algorithm demonstrates how to use the Chronos-Bolt time
    series forecasting model. It forecasts the future equity curves
    of the 5 most liquid assets, then finds portfolio weights that
    maximize the future Sharpe ratio. The portfolio is rebalanced
    every 3 months.
    """

    def initialize(self):

Algorithm Framework

Algorithm Framework

Overview

Introduction

Since QuantConnect was formed in 2013, the community has created more than 2 million algorithms. Although they all seek to achieve different results, they can all be abstracted into the same core features. The Algorithm Framework is our attempt to provide this well-defined structure to the community, encouraging good design and making your work more reusable. LEAN provides many pre-built Algorithm Framework models you can use in your algorithms.

Strategy Styles

The algorithm framework works best for portfolio rebalancing, ranking, and multi-factor style strategies. The default portfolio construction models are designed to weigh and invest in the assets as the signals values shift, aiming to be fully invested as much as possible.

Some strategies might find it difficult to fit this model. Technical entry signals are often tightly coupled with their exit criteria, they may not have defined hold periods, and they might follow the market to determine when to exit. This style of strategy can be addressed in a few ways:

1. Short Term Signals - Emitting insights for short periods until they are no longer valid.
2. Cancel Signals - Updating an insight's expiry time so that it's expired upon the exit signal.
3. Alpha Exit Signal - Treating exit as its own signal, a separate Alpha model could indicate exit.
4. Risk Model - Tracking exit using a risk model that attempts to lock in gains.

These techniques are still not ideal for many strategies. For example, with only a single signal, the built in `EqualWeightingPortfolioConstructionModel` will allocate 100% of buying power to a single asset, over concentrating risk. If a second signal comes a few days later, it would sell 50% of the portfolio to free cash and invest in the second asset. This can create high trading costs through portfolio churn.

With a custom portfolio construction model , signals can mean what you need for your specific strategy style. For example, you might create a " `MultiBetPortfolioConstructionModel` " that uses each insight to open a specific "bet" that is separately allocated capital and tracked.

Important Terminology

The following table defines important Algorithm Framework terminology:

Term	Description
Universe Selection model	A framework module that selects assets for your algorithm.
Alpha model	A framework module that generates trading signals on the assets in your universe.
Insight	An object that represents a trading signal. The Alpha model generates these objects for the Portfolio Construction model.
Portfolio Construction model	A framework module that determines position size targets based on the `Insight` objects it receives from the Alpha model.
PortfolioTarget	An object that represents the target position size for an asset in the universe. The Portfolio Construction model generates these objects for the Risk Management model.
Risk Management	A framework module that manages market risks and ensures the algorithm remains within target parameters. This model adjusts the `PortfolioTarget` objects it receives from the Portfolio Construction model before they reach the Execution model.
Execution	A framework module that places trades to reach the target risk-adjust portfolio based on the `PortfolioTarget` objects it receives from the Risk Management model.

Framework Advantages

We recommend you design strategies with the Algorithm Framework in most cases. The Algorithm Framework has many advantages over the classic algorithm design.

Pluggable Algorithm Modules

With the Algorithm Framework, your code can instantly utilize all modules built within the framework. The modules clip together in well-defined ways, which enable them to be shared and swapped interchangeably.

Focus On Your Strengths

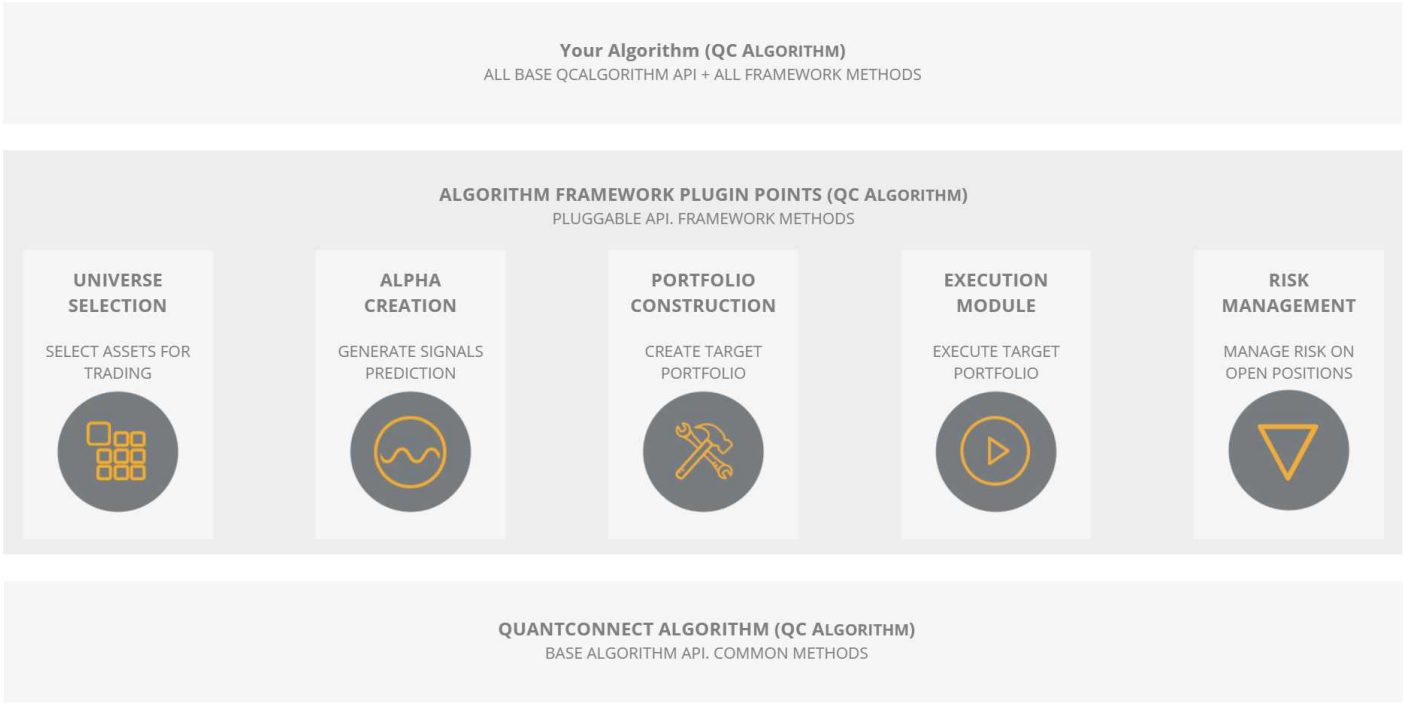
If you write code in modules, you can focus on your strengths. If you are great at building universes, you can build Universe Selection modules. If you have risk management experience, you could write reusable risk monitoring technology.

Reduce Development By Using Community Modules

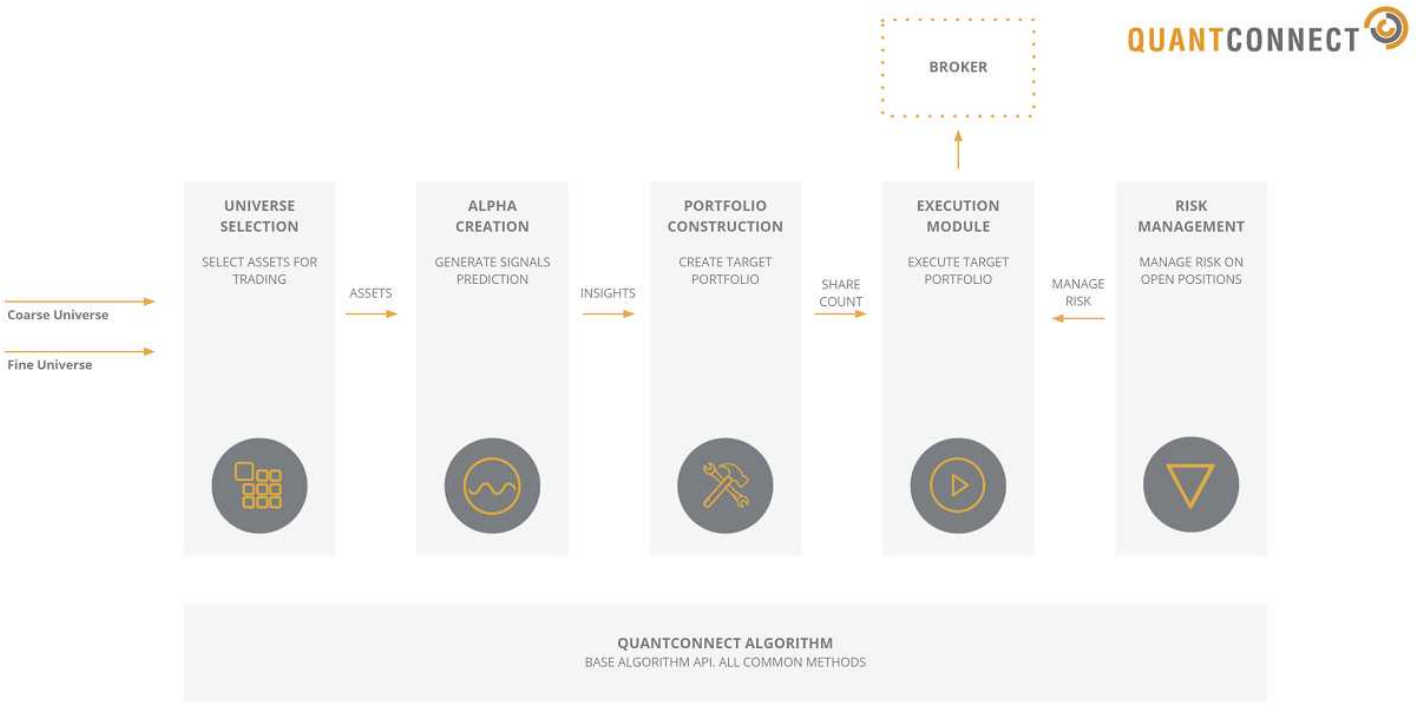
Easily share modules you've made between algorithms or pull in ones produced by the community. The strict separation of duties makes the Algorithm Framework perfect for reusing code between strategies.

System Architecture

The Algorithm Framework is built into the `QCAlgorithm` class, so your strategy can access all the normal methods you use for algorithm development. You should be able to copy and paste your algorithms across without any changes. You don't need a separate class.



The framework data output of each module flows into the following module. The assets that the Universe Selection model selects are fed into the Alpha model to generate trade signals (`Insight` objects). The `Insight` objects from the Alpha model are fed into the Portfolio Construction model to create `PortfolioTarget` objects, which contain the target number of units to hold for each asset. The `PortfolioTarget` objects from the Portfolio Construction model are fed into the Risk Management model to ensure the targets are within safe risk parameters and to adjust the `PortfolioTarget` objects if necessary. The `PortfolioTarget` objects from the Risk Management model are fed into the Execution model, which efficiently places trades to acquire the target portfolio.



```py
class MyFrameworkAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_universe_selection(EmaCrossUniverseSelectionModel())
        self.add_alpha(RsiAlphaModel())
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())
        self.set_execution(ImmediateExecutionModel())
        self.add_risk_management(NullRiskManagementModel())
```

For simple strategies, it may seem like overkill to abstract out your algorithm concepts. However, even simple strategies can benefit from reusing the ecosystem of modules available in QuantConnect. Imagine pairing your EMA-cross Alpha model with a better execution system or plugging in an

open-source trailing stop Risk Management model .

Separation of Concerns

The separation of concerns principle is an algorithm design principle where individual components are isolated and their responsibilities don't overlap. The Algorithm Framework is designed to uphold this design principle. The individual framework components shouldn't rely on the state of the other framework components in order to operate.

In the Algorithm Framework, the models should not communicate. The universe constituents and the `Insight` objects you emit should be the same, regardless of what you select for the Portfolio Construction, Risk Management, and Execution models. If your algorithm logic naturally violates the separation of concerns design principle, it's more appropriate to use the classic or hybrid design .

Framework vs Classic Design

Select the classic or Algorithm Framework design based on the needs of your algorithm. If your algorithm uses special order types or passes information between the different algorithm components, use the classic design. If you can reuse existing modules and the Algorithm Framework modules can work in isolation, use the Algorithm Framework design.

Algorithm Framework

Universe Selection

Universe Selection

Key Concepts

Introduction

The Universe Selection model creates `Universe` objects, which select the assets for your algorithm. As the universe changes, we notify your algorithm through the `on_securities_changed` event handler. With this event handler, you can track the current universe constituents in other parts of your algorithm without breaking the separation of concerns design principle.

Types of Universe Selection

We have identified several types of universes that cover most people's requirements and built helper classes to make their implementation easier. The following table describes the types of pre-built Universe Selection models:

Universe Type	Description
Manual Universes	Universes that use a fixed, static set of assets
Fundamental Universes	Universes for US Equities that are based on coarse price or fundamental data
Scheduled Universes	Universes that trigger on regular, custom intervals
Futures Universes	Universes that subscribe to Future chains
Option Universes	Universes that subscribe to Option chains

Add Models

To add a Universe Selection model, in the `initialize` method, call the `AddUniverseSelection` method.

```
PY
# Adds a universe selection model to the algorithm, manually defining the set of securities to include in the algorithm.
symbols = [Symbol.create("SPY", SecurityType.EQUITY, Market.USA)]
self.add_universe_selection(ManualUniverseSelectionModel(symbols))
```

To view all the pre-built Universe Selection models, see Types of Universe Selection .

Multi-Universe Algorithms

You can add multiple Universe Selection models to a single algorithm.

```
PY
# Configures asynchronous universe settings for faster updates and includes both manual and EMA cross universe selection models for
dynamic and static selection.
self.universe_settings.asynchronous = True
symbols = [Symbol.create("SPY", SecurityType.EQUITY, Market.USA)]
self.add_universe_selection(ManualUniverseSelectionModel(symbols))

self.add_universe_selection(EmaCrossUniverseSelectionModel())
```

If you add multiple Universe Selection models, the algorithm subscribes to the constituents of all the models.

Model Structure

Universe Selection models should extend the `UniverseSelectionModel` class. Extensions of the `UniverseSelectionModel` class must implement the `create_universes` method, which receives an `algorithm` object and returns an array of `Universe` objects.

```py
# Extend UniverseSelectionModel to define a custom security universe tailored to the algorithm.
class MyUniverseSelectionModel(UniverseSelectionModel):

    # Creates the universes for this algorithm
    def create_universes(self, algorithm: QCAlgorithm) -> List[Universe]:
        universes = []
        return universes

    # Gets the next time the framework should invoke the `CreateUniverses` method to refresh the set of universes.
    def get_next_refresh_time_utc(self):
        return datetime.max
```

The `algorithm` argument that the methods receive is an instance of the base `QCAlgorithm` class, not your subclass of it.

Generally, you should be able to extend one of the pre-built Universe Selection types. If you need to do something that doesn't fit into the pre-built types, let us know and we'll create a new foundational type of Universe Selection model.

Track Security Changes

When the Universe Selection model adjusts the universe constituents, we notify your algorithm through the `on_securities_changed` event handler on your other framework components. The method receives `QCAlgorithm` and `SecurityChanges` objects. The `QCAlgorithm` object is an instance of the base QCAlgorithm class, not a reference to your algorithm object. To access the added securities, check the `changes.added_securities` method property. To access the removed securities, check the `changes.removed_securities` method property.

```py
# Log added and removed securities to update the universe and adapt the strategy.
def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
    for security in changes.added_securities:
        self.log(f"Added {security.symbol}")

    for security in changes.removed_securities:
        self.log(f"Removed {security.symbol}")
```

Live Trading Considerations

In live trading, the securities in your brokerage account are added to your user-defined universe. If your Universe Selection model doesn't select these securities, they are not removed from your user-defined universe. When you liquidate the positions, you can remove them from the user-defined universe. If you call the `remove_security` method, it automatically liquidates the position.

To see the securities in your user-defined universe that were loaded from your brokerage account, check your algorithm's active_securities in the on_warmup_finished event handler.

Examples

The following examples demonstrate some common practices for implementing the universe selection model.

Example 1: Liquid Universe Selection Model

The following algorithm selects a universe of the top 20 liquid equity through the framework universe selection model. Then, buying and holding these popular equities equally to bet on their high demand will drive up the price.

```py
class FrameworkUniverseSelectionAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Rebalance weekly to allow time to capitalize on the trend
        self.universe_settings.schedule.on(self.date_rules.week_start())
        # Since the selection is based on daily data, we only require daily data to trade daily.
        self.universe_settings.resolution = Resolution.DAILY
        # Add a universe selection model to select the most liquid stocks to trade with.
        self.add_universe_selection(FundamentalUniverseSelectionModel(self.selection))

        # Sent insights on buying and holding the most liquid stocks weekly.
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(7)))
        # Evenly dissipate the capital risk among selected stocks.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

    def selection(self, fundamental: List[Fundamental]) -> List[Symbol]:
        # Select the top 20 liquid equity to trade the popularity, suggesting a higher demand to drive the price.
        sorted_by_dollar_volume = sorted(fundamental, key=lambda x: x.dollar_volume, reverse=True)
        return [x.symbol for x in sorted_by_dollar_volume[:20]]
```

Example 2: Multiple Universe Selection Models

The following algorithm implements two framework universe selection models to manually select the most liquid market ETFs and those with EMA crossing events to trade on trend changes. Then, buy and hold these equities equally to bet on the insights and dissipate the capital risk.

```py
class FrameworkUniverseSelectionAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Rebalance weekly to allow time to capitalize on the trend
        self.universe_settings.schedule.on(self.date_rules.week_start())
        # Since the selection is based on daily data, we only require daily data to trade daily.
        self.universe_settings.resolution = Resolution.DAILY
        # Add a universe selection model to select the most liquid ETFs manually.
        symbols = [
            Symbol.create("SPY", SecurityType.EQUITY, Market.USA),
            Symbol.create("QQQ", SecurityType.EQUITY, Market.USA)
        ]
        self.add_universe_selection(ManualUniverseSelectionModel(symbols))
        # Add another universe selection model to select the ones with EMA crosses.
        self.add_universe_selection(EmaCrossUniverseSelectionModel())

        # Sent insights on buying and holding the most liquid stocks weekly.
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(7)))
        # Evenly dissipate the capital risk among selected stocks.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())
```

Universe Selection

Universe Settings

Introduction

Universe settings and security initializers enable you to configure some properties of the securities in a universe.

Resolution

The `resolution` setting defines the time period of the asset data. The `Resolution` enumeration has the following members:

To view which resolutions are available for the asset class of your universe, follow these steps:

1. Open the Asset Classes documentation page.
2. Click an asset class.
3. Click Requesting Data .
4. On the Requesting Data page, in the table of contents, click Resolutions .

The default value is `Resolution.MINUTE` . To change the resolution, in the Initialize method, adjust the algorithm's `UniverseSettings` before you create the Universe Selection model.

```
PY
# Use daily data and select SPY ETF constituents as the trading universe.
self.universe_settings.resolution = Resolution.DAILY
self.add_universe_selection(ETFConstituentsUniverseSelectionModel("SPY"))
```

Leverage

The `leverage` setting is a `float` that defines the maximum amount of leverage you can use for a single asset in a non-derivative universe. The default value is `Security.NULL_LEVERAGE` (0). To change the leverage, in the Initialize method, adjust the algorithm's `universe_settings` before you create the Universe Selection model.

```
PY
# Set unviverse leverage to 2x to increase potential returns from each asset in the non-derivative universe to increase potential returns.
self.universe_settings.leverage = 2.0
# Select universe based on EMA cross signals to identify and trade assets with trending behaviors.
self.add_universe_selection(EmaCrossUniverseSelectionModel())
```

Fill Forward

The `fill_forward` setting is a `bool` that defines whether or not too fill forward data. The default value is `True` . To disable fill forward in non-derivative universes, in the Initialize method, adjust the algorithm's `universe_settings` before you create the Universe Selection model.

```
PY
# Disable fill forward to ensure each day's data is used exclusively, preventing previous day's data from influencing decisions and
select options for SPY with a daily update interval to track specific option contracts.
self.universe_settings.fill_forward = False
self.add_universe_selection(
    OptionUniverseSelectionModel(
        timedelta(1), lambda _: [Symbol.create("SPY", SecurityType.OPTION, Market.USA)]
    )
)
```

Extended Market Hours

The `extended_market_hours` setting is a `bool` that defines the trading schedule. If it's `True` , your algorithm receives price data for all trading hours. If it's `False` , your algorithm receives price data only for regular trading hours. The default value is `False` .

You only receive extended market hours data if you create the subscription with an intraday resolution. If you create the subscription with daily resolution, the daily bars only reflect the regular trading hours.

To view the trading schedule of an asset, open Asset Classes , click an asset class, then click Market Hours .

To enable extended market hours, in the initialize method, adjust the algorithm's `UniverseSettings` before you create the Universe Selection model.

```py
# Enable extended market hours for universe and manually select equity symbols for SPY, QQQ, and IWM to ensure trading during pre-market
and after-hours sessions.
self.universe_settings.extended_market_hours = True
tickers = ["SPY", "QQQ", "IWM"]
symbols = [ Symbol.create(ticker, SecurityType.EQUITY, Market.USA) for ticker in tickers]
self.add_universe_selection(ManualUniverseSelectionModel(symbols))
```

Minimum Time in Universe

The `minimum_time_in_universe` setting is a `timedelta` object that defines the minimum amount of time an asset must be in the universe before the universe can remove it. The default value is `timedelta(1)` . To change the minimum time, in the Initialize method, adjust the algorithm's `universe_settings` before you create the Universe Selection model.

```py
# Keep each security in the universe for a minimum of 7 days.
self.universe_settings.minimum_time_in_universe = timedelta(7)
self.add_universe_selection(ETFConstituentsUniverseSelectionModel("QQQ"))
```

Data Normalization Mode

The `data_normalization_mode` setting is an enumeration that defines how historical data is adjusted. This setting is only applicable for US Equities and Futures.

In the case of US Equities, the data normalization mode affects how historical data is adjusted for corporate actions . To view all the available options, see Data Normalization . To change the data normalization mode, in the initialize method, adjust the algorithm's `universe_settings` before you create the Universe Selection model.

In the case of Futures, the data normalization mode affects how historical data of two contracts is stitched together to form the continuous contract . To view all the available options, see Data Normalization .

The default value is `DataNormalizationMode.ADJUSTED` . To change the data normalization mode, in the Initialize method, adjust the algorithm's `UniverseSettings` before you create the Universe Selection model.

```py
# Set universe data normalization to use raw prices to reflect actual traded values without adjustments and manually select equities
MSTR, MSFT, and IBM.
self.universe_settings.data_normalization_mode = DataNormalizationMode.RAW

tickers = ["MSTR", "MSFT", "IBM"]
symbols = [ Symbol.create(ticker, SecurityType.EQUITY, Market.USA) for ticker in tickers]
self.add_universe_selection(ManualUniverseSelectionModel(symbols))
```

Contract Depth Offset

The `contract_depth_offset` setting is an `int` that defines which contract to use for the continuous Futures contract. 0 is the front month contract, 1 is the following back month contract, and 3 is the second back month contract. The default value is 0. To change the contract depth offset, in the Initialize method, adjust the algorithm's `universe_settings` before you create the Universe Selection model.

```py
# Select the following month contract dynamically to avoid low liquidity and high volatility, for S&P 500 E-mini futures with daily
updates.
self.universe_settings.contract_depth_offset = 1
self.add_universe_selection(
    FutureUniverseSelectionModel(
        timedelta(1),
        lambda _: [Symbol.create(Futures.Indices.SP_500_E_MINI, SecurityType.FUTURE, Market.CME)]
    )
)
```

Asynchronous Selection

The `asynchronous` setting is a `bool` that defines whether or not LEAN can run universe selection asynchronously, utilizing concurrent execution to

increase the speed of your algorithm. The default value for this setting is `False` . If you enable this setting, abide by the following rules:

- Don't make any history requests in your filter function . History requests can only provide data up to the algorithm time , but if your filter function runs asynchronously, the algorithm time may not be what you expect.
- Don't use the portfolio, security, or orders state. The `portfolio` , `securities` , and `transactions` objects are also functions of the algorithm time.
- If your filter function updates a class variable, don't update the class variable anywhere else in your algorithm.

To enable asynchronous universe selection, in the Initialize method, adjust the algorithm's `universe_settings` before you create the Universe Selection model.

```
PY
# Run universe selection asynchronously to speed up your algorithm.
self.universe_settings.asynchronous = True
self.add_universe_selection(EmaCrossUniverseSelectionModel())
```

Schedule

The `Schedule` setting defines the selection schedule of the universe. Most universes run on a daily schedule. To change the selection schedule, call the `universe_settings.schedule.on` method with an `IDateRule` object before you create the Universe Selection model.

```
PY
# Trigger selections at the begining of each month.
self.universe_settings.schedule.on(self.date_rules.month_start())
self.add_universe_selection(ETFConstituentsUniverseSelectionModel("QQQ"))
```

The following table describes the supported `DateRules` :

Member	Description
`self.date_rules.set_default_time_zone(time_zone: DateTimeZone)`	Sets the time zone for the `DateRules` object used in all methods in this table. The default time zone is the algorithm time zone .
`self.date_rules.on(year: int, month: int, day: int)`	Trigger an event on a specific date.
`self.date_rules.on(dates: list[datetime])`	Trigger an event on specific dates.
`self.date_rules.every_day()`	Trigger an event all seven days of the week.
`self.date_rules.every_day(symbol: Symbol, extended_market_hours: bool = False)`	Trigger an event every day a specific symbol is trading.
`self.date_rules.every(days: list[DayOfWeek])`	Trigger an event on specific days throughout the week. To view the `DayOfWeek` enum members, see DayOfWeek Enum in the .NET documentation.
`self.date_rules.month_start(days_offset: int = 0)`	Trigger an event on the first day of each month plus an offset.
`self.date_rules.month_start(symbol: Symbol, daysOffset: int = 0)`	Trigger an event on the first tradable date of each month for a specific symbol plus an offset.
`self.date_rules.month_end(days_offset: int = 0)`	Trigger an event on the last day of each month minus an offset.
`self.date_rules.month_end(symbol: Symbol, daysOffset: int = 0)`	Trigger an event on the last tradable date of each month for a specific symbol minus an offset.
`self.date_rules.week_start(days_offset: int = 0)`	Trigger an event on the first day of each week plus an offset.
`self.date_rules.week_start(symbol: Symbol, days_offset: int = 0)`	Trigger an event on the first tradable date of each week for a specific symbol plus an offset.
`self.date_rules.week_end(days_offset: int = 0)`	Trigger an event on the last day of each week minus an offset.
`self.date_rules.week_end(symbol: Symbol, days_offset: int = 0)`	Trigger an event on the last tradable date of each week for a specific symbol minus an offset.
`self.date_rules.year_start(days_offset: int = 0)`	Trigger an event on the first day of each year plus an offset.
`self.date_rules.year_start(symbol: Symbol, days_offset: int = 0)`	Trigger an event on the first tradable date of each year for a specific symbol plus an offset.
`self.date_rules.year_end(days_offset: int = 0)`	Trigger an event on the last day of each year minus an offset.
`self.date_rules.year_end(symbol: Symbol, days_offset: int = 0)`	Trigger an event on the last tradable date of each year for a specific symbol minus an offset.
`self.date_rules.today`	Trigger an event once today.
`self.date_rules.tomorrow`	Trigger an event once tomorrow.

To define custom date rules, create a `FuncDateRule` object. The `FuncDateRule` constructor expects a `name` argument of type `str` and a `get_dates_function` argument of type `Callable[[datetime, datetime], list[datetime]]` . The `get_dates_function` function receives the start and end dates of the algorithm and returns a list of dates for the date rule. In live trading, the end date is 12/31/2025. The following example demonstrates how to define a date rule that represents the 10th day of each month:

```py
# Create a date rule that specifies the 10th day of each month.
date_rule = FuncDateRule(
    name="10th_day_of_the_month",
    get_dates_function=lambda start, end: [
        datetime(year, month, 10)
        for year in range(start.year, end.year) for month in range(1,12)
    ]
)
```

Some date rules require a Symbol. However, they accept a string representation of the Symbol as well. If your algorithm doesn't add the security , it assumes the string refers to a US Equity Symbol. For example, if you use the `self.date_rules.every_day('ES')` method, it assumes that 'ES' refers to a US Equity. To create a Symbol without adding a security to your algorithm, call the `Symbol.create` method.

```
PY
symbol = Symbol.create('ES', SecurityType.FUTURE, Market.CME)
```

In live trading, scheduled universes run at roughly 8 AM Eastern Time to ensure there is enough time for the data to process.

Configure Securities

Instead of configuring global universe settings, you can individually configure the settings of each security in the universe with a security initializer. Security initializers let you apply any security-level reality model or special data requests on a per-security basis. To set the security initializer, in the `initialize` method, call the `set_security_initializer` method and then define the security initializer.

```
PY
# A custom security initializer can override default models such as
# setting new fee and fill models for the security.
self.set_security_initializer(self._custom_security_initializer)

def _custom_security_initializer(self, security: Security) -> None:
    security.set_fee_model(ConstantFeeModel(0, "USD"))
```

For simple requests, you can use the functional implementation of the security initializer. This style lets you configure the security object with one line of code.

```
PY
# Disable the trading fees for each security by using lambda function
# for the set_security_initializer argument.
self.set_security_initializer(lambda security: security.set_fee_model(ConstantFeeModel(0, "USD")))
```

If you call the `set_security_initializer` method, it overwrites the default security initializer. The default security initializer uses the security-level reality models of the brokerage model to set the following reality models of each security:

- Fill
- Slippage
- Fee
- Buying Power
- Settlement
- Short availability
- Margin Interest Rate

The default security initializer also sets the leverage of each security and intializes each security with a seeder function. To extend upon the default security initializer instead of overwriting it, call `add_security_initializer` before you create the subscriptions.

```
PY
class AddSecurityInitializerExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the security initializer to set models of assets.
        self.add_security_initializer(self._custom_security_initializer)

    def _custom_security_initializer(self, security: Security) -> None:
        # Overwrite some of the reality models
        security.set_fee_model(ConstantFeeModel(0, "USD"))
```

Examples

The following examples demonstrate some common practices for universe settings.

Example 1: Weekly-Updating Liquid Universe

The following algorithm demonstrates daily EMA cross, trading on the most liquid stocks. The universe is set to be updated weekly. Various universe settings have been set to simulate the brokerage environment best and for trading needs.

PY

```
class UniverseSettingsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # To avoid over-updating the universe, which causes insufficient time to earn the trend, update the universe weekly.
        self.universe_settings.schedule.on(self.date_rules.week_start())
        self.universe_settings.minimum_time_in_universe = timedelta(7)
        # Rebalancing frequency is daily, so we only need to subscribe to daily resolution.
        self.universe_settings.resolution = Resolution.DAILY
        # To best simulate IB's margin requirement, set the leverage to 50%.
        self.universe_settings.leverage = 2
        # Since we trade by market order, we cannot use extended market hours data to fill.
        self.universe_settings.extended_market_hours = False
        # We want to trade the EMA with raw price but not altered by splits.
        self.universe_settings.data_normalization_mode = DataNormalizationMode.SPLIT_ADJUSTED

                # Only trade on the top 10 most traded stocks since they have the most popularity to drive trends.
        self.add_universe(self.universe.top(10))

    def on_data(self, slice: Slice) -> None:
        for symbol, bar in slice.bars.items():
            # Trade the trend by EMA crossing.
            ema = self.securities[symbol].ema.current.value
            if bar.close > ema:
                self.set_holdings(symbol, 0.05)
            else:
                self.set_holdings(symbol, -0.05)

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        for removed in changes.removed_securities:
            # Liquidate the ones leaving the universe since we will not trade their EMA anymore.
            self.liquidate(removed.symbol)
            # Deregister the EMA indicator to free resources
            self.deregister_indicator(removed.ema)

        for added in changes.added_securities:
            # Create EMA indicator for trend trading signals.
            added.ema = self.ema(added.symbol, 50, Resolution.DAILY)
            # Warm up the EMA indicator to ensure its readiness for immediate use.
            self.warm_up_indicator(added.symbol, added.ema, Resolution.DAILY)
```

Manual Universes

Introduction

The `ManualUniverseSelectionModel` selects a static, fixed set of assets. It is similar to adding securities with the traditional `add_security` API methods. If your algorithm has a static universe, you can use automatic indicators instead of manual indicators in your algorithm.

Manual universes can be prone to look-ahead bias . For example, if you select a set of securities that have performed well during the backtest period, you are incorporating information from the future into the backtest and the algorithm may underperform in live mode.

Add Manual Universe Selection

To add a `ManualUniverseSelectionModel` to your algorithm, in the `initialize` method, call the `AddUniverseSelection` method. The `ManualUniverseSelectionModel` constructor expects a list of `Symbol` objects that represent the universe constituents.

```
PY
# Use ManualUniverseSelectionModel method to select a static set of equities, similar to traditional add_security methods, for a fixed
trading universe.
tickers = ["SPY", "QQQ", "IWM"]
symbols = [ Symbol.create(ticker, SecurityType.EQUITY, Market.USA) for ticker in tickers]
self.add_universe_selection(ManualUniverseSelectionModel(symbols))
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`symbols`	`List[Symbol]`	Universe constituents	
`universe_settings`	`UniverseSettings`	The universe settings . If you don't provide an argument, the model uses the `algorithm.universe_settings` by default.	`None`

To move the universe tickers and `Symbol` objects outside of the algorithm class, create a universe selection model that inherits the `ManualUniverseSelectionModel` class.

```
PY
# Create a custom universe selection model to move universe tickers and Symbol objects outside of the algorithm class for improved
modularity, reusability, and maintainability.
self.add_universe_selection(IndexUniverseSelectionModel())

# Outside of the algorithm class
class IndexUniverseSelectionModel(ManualUniverseSelectionModel):
    def __init__(self):
        tickers = ["SPY", "QQQ", "IWM"]
        symbols = [Symbol.create(ticker, SecurityType.EQUITY, Market.USA) for ticker in tickers]
        super().__init__(symbols)
```

For more information about this model, see the class reference and implementation .

Examples

The following examples demonstrate some common practices for implementing a manual universe selection model.

Example 1: Crypto List Selection Model

The following algorithm selects a list of preset cryptos, given we have information that they will perform better. So, we can use `ManualUniverseSelectionModel` to select this list and buy the listed cryptos.

PY

```
class FrameworkManualUniverseSelectionAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Add a universe selection model to select the most liquid cryptos manually.
        symbols = [
            Symbol.create("BTCUSD", SecurityType.CRYPTO, Market.COINBASE),
            Symbol.create("ETHUSD", SecurityType.CRYPTO, Market.COINBASE)
        ]
        self.add_universe_selection(ManualUniverseSelectionModel(symbols))

        # Sent insights on buying and holding the most liquid cryptos for one week.
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(7)))
        # Evenly dissipate the capital risk among selected cryptos.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())
```

Universe Selection

Fundamental Universes

Introduction

A `FundamentalUniverseSelectionModel` selects a universe of US Equities based on `Fundamental` data. Depending on the `Fundamental` properties you use, these universes rely on the US Equity Coarse Universe dataset, the US Fundamental dataset, or both.

These types of universes operate on daily schedule by default. In backtests, they select assets at midnight. In live trading, the selection timing depends on the data provider you use. To adjust the selection schedule, see Schedule .

If you use a fundamental Universe Selection model, the only way to unsubscribe from a security is to return a list from the selection function that doesn't include the security `Symbol` . The `remove_security` method doesn't work with these types of Universe Selection models.

Fundamental Selection

The `FundamentalUniverseSelectionModel` lets you select stocks based on corporate `Fundamental` data. You can specific the selection method, which takes a list of `Fundamental` objects as argument and returns a list of `Symbol` objects.

```py
def initialize(self) -> None:
    # Run asynchronous universe selection to speed up your algorithm.
    # In this case, you can't rely on the method or algorithm state between filter calls.
    self.universe_settings.asynchronous = True
    self.add_universe_selection(FundamentalUniverseSelectionModel(self._fundamental_filter_function))

def _fundamental_filter_function(self, fundamental: List[Fundamental]):
    # Select symbols with fundamental data and a price above $10.
    filtered = [f for f in fundamental if f.price > 10 and not np.isnan(f.valuation_ratios.pe_ratio)]
    # Sort the assets in ascending order by their P/E ratio.
    sorted_by_pe_ratio = sorted(filtered, key=lambda f: f.valuation_ratios.pe_ratio)
    # Select the first 10 assets.
    return [f.symbol for f in sorted_by_pe_ratio[:10]]
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`selector`	`Callable[[List[Fundamental]], List[Symbol]]`	Filter function to select assets based on fundamental data.	
`universe_settings`	`UniverseSettings`	The universe settings . If you don't provide an argument, the model uses the `algorithm.universe_settings` by default.	`None`

The `Fundamental` objects have the following properties:

To move the selection function outside of the algorithm class, create a universe selection model that inherits the `FundamentalUniverseSelectionModel` class and override its `select` method.

```
# In the initialize method, enable asynchronous universe selection to speed up your algorithm.
self.universe_settings.asynchronous = True
# Add a custom universe selection model that selects undervalued, liquid stocks.
self.add_universe_selection(LiquidAndLowPEUniverseSelectionModel())

# Outside of the algorithm class, define the universe selection model.
class LiquidAndLowPEUniverseSelectionModel(FundamentalUniverseSelectionModel):
    def select(self, fundamental: List[Fundamental]) -> List[Symbol]:
        # Select symbols with fundamental data and a price above $1.
        filtered = [x for x in fundamental if x.price > 1 and not np.isnan(x.valuation_ratios.pe_ratio)]
        # Select the 100 assets with the greatest daily dollar volume.
        most_liquid = sorted(filtered, key=lambda x: x.dollar_volume, reverse=True)[:100]
        # Select the 10 assets with the lowest PE ratio.
        lowest_pe_ratio = sorted(most_liquid, key=lambda x: x.valuation_ratios.pe_ratio, reverse=True)[:10]
        return [x.Symbol for x in lowest_pe_ratio]
```

To return the current universe constituents from the selection function, return `Universe. UNCHANGED`.

For more information about this model, see the class reference and implementation.

EMA Cross Selection

The `EmaCrossUniverseSelectionModel` applies two exponential moving average (EMA) indicators to the price history of assets and then selects the assets that have their fast EMA furthest above their slow EMA on a percentage basis.

```
# Initialize asynchronous universe settings for faster processing and add EmaCrossUniverseSelectionModel to dynamically manage the
universe based on EMA cross signals to identify trending assets.
def initialize(self) -> None:
    self.universe_settings.asynchronous = True
    self.add_universe_selection(EmaCrossUniverseSelectionModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`fast_period`	`int`	Fast EMA period	100
`slow_period`	`int`	Slow EMA period	300
`universe_count`	`int`	Maximum number of members of this universe selection	500
`universe_settings`	`UniverseSettings`	The universe settings. If you don't provide an argument, the model uses the `algorithm.universe_settings` by default.	`None`

For more information about this model, see the class reference and implementation.

Examples

The following examples demonstrate some common practices for implementing the framework fundamental universe model.

Example 1: 50 Stocks >10/Share and >10M in Daily Trading Volume

The following algorithm selects the 50 most liquid US Equities above 10/share and 10M daily volume. We pass a function to the `FundamentalUniverseSelectionModel` to filter the fundamental data for stock selection.

```
class FrameworkFundamentalUniverseSelectionAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 8)
        self.set_cash(100000)

        # Configure the universe to update at the start of each month. Most of the top 500 don't change very frequently.
        self.universe_settings.schedule.on(self.date_rules.month_start())
        # Add a universe with custom selection rules for filtering.
        self.add_universe_selection(FundamentalUniverseSelectionModel(
            lambda fundamental: [
                x.symbol for x in sorted(
                    # Large-cap non-penny stocks have a more stable trend and demand.
                    [f for f in fundamental if f.price > 10 and f.dollar_volume > 10_000_000],
                    key=lambda f: f.dollar_volume
                )[-500:]
            ]
        ))

        # Sent insights on buying and holding the most liquid cryptos for a week.
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(30)))
        # Evenly dissipate the capital risk among selected cryptos.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())
```

Example 2: 10 Stocks Above Their 200-Day EMA With >$1B of Daily Trading Volume

Another common request is to filter the universe by a technical indicator, such as only picking stocks above their 200-day Exponential Moving Average (EMA). The `Fundamental` object has adjusted price and volume information so that you can do any price-related analysis. The following algorithm defines a separate class to contain the indicator of each asset. We pass a function to the `FundamentalUniverseSelectionModel` to filter the fundamental data for stock selection.

```
class FrameworkFundamentalUniverseSelectionAlgorithm(QCAlgorithm):
 # Create a dictionary to store the EMA data for universe selection.
    _selection_data_by_symbol = {}

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Add a universe with custom selection rules for filtering.
        self.add_universe_selection(FundamentalUniverseSelectionModel(self._select_assets))

        # Sent insights on buying and holding the most liquid cryptos for a week.
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(1)))
        # Evenly dissipate the capital risk among selected cryptos.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

    def _select_assets(self, fundamental: List[Fundamental]) -> List[Symbol]:
        for f in fundamental:
            # Create/Update the EMA indicators of each stock.
            if f.symbol not in self._selection_data_by_symbol:
                self._selection_data_by_symbol[f.symbol] = SelectionData(self, f.symbol, 200)
            self._selection_data_by_symbol[f.symbol].update(f.end_time, f.adjusted_price, f.dollar_volume)

        # Select the Equities above their EMA and have a daily volume of $1B.
        # These assets are in an uptrend and are very liquid.
        selected = [x for x in self._selection_data_by_symbol.values() if x.is_above_ema and x.volume > 1_000_000_000]

        # Select the 10 most liquid Equities to avoid extra slippage.
        return [ x.symbol for x in sorted(selected, key=lambda x: x.volume)[-10:] ]

# Create a separate class to contain the EMA information of each asset.
class SelectionData(object):
    def __init__(self, algorithm: QCAlgorithm, symbol: Symbol, period: int):
        # Create an EMA indicator for trend estimation and filtering.
        self.symbol = symbol
        self._ema = ExponentialMovingAverage(period)
        self.is_above_ema = False
        self.volume = 0

        # Warm up the EMA indicator.
        algorithm.warm_up_indicator(symbol, self._ema, Resolution.Daily);

    # Update your variables and indicators with the latest data.
    # You may also want to use the History API here to warm up the indicator.
    def update(self, time: datetime, price: float, volume: float) -> None:
        self.volume = volume
        if self._ema.update(time, price):
            self.is_above_ema = price > self._ema.current.value
```

In this example, the `SelectionData` class group variables for the universe selection and update the indicator of each asset. We highly recommend

you follow this pattern to keep your algorithm tidy and bug-free. The following snippet shows an example implementation of the `SelectionData` class, but you can make whatever you need to store your custom universe filters. Note that the preceding `SelectionData` class uses a manual EMA indicator instead of the automatic version . For more information about universes that select assets based on indicators, see Indicator Universes . You need to use a `SelectionData` class instead of assigning the EMA to the `Fundamental` object because you can't create custom attributes on `Fundamental` objects like you can with `Security` objects.

Example 3: 10 Stocks Furthest Above their 10-day SMA of Volume

The process to get the 10-day Simple Moving Average (SMA) stock volume is the same process as in Example 2. First, define a `SelectionData` class that performs the averaging. This class tracks the ratio of today's volume relative to historical volumes. You can use this ratio to select assets above their 10-day SMA and sort the results by the Equities that have had the most significant jump since yesterday.

We inherit the `FundamentalUniverseSelectionModel` to create a custom universe selection model. Overriding the `select` method, we filter the fundamental data for stocks selection.

```py
class FrameworkFundamentalUniverseSelectionAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1_000_000)

        # Add a universe with custom selection rules for filtering.
        self.add_universe_selection(VolumeSMAUniverseSelectionModel(10))

        # Sent insights on buying and holding the selected securities.
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(1)))
        # Evenly dissipate the capital risk among selected securities.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

class VolumeSMAUniverseSelectionModel(FundamentalUniverseSelectionModel):
 # Create a dictionary to store the EMA data for universe selection.
    _selection_data_by_symbol = {}

    def __init__(self, period: int) -> None:
        self.period = period

    def create_universes(self, algorithm: QCAlgorithm) -> List[Universe]:
        return [FundamentalUniverseFactory(Market.USA, algorithm.universe_settings,
            lambda fundamental: self.select(algorithm, fundamental))]

    def select(self, algorithm: QCAlgorithm, fundamental: List[Fundamental]) -> List[Symbol]:
        # Create/Update the volume SMA indicator of each stock.
        selected = []
        for f in fundamental:
            selection_data = self._selection_data_by_symbol.get(f.symbol, self.SelectionData(algorithm, f.symbol, self.period))
            is_ready = selection_data.update(f.end_time, f.adjusted_price, f.dollar_volume)
            # Select the Equities with higher trading volume than their SMA, indicating higher capital flow.
            if is_ready and selection_data.volume_ratio > 1:
                selected.append(selection_data)
            self._selection_data_by_symbol[f.symbol] = selection_data

        # Select the 10 Equities with the highest relative volume since they have the highest capacity
        # for scalp-trading or intra-day movement.
        return [ x.symbol for x in sorted(selected, key=lambda x: x.volume_ratio)[-10:] ]

    # Create a separate class to contain the EMA information of each asset.
    class SelectionData(object):
        def __init__(self, algorithm: QCAlgorithm, symbol: Symbol, period: int) -> None:
            self.symbol = symbol
            self.volume_ratio = 0
            # Create an SMA of volume to track the popularity of the stock.
            self._sma = SimpleMovingAverage(period)

            # Warm up the volume SMA indicator.
            algorithm.warm_up_indicator(symbol, self._sma, Resolution.DAILY, lambda data: data.volume)

        def update(self, time: datetime, price: float, volume: float) -> bool:
            # Update the SMA with today's data and calculate the relative volume position for filtering.
            if not self._sma.update(time, volume):
                return False
            sma = self._sma.current.value
            self.volume_ratio = volume / sma if sma > 0 else 0
            return True
```

Example 4: 10 "Fastest Moving" Stocks With a 50-Day EMA > 200 Day EMA

You can construct complex universe filters with the `SelectionData` helper class pattern. To view a full example of this algorithm, see the EmaCrossUniverseSelectionAlgorithm in the LEAN GitHub repository or take the related Boot Camp lesson .

PY

```
class FrameworkFundamentalUniverseSelectionAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Add a universe with custom selection rules for filtering.
        self.add_universe_selection(EmaUniverseSelectionModel(10))

        # Sent insights on buying and holding the selected securities.
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(1)))
        # Evenly dissipate the capital risk among selected securities.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

class EmaUniverseSelectionModel(FundamentalUniverseSelectionModel):
 # Create a dictionary to store the EMA data for universe selection.
    averages = {}

    def __init__(self, selection_number: int) -> None:
        super().__init__()
        self.selection_number = selection_number

    def select(self, algorithm: QCAlgorithm, fundamental: List[Fundamental]) -> List[Symbol]:
        # We are going to use a dictionary to refer to the object that will keep the moving averages
        for f in fundamental:
            if f.symbol not in self.averages:
                self.averages[f.symbol] = self.SelectionData(algorithm, f.symbol)

            # Updates the SymbolData object with current EOD price
            avg = self.averages[f.symbol]
            avg.update(f.end_time, f.adjusted_price)

        # Filter the values of the dict: we only want up-trending securities
        values = list(filter(lambda x: x.is_uptrend, self.averages.values()))

        # Sorts the values of the dict: we want those with greater differences between the moving average
        values.sort(key=lambda x: x.scale, reverse=True)

        # we need to return only the symbol objects
        return [ x.symbol for x in values[:self.selection_number] ]

    # class used to improve the readability of the fundamental selection function
    class SelectionData(object):
        def __init__(self, algorithm: QCAlgorithm, symbol: Symbol) -> None:
            self.symbol = symbol
            self.tolerance = 1.01
            self.fast = ExponentialMovingAverage(100)
            self.slow = ExponentialMovingAverage(300)
            self.is_uptrend = False
            self.scale = 0

            # Warm up the indicators.
            algorithm.warm_up_indicator(symbol, self.fast, Resolution.DAILY)
            algorithm.warm_up_indicator(symbol, self.slow, Resolution.DAILY)

        def update(self, time: datetime, price: float) -> None:
            if self.fast.update(time, price) and self.slow.update(time, price):
                fast = self.fast.current.value
                slow = self.slow.current.value
                self.is_uptrend = fast > slow * self.tolerance

            if self.is_uptrend:
                # computes an object score of how much larger the fast is than the slow
                self.scale = (fast - slow) / ((fast + slow) / 2.0)
```

Universe Selection

ETF Constituents Universes

Introduction

The `ETFConstituentsUniverseSelectionModel` selects a universe of US Equities based on the constituents of an ETF. These Universe Selection models rely on the US ETF Constituents dataset. They run on a daily schedule by default. To adjust the selection schedule, see Schedule .

Add ETF Constituents Universe Selection

To add an `ETFConstituentsUniverseSelectionModel` to your algorithm, in the `initialize` method, call the `add_universe_selection` method. The `ETFConstituentsUniverseSelectionModel` constructor expects an ETF ticker.

```
PY
# Run universe selection asynchronously to speed up your algorithm.
self.universe_settings.asynchronous = True
self.add_universe_selection(ETFConstituentsUniverseSelectionModel("SPY"))
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`etf_ticker`	`string`	Ticker of the ETF to get constituents for. To view the available ETFs, see Supported ETFs .	
`universe_settings`	`UniverseSettings`	The universe settings . If you don't provide an argument, the model uses the `algorithm.universe_settings` by default.	`None`
`universe_filter_func`	`Callable[[List[ETFConstituentUniverse]], List[Symbol]]`	Function to filter ETF constituents. If you don't provide an argument, the model selects all of the ETF constituents by default.	`None`

If you provide a `universe_filter_func` argument, you can use the following attributes of the `ETFConstituentUniverse` objects to select your universe:

The following example shows how to select the 10 Equities with the largest weight in the SPY ETF:

```
PY
# Initialize asynchronous settings for speed and use the ETFConstituentsUniverseSelectionModel
# to select the top 10 SPY constituents by weight, focusing on blue-chip stocks with minimal risk.
def initialize(self) -> None:
    self.universe_settings.asynchronous = True
    self.add_universe_selection(
        ETFConstituentsUniverseSelectionModel("SPY", universe_filter_func=self._etf_constituents_filter)
    )

def _etf_constituents_filter(self, constituents: List[ETFConstituentUniverse]) -> List[Symbol]:
    # Select the 10 largest Equities in the ETF.
    selected = sorted(
        [c for c in constituents if c.weight],
        key=lambda c: c.weight, reverse=True
    )[:10]
    return [c.symbol for c in selected]
```

To move the ETF `Symbol` and the selection function outside of the algorithm class, create a universe selection model that inherits the `ETFConstituentsUniverseSelectionModel` class.

```py
# Initialize asynchronous settings for speed and use the LargestWeightSPYETFUniverseSelectionModel
# to select the top 10 blue-chip SPY constituents by weight, focusing on stocks with minimal risk.
self.universe_settings.asynchronous = True
self.add_universe_selection(LargestWeightSPYETFUniverseSelectionModel())

# Outside of the algorithm class
class LargestWeightSPYETFUniverseSelectionModel(ETFConstituentsUniverseSelectionModel):

    def __init__(self) -> None:
        super().__init__('SPY', universe_filter_func=self._etf_constituents_filter)

    def _etf_constituents_filter(self, constituents: List[ETFConstituentUniverse]) -> List[Symbol]:
        # Select the 10 largest Equities in the ETF.
        selected = sorted(
            [c for c in constituents if c.weight],
            key=lambda c: c.weight, reverse=True
        )[:10]
        return [c.symbol for c in selected]
```

To return the current universe constituents from the selection function, return `Universe. UNCHANGED` .

For more information about this model, see the class reference and implementation .

Examples

The following examples demonstrate some common practices for implementing the framework ETF constituent universe selection model.

Example 1: Weighted ETF Constituents

A subset of the SPY constituents outperform the SPY while many underperform the overall index. In an attempt to buy the ETF constituents that outperform the index, the following algorithm buys the top 50 weighted assets in the ETF. In this example, we will pass a function to the `ETFConstituentsUniverseSelectionModel` for selection.

```py
class FrameworkETFConstituentsUniverseSelectionAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(10000000)

        self.etf_weight_by_symbol = {}

        # Add a universe of the SPY constituents.
        self.add_universe_selection(
            ETFConstituentsUniverseSelectionModel("SPY", universe_filter_func=self._etf_constituents_filter)
        )
        # Add an Alpha model to trade based on the constituent weights.
        self.add_alpha(EtfAlphaModel(self))
        # Position sizing was handled by insight weight (from ETF weight).
        self.set_portfolio_construction(InsightWeightingPortfolioConstructionModel())

    def _etf_constituents_filter(self, constituents: List[ETFConstituentUniverse]) -> List[Symbol]:
        # Cache the constituent weights in a dictionary for filtering and position sizing.
        self.etf_weight_by_symbol = {x.symbol: x.weight for x in constituents if x.weight}
        # Select the 50 constituents with the largest weight in the ETF.
        # They should have positive excess returns.
        return [x[0] for x in sorted(self.etf_weight_by_symbol.items(), key=lambda x: x[1], reverse=True)[:50]]

class EtfAlphaModel(AlphaModel):
    def __init__(self, algorithm: FrameworkETFConstituentsUniverseSelectionAlgorithm) -> None:
        self._algorithm = algorithm
        self._day = -1

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        insights = []

        # Daily rebalance only.
        if self._day == slice.time.day:
            return insights

        for symbol, weight in self._algorithm.etf_weight_by_symbol.items():
            # Get the ETF weight of all the assets currently in the universe.
            # To avoid trading errors, skip assets that have no price yet.
            if symbol in slice.bars:
                if not algorithm.securities[symbol].price:
                    continue
                insights.append(Insight.price(symbol, timedelta(1), InsightDirection.UP, weight=weight))

        self._day = slice.time.day

        return insights
```

Example 2: Weight Trend Selection

The following algorithm trades the QQQ constituents with the upward trend of its weight constitution, indicated by an EMA indicator, suggesting its price trend is outperforming other constituents, or its weight was promoted by the NASDAQ index, which brings positive sentiment. To better utilize the EMA indicator, we inherit the `ETFConstituentsUniverseSelectionModel` superclass to create a custom universe selection model.

```py
class FrameworkETFConstituentsUniverseSelectionAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(10000000)

        # Add a universe of the SPY constituents.
        self.add_universe_selection(
            UptrendETFUniverseSelectionModel("QQQ")
        )
        # Add Alpha model to trade based on the selections.
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(1)))
        # Equally invest in insights to dissipate the capital risk evenly.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

        # Warm up the indicators.
        self.set_warm_up(60, Resolution.DAILY)

class UptrendETFUniverseSelectionModel(ETFConstituentsUniverseSelectionModel):
    ema_by_symbol = {}

    def __init__(self, etf_ticker: str) -> None:
        super().__init__(etf_ticker, universe_filter_func=self.etf_constituent_filter)

    def etf_constituent_filter(self, constituents: List[ETFConstituentUniverse]) -> List[Symbol]:
        # Remove the ones that are not in the ETF anymore.
        to_remove = set(self.ema_by_symbol.keys()).difference(set([x.symbol for x in constituents]))
        for symbol in to_remove:
            del self.ema_by_symbol[symbol]

        for c in constituents:
            symbol = c.symbol
            if symbol in self.ema_by_symbol and c.weight:
                # Update EMA with the latest weight.
                self.ema_by_symbol[symbol].update(c.EndTime, c.weight)
            else:
                # Create an EMA to filter by trend.
                self.ema_by_symbol[symbol] = ExponentialMovingAverage(60)

        # Select the ones with the increasing trend of constituent weight.
        return [symbol for symbol, ema in self.ema_by_symbol.items() if ema.is_ready and ema.current.value > ema.previous.value]
```

Universe Selection

Scheduled Universes

Introduction

A Scheduled Universe Selection model selects assets at fixed, regular intervals. In live trading, you can use this type of model to fetch tickers from Dropbox or to perform periodic historical analysis and select some assets.

Scheduled Universe Selection

The `ScheduledUniverseSelectionModel` selects assets on the schedule you provide. To use this model, provide a `DateRule` , `TimeRule` , and a selector function. The `DateRule` and `TimeRule` define the selection schedule. The selector function receives a `datetime` object and returns a list of `Symbol` objects. The `Symbol` objects you return from the selector function are the constituents of the universe.

```
# Enable asynchronous universe selection to speed up your algorithm.
self.universe_settings.asynchronous = True
# Add a universe that selects assets at the beginning of each month.
self.add_universe_selection(
    ScheduledUniverseSelectionModel(
        self.date_rules.month_start(),
        self.time_rules.midnight,
        # Select SPY for October. Otherwise, select QQQ.
        lambda dt: [Symbol.create("SPY" if dt.month == 10 else "QQQ", SecurityType.EQUITY, Market.USA)]
    )
)
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`date_rule`	`IDateRule`	Date rule defines what days the universe selection function will be invoked	
`time_rule`	`ITimeRule`	Time rule defines what times on each day selected by date rule the universe selection function will be invoked	
`selector`	`Callable[[datetime], List[Symbol]]`	Selector function accepting the date time firing time and returning the universe selected symbols	
`settings`	`UniverseSettings`	The universe settings . If you don't provide an argument, the model uses the `algorithm.universe_settings` by default.	`None`

The model assumes the `time_rule` argument is in Coordinated Universal Time (UTC). To use a different timezone, pass a `timeZone` argument of type `DateTimeZone` before the `date_rule` argument.

To return the current universe constituents from the selector function, return `Universe. UNCHANGED` .

```py
# Add a universe that selects assets on Monday, Tuesday, and Thursday at 00:00, 06:00, 12:00, and 18:00 UTC.
self.add_universe_selection(ScheduledUniverseSelectionModel(
    self.date_rules.every(DayOfWeek.MONDAY, DayOfWeek.TUESDAY, DayOfWeek.THURSDAY),
    self.time_rules.every(timedelta(hours = 6)),
    self.select_symbols # selection function in algorithm.
))

# Define the selection function.
def select_symbols(self, date_time: datetime) -> List[Symbol]:
    tickers = ['SPY', 'AAPL', 'IBM']
    return [Symbol.create(ticker, SecurityType.EQUITY, Market.USA)
        for ticker in tickers]
```

For more information about this model, see the class reference and implementation .

Date Rules

The following table describes the supported `DateRules` :

Member	Description
`self.date_rules.set_default_time_zone(time_zone: DateTimeZone)`	Sets the time zone for the `DateRules` object used in all methods in this table. The default time zone is the algorithm time zone .
`self.date_rules.on(year: int, month: int, day: int)`	Trigger an event on a specific date.
`self.date_rules.on(dates: list[datetime])`	Trigger an event on specific dates.
`self.date_rules.every_day()`	Trigger an event all seven days of the week.
`self.date_rules.every_day(symbol: Symbol, extended_market_hours: bool = False)`	Trigger an event every day a specific symbol is trading.
`self.date_rules.every(days: list[DayOfWeek])`	Trigger an event on specific days throughout the week. To view the `DayOfWeek` enum members, see DayOfWeek Enum in the .NET documentation.
`self.date_rules.month_start(days_offset: int = 0)`	Trigger an event on the first day of each month plus an offset.
`self.date_rules.month_start(symbol: Symbol, daysOffset: int = 0)`	Trigger an event on the first tradable date of each month for a specific symbol plus an offset.
`self.date_rules.month_end(days_offset: int = 0)`	Trigger an event on the last day of each month minus an offset.
`self.date_rules.month_end(symbol: Symbol, daysOffset: int = 0)`	Trigger an event on the last tradable date of each month for a specific symbol minus an offset.
`self.date_rules.week_start(days_offset: int = 0)`	Trigger an event on the first day of each week plus an offset.
`self.date_rules.week_start(symbol: Symbol, days_offset: int = 0)`	Trigger an event on the first tradable date of each week for a specific symbol plus an offset.
`self.date_rules.week_end(days_offset: int = 0)`	Trigger an event on the last day of each week minus an offset.
`self.date_rules.week_end(symbol: Symbol, days_offset: int = 0)`	Trigger an event on the last tradable date of each week for a specific symbol minus an offset.
`self.date_rules.year_start(days_offset: int = 0)`	Trigger an event on the first day of each year plus an offset.
`self.date_rules.year_start(symbol: Symbol, days_offset: int = 0)`	Trigger an event on the first tradable date of each year for a specific symbol plus an offset.
`self.date_rules.year_end(days_offset: int = 0)`	Trigger an event on the last day of each year minus an offset.
`self.date_rules.year_end(symbol: Symbol, days_offset: int = 0)`	Trigger an event on the last tradable date of each year for a specific symbol minus an offset.
`self.date_rules.today`	Trigger an event once today.
`self.date_rules.tomorrow`	Trigger an event once tomorrow.

To define custom date rules, create a `FuncDateRule` object. The `FuncDateRule` constructor expects a `name` argument of type `str` and a `get_dates_function` argument of type `Callable[[datetime, datetime], list[datetime]]` . The `get_dates_function` function receives the start and end dates of the algorithm and returns a list of dates for the date rule. In live trading, the end date is 12/31/2025. The following example demonstrates how to define a date rule that represents the 10th day of each month:

```py
# Create a date rule that specifies the 10th day of each month.
date_rule = FuncDateRule(
    name="10th_day_of_the_month",
    get_dates_function=lambda start, end: [
        datetime(year, month, 10)
        for year in range(start.year, end.year) for month in range(1,12)
    ]
)
```

Some date rules require a Symbol. However, they accept a string representation of the Symbol as well. If your algorithm doesn't add the security , it assumes the string refers to a US Equity Symbol. For example, if you use the `self.date_rules.every_day('ES')` method, it assumes that 'ES' refers to a US Equity. To create a Symbol without adding a security to your algorithm, call the `Symbol.create` method.

```
symbol = Symbol.create('ES', SecurityType.FUTURE, Market.CME)
```

PY

Time Rules

The following table describes the supported `TimeRules` :

Member	Description
`self.time_rules.set_default_time_zone(time_zone: DateTimeZone)`	Sets the time zone for the `TimeRules` object used in all methods in this table, except when a different time zone is given. The default time zone is the algorithm time zone .
`self.time_rules.before_market_open(symbol: Symbol, minutes_before_open: float = 0, extended_market_open: bool = False)`	Trigger an event a few minutes before market open for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`self.time_rules.after_market_open(symbol: Symbol, minutes_after_open: float = 0, extended_market_open: bool = False)`	Trigger an event a few minutes after market open for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`self.time_rules.before_market_close(symbol: Symbol, minutes_before_close: float = 0, extended_market_open: bool = False)`	Trigger an event a few minutes before market close for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`self.time_rules.after_market_close(symbol: Symbol, minutes_after_close: float = 0, extended_market_open: bool = False)`	Trigger an event a few minutes after market close for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`self.time_rules.every(interval: timedelta)`	Trigger an event every period interval starting at midnight. This time rule triggers every period, regardless of whether or not the market is open.
`self.time_rules.now`	Trigger an event at the current time of day.
`self.time_rules.midnight`	Trigger an event at midnight.
`self.time_rules.noon`	Trigger an event at noon.
`self.time_rules.at(hour: int, minute: int, second: int = 0)`	Trigger an event at a specific time of day (e.g. 13:10).
`self.time_rules.at(hour: int, minute: int, second: int, time_zone: DateTimeZone)`	Trigger an event at a specific time of day in the given time zone (e.g. 13:10 UTC).

To define custom time rules, create a `FuncTimeRule` object. The `FuncTimeRule` constructor expects a `name` argument of type `str` and a `create_utc_event_times_function` argument of type `Callable[[list[datetime]], list[datetime]]` . The function receives the list of dates from the date rule and then returns a list of `datetime` that define the time rule.

```
time_rule = FuncTimeRule(
    name="CustomTimeRule",
    create_utc_event_times_function=lambda dates: [d + timedelta(hours=10) for d in dates]
)
```

PY

Some time rules require a Symbol. However, they accept a string representation of the Symbol as well. If your algorithm doesn't add the security , it assumes the string refers to a US Equity Symbol. For example, if you use the `self.time_rules.before_market_open('ES', 15)` method, it assumes that 'ES' refers to a US Equity. To create a Symbol without adding a security to your algorithm, call the `Symbol.create` method.

```
symbol = Symbol.create('ES', SecurityType.FUTURE, Market.CME)
```

PY

Examples

The following examples demonstrate some common practices for implementing a dateless scheduled universe selection model.

Example 1: From External Source

The following example selects its universe every week starting before the market opens from a source URL of Dropbox. It reloads on every selection so that you can hook up to the continuously updating source file.

```py
from io import StringIO

class FrameworkScheduledUniverseSelectionAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(10000000)

        # Add a universe of that read from a Dropbox source to select the stocks 30 minutes before the week's first trading day.
        spy = Symbol.create("SPY", SecurityType.EQUITY, Market.USA)
        self.add_universe_selection(ScheduledUniverseSelectionModel(
            self.date_rules.week_start(spy),
            self.time_rules.before_market_open(spy, 10),
            self.select_symbols
        ))
        # Add Alpha model to trade based on the selections; the signals last for a week until the next selection.
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(7)))
        # Equally invest in insights to dissipate the capital risk evenly.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

    def _download_universe_file(self, dt: datetime) -> str:
        # Download the universe CSV file. Dropbox links require the "dl=1" URL parameter.
        file = self.download(
            "https://www.dropbox.com/scl/fi/fbrxitk4ec3w91nse1raa/df.csv?rlkey=7r042rukzkthp7y1srloyhkov&st=5r4sdfwd&dl=1"
        )
        # Convert the CSV file data into a dictionary where the key is the date and
        # the value is a comma-separated string of stock tickers.
        df = pd.read_csv(StringIO(file), index_col=0).iloc[:, 0]
        df.index = pd.to_datetime(df.index).date
        date = dt.date()
        # Return the universe if the date matches.
        if date in df:
            return df.loc[dt.date()]
        return ''

    def select_symbols(self, dt: datetime) -> List[Symbol]:
        # Re-download the CSV file each day to get today's row.
        tickers = self._download_universe_file(dt)
        # If there isn't an entry for the current date, return an empty universe.
        if not tickers:
            return []
        # Convert the stock tickers in the CSV file to Symbol objects.
        return [Symbol.create(x, SecurityType.EQUITY, Market.USA) for x in tickers.split(",")]
```

Example 2: Seasonality

The following algorithm selects between SPY and short-term bond ETF according to the current month. It holds SPY on May, June, July, November, and December since they are historically better-performing months while holding SHV to preserve funds and earn interest in the remaining months.

```py
class FrameworkScheduledUniverseSelectionAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Add a universe of that select based on the time to trade seasonality.
        self.add_universe_selection(ScheduledUniverseSelectionModel(
            self.date_rules.week_start(),
            self.time_rules.at(0, 0),
            self.select_symbols
        ))
        # Add an Alpha model to trade based on the selections; the signals will last until the next selection.
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(7)))
        # Equally invest in insights to dissipate the capital risk evenly.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

    def select_symbols(self, date_time: datetime) -> List[Symbol]:
        # May/Jun/Jul/Nov/Dec are statistically better-performing months of SPY.
        if date_time.month in [5, 6, 7, 11, 12]:
            return [Symbol.create("SPY", SecurityType.EQUITY, Market.USA)]
        # In other months, hold short-term bonds to preserve funds while earning interest.
        return [Symbol.create("SHV", SecurityType.EQUITY, Market.USA)]
```

Universe Selection

Futures Universes

Introduction

A Future Universe Selection model selects contracts for a set of Futures.

Future Universe Selection

The `FutureUniverseSelectionModel` selects all the contracts for a set of Futures you specify. To use this model, provide a `refresh_interval` and a selector function. The `refresh_interval` defines how frequently LEAN calls the selector function. The selector function receives a `datetime` object that represents the current Coordinated Universal Time (UTC) and returns a list of `Symbol` objects. The `Symbol` objects you return from the selector function are the Futures of the universe.

```
# Run universe selection asynchronously to speed up your algorithm.
# This setting means you cannot rely on the method or algorithm state between filter calls.
self.universe_settings.asynchronous = True
# Add a universe of E-mini S&P 500 Futures contracts.
self.add_universe_selection(
    FutureUniverseSelectionModel(
        # Refresh the universe daily.
        timedelta(1),
        lambda _: [Symbol.create(Futures.Indices.SP_500_E_MINI, SecurityType.FUTURE, Market.CME)]
    )
)
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`refresh_interval`	`timedelta`	Time interval between universe refreshes	
`future_chain_symbol_selector`	`Callable[[datetime], List[Symbol]]`	A function that selects the Future symbols for a given Coordinated Universal Time (UTC). To view the supported assets in the US Futures dataset, see Supported Assets .	
`universe_settings`	`UniverseSettings`	The universe settings . If you don't provide an argument, the model uses the `algorithm.universe_settings` by default.	`None`

The following example shows how to define the Future chain Symbol selector as an isolated method:

```
# In the initialize method, add the FutureUniverseSelectionModel with a custom selection function.
def initialize(self) -> None:
    self.set_universe_selection(
        FutureUniverseSelectionModel(timedelta(days=1), self.select_future_chain_symbols)
    )

def select_future_chain_symbols(self, utc_time: datetime) -> List[Symbol]:
    # Add E-mini S&P 500 and Gold Futures to the universe.
    return [
        Symbol.create(Futures.Indices.SP_500_E_MINI, SecurityType.FUTURE, Market.CME),
        Symbol.create(Futures.Metals.GOLD, SecurityType.FUTURE, Market.COMEX)
    ]
```

This model uses the default Future contract filter, which doesn't select any Futures contracts. To use a different filter, subclass the `FutureUniverseSelectionModel` and define a `filter` method. The `filter` method accepts and returns a `FutureFilterUniverse` object to select the Futures contracts. The following table describes the filter methods of the `FutureFilterUniverse` class:

`standards_only()` Selects standard contracts
`front_month()` Selects the front month contract
`back_months()` Selects the non-front month contracts
`back_month()` Selects the back month contracts
`expiration(min_expiry: timedelta, max_expiry: timedelta)` Selects contracts that expire within a range of dates relative to the current day
`expiration(min_expiry_days: int, max_expiry_days: int)` Selects contracts that expire within a range of dates relative to the current day
`contracts(contracts: list[Symbol])` Selects a list of contracts
`contracts(contractSelector: Callable[[list[Symbol]], list[Symbol]])` Selects contracts that a selector function selects

The contract filter runs at the first time step of each day.

To move the Future chain Symbol selector and the contract selection function outside of the algorithm class, create a universe selection model that inherits the FundamentalUniverseSelectionModel class and override its Select method.

```
# In the initialize method, define the universe settings and add data.
self.universe_settings.asynchronous = True
self.add_universe_selection(FrontMonthFutureUniverseSelectionModel())

# Outside of the algorithm class, define the universe selection model.
class FrontMonthFutureUniverseSelectionModel(FutureUniverseSelectionModel):
    def __init__(self) -> None:
        # Refresh the universe daily.
        super().__init__(timedelta(1), self.select_future_chain_symbols)

    def select_future_chain_symbols(self, utc_time: datetime) -> List[Symbol]:
        # Add E-mini S&P 500 and Gold Futures to the universe.
        return [
            Symbol.create(Futures.Indices.SP_500_E_MINI, SecurityType.FUTURE, Market.CME),
            Symbol.create(Futures.Metals.GOLD, SecurityType.FUTURE, Market.COMEX)
        ]

    def filter(self, filter: FutureFilterUniverse) -> FutureFilterUniverse:
        # Select the front month contracts.
        return filter.front_month()
```

Some of the preceding filter methods only set an internal enumeration in the `FutureFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `FutureFilterUniverse` .

The `add_universe_selection` method doesn't return a `Future` object like the add_future method. The `Future` object contains `Symbol` and `mapped` properties, which reference the continuous contract and the currently selected contract in the continuous contract series, respectively. To get the

Future object, define the on_securities_changed method in your algorithm class or framework models and check the result of the is_canonical method.

```
# Save the Future object if the security added to the universe is the canonical asset.
def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
    for security in changes.added_securities:
        if security.symbol.is_canonical():
            self.future = security
```

For more information about this model, see the class reference and implementation .

Open Interest Future Universe Selection

The OpenInterestFutureUniverseSelectionModel is an extension of the FutureUniverseSelectionModel that selects the contract with the greatest open interest on a daily basis.

```
# Enable asynchronous universe settings for faster performance.
self.universe_settings.asynchronous = True
# Add an OpenInterestFutureUniverseSelectionModel for E-mini S&P 500 Futures, incorporating contracts with high
# open interest into the trading universe.
self.add_universe_selection(
    OpenInterestFutureUniverseSelectionModel(
        self,
        lambda utc_time: [Symbol.create(Futures.Indices.SP_500_E_MINI, SecurityType.FUTURE, Market.CME)]
    )
)
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
algorithm	IAlgorithm	Algorithm	
future_chain_symbol_selector	Callable[[datetime], List[Symbol]]	A function that selects the Future symbols for a given Coordinated Universal Time (UTC). To view the supported assets in the US Futures dataset, see Supported Assets .	
chain_contracts_lookup_limit	int/None	Limit on how many contracts to query for open interest	6
results_limit	int/None	Limit on how many contracts will be part of the universe	1

The following example shows how to define the Future chain Symbol selector as an isolated method:

```
# In the Initialize method, define the universe settings and add a universe.
def initialize(self) -> None:
    self.universe_settings.asynchronous = True
    self.add_universe_selection(
        OpenInterestFutureUniverseSelectionModel(self, self.select_future_chain_symbols)
    )

# Define the selection function, which returns Symbol objects.
def select_future_chain_symbols(self, utc_time: datetime) -> List[Symbol]:
    return [
        Symbol.create(Futures.Indices.SP_500_E_MINI, SecurityType.FUTURE, Market.CME),
        Symbol.create(Futures.Metals.GOLD, SecurityType.FUTURE, Market.COMEX)
    ]
```

To move the Future chain Symbol selector outside of the algorithm class, create a universe selection model that inherits the OpenInterestFutureUniverseSelectionModel class.

```py
# In the Initialize method, define the universe settings and add a universe.
self.universe_settings.asynchronous = True
self.add_universe_selection(GoldOpenInterestFutureUniverseSelectionModel(self))

# Outside of the algorithm class, define the universe selection model.
class GoldOpenInterestFutureUniverseSelectionModel(OpenInterestFutureUniverseSelectionModel):
    def __init__(self, algorithm: QCAlgorithm, chain_contracts_lookup_limit: int=6, results_limit: int=1):
        super().__init__(algorithm, self.select_future_chain_symbols, chain_contracts_lookup_limit, results_limit)

    def select_future_chain_symbols(self, utcTime: datetime) -> List[Symbol]:
        return [Symbol.create(Futures.Metals.GOLD, SecurityType.FUTURE, Market.COMEX)]
```

The `add_universe_selection` method doesn't return a `Future` object like the add_future method. The `Future` object contains `Symbol` and `mapped` properties, which reference the continuous contract and the currently selected contract in the continuous contract series, respectively. To get the `Future` object, define the `on_securities_changed` method in your algorithm class or framework models and check the result of the `is_canonical` method.

```py
# Save the Future object if the security added to the universe is the canonical asset.
def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
    for security in changes.added_securities:
        if security.symbol.is_canonical():
            self.future = security
```

For more information about this model, see the class reference and implementation .

Examples

The following examples demonstrate some common practices for implementing a Futures universe selection model.

Example 1: Front Month Contracts

The following algorithm selects a list of Futures to buy and hold equally. To ensure liquidity and efficiency, we will select only their front-month contracts. We can do so in the algorithm framework through a child class inheriting the `FutureUniverseSelectionModel` while providing the list of Futures and overriding the `filter` method to select the front month contracts.

```py
class FrameworkFutureUniverseSelectionAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # It is usual to trade Futures during extended market hours.
        self.universe_settings.extended_market_hours = True
        # Add a universe with custom selection rules for filtering.
        self.add_universe_selection(FrontMonthFutureUniverseSelectionModel(7))

        # Sent insights on buying and holding the selected securities.
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(7)))
        # Evenly dissipate the capital risk among selected securities.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

class FrontMonthFutureUniverseSelectionModel(FutureUniverseSelectionModel):
    '''Creates futures chain universes that select the front month contract and run a user-defined
    futureChainSymbolSelector every day to enable choosing different futures chains'''
    def __init__(self, rebalance_period: int = 7) -> None:
        super().__init__(timedelta(rebalance_period), self.select_future_chain_symbols)

    def filter(self, filter: FutureFilterUniverse) -> FutureFilterUniverse:
        # Defines the futures chain universe filter to select only the front-month contracts at market open.
        return filter.front_month()

    def select_future_chain_symbols(self, utc_time: datetime) -> List[Symbol]:
        return [
            Symbol.create(Futures.Indices.VIX, SecurityType.FUTURE, Market.CFE),
            Symbol.create(Futures.Indices.SP_500_E_MINI, SecurityType.FUTURE, Market.CME),
            Symbol.create(Futures.Indices.NASDAQ_100_E_MINI, SecurityType.FUTURE, Market.CME),
            Symbol.create(Futures.Indices.DOW_30_E_MINI, SecurityType.FUTURE, Market.CBOT),
            Symbol.create(Futures.Energy.GASOLINE, SecurityType.FUTURE, Market.NYMEX),
            Symbol.create(Futures.Energy.HEATING_OIL, SecurityType.FUTURE, Market.NYMEX),
            Symbol.create(Futures.Energy.NATURAL_GAS, SecurityType.FUTURE, Market.NYMEX),
            Symbol.create(Futures.Grains.CORN, SecurityType.FUTURE, Market.CBOT),
            Symbol.create(Futures.Grains.OATS, SecurityType.FUTURE, Market.CBOT),
            Symbol.create(Futures.Grains.SOYBEANS, SecurityType.FUTURE, Market.CBOT),
            Symbol.create(Futures.Grains.WHEAT, SecurityType.FUTURE, Market.CBOT),
        ]
```

Example 2: Seasonal Contracts

Some Futures exhibit a seasonality effect, i.e., a yearly cycle in its price fluctuation. Studies show that the Natural Gas contract has a yearly cycle of maximizing its price in early December and minimizing it in early April. It might be due to the high demand for natural gas during winter warming. The following algorithm will hold Natural Gas contracts from summer to winter with a similar universe selection model in Example 1, but using a custom selection function with a time argument to select the contract.

PY

```
class FrameworkFutureUniverseSelectionAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # It is usual to trade Futures during extended market hours.
        self.universe_settings.extended_market_hours = True
        # We hold the Future and will not frequently trade it; using Daily resolution is sufficient for computational efficiency.
        self.universe_settings.resolution = Resolution.DAILY
        # Add a universe with custom selection rules for filtering.
        # Rescan every week to ensure we are on our plan.
        self.add_universe_selection(FrontMonthFutureUniverseSelectionModel(7))

        # Sent insights on buying and holding the selected securities.
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(7)))
        # Place orders for a single contract to control risk exposure and avoid over-leveraging.
        self.set_portfolio_construction(SingleSharePortfolioConstructionModel())

class FrontMonthFutureUniverseSelectionModel(FutureUniverseSelectionModel):
    '''Creates futures chain universes that select the front month contract and run a user-defined
     futureChainSymbolSelector every day to enable choosing different futures chains'''
    def __init__(self, rebalance_period: int = 7) -> None:
        super().__init__(timedelta(rebalance_period), self.select_future_chain_symbols)

    def filter(self, filter: FutureFilterUniverse) -> FutureFilterUniverse:
        # Defines the futures chain universe filter to select only the front-month contracts.
        return filter.front_month()

    def select_future_chain_symbols(self, utc_time: datetime) -> List[Symbol]:
        # We hold Natural Gas from summer to winter since it is in an upward cycle.
        if 4 <= utc_time.month <= 11:
            return [ Symbol.create(Futures.Energy.NATURAL_GAS, SecurityType.FUTURE, Market.NYMEX) ]
        # We do not hold any contracts during the time of the downward cycle.
        return []

class SingleSharePortfolioConstructionModel(PortfolioConstructionModel):
    def create_targets(self, algorithm: QCAlgorithm, insights: List[Insight]) -> List[PortfolioTarget]:
        targets = []
        for insight in insights:
            if algorithm.securities[insight.symbol].is_tradable:
                # Use integer target to create a portfolio target to trade a single contract
                targets.append(PortfolioTarget(insight.symbol, insight.direction))
        return targets
```

Universe Selection

Options Universes

Introduction

An Option Universe Selection model selects contracts for a set of Options.

Options Universe Selection

The `OptionUniverseSelectionModel` selects all the available contracts for the Equity Options, Index Options, and Future Options you specify. To use this model, provide a `refresh_interval` and a selector function. The `refresh_interval` defines how frequently LEAN calls the selector function. The selector function receives a `datetime` object that represents the current Coordinated Universal Time (UTC) and returns a list of `Symbol` objects. The `Symbol` objects you return from the selector function are the Options of the universe.

```
# Run universe selection asynchronously to speed up your algorithm.
# In this case, you can't rely on the method or algorithm state between filter calls.
self.universe_settings.asynchronous = True
# Add a universe of SPY Options.
self.set_universe_selection(
    OptionUniverseSelectionModel(
        # Refresh the universe daily.
        timedelta(1), lambda _: [Symbol.create("SPY", SecurityType.OPTION, Market.USA)]
    )
)
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`refresh_interval`	`timedelta`	Time interval between universe refreshes	
`option_chain_symbol_selector`	`Callable[[datetime], List[Symbol]]`	A function that selects the Option symbols	
`universe_settings`	`UniverseSettings`	The universe settings . If you don't provide an argument, the model uses the `algorithm.universe_settings` by default.	`None`

The following example shows how to define the Option chain Symbol selector as an isolated method:

```
# In the initialize method, add the OptionUniverseSelectionModel with a custom selection function.
def initialize(self) -> None:
    self.add_universe_selection(
        OptionUniverseSelectionModel(timedelta(days=1), self.select_option_chain_symbols)
    )

# Define the selection function.
def select_option_chain_symbols(self, utc_time: datetime) -> List[Symbol]:
    # Equity Options example:
    #tickers = ["SPY", "QQQ", "TLT"]
    #return [Symbol.create(ticker, SecurityType.OPTION, Market.USA) for ticker in tickers]

    # Index Options example:
    #tickers = ["VIX", "SPX"]
    #return [Symbol.create(ticker, SecurityType.INDEX_OPTION, Market.USA) for ticker in tickers]

    # Future Options example:
    future_symbol = Symbol.create(Futures.Indices.SP_500_E_MINI, SecurityType.FUTURE, Market.CME)
    return [Symbol.create_canonical_option(contract.symbol) for contract in self.futures_chain(future_symbol)]
```

This model uses the default Option filter, which selects all of the available Option contracts at the current time step. To use a different filter for the contracts, subclass the `OptionUniverseSelectionModel` and define a method. The method accepts and returns an `OptionFilterUniverse` object to

select the Option contracts. The following table describes the methods of the `OptionFilterUniverse` class:

The following table describes the filter methods of the `OptionFilterUniverse` class:

`strikes(min_strike: int, max_strike: int)` Selects contracts that are within `m_strike` strikes below the underlying price and `max_strike` strikes above the underlying price.
`calls_only()` Selects call contracts.
`puts_only()` Selects put contracts.
`standards_only()` Selects standard contracts.
`weeklys_only()` Selects weekly contracts.
`front_month()` Selects the front month contract.
`back_months()` Selects the non-front month contracts.
`back_month()` Selects the back month contracts.
`expiration(min_expiryDays: int, max_expiryDays: int)` Selects contracts that expire within a range of dates relative to the current day.
`contracts(contracts: list[Symbol])` Selects a list of contracts.
`contracts(contract_selector: Callable[[list[Symbol]], list[Symbol]])` Selects contracts that a selector function selects.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

The contract filter runs at the first time step of each day.

To move the Option chain Symbol selector outside of the algorithm class, create a universe selection model that inherits the `OptionUniverseSelectionModel` class.

```
# In the initialize method, define the universe settings and add data.
self.universe_settings.asynchronous = True
self.add_universe_settings(EarliestExpiringAtTheMoneyCallOptionUniverseSelectionModel(self))

# Outside of the algorithm class, define the universe selection model.
class EarliestExpiringAtTheMoneyCallOptionUniverseSelectionModel(OptionUniverseSelectionModel):
    def __init__(self, algorithm):
        self.algo = algorithm
        super().__init__(timedelta(1), self.select_option_chain_symbols)

    def select_option_chain_symbols(self, utc_time: datetime) -> List[Symbol]:
        # Equity Options example:
        #tickers = ["SPY", "QQQ", "TLT"]
        #return [Symbol.create(ticker, SecurityType.OPTION, Market.USA) for ticker in tickers]

        # Index Options example:
        #tickers = ["VIX", "SPX"]
        #return [Symbol.create(ticker, SecurityType.INDEX_OPTION, Market.USA) for ticker in tickers]

        # Future Options example:
        future_symbol = Symbol.create(Futures.Indices.SP_500_E_MINI, SecurityType.FUTURE, Market.CME)
        return [Symbol.create_canonical_option(contract.symbol) for contract in self.algo.futures_chain(future_symbol)]

    # Create a filter to select contracts that have the strike price within 1 strike level and expire within 7 days.
    def Filter(self, option_filter_universe: OptionFilterUniverse) -> OptionFilterUniverse:
        return option_filter_universe.strikes(-1, -1).expiration(0, 7).calls_only()
```

Some of the preceding filter methods only set an internal enumeration in the `OptionFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `OptionFilterUniverse` .

To override the default pricing model of the Options, set a pricing model in a security initializer.

To override the initial guess of implied volatility , set and warm up the underlying volatility model .

For more information about this model, see the class reference and implementation .

Option Chained Universe Selection

An Option chained universe subscribes to Option contracts on the constituents of a US Equity universe .

```
# Configure the universe to use price data unadjusted for splits and dividends ("raw") into the algorithm.
# Options require raw Equity prices.
self.universe_settings.data_normalization_mode = DataNormalizationMode.RAW
self.universe_settings.asynchronous = True
self.add_universe_selection(
    OptionChainedUniverseSelectionModel(
        # Add a universe of the 10 most liquid US Equities.
        self.add_universe(self.universe.top(10)),
        # Select call Option contracts on the underlying Equities that have the strike price within 2 strike levels.
        lambda option_filter_universe: option_filter_universe.strikes(-2, +2).front_month().calls_only()
    )
)
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`universe`	`Universe`	The universe to chain onto the Option Universe Selection model	
`option_filter`	`Callable[[OptionFilterUniverse], OptionFilterUniverse]`	The Option filter universe to use	
`universe_settings`	`UniverseSettings`	The universe settings . If you don't provide an argument, the model uses the `algorithm.universe_settings` by default.	`None`

The `option_filter` function receives and returns an `OptionFilterUniverse` to select the Option contracts. The following table describes the methods of the `OptionFilterUniverse` class:

The following table describes the filter methods of the `OptionFilterUniverse` class:

`strikes(min_strike: int, max_strike: int)` Selects contracts that are within `m_strike` strikes below the underlying price and `max_strike` strikes above the underlying price.
`calls_only()` Selects call contracts.
`puts_only()` Selects put contracts.
`standards_only()` Selects standard contracts.
`weeklys_only()` Selects weekly contracts.
`front_month()` Selects the front month contract.
`back_months()` Selects the non-front month contracts.
`back_month()` Selects the back month contracts.
`expiration(min_expiryDays: int, max_expiryDays: int)` Selects contracts that expire within a range of dates relative to the current day.
`contracts(contracts: list[Symbol])` Selects a list of contracts.
`contracts(contract_selector: Callable[[list[Symbol]], list[Symbol]])` Selects contracts that a selector function selects.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

The following example shows how to define the Option filter as an isolated method:

```
# In the initialize method, define the universe settings and add the universe selection model.
def initialize(self) -> None:
    self.universe_settings.data_normalization_mode = DataNormalizationMode.RAW
    self.universe_settings.asynchronous = True
    self.add_universe_selection(
        OptionChainedUniverseSelectionModel(
            self.add_universe(self.universe.top(10)), self.option_filter_function
        )
    )

# Define the contract filter function to select front month call contracts with a strike price within 2 strike levels.
def option_filter_function(self, option_filter_universe: OptionFilterUniverse) -> OptionFilterUniverse:
    return option_filter_universe.strikes(-2, +2).front_month().calls_only()
```

Some of the preceding filter methods only set an internal enumeration in the `OptionFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `OptionFilterUniverse` .

For more information about this model, see the class reference and implementation .

Examples

The following examples demonstrate some common practices for implementing the framework Option Universe Selection Model.

Example 1: Horizontal Jelly Roll

The following algorithm selects SPX index options to construct a Jelly Roll strategy. It filters for ATM calls and puts with 30 days and 90 days till expiration. Using the SMA indicator to predict the interest rate cycle, it longs Jelly Roll if the cycle is considered uprising, otherwise selling the Jelly Roll.

```
class FrameworkOptionUniverseSelectionAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(500_000)

        # Add a universe that selects the needed option contracts.
        self.add_universe_selection(AtmOptionHorizontalSpreadUniverseSelectionModel())
        # Add Alpha model to trade Jelly Roll, using interest rate data.
        self.add_alpha(JellyRollAlphaModel(self))
        # Invest in the same number of contracts per leg in the Jelly Roll.
        self.set_portfolio_construction(SingleSharePortfolioConstructionModel())

class AtmOptionHorizontalSpreadUniverseSelectionModel(OptionUniverseSelectionModel):
    # 30d update with the SelectOptionChainSymbols function since the filter returns at least 30d expiry options.
    def __init__(self) -> None:
        super().__init__(timedelta(30), self.selection_option_chain_symbols)

    def selection_option_chain_symbols(self, utc_time: datetime) -> List[Symbol]:
        # We will focus only on SPX options since they have a relatively stable dividend yield, which we assume will remain the same over
time.
        # Also, assignment handling is not required since it is cash-settled.
        return [Symbol.create("SPX", SecurityType.INDEX_OPTION, Market.USA)]

    def filter(self, filter: OptionFilterUniverse) -> OptionFilterUniverse:
        # Jelly Roll is one of the best strategies for trading interest rates using options.
        # It is market-neutral but sensitive to interest rate and dividend yield changes.
        # We target to trade the market speculation between 30d and 90d options interest rate.
        return filter.jelly_roll(0, 30, 90)

class JellyRollAlphaModel(AlphaModel):
    _symbol = Symbol.create("SPX", SecurityType.INDEX_OPTION, Market.USA)
    # Use a 365d SMA indicator of daily interest rate to estimate if the interest rate cycle is upward or downward.
    _sma = SimpleMovingAverage(365)

                Insight.price(far_put.symbol, timedelta(30), InsightDirection.DOWN)
            ])

        return insights

class SingleSharePortfolioConstructionModel(PortfolioConstructionModel):
    def create_targets(self, algorithm: QCAlgorithm, insights: List[Insight]) -> List[PortfolioTarget]:
        targets = []
        for insight in insights:
            if algorithm.securities[insight.symbol].is_tradable:
                # Use integer target to create a portfolio target to trade a single contract
                targets.append(PortfolioTarget(insight.symbol, insight.direction))
        return targets
```

Example 2: Options of an Equity Universe

The following hybrid algorithm example chains a fundamental universe and an Equity Options universe . It first selects 10 stocks with the lowest PE ratio and then selects their front-month call Option contracts. It buys one front-month call Option contract every day.

To override the default pricing model of the Options, set a pricing model in a security initializer.

To override the initial guess of implied volatility , set and warm up the underlying volatility model .

PY

```
# Example code to chain a fundamental universe and an Equity Options universe by selecting top 10 stocks with lowest PE, indicating
potentially undervalued stocks and then selecting their from-month call Option contracts to target contracts with high liquidity.
from AlgorithmImports import *

class ChainedUniverseAlgorithm(QCAlgorithm):
    _day = 0
    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.settings.seed_initial_prices = True
        self.universe_settings.asynchronous = True
        self.universe_settings.data_normalization_mode = DataNormalizationMode.RAW
        self.add_security_initializer(self._custom_security_initializer)

        self.add_universe_selection(OptionChainedUniverseSelectionModel(

Universe Selection

Legacy Fundamental Universes

Introduction

Warning: This API for Universe Selection was deprecated on November 2023. Please refer to the new Fundamental Selection API .

A `FundamentalUniverseSelectionModel` selects a universe of US Equities based on `CoarseFundamental` and, sometimes, `FineFundamental` data. If the model uses `CoarseFundamental` data, it relies on the US Equity Coarse Universe dataset. If the Universe Selection model uses `FineFundamental` data, it relies on the US Fundamental dataset.

These types of universes operate on daily schedule. In backtests, they select assets at midnight. In live trading, the selection timing depends on the data provider you use.

If you use a fundamental Universe Selection model, the only way to unsubscribe from a security is to return a list from the selection functions that doesn't include the security `Symbol` . The `remove_security` method doesn't work with these types of Universe Selection models.

Coarse Fundamental Selection

The `CoarseFundamentalUniverseSelectionModel` selects assets based on `CoarseFundamental` data. To use this model, define a coarse selection function. The coarse selection function receives a list of `CoarseFundamental` objects and returns a list of `Symbol` objects. The `Symbol` objects you return from the coarse selection function are the constituents of the universe.

```
# Set asynchronous universe settings for improved speed and use CoarseFundamentalUniverseSelectionModel with a custom function to select
the top 100 most liquid assets with available fundamental data, ensuring the universe consists of liquid and fundamentally strong
securities for stable returns.
def initialize(self) -> None:
    self.universe_settings.asynchronous = True
    self.add_universe_selection(CoarseFundamentalUniverseSelectionModel(self.select_coarse))

def select_coarse(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
    selected = [c for c in coarse if c.has_fundamental_data]
    sorted_by_dollar_volume = sorted(selected, key=lambda c: c.dollar_volume, reverse=True)
    return [c.symbol for c in sorted_by_dollar_volume[:100]] # Return most liquid assets w/ fundamentals
```

PY

To move the coarse selection function outside of the algorithm class, create a universe selection model that inherits the `CoarseFundamentalUniverseSelectionModel` class.

```
# Move the coarse selection function outside of the algorithm class by creating a custom universe selection model inheriting from
CoarseFundamentalUniverseSelectionModel, allowing for modification and reusability of the selection logic.
self.universe_settings.asynchronous = True
self.add_universe_selection(MostLiquidFundamentalUniverseSelectionModel(self.universe_settings))

# Outside of the algorithm class
class MostLiquidFundamentalUniverseSelectionModel(CoarseFundamentalUniverseSelectionModel):
    def __init__(self, universe_settings: UniverseSettings) -> None:
        super().__init__(self.select_coarse, universe_settings)

    def select_coarse(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
        selected = [c for c in coarse if c.has_fundamental_data]
        sorted_by_dollar_volume = sorted(selected, key=lambda c: c.dollar_volume, reverse=True)
        return [c.symbol for c in sorted_by_dollar_volume[:100]]
```

PY

To return the current universe constituents from the coarse selection function, return `Universe.Unchanged` .

For more information about this model, see the class reference and implementation .

Fine Fundamental Selection

The `FineFundamentalUniverseSelectionModel` selects assets based on `CoarseFundamental` and `FineFundamental` data. This is the only model that provides corporate fundamental data to your algorithm. To use this model, define a coarse selection function and a fine selection function. The coarse selection function receives a list of `CoarseFundamental` objects and returns a list of `Symbol` objects. To filter the `CoarseFundamental` down to the securities that have fundamental data, add a `has_fundamental_data` filter to the coarse selection function. The fine selection function receives a

subset of `FineFundamental` objects generated from coarse selection results and returns a list of `Symbol` objects. The `Symbol` objects you return from the fine selection function are the constituents of the universe.

```py
# FineFundamentalUniverseSelectionModel integrates corporate fundamental data into the algorithm through a two-step filtering process:
coarse selection ensures liquidity and fundamental data availability, while fine selection focuses on valuation metrics, refining the
universe of selected stocks.
def initialize(self) -> None:
    self.universe_settings.asynchronous = True
    self.add_universe_selection(FineFundamentalUniverseSelectionModel(self.select_coarse, self.select_fine))

def select_coarse(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
    selected = [c for c in coarse if c.has_fundamental_data]
    sorted_by_dollar_volume = sorted(selected, key=lambda c: c.dollar_volume, reverse=True)
    return [c.symbol for c in sorted_by_dollar_volume[:100]] # Return most liquid assets w/ fundamentals

def select_fine(self, fine: List[FineFundamental]) -> List[Symbol]:
    sorted_by_pe_ratio = sorted(fine, key=lambda x: x.valuation_ratios.pe_ratio, reverse=False)
    return [c.symbol for c in sorted_by_pe_ratio[:10]] # Return assets with lowest P/E ratios
```

To move the selection functions outside of the algorithm class, create a universe selection model that inherits the `FineFundamentalUniverseSelectionModel` class.

```py
# Create a custom universe selection model inheriting from FineFundamentalUniverseSelectionModel to move both coarse and fine selection
functions outside the algorithm class, enabling easier modification and reusability of the filtering and ranking logic.
self.universe_settings.asynchronous = True
self.add_universe_selection(LowPERatioUniverseSelectionModel(self.universe_settings))

# Outside of the algorithm class
class LowPERatioUniverseSelectionModel(FineFundamentalUniverseSelectionModel):
    def __init__(self, universe_settings: universe_settings = None) -> None:
        super().__init__(self.select_coarse, self.select_fine, universe_settings)

    def select_coarse(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
        selected = [c for c in coarse if c.has_fundamental_data]
        sorted_by_dollar_volume = sorted(selected, key=lambda c: c.dollar_volume, reverse=True)
        return [c.symbol for c in sorted_by_dollar_volume[:100]]

    def select_fine(self, fine: List[FineFundamental]) -> List[Symbol]:
        sorted_by_pe_ratio = sorted(fine, key=lambda x: x.valuation_ratios.pe_ratio, reverse=False)
        return [c.symbol for c in sorted_by_pe_ratio[:10]]
```

To return the current universe constituents from the coarse or fine selection function, return `Universe. UNCHANGED` .

If you add a `FineFundamentalUniverseSelectionModel` to your algorithm, you can access fundamental data in the fine selection function or from the `Equity` object. To access fundamental data from the `Equity` object, use the `Equity. fundamentals` property.

For more information about this model, see the class reference and implementation .

Algorithm Framework

Alpha

Alpha

Key Concepts

Introduction

The Alpha model predicts market trends and signals the best moments to trade. These signals, or `Insight` objects, contain the `Direction` , `Magnitude` , and `Confidence` of a market prediction and the suggested portfolio `Weight` . You should generate insights on the set of assets provided by the Universe Selection model and only generate them when your predictions change.

Add Models

To add an Alpha model, in the `initialize` method, call the `AddAlpha` method.

```
# Add EmaCrossAlphaModel to generate market trend insights and trading signals based on EMA crossovers, providing Direction, Magnitude,
and Confidence for the universe-selected assets.
self.add_alpha(EmaCrossAlphaModel())
```

PY

To view all the pre-built Alpha models, see Supported Models .

Multi-Alpha Algorithms

You can add multiple Alpha models to a single algorithm and generate Insight objects with all of them.

```
# Add RsiAlphaModel and EmaCrossAlphaModel to generate trading signals based on RSI and EMA crossovers, utilizing multiple alpha models to
capture different market signals and trends for robust predictions.
self.add_alpha(RsiAlphaModel())
self.add_alpha(EmaCrossAlphaModel())
```

PY

Each Alpha model has a unique name. The Insight objects they generate are automatically named according to the Alpha model name.

If you add multiple Alpha models, each alpha model receives the current slice in the order that you add the Alphas. The combined stream of Insight objects is passed to the Portfolio Construction model that defines how the Insight collection is combined. If you have a hybrid algorithm, the combined stream of Insight objects is passed to the event handler .

Model Structure

Alpha models should extend the `AlphaModel` class. Extensions of the `AlphaModel` class must implement the `update` method, which receives a Slice object and returns an array of `Insight` objects. Extensions should also implement the `on_securities_changed` method to track security changes in the universe.

```
# Algorithm framework model that produces insights
class MyAlphaModel(AlphaModel):

    def update(self, algorithm: QCAlgorithm, data: Slice) -> List[Insight]:
        # Updates this Alpha model with the latest data from the algorithm.
        # This is called each time the algorithm receives data for subscribed securities
        # Generate insights on the securities in the universe.
        insights = []
        return insights

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        # Security additions and removals are pushed here.
        # This can be used for setting up algorithm state.
        # changes.added_securities
        # changes.removed_securities
        pass
```

Method Parameters

The `algorithm` parameter that the methods receive is an instance of the base `QCAlgorithm` class, not your subclass of it. To access members of your algorithm object, either use a global variable or pass an algorithm reference to Alpha model constructor. Both of these approaches violate the separation of concerns principle.

The `data` parameter contains the latest data available to the algorithm.

The `changes` parameter contains the universe changes.

Model Names

To ensure your Alpha model is compatible with all Portfolio Construction models , assign a unique name to your Alpha model. Some Portfolio Construction models can combine multiple Alpha models together, so it can be important to distinguish between the Alpha models.

```
# Assign a unique name to RsiAlphaModel to ensure compatibility and distinguish it when combining with other Alpha models in portfolio
construction.
class RsiAlphaModel(AlphaModel):
    name = "RsiAlphaModel"
```

By default, LEAN uses the string representation of a Guid object to set the Alpha model name. An example default name is "0f8fad5b-d9cb-469f-a165-70867728950e". This default name is different for every backtest you run and every live algorithm you deploy. For consistent behavior, manually set the Alpha model name.

Example

To view a full example of an `AlphaModel` subclass, see the ConstantAlphaModel in the LEAN GitHub repository.

Track Security Changes

The Universe Selection model may select a dynamic universe of assets, so you should not assume a fixed set of assets in the Alpha model. When the Universe Selection model adds and removes assets from the universe, it triggers an `on_securities_changed` event. In the `on_securities_changed` event handler, you can initialize the security-specific state or load any history required for your Alpha model. If you need to save data for individual securities, add custom members to the respective `Security` object .

```
# Handle dynamic asset changes by initializing indicators for new securities and removing them for removed securities to keep the Alpha
model adaptive and accurate.
class MyAlphaModel(AlphaModel):
    _securities = []

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            security.indicator = algorithm.sma(security.symbol, 20)
            algorithm.warm_up_indicator(security.symbol, security.indicator)
            self._securities.append(security)

        for security in changes.removed_securities:
            if security in self._securities:
                algorithm.deregister_indicator(security.indicator)
                self._securities.remove(security)
```

Insights

An Insight is a single prediction for an asset. The `update` method returns an array of Insight objects. You can think of these as actionable trading signals, indicating the asset direction, magnitude, and confidence in the near future. All insights can take a weight parameter to set the desired weighting for the insight. If you change the cash of the algorithm, it will affect the orders, but not necessarily the insights.

The Portfolio Construction model consumes the Insight objects from the Alpha model. It's up to the Portfolio Construction model to define how Insight objects are converted into `PortfolioTarget` objects. In the pre-built Portfolio Construction models, down insights translate to short-biased trades, up insights translate to long-biased trades, and flat insights usually close open positions, but this doesn't have to be the case in custom Portfolio Construction models .

Insight Properties

`Insight` objects have the following properties:

Create Insights

To create an `Insight` , call the `Insight` constructor.

```
# Insight(symbol, period, type, direction, magnitude=None, confidence=None, source_model=None, weight=None, tag='')
insight = Insight("IBM", timedelta(minutes=20), InsightType.PRICE, InsightDirection.UP)
```

In the `Insight` constructor, the `period` argument can be a `timedelta` object or a function that receives a `datetime` object and returns the expiry `datetime` . Some of the constructor arguments are optional to create the `Insight` object, but some of the Portfolio Construction models may require these properties. To check which `Insight` properties a Portfolio Construction model requires, see Supported Models .

You can also use the helper method to create Insight objects of the Price type.

```
# Insight.price(symbol, period, direction, magnitude=None, confidence=None, source_model=None, weight=None, tag='')
insight = Insight.price("IBM", timedelta(minutes = 20), InsightDirection.UP)

# Insight.price(symbol, resolution, barCount, direction, magnitude=None, confidence=None, source_model=None, weight=None, tag='')
insight = Insight.price("IBM", Resolution.MINUTE, 20, InsightDirection.UP)
```

In the `price` method, the `period` argument can be a `timedelta` object, a `datetime` object, or a function that receives a `datetime` object and returns the expiry `datetime` .

Group Insights

Sometimes an algorithm's performance relies on multiple insights being traded together, like in pairs trading and options straddles. These types insights should be grouped. Insight groups signal to the Execution model that the insights need to be acted on as a single unit to maximize the alpha created.

To mark insights as a group, call the `Insight.Group` method.

```
# Generate and group insights for a set of tickers with a 20-minute prediction horizon; each Insight object provides directional signals,
magnitudes, and confidence for price movement.
tickers = ["IBM", "SPY", "AAPL"]
insights = [Insight.price(ticker, timedelta(minutes = 20), InsightDirection.UP) for ticker in tickers]
return Insight.group(insights)
```

Cancel Insights

If an Alpha model in your algorithm emits an Insight to enter a position but it determines the trading opportunity has pre-maturely ended, you should cancel the Insight. For example, say you want your algorithm to enter a long position in a security when its Relative Strength Index (RSI) moves below 20 and then liquidate the position when the security's RSI moves above 30. If you emit an Insight that has a duration of 30 days when the RSI moves below 20 but the RSI moves above 30 in 10 days, you should cancel the Insight.

To cancel an Insight, call its `cancel` / `Expire` method with the algorithm's Coordinated Universal Time (UTC).

```
# Cancel any outstanding insights to ensure only current predictions are considered and to avoid outdated signals influencing trading
decisions.
self.insight.cancel(algorithm.utc_time)
```

If you don't have a reference to the Insight you want to cancel, get it from the InsightManager .

When you cancel an insight, it's `close_time_utc` property is set to one second into the past.

Stop Loss Orders Workaround

In some cases, if you add a Risk Management model that uses stop loss logic, the Risk Management model generates `PortfolioTarget` objects with a 0 quantity to make the Execution model liquidate your positions, but then the Portfolio Construction model generates `PortfolioTarget` objects with a non-zero quantity to make the Execution model re-enter the same position. This issue can occur if your Portfolio Construction model rebalances and your Alpha model still has an active insight for the liquidated securities. To avoid this issue, add the stop loss order logic to the Alpha model. When the stop loss is hit, emit a flat insight for the security. Note that this is a workaround, but it violates the separation of concerns principle since the Alpha Model shouldn't react to open positions.

Universe Timing Considerations

If the Alpha model manages some indicators or consolidators for securities in the universe and the universe selection runs during the indicator sampling period or the consolidator aggregation period, the indicators and consolidators might be missing some data. For example, take the following scenario:

- The security resolution is minute
- You have a consolidator that aggregates the security data into daily bars to update the indicator
- The universe selection runs at noon

In this scenario, you create and warm-up the indicator at noon. Since it runs at noon, the history request that gathers daily data to warm up the indicator won't contain any data from the current day and the consolidator that updates the indicator also won't aggregate any data from before noon. This process doesn't cause issues if the indicator only uses the close price to calculate the indicator value (like the simple moving average indicator) because the first consolidated bar that updates the indicator will have the correct close price. However, if the indicator uses more than just the close price to calculate its value (like the True Range indicator), the open, high, and low values of the first consolidated bar may be incorrect, causing the initial indicator values to be incorrect.

Examples

The following examples demonstrate common practices for implementing the framework alpha model.

Example 1: EMA Cross On Liquid Stocks

The following algorithm selects the top 500 liquid US stocks traded within the SPY ETF, then emits trade signals 60-day versus 200-day EMA cross through the `EmaCrossAlphaModel` . The `EqualWeightingPortfolioConstructionModel` ensures each asset with an insight gets an allocation of equal magnitude.

```
class FrameworkAlphaModelAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Add a universe of liquid equities since they have capital to support demand and trends.
        self.universe_settings.resolution = Resolution.DAILY
        self.add_universe_selection(ETFConstituentsUniverseSelectionModel("SPY"))
        # Using an EMA cross-alpha model to trade on medium versus long-term trends.
        self.add_alpha(EmaCrossAlphaModel(60, 200, Resolution.DAILY))
        # Equally invested in insights to dissipate capital risk evenly.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())
```

Example 2: Interest Rate Effect On Forex

The following algorithm implements a custom alpha model that uses the interest rate cycle as a signal to trade Forex. We trade the top 6 forexes: AUDUSD, EURUSD, GBPUSD, USDCAD, USDCHF, and USDJPY. For the ones with USD as quote currencies, we buy them during the US interest rate down cycle since USD is relatively weak while shorting them during the upcycle. The opposite is true for the ones with USD as the base currency.

PY

```
class FrameworkAlphaModelAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Use daily resolution since the interest rate signal is daily.
        self.universe_settings.resolution = Resolution.DAILY
        # Add a universe of selected list of Forex.
        forex = [
            Symbol.create("AUDUSD", SecurityType.FOREX, Market.OANDA),
            Symbol.create("EURUSD", SecurityType.FOREX, Market.OANDA),
            Symbol.create("GBPUSD", SecurityType.FOREX, Market.OANDA),
            Symbol.create("USDCAD", SecurityType.FOREX, Market.OANDA),
            Symbol.create("USDCHF", SecurityType.FOREX, Market.OANDA),
            Symbol.create("USDJPY", SecurityType.FOREX, Market.OANDA)
        ]
        self.add_universe_selection(ManualUniverseSelectionModel(forex))
        # Using a custom alpha model to trade forex based on interest rate.
        self.add_alpha(InterestRateAlphaModel(self))
        # Equally invested in insights to dissipate capital risk evenly.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

class InterestRateAlphaModel(AlphaModel):
    # Use a 365d SMA indicator of daily interest rate to estimate if the interest rate cycle is upward or downward.
    _sma = SimpleMovingAverage(365)

    def __init__(self, algorithm: QCAlgorithm) -> None:
        self._algorithm = algorithm

            )
        # If the interest rate cycle is steady for a long time, we expect a flip in the cycle.
        elif self._was_rising:
            insights.extend(
                [Insight.price(symbol, timedelta(1), InsightDirection.DOWN) for symbol in base_usd] +
                [Insight.price(symbol, timedelta(1), InsightDirection.UP) for symbol in quote_usd]
            )
        else:
            insights.extend(
                [Insight.price(symbol, timedelta(1), InsightDirection.UP) for symbol in base_usd] +
                [Insight.price(symbol, timedelta(1), InsightDirection.DOWN) for symbol in quote_usd]
            )

        return insights
```

Alpha

Supported Models

Introduction

This page describes the pre-built Alpha models in LEAN. The number of models grows over time. To add a model to LEAN, make a pull request to the GitHub repository . If none of these models perform exactly how you want, create a custom Alpha model .

Null Model

The `NullAlphaModel` doesn't emit any insights. It's the default Alpha model.

```py
# NullAlphaModel doesn't emit insights.
self.add_alpha(NullAlphaModel())
```

For more information about this model, see the class reference and implementation .

Constant Model

The `ConstantAlphaModel` always returns the same insight for each security.

```py
# Emit up insights that expire in 30 days for all assets.
self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(30)))
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`type`	`InsightType`	The type of insight	
`direction`	`InsightDirection`	The direction of the insight	
`period`	`timedelta`	The period over which the insight will come to fruition	
`magnitude`	`float/NoneType`	The predicted change in magnitude as a +/- percentage	`None`
`confidence`	`float/NoneType`	The confidence in the insight	`None`
`weight`	`float/NoneType`	The portfolio weight of the insights	`None`

For more information about this model, see the class reference and implementation .

Historical Returns Model

The `HistoricalReturnsAlphaModel` buys securities that have a positive trailing return and sells securities that have a negative trailing return. It sets the magnitude of the Insight objects to the trailing rate of change.

```py
# Add HistoricalReturnsAlphaModel to leverage historical return data for generating alpha signals, identifying trends based on past
performance.
self.add_alpha(HistoricalReturnsAlphaModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`lookback`	`int`	Historical return lookback period	1
`resolution`	`Resolution`	The resolution of historical data	`Resolution.DAILY`

This model cancels all the active insights it has emit for a security when the security has a 0% historical return.

For more information about this model, see the class reference and implementation .

EMA Cross Model

The `EmaCrossAlphaModel` uses an exponential moving average (EMA) cross to create insights. When the fast EMA crosses above the slow EMA, it emits up insights. When the fast EMA crosses below the slow EMA, it emits down insights. It sets the duration of Insight objects to be the product of the `resolution` and `fast_period` arguments.

```
# Add EmaCrossAlphaModel to generate trading insights based on the crossing of fast and slow exponential moving averages identifying
trends and potential reversals. The duration of insights is set by the resolution and fast_period to ensure timely and relevant trading
signals.
self.add_alpha(EmaCrossAlphaModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`fast_period`	`int`	The fast EMA period	12
`slow_period`	`int`	The slow EMA period	26
`resolution`	`Resolution`	The resolution of data sent into the EMA indicators	`Resolution.DAILY`

For more information about this model, see the class reference and implementation .

MACD Model

The `MacdAlphaModel` emits insights based on moving average convergence divergence (MACD) crossovers. If the MACD signal line is 1% above the security price, the model emits an up insight. If the MACD signal line is 1% below the security price, the model emits a down insight. If the MACD signal line is within 1% of the security price, the model cancels all the active insights it has emitted for the security.

```
# Use MacdAlphaModel to generate insights based on MACD crossovers, emitting up signals when the MACD signal line is 1% above the security
price and down signals when it is 1% below, while canceling insights if within 1% capturing significant trend changes while avoiding
noise from minor fluctuations.
self.add_alpha(MacdAlphaModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`fast_period`	`int`	The MACD fast period	12
`slow_period`	`int`	The MACD slow period	26
`signal_period`	`int`	The smoothing period for the MACD signal	9
`moving_average_type`	`MovingAverageType`	The type of moving average to use in the MACD	`MovingAverageType. EXPONENTIAL`
`resolution`	`Resolution`	The resolution of data sent into the MACD indicator	`Resolution.DAILY`

For more information about this model, see the class reference and implementation .

RSI Model

The `RsiAlphaModel` generates insights based on the relative strength index (RSI) indicator values. When the RSI value passes above 70, the model emits a down insight. When the RSI value passes below 30, the model emits an up insight. The model uses the Wilder moving average type and sets the duration of Insight objects to be the product of the `resolution` and `period` arguments.

```
# The RsiAlphaModel generates insights based on the RSI indicator: emits a down insight when RSI exceeds 70 (overbought) and an up insight
when RSI falls below 30 (oversold). This helps identify potential price reversals based on momentum.
self.add_alpha(RsiAlphaModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`period`	`int`	The RSI indicator period	14
`resolution`	`Resolution`	The resolution of data sent into the RSI indicator	`Resolution.DAILY`

For more information about this model, see the class reference and implementation .

Base Pairs Trading Model

The `BasePairsTradingAlphaModel` analyzes every possible pair combination from securities that the Universe Selection model selects. This model calculates a ratio between the two securities by dividing their historical prices over a lookback window. It then calculates the mean of this ratio by taking the 500-period EMA of the quotient. When the ratio diverges far enough from the mean ratio, this model emits generates alternating long ratio/short ratio insights emitted as a group to capture the reversion of the ratio.

```
# Use BasePairsTradingAlphaModel to analyze security pairs from the universe, generating long/short insights based on deviations from a
500-period EMA of their price ratio to capture mean-reversion opportunities.
self.add_alpha(BasePairsTradingAlphaModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`lookback`	`int`	Lookback period of the analysis	1
`resolution`	`Resolution`	Analysis resolution	`Resolution.DAILY`
`threshold`	`float`	The percent [0, 100] deviation of the ratio from the mean before emitting an insight	1

For more information about this model, see the class reference and implementation .

Pearson Correlation Pairs Trading Model

The `PearsonCorrelationPairsTradingAlphaModel` ranks every pair combination by its Pearson correlation coefficient and trades the pair with the highest correlation. This model follows the same insight logic as the `BasePairsTradingModel` .

```
# Add PearsonCorrelationPairsTradingAlphaModel to rank and trade the most correlated security pairs based on Pearson correlation
coefficients, using a similar insight logic as BasePairsTradingModel to capture mean-reversion opportunities.
self.add_alpha(PearsonCorrelationPairsTradingAlphaModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`lookback`	`int`	Lookback period of the analysis	15
`resolution`	`Resolution`	Analysis resolution	`Resolution.MINUTE`
`threshold`	`float`	The percent [0, 100] deviation of the ratio from the mean before emitting an insight	1
`minimum_correlation`	`float`	The minimum correlation to consider a tradable pair	0.5

For more information about this model, see the class reference and implementation .

Algorithm Framework

Portfolio Construction

Portfolio Construction

Key Concepts

Introduction

The Portfolio Construction model receives `Insight` objects from the Alpha model and creates `PortfolioTarget` objects for the Risk Management model. A `PortfolioTarget` provides the number of units of an asset to hold.

Set Models

To set a Portfolio Construction model, in the `initialize` method, call the `set_portfolio_construction` method.

```
PY
# Create PortfolioTarget objects to form an equal weighted portfolio based on the Insight objects.
self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())
```

To view all the pre-built Portfolio Construction models, see Supported Models .

Model Structure

Portfolio Construction models should extend the `PortfolioConstructionModel` class or one of the supported models . Extensions of the `PortfolioConstructionModel` class should implement the `create_targets` method, which receives an array of `Insight` objects from the Alpha model at every time step and returns an array of `PortfolioTarget` objects. The Portfolio Construction model seeks to answer the question, "how many units should I buy based on the insight predictions I've been presented?".

If you don't override the `create_targets` method, the base class implementation calls the model's `is_rebalance_due` , `determine_target_percent` , and `get_target_insights` helper methods. The `get_target_insights` method, in turn, calls the model's `should_create_target_for_insight` method. You can override any of these helper methods. If you don't override the `create_targets` method from the `PortfolioConstructionModel` class, your class must at least override the `determine_target_percent` method.

```
PY
 # Portfolio construction scaffolding class; basic method arguments.
class MyPortfolioConstructionModel(PortfolioConstructionModel):
    # Create list of PortfolioTarget objects from Insights.
    def create_targets(self, algorithm: QCAlgorithm, insights: List[Insight]) -> List[PortfolioTarget]:
        return super().create_targets(algorithm, insights)

    # Determine if the portfolio should rebalance based on the provided rebalancing function.
    def is_rebalance_due(self, insights: List[Insight], algorithmUtc: datetime) -> bool:
        return super().is_rebalance_due(insights, algorithmUtc)

    # Determine the target percent for each insight.
    def determine_target_percent(self, activeInsights: List[Insight]) -> dict[Insight, float]:
        return {}

    # Get the target insights to calculate a portfolio target percent.
    # They will be piped to the determine_target_percent method.
    def get_target_insights(self) -> List[Insight]:
        return super().get_target_insights()

    # Determine if the portfolio construction model should create a target for this insight.
    def should_create_target_for_insight(self, insight: Insight) -> bool:
        return super().should_create_target_for_insight(insight)

    # Track universe changes.
    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        super().on_securities_changed(algorithm, changes)
```

The Portfolio Construction model should remove expired insights from the Insight Manager . The `create_targets` definition of the base `PortfolioConstructionModel` class already removes them during each rebalance. Therefore, if you override the `create_targets` method and don't call the `create_targets` definition of the base class, your new method definition should remove expired insights from the Insight Manager.

The model should also remove all a security's insights from the Insight Manager when the security is removed from the universe . The `on_securities_changed` definition of the base `PortfolioConstructionModel` class already does this. Therefore, if you override the `on_securities_changed` method and don't call the `on_securities_changed` definition of the base class, your new method definition should remove the security's insights from the Insight Manager.

The `algorithm` argument that the methods receive is an instance of the base `QCAlgorithm` class, not your subclass of it.

You may use the `PortfolioBias` enumeration in the definition of Portfolio Construction model methods. The `PortfolioBias` enumeration has the following members:

To view a full example of a `PortfolioConstructionModel` subclass, see the EqualWeightingPortfolioConstructionModel in the LEAN GitHub repository.

Multi-Alpha Algorithms

If you add multiple Alpha models , each Alpha model receives the current slice in the order that you add the Alphas. The combined stream of Insight objects is passed to the Portfolio Construction model.

Each Portfolio Construction model has a unique method to combine Insight objects. The base `PortfolioConstructionModel` that most PCM's inherit from doesn't combine information from Insight objects with the same `Symbol` - but just gets the most recent active insight. To combine the active insights differently, override the `get_target_insights` , and return all active insights. The `determine_target_percent` method implements the combination criteria and determines the target for each `Symbol` .

```
PY
# Implement MultipleAlphaPortfolioConstructionModel to handle and utilize insights from multiple Alpha models.
# The get_target_insights method retrieves current active insights, and determine_target_percent allocates portfolio weights accordingly
for integrating and balancing multiple Alpha signals within the portfolio.
class MultipleAlphaPortfolioConstructionModel(PortfolioConstructionModel):
    def get_target_insights(self) -> List[Insight]:
        return self.algorithm.insights.get_active_insights(self.algorithm.utc_time)

    def determine_target_percent(self, activeInsights: List[Insight]) -> dict[Insight, float]:
        return {}
```

Portfolio Targets

The Portfolio Construction model returns `PortfolioTarget` objects, which are passed to the Risk Management model.

To create a `PortfolioTarget` object based on a quantity, pass the `Symbol` and quantity to the `PortfolioTarget` constructor.

```
PY
# Create a new portfolio target for 1200 IBM shares.
target = PortfolioTarget("IBM", 1200)
```

To create a `PortfolioTarget` object based on a portfolio weight, call the `percent` method. This method is only available for margin accounts.

```
PY
# Calculate target equivalent to 10% of portfolio value
target = PortfolioTarget.percent(algorithm, "IBM", 0.1)
```

To include more information in the `PortfolioTarget` object, pass a `tag` argument to the constructor or the `percent` method.

The `create_targets` method of your Portfolio Construction model must return an array of `PortfolioTarget` objects.

```
PY
return [ PortfolioTarget("IBM", 1200) ]
```

Portfolio Target Collection

The `PortfolioTargetCollection` class is a helper class to manage `PortfolioTarget` objects. The class manages an internal dictionary that has the

security `Symbol` as the key and a `PortfolioTarget` as the value.

Add Portfolio Targets

To add a `PortfolioTarget` to the `PortfolioTargetCollection` , call the `add` method.

```
self.targets_collection.add(portfolio_target)
```

To add a list of `PortfolioTarget` objects, call the `add_range` method.

```
self.targets_collection.add_range(portfolio_targets)
```

Check Membership

To check if a `PortfolioTarget` exists in the `PortfolioTargetCollection` , call the `contains` method.

```
target_in_collection = self.targets_collection.contains(portfolio_target)
```

To check if a Symbol exists in the `PortfolioTargetCollection` , call the `contains_key` method.

```
symbol_in_collection = self.targets_collection.contains_key(symbol)
```

To get all the Symbol objects, use the `keys` property.

```
symbols = self.targets_collection.keys
```

Access Portfolio Targets

To access the `PortfolioTarget` objects for a Symbol, index the `PortfolioTargetCollection` with the Symbol.

```
portfolio_target = self.targets_collection[symbol]
```

To iterate through the `PortfolioTargetCollection` , call the `get_enumerator` method.

```
enumerator = self.targets_collection.get_enumerator()
```

To get all the `PortfolioTarget` objects, use the `values` property

```
portfolio_targets = self.targets_collection.values
```

Order Portfolio Targets by Margin Impact

To get an enumerable where position reducing orders are executed first and the remaining orders are executed in decreasing order value, call the `order_by_margin_impact` method.

```
for target in self.targets_collection.order_by_margin_impact(algorithm):
    # Place order
```

This method won't return targets for securities that have no data yet. This method also won't return targets for which the sum of the current holdings and open orders quantity equals the target quantity.

Remove Portfolio Targets

To remove a `PortfolioTarget` from the `PortfolioTargetCollection` , call the `remove` method.

```
PY
remove_successful = self.targets_collection.remove(symbol)
```

To remove all the `PortfolioTarget` objects, call the `clear` method.

```
PY
self.targets_collection.clear()
```

To remove all the `PortfolioTarget` objects that have been fulfilled, call the `clear_fulfilled` method.

```
PY
self.targets_collection.clear_fulfilled(algorithm)
```

Rebalance Frequency

If you use a Portfolio Construction model that is a subclass of the `PortfolioConstructionModel` class, you can set the rebalancing frequency of the model with a function. The rebalancing function receives the Coordinated Universal Time (UTC) of the algorithm and should return the next rebalance UTC time or `None` . If the function returns `None` , the model doesn't rebalance unless the rebalance settings trigger a rebalance. For a full example of a custom rebalance function, see the PortfolioRebalanceOnCustomFuncRegressionAlgorithm .

If you use a Portfolio Construction model with the following characteristics, you can also set the rebalancing frequency of the model with a `timedelta` , `Resolution` , or DateRules :

- The model is a subclass of the `EqualWeightingPortfolioConstructionModel` class.
- The model constructor calls the `EqualWeightingPortfolioConstructionModel` constructor.
- The model doesn't override the `create_targets` method.

To check which of the pre-built Portfolio Construction models support this functionality, see Supported Models .

Rebalance Settings

By default, portfolio construction models create `PortfolioTarget` objects to rebalance the portfolio when any of the following events occur:

- The model's rebalance function signals it's time to rebalance
- The Alpha model emits new insights
- The universe changes

To disable rebalances when the Alpha model emits insights or when insights expire, set `rebalance_portfolio_on_insight_changes` to false.

```
PY
# Disable automatic portfolio rebalancing upon insight change, allowing for manual control over when portfolio adjustments are made based
on insights.
self.settings.rebalance_portfolio_on_insight_changes = False
```

To disable rebalances when security changes occur, set `rebalance_portfolio_on_security_changes` to false.

```
PY
# Disable automatic portfolio rebalancing upon security change, allowing for manual control over when portfolio adjustments are made
based on security additions or removals.
self.settings.rebalance_portfolio_on_security_changes = False
```

Portfolio Optimizer Structure

Some portfolio construction models contain an optimizer that accepts the historical returns of each security and returns a list of optimized portfolio weights. Portfolio optimizer models must implement the `IPortfolioOptimizer` interface, which has an `optimize` method.

```py
# Implement an equal-weighted portfolio optimizer to assign equal weights to all securities, providing basic diversification to reduce
risk compared to a concentrated portfolio.
class MyPortfolioOptimizer:

    def optimize(self, historicalReturns: pd.DataFrame, expectedReturns: pd.Series = None, covariance: pd.DataFrame = None) -> pd.Series:
        # Create weights
        #  For example, equal-weighting:
        num_assets = historical_returns.shape[1]
        weights = [1/num_assets] * num_assets

        return weights
```

The following table describes the arguments the `optimize` method accepts:

Argument	Data Type	Description	Default Value
`historical_returns`	`DataFrame`	Matrix of historical returns where each column represents a security and each row returns for the given date/time (size: K x N)	
`expected_returns`	`Series`	Array of double with the portfolio annualized expected returns (size: K x 1)	`None`
`covariance`	`DataFrame`	Multi-dimensional array of double with the portfolio covariance of annualized returns (size: K x K)	`None`

The method should return a K x 1 array of double objects that represent the portfolio weights.

To view all the pre-built portfolio optimization algorithms, see Supported Optimizers .

To view a full example of an `IPortfolioOptimizer` implementation, see the MaximumSharpeRatioPortfolioOptimizer in the LEAN GitHub repository.

If you define a custom optimizer and want to use it as the `optimizer` argument for one of the pre-built Portfolio Construction models , import the Python version of the Portfolio Construction model into your project file. For example, to pair your optimizer with the Black Litterman Optimization Model , add the following line:

```py
from Portfolio.BlackLittermanOptimizationPortfolioConstructionModel import BlackLittermanOptimizationPortfolioConstructionModel
```

Track Security Changes

The Universe Selection model may select a dynamic universe of assets, so you should not assume a fixed set of assets in the Portfolio Construction model. When the Universe Selection model adds and removes assets from the universe, it triggers an `on_securities_changed` event. In the `on_securities_changed` event handler, you can initialize the security-specific state or load any history required for your Portfolio Construction model. If you need to save data for individual securities, add custom members to the respective `Security` object .

```py
class MyPortfolioConstructionModel(PortfolioConstructionModel):
    _securities = []

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        super().on_securities_changed(algorithm, changes)
        for security in changes.added_securities:
            # Store and manage Symbol-specific data
            security.indicator = algorithm.sma(security.symbol, 20)
            algorithm.warm_up_indicator(security.symbol, security.indicator)

            self._securities.append(security)

        for security in changes.removed_securities:
            if security in self.securities:
                algorithm.deregister_indicator(security.indicator)
                self._securities.remove(security)
```

Universe Timing Considerations

If the Portfolio Construction model manages some indicators or consolidators for securities in the universe and the universe selection runs during the indicator sampling period or the consolidator aggregation period, the indicators and consolidators might be missing some data. For example, take the following scenario:

- The security resolution is minute
- You have a consolidator that aggregates the security data into daily bars to update the indicator
- The universe selection runs at noon

In this scenario, you create and warm-up the indicator at noon. Since it runs at noon, the history request that gathers daily data to warm up the indicator won't contain any data from the current day and the consolidator that updates the indicator also won't aggregate any data from before noon. This process doesn't cause issues if the indicator only uses the close price to calculate the indicator value (like the simple moving average indicator) because the first consolidated bar that updates the indicator will have the correct close price. However, if the indicator uses more than just the close price to calculate its value (like the True Range indicator), the open, high, and low values of the first consolidated bar may be incorrect, causing the initial indicator values to be incorrect.

Examples

The following examples demonstrate common practices for implementing the framework portfolio construction model.

Example 1: All-Weather Portfolio

The following algorithm uses `RiskParityPortfolioConstructionModel` to construct an all-weather portfolio that dissipates 1-year daily variance equally among ETFs that represent different asset classes, including stock market (SPY), bond (TLT), gold (GLD), oil (USO), and agricultural(DBA).

```
class FrameworkPortfolioConstructionModelAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Add a universe of selected lists of ETFs that represent various asset classes.
        etfs = [
            Symbol.create("SPY", SecurityType.EQUITY, Market.USA),  # stock market
            Symbol.create("TLT", SecurityType.EQUITY, Market.USA),  # bond
            Symbol.create("GLD", SecurityType.EQUITY, Market.USA),  # gold
            Symbol.create("USO", SecurityType.EQUITY, Market.USA),  # oil
            Symbol.create("DBA", SecurityType.EQUITY, Market.USA)   # agricultural
        ]
        self.add_universe_selection(ManualUniverseSelectionModel(etfs))
        # Emit insights for all selected ETFs.
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(1)))# Using risk parity PCM to construct an
all-weather portfolio to dissipate risk.
        self.set_portfolio_construction(RiskParityPortfolioConstructionModel())
```

Example 2: Protective Position

The following algorithm implements an equal-weighting portfolio on the given insights. To hedge catastrophic downside risk, each position would order a protective call/put 10% OTM.

PY

```
class FrameworkPortfolioConstructionModelAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000000)

        # Set to raw data normalization for a strike and the underlying price fair comparison.
        self.universe_settings.data_normalization_mode = DataNormalizationMode.RAW
        # Add a universe of the market representative SPY.
        spy = [Symbol.create("SPY", SecurityType.EQUITY, Market.USA)]
        self.add_universe_selection(ManualUniverseSelectionModel(spy))
        # Emit insights for all selected ETFs. Each insight lasts for 7 days for the option hedge expiry.
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(7)))
        # Using a custom PCM to control the order size and hedge option position ordering with a 10% OTM threshold.
        self.set_portfolio_construction(ProtectivePositionPortfolioConstructionModel(0.1))

class ProtectivePositionPortfolioConstructionModel(PortfolioConstructionModel):
    def __init__(self, threshold: float) -> None:
        self.threshold = threshold

    def create_targets(self, algorithm: QCAlgorithm, insights: List[Insight]) -> List[PortfolioTarget]:
        targets = []
        if not insights:
            return targets

        # Equally invest in each position group to dissipate the capital risk.
        fund_per_insight = algorithm.portfolio.total_portfolio_value / len(insights)

        for insight in insights:
            underlying = insight.symbol
            # Hedge position option right: long position should purchase OTM put, while short should purchase OTM call.
            right = OptionRight.PUT if insight.direction == InsightDirection.UP else OptionRight.CALL
            threshold = 1 - self.threshold if insight.direction == InsightDirection.UP else 1 + self.threshold

            # Select a protective option position that expires in 7 days.
            hedge = sorted([x for x in algorithm.option_chain(underlying) if x.expiry < algorithm.time + timedelta(7) and x.right ==
right],
                           key=lambda x: (x.expiry, -abs(x.strike - x.underlying_last_price * threshold)),
                           reverse=True)[0]
            # Request the protective position data for trading.
            hedge_symbol = algorithm.add_option_contract(hedge).symbol

            # Each insight will be ordered by the position group of the underlying and the hedging option positions.
            contract_multiplier = algorithm.securities[underlying].symbol_properties.contract_multiplier
            quantity = fund_per_insight // (contract_multiplier * (hedge.bid_price + hedge.underlying_last_price))
            targets.append(PortfolioTarget(underlying, int(quantity * contract_multiplier)))
            targets.append(PortfolioTarget(hedge_symbol, int(quantity)))

        return targets
```

Portfolio Construction

Supported Models

Introduction

This page describes the pre-built Portfolio Construction models in LEAN. The number of models grows over time. To add a model to LEAN, make a pull request to the GitHub repository . If none of these models perform exactly how you want, create a custom Portfolio Construction model .

Null Model

The `NullPortfolioConstructionModel` is the default Portfolio Construction model. It doesn't return any `PortfolioTarget` objects. It's useful if you need to analyze an Alpha model in isolation.

```
PY
# Set portfolio construction to NullPortfolioConstructionModel to bypass custom logic, useful for simplifying testing or initial
development when you want to manually manage or skip automatic portfolio adjustments.
self.set_portfolio_construction(NullPortfolioConstructionModel())
```

For more information about this model, see the class reference and implementation .

Equal Weighting Model

The `EqualWeightingPortfolioConstructionModel` assigns an equal share of the portfolio to the securities with active insights. This weighting scheme is useful for universe rotation based on simple portfolio strategies.

```
PY
# Set portfolio construction to EqualWeightingPortfolioConstructionModel to allocate capital equally across selected securities, ensuring
balanced exposure and reducing the influence of any single asset on the portfolio.
self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`rebalance`	`Resolution`	Rebalancing frequency	`Resolution.DAILY`

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

For more information about this model, see the class reference and implementation .

Confidence Weighted Model

The `ConfidenceWeightedPortfolioConstructionModel` generates target portfolio weights based on the `Insight. confidence` for the last Insight of each Symbol. If the Insight has a direction of `InsightDirection. UP` , the model generates long targets. If the Insight has a direction of `InsightDirection. DOWN` , the model generates short targets. If the sum of all the last active Insight per Symbol is greater than 1, the model factors down each target percent holdings proportionally so the sum is 1. The model ignores `Insight` objects that have no `Confidence` value.

```
PY
# Use ConfidenceWeightedPortfolioConstructionModel to assign portfolio weights based on the confidence level of the latest Insights,
creating long or short positions accordingly, and normalizing weights if the total exceeds 1, leveraging the strength of predictions for
better allocation and risk management.
self.set_portfolio_construction(ConfidenceWeightedPortfolioConstructionModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`rebalance`	`Resolution`	Rebalancing frequency	`Resolution.DAILY`
`portfolio_bias`	`PortfolioBias`	The bias of the portfolio	`PortfolioBias. LONG_SHORT`

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

For more information about this model, see the class reference and implementation .

Insight Weighting Model

The `InsightWeightingPortfolioConstructionModel` generates target portfolio weights based on the `Insight. weight` for the last Insight of each Symbol. If the Insight has a direction of `InsightDirection. UP` , the model generates long targets. If the Insight has a direction of `InsightDirection. DOWN` , the model generates short targets. If the sum of all the last active Insight per Symbol is greater than 1, the model factors down each target percent holdings proportionally so the sum is 1. The model takes the absolute value of the `Weight` of each `Insight` object and ignores `Insight` objects that have no `Weight` value.

```
# Use InsightWeightingPortfolioConstructionModel to allocate capital based on the latest Insight weights, generating long or short targets
as per the Insight direction and adjusting allocations if total weights exceed 1, ensuring portfolio weights reflect current market
insights and maintains proper risk management.
self.set_portfolio_construction(InsightWeightingPortfolioConstructionModel())
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`rebalance`	`Resolution`	Rebalancing frequency	`Resolution.DAILY`
`portfolio_bias`	`PortfolioBias`	The bias of the portfolio	`PortfolioBias. LONG_SHORT`

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

For more information about this model, see the class reference and implementation .

Sector Weighting Model

The `SectorWeightingPortfolioConstructionModel` generates target portfolio weights based on the `company_reference.industry_template_code` provided by the US Fundamental dataset . The target percent holdings of each sector is 1/S where S is the number of sectors and the target percent holdings of each security is 1/N where N is the number of securities of each sector. If the insight has a direction of `InsightDirection. UP` , the model generates long targets. If the insight has a direction of `InsightDirection. DOWN` , the model generates short targets. The model ignores `Insight` objects for Symbols that have no `company_reference.industry_template_code` .

```
# Use SectorWeightingPortfolioConstructionModel to ensure diversified sector exposure and balanced allocation, aligning portfolio weights
with sector insights while managing long and short positions based on insight direction.
self.set_portfolio_construction(SectorWeightingPortfolioConstructionModel())
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
rebalance	Resolution	Rebalancing frequency	Resolution.DAILY

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

For more information about this model, see the class reference and implementation .

Accumulative Insight Model

The AccumulativeInsightPortfolioConstructionModel generates target portfolio weights based on all the active insights of a security. For each active Insight of direction InsightDirection. UP , it increases the position size by a fixed percent. For each active Insight of direction InsightDirection. DOWN , it decreases the position size by a fixed percent. For each active Insight of direction InsightDirection.Flat , it moves the position size towards 0 by a fixed percent.

```
# Use AccumulativeInsightPortfolioConstructionModel to adjust portfolio weights based on the cumulative value of all active insights, increasing position size for insights with UP direction to capitalize on expected upward movements, while reducing position size with down or flat insights to mitigate potential losses.
self.set_portfolio_construction(AccumulativeInsightPortfolioConstructionModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
rebalance	Any of the following types: • timedelta • Resolution • DateRules • None Callable[[datetime], datetime]	Rebalancing parameter. If it's a timedelta , DateRules or Resolution , it's converted into a function. If it's None , it's ignored. The function returns the next expected rebalance time for a given algorithm UTC DateTime. The function returns None if unknown, in which case the function will be called again in the next loop. If the function returns the current time, the portfolio rebalances.	None
portfolio_bias	PortfolioBias	The bias of the portfolio	PortfolioBias. LONG_SHORT
percent	float	The percentage amount of the portfolio value to allocate to a single insight	0.03 (3%)

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

For more information about this model, see the class reference and implementation .

Mean Variance Optimization Model

The MeanVarianceOptimizationPortfolioConstructionModel seeks to build a portfolio with the least volatility possible and achieve a target return.

```
# Use MeanVarianceOptimizationPortfolioConstructionModel to determine portfolio weights by optimizing for the best risk-return trade-off balancing the expected returns against the risk of each security to construct a portfolio aiming to maximize returns for a given level of risk or minimize risk for a given level of returns.
self.set_portfolio_construction(MeanVarianceOptimizationPortfolioConstructionModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`rebalance`	`Resolution`	Rebalancing frequency	`Resolution.DAILY`
`portfolio_bias`	`PortfolioBias`	The bias of the portfolio	`PortfolioBias. LONG_SHORT`
`lookback`	`int`	Historical return lookback period	1
`period`	`int`	The time interval of history price to calculate the weight	63
`resolution`	`Resolution`	The resolution of the history price	`Resolution.DAILY`
`target_return`	`float`	The target portfolio return	0.02 (2%)
`optimizer`	`IPortfolioOptimizer`	The portfolio optimization algorithm	`None`

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency . If you don't provide an `optimizer` argument, the default one is the MinimumVariancePortfolioOptimizer with upper and lower weights that respect the `portfolioBias` .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

For more information about this model, see the class reference and implementation .

Black Litterman Optimization Model

The `BlackLittermanOptimizationPortfolioConstructionModel` receives `Insight` objects from multiple Alphas and combines them into a single portfolio. These multiple sources of Alpha models can be seen as the "investor views" required in the classical model.

```
# Use BlackLittermanOptimizationPortfolioConstructionModel to incorporate market equilibrium portfolio and the investor views to create
an improved portfolio aligning with both market expectations and investor insights.
self.set_portfolio_construction(BlackLittermanOptimizationPortfolioConstructionModel())
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
rebalance	Resolution	Rebalancing frequency	Resolution.DAILY
portfolio_bias	PortfolioBias	The bias of the portfolio	PortfolioBias. LONG_SHORT
lookback	int	Historical return lookback period	1
period	int	The time interval of history price to calculate the weight	63
resolution	Resolution	The resolution of the history price	Resolution.DAILY
risk_free_rate	float	The risk free rate	0.0
delta	float	The risk aversion coefficient of the market portfolio	2.5
tau	float	The model parameter indicating the uncertainty of the CAPM prior	0.05
optimizer	IPortfolioOptimizer	The portfolio optimization algorithm	None

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency . If you don't provide an `optimizer` argument, the default one is the MinimumVariancePortfolioOptimizer with upper and lower weights that respect the `portfolioBias` .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

For more information about this model, see the class reference and implementation .

Mean Reversion Model

The `MeanReversionPortfolioConstructionModel` implements an on-line portfolio selection technique, named "On-Line Moving Average Reversion" (OLMAR). The basic idea is to represent multi-period mean reversion as "Moving Average Reversion" (MAR), which explicitly predicts next price relatives using moving averages and then forms portfolios with online learning techniques.

```
# Use MeanReversionPortfolioConstructionModel to build a portfolio that capitalizes on the expected mean-reversion of asset prices,
adjusting allocations based on deviations from historical averages to potentially enhance returns by exploiting price reversions.
self.set_portfolio_construction(MeanReversionPortfolioConstructionModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
rebalance	Resolution	Rebalancing frequency	Resolution.DAILY
portfolio_bias	PortfolioBias	The bias of the portfolio	PortfolioBias. LONG_SHORT
reversion_threshold	float	Reversion threshold	1
window_size	int	The window size of mean price	20
resolution	Resolution	The resolution of the history price	Resolution.DAILY

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is

removed from the universe .

For more information about this model, see the class reference and implementation .

Risk Parity Model

The `RiskParityPortfolioConstructionModel` seeks to build a portfolio with the equal contribution of risk to the total portfolio risk from all assets.

```
# Use RiskParityPortfolioConstructionModel to allocate portfolio weights based on risk contributions, ensuring that each asset
contributes equally to the portfolio's overall risk, aiming for balanced risk exposure and potentially improved risk-adjusted returns.
self.set_portfolio_construction(RiskParityPortfolioConstructionModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`rebalance`	`Resolution`	Rebalancing frequency	`Resolution.DAILY`
`portfolio_bias`	`PortfolioBias`	The bias of the portfolio	`PortfolioBias. LONG_SHORT`
`lookback`	`int`	Historical return lookback period	1
`period`	`int`	The time interval of history price to calculate the weight	252
`resolution`	`Resolution`	The resolution of the history price	`Resolution.DAILY`
`optimizer`	`IPortfolioOptimizer`	The portfolio optimization algorithm	`None`

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency . If you don't provide an `optimizer` argument, the default one is the RiskParityPortfolioOptimizer .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

For more information about this model, see the class reference and implementation .

Portfolio Construction

Supported Optimizers

Introduction

This page describes the pre-built Portfolio Optimizer models in LEAN. The number of models grows over time. To add a model to LEAN, make a pull request to the GitHub repository . If none of these models perform exactly how you want, create a custom Portfolio Optimizer model .

Maximum Sharpe Ratio Optimizer

The `MaximumSharpeRatioPortfolioOptimizer` seeks to maximize the portfolio Sharpe Ratio .

```
optimizer = MaximumSharpeRatioPortfolioOptimizer()
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`minimum_weight`	`float`	The lower bounds on portfolio weights	-1
`maximum_weight`	`float`	The upper bounds on portfolio weights	1
`risk_free_rate`	`float`	The risk free rate	0

For more information about this model, see the class reference and implementation .

Minimum Variance Optimizer

The `MinimumVariancePortfolioOptimizer` seeks to minimize the portfolio variance and achieve a target return.

```
optimizer = MinimumVariancePortfolioOptimizer()
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`minimum_weight`	`float`	The lower bounds on portfolio weights	-1
`maximum_weight`	`float`	The upper bounds on portfolio weights	1
`target_return`	`float`	The target portfolio return	0.02 (2%)

For more information about this model, see the class reference and implementation .

Unconstrained Mean Variance Optimizer

The `UnconstrainedMeanVariancePortfolioOptimizer` seeks to find the optimal risk-adjusted portfolio that lies on the efficient frontier.

```
optimizer = UnconstrainedMeanVariancePortfolioOptimizer()
```

For more information about this model, see the class reference and implementation .

Risk Parity Optimizer

The `RiskParityPortfolioOptimizer` seeks to equalize the individual risk contribution to the total portfolio risk from each asset.

```
optimizer = RiskParityPortfolioOptimizer()
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`minimum_weight`	`float`	The lower bounds on portfolio weights	1e-05
`maximum_weight`	`float`	The upper bounds on portfolio weights	`sys.float_info.max`

For more information about this model, see the class reference and implementation .

Algorithm Framework

Risk Management

Risk Management

Key Concepts

Introduction

The Risk Management model seeks to manage risk on the `PortfolioTarget` collection it receives from the Portfolio Construction model before the targets reach the Execution model. There are many creative ways to manage risk. Some examples of risk management include the following:

- *"Trailing Stop Risk Management Model"*
  Create and manage trailing stop-loss orders for open positions.
- *"Option Hedging Risk Management Model"*
  Purchase options to hedge large equity exposures.
- *"Sector Exposure Risk Management Model"*
  Reduce position sizes when overexposed to sectors or individual assets, keeping the portfolio within diversification requirements.
- *"Flash Crash Detection Risk Management Model"*
  Scan for strange market situations that might be precursors to a flash crash and attempt to protect the portfolio when they are detected.

Add Models

To set a Risk Management model, in the `initialize` method, call the `add_risk_management` method.

```
# Add the null risk management model, which doesn't affect the portfolio targets.
self.add_risk_management(NullRiskManagementModel())
```

To view all the pre-built Risk Management models, see Supported Models .

Multi-Model Algorithms

To add multiple Risk Management models, in the `initialize` method, call the `AddRiskManagement` method multiple times.

```
# Add multiple Risk Management models to sequentially adjust portfolio targets, with each model refining the targets passed from the
previous model, managing risk across individual securities and sectors.
self.add_risk_management(MaximumDrawdownPercentPerSecurity())
self.add_risk_management(MaximumSectorExposureRiskManagementModel())
```

If you add multiple Risk Management models, the original collection of `PortfolioTarget` objects from the Portfolio Construction model is passed to the first Risk Management model. The risk-adjusted targets from the first Risk Management model are passed to the second Risk Management model. The process continues sequentially until all of the Risk Management models have had an opportunity to adjust the targets.

Model Structure

Risk Management models should extend the `RiskManagementModel` class. Extensions of the `RiskManagementModel` class must implement the `manage_risk` method, which receives an array of `PortfolioTarget` objects from the Portfolio Construction model at every time step and should return an array of risk-adjusted `PortfolioTarget` objects. The method should only return the adjusted targets, not all of targets. If the method creates a `PortfolioTarget` object to liquidate a security, cancel the security's insights to avoid re-entering the position.

```
# Extend the RiskManagementModel class by implementing the manage_risk method, which receives PortfolioTarget objects from the Portfolio
Construction model and returns only the risk-adjusted targets.
class MyRiskManagementModel(RiskManagementModel):
    # Adjust the portfolio targets and return them. If no changes emit nothing.
    def manage_risk(self, algorithm: QCAlgorithm, targets: List[PortfolioTarget]) -> List[PortfolioTarget]:
        return []

    # Optional: Be notified when securities change
    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        # Security additions and removals are pushed here.
        # This can be used for setting up algorithm state.
        # changes.added_securities
        # changes.removed_securities
        pass
```

The `algorithm` argument that the methods receive is an instance of the base `QCAlgorithm` class, not your subclass of it.

To view a full example of a `RiskManagementModel` subclass, see the MaximumDrawdownPercentPerSecurity in the LEAN GitHub repository.

Track Security Changes

The Universe Selection model may select a dynamic universe of assets, so you should not assume a fixed set of assets in the Risk Management model. When the Universe Selection model adds and removes assets from the universe, it triggers an `on_securities_changed` event. In the `on_securities_changed` event handler, you can initialize the security-specific state or load any history required for your Risk Management model. If you need to save data for individual securities, add custom members to the respective `Security` object .

```
class MyRiskManagementModel(RiskManagementModel):
    _securities = []

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        super().on_securities_changed(algorithm, changes)
        for security in changes.added_securities:
            # Store and manage Symbol-specific data
            security.indicator = algorithm.sma(security.symbol, 20)
            algorithm.warm_up_indicator(security.symbol, security.indicator)

            self._securities.append(security)

        for security in changes.removed_securities:
            if security in self.securities:
                algorithm.deregister_indicator(security.indicator)
                self._securities.remove(security)
```

Portfolio Target Collection

The `PortfolioTargetCollection` class is a helper class to manage `PortfolioTarget` objects. The class manages an internal dictionary that has the security `Symbol` as the key and a `PortfolioTarget` as the value.

Add Portfolio Targets

To add a `PortfolioTarget` to the `PortfolioTargetCollection` , call the `add` method.

```
self.targets_collection.add(portfolio_target)
```

To add a list of `PortfolioTarget` objects, call the `add_range` method.

```
self.targets_collection.add_range(portfolio_targets)
```

Check Membership

To check if a `PortfolioTarget` exists in the `PortfolioTargetCollection` , call the `contains` method.

```
target_in_collection = self.targets_collection.contains(portfolio_target)
```

To check if a Symbol exists in the `PortfolioTargetCollection` , call the `contains_key` method.

```
symbol_in_collection = self.targets_collection.contains_key(symbol)
```

To get all the Symbol objects, use the `keys` property.

```
symbols = self.targets_collection.keys
```

Access Portfolio Targets

To access the `PortfolioTarget` objects for a Symbol, index the `PortfolioTargetCollection` with the Symbol.

```
portfolio_target = self.targets_collection[symbol]
```

To iterate through the `PortfolioTargetCollection` , call the `get_enumerator` method.

```
enumerator = self.targets_collection.get_enumerator()
```

To get all the `PortfolioTarget` objects, use the `values` property

```
portfolio_targets = self.targets_collection.values
```

Order Portfolio Targets by Margin Impact

To get an enumerable where position reducing orders are executed first and the remaining orders are executed in decreasing order value, call the `order_by_margin_impact` method.

```
for target in self.targets_collection.order_by_margin_impact(algorithm):
    # Place order
```

This method won't return targets for securities that have no data yet. This method also won't return targets for which the sum of the current holdings and open orders quantity equals the target quantity.

Remove Portfolio Targets

To remove a `PortfolioTarget` from the `PortfolioTargetCollection` , call the `remove` method.

```
remove_successful = self.targets_collection.remove(symbol)
```

To remove all the `PortfolioTarget` objects, call the `clear` method.

```
self.targets_collection.clear()
```

To remove all the `PortfolioTarget` objects that have been fulfilled, call the `clear_fulfilled` method.

```
self.targets_collection.clear_fulfilled(algorithm)
```

Universe Timing Considerations

If the Risk Management model manages some indicators or consolidators for securities in the universe and the universe selection runs during the indicator sampling period or the consolidator aggregation period, the indicators and consolidators might be missing some data. For example, take the following scenario:

- The security resolution is minute
- You have a consolidator that aggregates the security data into daily bars to update the indicator
- The universe selection runs at noon

In this scenario, you create and warm-up the indicator at noon. Since it runs at noon, the history request that gathers daily data to warm up the indicator won't contain any data from the current day and the consolidator that updates the indicator also won't aggregate any data from before noon. This process doesn't cause issues if the indicator only uses the close price to calculate the indicator value (like the simple moving average indicator) because the first consolidated bar that updates the indicator will have the correct close price. However, if the indicator uses more than just the close price to calculate its value (like the True Range indicator), the open, high, and low values of the first consolidated bar may be incorrect, causing the initial indicator values to be incorrect.

Examples

The following examples demonstrate some common practices for implementing a risk management model.

Example 1: Take Profit Stop Loss

The following algorithm trades 20-60 EMA crosses on the top 500 liquid US stocks in equal weighting. To minimize risk and capture early profit, we can implement both `MaximumUnrealizedProfitPercentPerSecurity` to take profit and `TrailingStopRiskManagementModel` to stop loss by trailing high price.

```
class FrameworkRiskManagementAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Add a universe of the most liquid stocks since their trend is more capital-supported.
        self.add_universe_selection(QC500UniverseSelectionModel())
        # Emit insights on EMA cross, indicating the trend changes. We use short-term versus medium-term for more trade opportunities.
        self.add_alpha(EmaCrossAlphaModel(20, 60, Resolution.DAILY))
        # Equal weighting on each insight to dissipate capital risk evenly.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

        # Take profit at 10%.
        self.add_risk_management(MaximumUnrealizedProfitPercentPerSecurity(0.1))
        # Trailing stop loss at 5%.
        self.add_risk_management(TrailingStopRiskManagementModel(0.05))
```

Example 2: Tail Value At Risk

The following algorithm implements a custom risk management model that liquidates the position if an asset has PnL lower than the tail value-at-risk (TVaR) throughout the insight to avoid large catastrophic losses. To calculate the TVaR, we create a log return indicator and use the following formula for the calculation: $\textrm{TVaR}_{\alpha} = \mu + \sigma \times \phi[\Phi^{-1}(\alpha)] / (1 - \alpha)$

```
from scipy.stats import norm

class FrameworkRiskManagementAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 15)
        self.set_cash(1000000)

        # Add a universe of the most liquid stocks since their trend is more capital-supported.
        self.add_universe_selection(QC500UniverseSelectionModel())
        # Emit insights all for selected stocks, rebalancing every 2 weeks.
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(14)))
        # Equal weighting on each insight to dissipate capital risk evenly.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

        # Liquidate on extreme catastrophic events.
        self.add_risk_management(TailValueAtRiskRiskManagementModel(0.05, 14))

class TailValueAtRiskRiskManagementModel(RiskManagementModel):
    _log_ret_by_symbol = {}

    def __init__(self, alpha: float = 0.05, num_days: float = 7) -> None:
        # The alpha level on TVaR calculation.
        self.alpha = alpha
        # The number of days that the insight signal lasts for.
        self.days = num_days

    # Adjust the portfolio targets and return them. If there are no changes, emit nothing.
```

```
    def manage_risk(self, algorithm: QCAlgorithm, targets: List[PortfolioTarget]) -> List[PortfolioTarget]:
        targets = []
        for kvp in algorithm.securities:
            security = kvp.value
            if not security.invested:
                continue

            pnl = security.holdings.unrealized_profit_percent
            symbol = security.symbol
            # If the %PnL is worse than the preset level TVaR, we liquidate it.
            if pnl < self.get_tvar(symbol):
                # Cancel insights to avoid reordering afterward.
                algorithm.insights.cancel([symbol])
                # Liquidate.
                targets.append(PortfolioTarget(symbol, 0, tag="Liquidate due to TVaR"))

        return targets

    def get_tvar(self, symbol: Symbol) -> float:
        symbol_data = self._log_ret_by_symbol.get(symbol)
        if not symbol_data:
            return 0

        # TVaR = \mu + \sigma * \phi[\Phi^{-1}(p)] / (1 - p)
        # Scale up to the days of the signal. By stochastic calculus, we multiply by sqrt(days).
        daily_tvar = symbol_data.mean_log_ret + symbol_data.sd_log_ret * np.sqrt(self.days) * norm.pdf(norm.ppf(self.alpha)) / (1 -
self.alpha)
        # We want the left side of the symmetric distribution.
        return -daily_tvar

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for added in changes.added_securities:
            # Add SymbolData class to handle log returns.
            self._log_ret_by_symbol[added.symbol] = SymbolData(algorithm, added.symbol)

        for removed in changes.removed_securities:
            # Stop subscription on the data to release computational resources.
            symbol_data = self._log_ret_by_symbol.pop(removed.symbol, None)
            if symbol_data:
                symbol_data.dispose()

class SymbolData:
    def __init__(self, algorithm: QCAlgorithm, symbol: Symbol) -> None:
        self.algorithm = algorithm
        self.symbol = symbol

        # Since the return is assumed log-normal, we use the log return indicator to calculate TVaR later.
        self.log_ret = LogReturn(1)
        # Register the indicator for automatic updating for daily log returns.
        algorithm.register_indicator(symbol, self.log_ret, Resolution.DAILY)
        # Set up a rolling window to save the log return for calculating the mean and SD for TVaR calculation.
        self.window = RollingWindow(252)
        # Add a handler to save the log return to the rolling window.
        self.log_ret.updated += lambda _, point: self.window.add(point.value)
        # Warm up the rolling window.
        history = algorithm.history[TradeBar](symbol, 253, Resolution.DAILY)
        for bar in history:
            self.log_ret.update(bar.end_time, bar.close)

    @property
    def is_ready(self) -> bool:
        return self.window.is_ready

    @property
    def mean_log_ret(self) -> float:
        # Mean log return for TVaR calculation.
        return np.mean(list(self.window))

    @property
    def sd_log_ret(self) -> float:
        # SD of log return for TVaR calculation.
        return np.std(list(self.window), ddof=1)

    def dispose(self) -> None:
        # Stop subscription on the data to release computational resources.
        self.algorithm.deregister_indicator(self.log_ret)
```

Example 3: Bracket Risk Model

The following algorithm implements a custom bracket risk management model that combines a trailing stop-loss with a take-profit target. Positions are exited when unrealized profit exceeds a threshold or when the price falls by more than a specified percentage from the trailing high. It is used alongside an XGBoost Alpha model that trades Equities near their earnings dates.

```
PY

from sklearn.model_selection import RandomizedSearchCV, train_test_split
from sklearn.preprocessing import MinMaxScaler
import xgboost as xgb
```

```
class ModulatedNadionReplicator(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

```

Risk Management

Supported Models

Introduction

This page describes the pre-built Risk Management models in LEAN. The number of models grows over time. To add a model to LEAN, make a pull request to the GitHub repository . If none of these models perform exactly how you want, create a custom Risk Management model .

Null Model

The `NullRiskManagementModel` is the default Risk Management model. It doesn't adjust any of the `PortfolioTarget` objects it receives from the Portfolio Construction model.

```
# Adding the null risk management model doesn't affect the portfolio targets.
self.add_risk_management(NullRiskManagementModel())
```

For more information about this model, see the class reference and implementation .

Maximum Security Drawdown Model

The `MaximumDrawdownPercentPerSecurity` model monitors the unrealized profit percentage of each security in the portfolio. When the percentage drops below a threshold relative to the opening price, it liquidates the position and cancels all insights in the Insight Manager that are for the security. This model can operate even when the Portfolio Construction model provides an empty list of `PortfolioTarget` objects.

```
# Add risk management model to limit maximum drawdown per security, reducing position size to prevent further losses.
self.add_risk_management(MaximumDrawdownPercentPerSecurity())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`maximum_drawdown_percent`	`float`	The maximum percentage drawdown allowed for any single security holding	0.05 (5%)

For more information about this model, see the class reference and implementation .

Maximum Portfolio Drawdown Model

The `MaximumDrawdownPercentPortfolio` model monitors the portfolio drawdown . The drawdown can be relative to the starting portfolio value or the maximum portfolio value. When the portfolio value drops below a percentage threshold, the model liquidates the portfolio and cancels all insights in the Insight Manager . To liquidate the portfolio, the model must receive at least 1 `PortfolioTarget` after the drawdown threshold is passed. After the portfolio is liquidated, the model resets. This model can operate even when the Portfolio Construction model provides an empty list of `PortfolioTarget` objects.

```
# Add risk management model to limit maximum drawdown for the entire portfolio, protecting overall portfolio value from significant
losses.
self.add_risk_management(MaximumDrawdownPercentPortfolio())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`maximum_drawdown_percent`	`float`	Maximum spread accepted comparing to current price in percentage	0.05 (5%)
`is_trailing`	`bool`	If `False` , the drawdown is relative to the starting value of the portfolio. If `True` , the drawdown is relative the last maximum portfolio value	`False`

For more information about this model, see the class reference and implementation .

Maximum Unrealized Profit Model

The `MaximumUnrealizedProfitPercentPerSecurity` model monitors the unrealized profit of each security in the portfolio. When the unrealized profit exceeds a profit threshold, it liquidates the position and cancels all insights in the Insight Manager that are for the security. This model can operate even when the Portfolio Construction model provides an empty list of `PortfolioTarget` objects.

```py
# Add risk management model to secure gains by limiting the maximum unrealized profit for each security, locking in profits before
potential reversals.
self.add_risk_management(MaximumUnrealizedProfitPercentPerSecurity())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`maximum_unrealized_profit_percent`	`float`	The maximum percentage unrealized profit allowed for any single security holding	0.05 (5%)

For more information about this model, see the class reference and implementation .

Maximum Sector Exposure Model

The `MaximumSectorExposureRiskManagementModel` limits the absolute portfolio exposure in a each industry sector to a predefined maximum percentage. If the absolute portfolio exposure exceeds the maximum percentage, the weight of each Equity in the sector is scaled down so the sector doesn't exceed the maximum percentage. This process requires assets that are selected by Morningstar fundamental data . This model can operate even when the Portfolio Construction model provides an empty list of `PortfolioTarget` objects.

```py
# Add risk management model to limit exposure to any single sector, ensuring diversification and reducing sector-specific risk.
self.add_risk_management(MaximumSectorExposureRiskManagementModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`maximum_sector_exposure`	`float`	The maximum exposure for any sector	0.2 (20%)

For more information about this model, see the class reference and implementation .

Trailing Stop Model

The `TrailingStopRiskManagementModel` monitors the drawdown of each security in the portfolio. When the peak-to-trough drawdown of the unrealized profit exceeds a threshold, it liquidates the position and cancels all insights in the Insight Manager that are for the security. This model can operate even when the Portfolio Construction model provides an empty list of `PortfolioTarget` objects.

```
# Add risk management model to implement trailing stops, which adjusts stop-loss levels as the price moves favorably, helping to lock in
gains and limit losses.
self.add_risk_management(TrailingStopRiskManagementModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`maximum_drawdown_percent`	`float`	The maximum percentage drawdown allowed for algorithm portfolio compared with the highest unrealized profit	0.05 (5%)

For more information about this model, see the class reference and implementation .

Algorithm Framework

Execution

Execution

Key Concepts

Introduction

The Execution model receives an array of risk-adjusted `PortfolioTarget` objects from the Risk Management model and places trades in the market to satisfy the targets. The Execution model only receives updates to the portfolio target share counts. It doesn't necessarily receive all of the targets at once.

Set Models

To set an Execution model, in the `initialize` method, call the `set_execution` method.

```
# Satisify portfolio targets by immediately sending market orders.
self.set_execution(ImmediateExecutionModel())
```

To view all the pre-built Execution models, see Supported Models .

Model Structure

Execution models should extend the `ExecutionModel` class. Extensions of the `ExecutionModel` must implement the `execute` method, which receives an array of `PortfolioTarget` objects at every time step and is responsible for reaching the target portfolio as efficiently as possible. The Portfolio Construction model creates the `PortfolioTarget` objects, the Risk Management model may adjust them, and then the Execution model places the orders to fulfill them.

```
# Execution Model scaffolding structure example
class MyExecutionModel(ExecutionModel):

    # Fill the supplied portfolio targets efficiently
    def execute(self, algorithm: QCAlgorithm, targets: List[PortfolioTarget]) -> None:
        pass

    # Optional: Securities changes event for handling new securities.
    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        # Security additions and removals are pushed here.
        # This can be used for setting up algorithm state.
        # changes.added_securities
        # changes.removed_securities
        pass

    # Optional: Order event for handling new order events.
    def on_order_event(self, algorithm: QCAlgorithm, order_event: OrderEvent) -> None:
        # Order events are pushed here.
        # This can be used for tracking order status or handling invalid and cancelled orders.
        pass
```

The `algorithm` argument that the methods receive is an instance of the base `QCAlgorithm` class, not your subclass of it.

The following table describes the properties of the `PortfolioTarget` class that you may access in the Execution model:

Property	Data Type	Description
`symbol`	`Symbol`	Asset to trade
`quantity`	`float`	Number of units to hold

To view a full example of an `ExecutionModel` subclass, see the ImmediateExecutionModel in the LEAN GitHub repository.

Track Security Changes

The Universe Selection model may select a dynamic universe of assets, so you should not assume a fixed set of assets in the Execution model. When the Universe Selection model adds and removes assets from the universe, it triggers an `on_securities_changed` event. In the `on_securities_changed` event handler, you can initialize the security-specific state or load any history required for your Execution model. If you need to save data for individual securities, add custom members to the respective `Security` object .

```
class MyExecutionModel(ExecutionModel):
    _securities = []

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            # Store and manage Symbol-specific data
            security.indicator = algorithm.sma(security.symbol, 20)
            algorithm.warm_up_indicator(security.symbol, security.indicator)

            self._securities.append(security)

        for security in changes.removed_securities:
            if security in self.securities:
                algorithm.deregister_indicator(security.indicator)
                self._securities.remove(security)
```

PY

Portfolio Target Collection

The `PortfolioTargetCollection` class is a helper class to manage `PortfolioTarget` objects. The class manages an internal dictionary that has the security `Symbol` as the key and a `PortfolioTarget` as the value.

Add Portfolio Targets

To add a `PortfolioTarget` to the `PortfolioTargetCollection` , call the `add` method.

```
self.targets_collection.add(portfolio_target)
```

PY

To add a list of `PortfolioTarget` objects, call the `add_range` method.

```
self.targets_collection.add_range(portfolio_targets)
```

PY

Check Membership

To check if a `PortfolioTarget` exists in the `PortfolioTargetCollection` , call the `contains` method.

```
target_in_collection = self.targets_collection.contains(portfolio_target)
```

PY

To check if a Symbol exists in the `PortfolioTargetCollection` , call the `contains_key` method.

```
symbol_in_collection = self.targets_collection.contains_key(symbol)
```

PY

To get all the Symbol objects, use the `keys` property.

```
symbols = self.targets_collection.keys
```

Access Portfolio Targets

To access the `PortfolioTarget` objects for a Symbol, index the `PortfolioTargetCollection` with the Symbol.

```
portfolio_target = self.targets_collection[symbol]
```

To iterate through the `PortfolioTargetCollection` , call the `get_enumerator` method.

```
enumerator = self.targets_collection.get_enumerator()
```

To get all the `PortfolioTarget` objects, use the `values` property

```
portfolio_targets = self.targets_collection.values
```

Order Portfolio Targets by Margin Impact

To get an enumerable where position reducing orders are executed first and the remaining orders are executed in decreasing order value, call the `order_by_margin_impact` method.

```
for target in self.targets_collection.order_by_margin_impact(algorithm):
    # Place order
```

This method won't return targets for securities that have no data yet. This method also won't return targets for which the sum of the current holdings and open orders quantity equals the target quantity.

Remove Portfolio Targets

To remove a `PortfolioTarget` from the `PortfolioTargetCollection` , call the `remove` method.

```
remove_successful = self.targets_collection.remove(symbol)
```

To remove all the `PortfolioTarget` objects, call the `clear` method.

```
self.targets_collection.clear()
```

To remove all the `PortfolioTarget` objects that have been fulfilled, call the `clear_fulfilled` method.

```
self.targets_collection.clear_fulfilled(algorithm)
```

Universe Timing Considerations

If the Execution model manages some indicators or consolidators for securities in the universe and the universe selection runs during the indicator sampling period or the consolidator aggregation period, the indicators and consolidators might be missing some data. For example, take the following scenario:

- The security resolution is minute
- You have a consolidator that aggregates the security data into daily bars to update the indicator
- The universe selection runs at noon

In this scenario, you create and warm-up the indicator at noon. Since it runs at noon, the history request that gathers daily data to warm up the indicator won't contain any data from the current day and the consolidator that updates the indicator also won't aggregate any data from before noon. This process doesn't cause issues if the indicator only uses the close price to calculate the indicator value (like the simple moving average indicator) because the first consolidated bar that updates the indicator will have the correct close price. However, if the indicator uses more than just the close price to calculate its value (like the True Range indicator), the open, high, and low values of the first consolidated bar may be incorrect, causing the initial indicator values to be incorrect.

Examples

The following examples demonstrate some common practices for implementing the execution model.

Example 1: Iceberg Execution

The following algorithm simulates an account with large capital that equally holds the most liquid stocks. To hide the footprint and avoid a large market impact that might erode the profit margin, we can set up an iceberg execution system, submitting only 10% of the volume of the bid/ask side order book to the order direction.

```
class FrameworkExecutionModelAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000000)

        # Add a universe of the most liquid stocks since their trend is more capital-supported.
        self.add_universe_selection(QC500UniverseSelectionModel())
        # Emit insights all for selected stocks.
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(7)))
        # Equal weighting on each insight to dissipate capital risk evenly.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

        # Iceberg ordering to hide traces and avoid market impact.
        # Since quote data will be used, ensure the asset class and resolution are compatible.
        self.set_execution(IcebergExecutionModel(0.1))

class IcebergExecutionModel(ExecutionModel):
    def __init__(self, order_percent_volume: float = 0.1) -> None:
        self.targets_collection = PortfolioTargetCollection()
        # The maximum order size is taken from the order book in percentage.
        self.maximum_order_quantity_percent_volume = order_percent_volume

    def execute(self, algorithm: QCAlgorithm, targets: List[PortfolioTarget]) -> None:
        # update the complete set of portfolio targets with the new targets
        self.targets_collection.add_range(targets)

        if not self.targets_collection.is_empty:
            for target in self.targets_collection.order_by_margin_impact(algorithm):
                symbol = target.symbol

                # Calculate the remaining quantity to be ordered
                unordered_quantity = OrderSizing.get_unordered_quantity(algorithm, target)
                # adjust order size to respect maximum order size based on a percentage of current volume
                order_size = self.get_order_size_for_percent_volume(algorithm.securities[symbol],
self.maximum_order_quantity_percent_volume, unordered_quantity)

                if order_size != 0:
                    algorithm.market_order(symbol, order_size)

            self.targets_collection.clear_fulfilled(algorithm)

    def get_order_size_for_percent_volume(self, security: Security, maximum_percent_current_volume: float, desired_order_size: float) ->
float:
        # Take N% from the order book according to the order direction.
        max_order_size = maximum_percent_current_volume * (security.bid_size if desired_order_size > 0 else security.ask_size)
        order_size = min(max_order_size, abs(desired_order_size))
        return np.sign(desired_order_size) * OrderSizing.adjust_by_lot_size(security, order_size)
```

Example 2: More Favorable Than Signal Time

Some algorithms are signaling based on daily close data. However, their orders often emit when the next market opens, making the filling price slip. To avoid this slippage negatively impacting your expectations, we can construct a custom execution model to place orders only when the price is more favorable than the last close price. Although we did not set a time limit in this example, you may consider doing so.

PY

```
class FrameworkExecutionModelAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 1)

        # Add a universe of the most liquid stocks since their trend is more capital-supported.
        self.add_universe_selection(QC500UniverseSelectionModel())
        # Emit insights all for selected stocks.
        self.add_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(7)))
        # Equal weighting on each insight to dissipate capital risk evenly.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

        # Only place an order if the price is more favorable than the price at the insight signal.
        self.set_execution(FavorableExecutionModel())

class FavorableExecutionModel(ExecutionModel):
    def __init__(self) -> None:
        self.targets_collection = PortfolioTargetCollection()
        self.lag_price_by_symbol = {}

    def execute(self, algorithm: QCAlgorithm, targets: List[PortfolioTarget]) -> None:
        self.targets_collection.add_range(targets)
        if not self.targets_collection.is_empty:
            for target in self.targets_collection.order_by_margin_impact(algorithm):
                symbol = target.symbol
                security = algorithm.securities[symbol]
                # Calculate the remaining quantity to be ordered
                quantity = OrderSizing.get_unordered_quantity(algorithm, target, security, True)

                if quantity != 0:
                    above_minimum_portfolio = BuyingPowerModelExtensions.above_minimum_order_margin_portfolio_percentage(
                        security.buying_power_model,
                        security,
                        quantity,
                        algorithm.portfolio,
                        algorithm.settings.minimum_order_margin_portfolio_percentage)
                    if above_minimum_portfolio:
                        # Cache the price at signal emission to compare if the current price is more favorable.
                        if not symbol in self.lag_price_by_symbol:
                            history = algorithm.history[TradeBar](symbol, 1, Resolution.DAILY)
                            self.lag_price_by_symbol[symbol] = list(history)[-1].close

                        # Only order if the price is more favorable than the price at signal emission.
                        if (security.price <= self.lag_price_by_symbol[symbol] and quantity > 0)\
                        or (security.price >= self.lag_price_by_symbol[symbol] and quantity < 0):
                            algorithm.market_order(security, quantity)
                    elif not PortfolioTarget.minimum_order_margin_percentage_warning_sent:
                        # will trigger the warning if it has not already been sent
                        PortfolioTarget.minimum_order_margin_percentage_warning_sent = False

            self.targets_collection.clear_fulfilled(algorithm)
```

Execution

Supported Models

Introduction

This page describes the pre-built Execution models in LEAN. The number of models grows over time. To add a model to LEAN, make a pull request to the GitHub repository . If none of these models perform exactly how you want, create a custom Execution model .

Null Model

The `NullExecutionModel` doesn't place any trades.

```
# Set the execution model to NullExecutionModel, which disables execution functionality for debugging or when the execution logic is not
needed for the current strategy.
self.set_execution(NullExecutionModel())
```

For more information about this model, see the class reference and implementation .

Immediate Model

The `ImmediateExecutionModel` is the default Execution model. It uses market orders to immediately fill portfolio targets. It's similar to placing market orders in line with your algorithm logic.

```
# Use ImmediateExecutionModel for executing trades instantly at market price to minimize execution delay. This may incur extra slippage.
self.set_execution(ImmediateExecutionModel())
```

For more information about this model, see the class reference and implementation .

Spread Model

The `SpreadExecutionModel` executes trades with market orders if the exchange is open and the bid-ask spread is within a threshold percentage. The model only works if the security subscription provides QuoteBar data. The spread percentage is calculated as

$$\frac{a - b}{p}$$

where a is the ask price, b is the bid price, and p is the price.

```
# Use SpreadExecutionModel to manage trade execution based on bid-ask spreads, aiming to optimize trade execution costs and reduce
slippage.
self.set_execution(SpreadExecutionModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`accepting_spread_percent`	`float`	Maximum spread accepted comparing to current price in percentage	0.005 (0.5%)

For more information about this model, see the class reference and implementation .

Standard Deviation Model

The `StandardDeviationExecutionModel` seeks to fill orders when the price is more than 2 standard deviations lower than the average price over a trailing period. The intent is to find dips in the market to place trades. In strongly trending markets, this procedure can result in delayed trade placement since it might be a while before the next price spike or dip.

```
# Use StandardDeviationExecutionModel to execute trades based on volatility measures, aiming to adapt trade sizes and timing according to
market volatility.
self.set_execution(StandardDeviationExecutionModel())
```

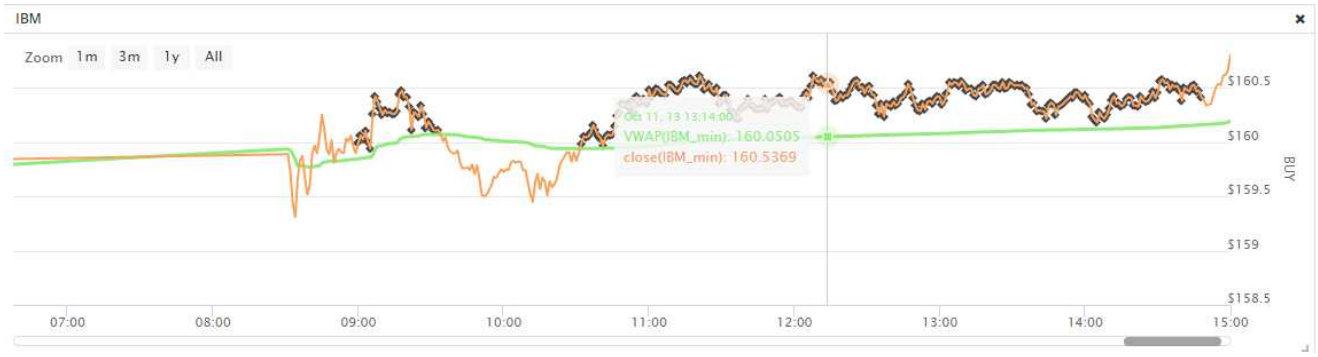
The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`period`	`float`	Period of the standard deviation indicator	60
`deviations`	`int`	The number of deviations away from the mean before submitting an order	2
`resolution`	`Resolution`	The resolution of the STD and SMA indicators	`Resolution.MINUTE`

For more information about this model, see the class reference and implementation .

VWAP Model

The `VolumeWeightedAveragePriceExecutionModel` works to fill your orders at or better than the volume-weighted average price (VWAP) for the trading day. This is a best-effort algorithm, so no guarantee can be made that it will reach the VWAP.



VWAP Execution Model Fill Placements

The model uses market orders and it only works if the security subscription provides intraday data. It sets a maximum order size of 1% of the current bar's volume, but you can update the maximum order size through the `maximum_order_quantity_percent_volume` member.

```
# Use VolumeWeightedAveragePriceExecutionModel to execute trades based on volume-weighted average price, aiming to minimize market impact
and achieve better execution prices.
self.set_execution(VolumeWeightedAveragePriceExecutionModel())
```

For more information about this model, see the class reference and implementation .

Algorithm Framework

Hybrid Algorithms

Introduction

Classic style algorithms can also use Algorithm Framework modules. This allows you to get the best of both styles of algorithm design, combining easily pluggable modules with the superior control of classic format.

Examples of popular use-cases of a hybrid approach are:

- Using framework universe selection models as the assets to select.
- Using portfolio construction models to decide portfolio allocations.
- Using a risk control model for free portfolio risk monitoring.
- Passing data between modules freely without concerns of the module interface.

Universe Selection

You can add one or more Framework Universe Selection Models to your algorithm and it will operate normally. You can also combine it with the `add_universe` method of the classic approach. The following example initializes a classic algorithm with framework universe selection models:

```py
# Use a hybrid approach by combining Framework Universe Selection Models with classic methods to leverage both the modular flexibility of
Framework modules and the control of classic design. This allows for better universe selection, portfolio allocation, and risk
management.
def initialize(self):
    self.universe_settings.asynchronous = True
    self.set_universe_selection(ManualUniverseSelectionModel([ Symbol.create("SPY", SecurityType.EQUITY, Market.USA) ]))
    self.add_universe_selection(ManualUniverseSelectionModel([ Symbol.create("AAPL", SecurityType.EQUITY, Market.USA) ]))
    self.add_universe(self.universe.top(5))
```

Alpha

You can add one or multiple Alpha models to your classic algorithm and place the orders using `Insight` objects without a Portfolio Construction model. To receive the collection of `Insight` objects in a classic algorithm, implement the `insights_generated` event handler:

```py
# Add one or multiple Alpha models to a classic algorithm allowing for direct trading based on generated Insight objects, bypassing the
need for a Portfolio Construction model.
def initialize(self):
    self.add_alpha(EmaCrossAlphaModel())
    # The insights_generated event handler is used to receive and process the collection of insights, facilitating flexible and dynamic
trading strategies.
    self.insights_generated += self.on_insights_generated

def on_insights_generated(self, algorithm: IAlgorithm, insights_collection: GeneratedInsightsCollection) -> None:
    insights = insights_collection.insights
```

Portfolio Construction

You can add a Portfolio Construction model to your classic algorithm and have it place orders without returning `Insight` objects from an Alpha model. To emit insights without an Alpha model, in the `on_data` method, call the `EmitInsights` method.

The following example uses a Portfolio Construction Framework model with `EmitInsights` method in a classic algorithm:

```py
# Add a Portfolio Construction model to place orders directly without relying on Alpha-generated insights.
def initialize(self):
    self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

# Use the emit_insights method in the on_data method to provide trading signals for executing trades, ensuring balanced investment with
the chosen Portfolio Construction model.
def on_data(self, slice):
 self.emit_insights(Insight("GOOG", timedelta(minutes=20), InsightType.PRICE, InsightDirection.UP))
 self.emit_insights([
  Insight("AAPL", timedelta(minutes=20), InsightType.PRICE, InsightDirection.UP),
  Insight("MSFT", timedelta(minutes=20), InsightType.PRICE, InsightDirection.UP)
 ])
```

Risk Management

Some Risk Management Models don't require a Portfolio Construction model to provide `PortfolioTarget` objects, allowing them to directly monitor the portfolio holdings and liquidate positions when neccessary. To see which pre-built Risk Management models don't need the Portfolio Construction model to provide `PortfolioTarget` objects, see Supported Models .

You can add one or more Risk Management Models to your algorithm and it will operate normally. The following example initializes a classic algorithm with framework risk management models:

```py
# Add Risk Management models to monitor portfolio risk directly, without needing PortfolioTargets from a Portfolio Construction model.
These models can independently manage holdings and trigger liquidations as needed.
def initialize(self):
    self.add_risk_management(MaximumDrawdownPercentPerSecurity(0.05))
    self.add_risk_management(MaximumUnrealizedProfitPercentPerSecurity(0.1))
```

Execution

Execution models can place orders for your strategy instead of placing them manually. LEAN routes PortfolioTarget objects to the `execute` method of the Execution Model to place orders.

The following example uses a Framework Execution Model in a classic style algorithm:

```py
# Use set_execution to place orders via the Execution Model, which routes PortfolioTarget objects to its
# execute method, instead of placing orders manually. This ensures automated and consistent order execution.
def initialize(self):
    # Execute the market order imediately to fill the portfolio targets.
    self.set_execution(ImmediateExecutionModel())
```

Universe Timing Considerations

If the Alpha, Portfolio Construction, Risk Management, or Execution model manages some indicators or consolidators for securities in the universe and the universe selection runs during the indicator sampling period or the consolidator aggregation period, the indicators and consolidators might be missing some data. For example, take the following scenario:

- The security resolution is minute
- You have a consolidator that aggregates the security data into daily bars to update the indicator
- The universe selection runs at noon

In this scenario, you create and warm-up the indicator at noon. Since it runs at noon, the history request that gathers daily data to warm up the indicator won't contain any data from the current day and the consolidator that updates the indicator also won't aggregate any data from before noon. This process doesn't cause issues if the indicator only uses the close price to calculate the indicator value (like the simple moving average indicator) because the first consolidated bar that updates the indicator will have the correct close price. However, if the indicator uses more than just the close price to calculate its value (like the True Range indicator), the open, high, and low values of the first consolidated bar may be incorrect, causing the initial indicator values to be incorrect.

Examples

The following examples demonstrate common practices for implementing hybrid algorithms.

Example 1: Corresponding Alpha

The following algorithm trades two separate logics:

- EMA cross on the 20 most liquid stocks
- Buy and hold the top 20 weighted SPY constituents

To do so, we can save the universe and allow an access point in the corresponding alpha model to filter the signals that are only applicable to the selected equities from each universe.

```py
from Alphas.EmaCrossAlphaModel import EmaCrossAlphaModel, SymbolData

class FrameworkHybridAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Add a universe of the most liquid stocks since their trend is more capital-supported to trend EMA cross.
        self.universe1 = self.add_universe(self.liquid_selection)
        # Emit insights if the trend of selected liquid stocks changes.
        self.add_alpha(CustomEmaCrossAlphaModel(self))

        # Add another universe set to pick the most weighted SPY constituents since they usually have excess return compared to the rest.
        self.universe2 = self.add_universe(self.universe.etf("SPY", Market.USA, self.universe_settings, self.etf_constituents_filter))
        # Emit insights for all selected SPY constituents.
        self.add_alpha(CustomConstantAlphaModel(self))

        # Equal weighting on each insight to dissipate capital risk evenly.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

    def liquid_selection(self, fundamentals: List[Fundamental]) -> List[Symbol]:
        # Select the top 20 liquid equities for EMA cross trading.
        return [x.symbol for x in sorted(fundamentals, key=lambda f: f.dollar_volume, reverse=True)[:20]]

    def etf_constituents_filter(self, constituents: List[ETFConstituentUniverse]) -> List[Symbol]:
        # Select the top 20 weighted stocks of SPY constituents to hold.
        return [x.symbol for x in sorted([c for c in constituents if c.weight], key=lambda c: c.weight, reverse=True)[:20]]

class CustomEmaCrossAlphaModel(EmaCrossAlphaModel):
    def __init__(self, algorithm: FrameworkHybridAlgorithm, fast_period: int = 20, slow_period: int = 60, resolution: Resolution =
Resolution.DAILY) -> None:
        self.algorithm = algorithm
        super().__init__(fast_period, slow_period, resolution)

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for added in changes.added_securities:
            # Only trade the liquid universe for this alpha model.
            if added.symbol in self.algorithm.universe1.selected:
                symbol_data = self.symbol_data_by_symbol.get(added.symbol)
                if symbol_data is None:
                    symbol_data = SymbolData(added, self.fast_period, self.slow_period, algorithm, self.resolution)
                    self.symbol_data_by_symbol[added.symbol] = symbol_data
                else:
                    # A security that was already initialized was re-added, reset the indicators.
                    symbol_data.fast.reset()
                    symbol_data.slow.reset()

        for removed in changes.removed_securities:
            data = self.symbol_data_by_symbol.pop(removed.symbol, None)
            if data is not None:
                # clean up our consolidators.
                data.remove_consolidators()

class CustomConstantAlphaModel(ConstantAlphaModel):
    def __init__(self, algorithm: FrameworkHybridAlgorithm) -> None:
        self.algorithm = algorithm
        # Daily insight length due to daily signals.
        super().__init__(InsightType.PRICE, InsightDirection.UP, timedelta(1))

    def update(self, algorithm: QCAlgorithm, data: Slice) -> List[Insight]:
        insights = super().update(algorithm, data)
        # Only trade the selected SPY constituents universe for this alpha model.
        return [i for i in insights if i.symbol in self.algorithm.universe2.selected]
```

Example 2: Bracket Order On Insight

The following algorithm uses framework universe selection and alpha model to filter the universe and generate insights. However, the portfolio construction model cannot handle bracket orders easily. Hence, we will access the active insights to place bracket orders using the classic implementation, with stop losses at 1% and take profits at 2%.

PY

```
class FrameworkHybridAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Add a universe of the most liquid stocks since their trend is more capital-supported to trend EMA cross.
        self.universe1 = self.add_universe(self.liquid_selection)
        # Emit insights if the trend of selected liquid stocks changes.
        self.add_alpha(EmaCrossAlphaModel(20, 60, Resolution.DAILY))

        self.ordered_insights = []

    def liquid_selection(self, fundamentals: List[Fundamental]) -> List[Symbol]:
        # Select the top 20 liquid equities for EMA cross trading.
        return [x.symbol for x in sorted(fundamentals, key=lambda f: f.dollar_volume, reverse=True)[:20]]

    def on_data(self, slice: Slice) -> None:
        # Exit positions if insight is expired.
        for insight in self.ordered_insights.copy():
            # If the insight is expired or profit or loss are taken.
            if insight.is_expired(self.utc_time) or not self.portfolio[insight.symbol].invested:
                # Discontinue the insight.
                self.insights.cancel([insight])
                # Liquidate any positions and any open (bracket) orders.
                self.liquidate(insight.symbol)
                # Remove from the cache.
                self.ordered_insights.remove(insight)

        # Place orders for active insights if it has not yet been ordered.
        active_insights = self.insights.get_active_insights(self.utc_time)
        for insight in active_insights:
            if insight not in self.ordered_insights:
                # Position sizing by given weight or equal weighting to dissipate capital risk.
                if insight.weight:
                    size = insight.weight
                else:
                    size = 1 / len(active_insights)
                self.set_holdings(insight.symbol, size)
                # Add to cache to avoid re-order.
                self.ordered_insights.append(insight)

    def on_order_event(self, order_event: OrderEvent) -> None:
        if order_event.status == OrderStatus.FILLED:
            if order_event.ticket.order_type == OrderType.MARKET and self.portfolio[order_event.symbol].quantity:
                # Stop loss order at 1%.
                stop_price = order_event.fill_price * (0.99 if order_event.fill_quantity > 0 else 1.01)
                self.stop_market_order(order_event.symbol, -self.portfolio[order_event.symbol].quantity, stop_price)
                # Take profit order at 2%.
                take_profit_price = order_event.fill_price * (1.02 if order_event.fill_quantity > 0 else 0.98)
                self.limit_order(order_event.symbol, -self.portfolio[order_event.symbol].quantity, take_profit_price)
            elif order_event.ticket.order_type == OrderType.STOP_MARKET or order_event.ticket.order_type == OrderType.LIMIT:
                # Cancel any open order if stop loss or take profit order filled.
                self.transactions.cancel_open_orders()
```

Algorithm Framework

Insight Manager

Introduction

The `InsightManager` tracks all of the Insight objects in your algorithm. It's an `InsightCollection` , which stores all of your insights in an internal dictionary that has the security `Symbol` as the key and a list of `Insight` objects as the value. You can access the manager anywhere in your algorithm where you have reference to the algorithm class. If you want to use an `InsightCollection` in your algorithm that's seperate from the `InsightManager` , create a new `InsightCollection` .

Check Membership

To check if an insight exists in the `InsightManager` , call the `contains` method.

```
PY
# Check the algorithms central insight collection (InsightManager) to avoid emitting duplicates, reducing the processing work.
if algorithm.insights.contains(insight):
    pass
```

To check if the `InsightManager` has an insight for a `Symbol` , call the `contains_key` method.

```
PY
# Check the algorithms central insight collection (InsightManager) if there's already been an insight for this symbol across the other
alphas.
if algorithm.insights.contains_key(symbol):
    pass
```

To check if the `InsightManager` has active insights for a `Symbol` at a specific Coordinated Universal Time (UTC), call the `has_active_insights` method.

```
PY
# Check if there are active insights for a specific symbol at the given time to determine if alpha should emit more insights
if algorithm.insights.has_active_insights(symbol, utc_time):
    pass
```

Get Insights

To get the insights for a `Symbol` , index the `InsightManager` with the `Symbol` .

```
PY
if algorithm.insights.contains_key(symbol):
    insights = algorithm.insights[symbol]
```

To get the insights that pass a filter, call the `get_insights` method.

```
PY
insights = algorithm.insights.get_insights(lambda insight: insight.direction == Insightdirection.up)
```

To iterate through the `InsightManager` , call the `get_enumerator` method.

```
PY
enumerator = algorithm.insights.get_enumerator()
```

To get all of the insights that will be active at a certain UTC time, call the `get_active_insights` method.

```
PY
active_insights = algorithm.insights.get_active_insights(utc_time)
```

Get the Next Expiry Time

To get the next insight expiry time in UTC, call the `get_next_expiry_time` method.

```
next_expiry = algorithm.insights.get_next_expiry_time()
```

Remove Insights

Only the Portfolio Construction model should remove insights from the `InsightManager` . It should remove insights when the insights expire and when the corresponding security leaves the universe .

To remove an insight from the `InsightManager` , call the `remove` method.

```
remove_successful = algorithm.insights.remove(insight)
```

To remove all the insights for a set of `Symbol` objects, pass a list of `Symbol` objects the `clear` method.

```
algorithm.insights.clear(symbols)
```

To remove all the insights that will be expired at a certain UTC time, call the `remove_expired_insights` method.

```
expired_insights = algorithm.insights.remove_expired_insights(utc_time)
```

Cancel Insights

In some cases, you may want to cancel an Insight. For example, if a Risk Management model in your algorithm liquidates a security, it should also cancel all of the active insights for the security. If you don't cancel the insights, the Portfolio Construction model might create a new PortfolioTarget to re-enter the position.

Another example of a situtation where you would want to cancel an Insight is when an Alpha model in your algorithm determines the trading opportunity has pre-maturely ended. For instance, say you want your algorithm to enter a long position in a security when its Relative Strength Index (RSI) moves below 20 and then liquidate the position when the security's RSI moves above 30. If you emit an Insight that has a duration of 30 days when the RSI moves below 20 but the RSI moves above 30 in 10 days, you should cancel the Insight when the RSI moves above 30.

To cancel insights, call the `cancel` / `Expire` method with a list of `Insight` objects.

```
algorithm.insights.cancel(insights)
```

To cancel all the insights for some securities, call the `cancel` / `Expire` method with a list of `Symbol` objects.

```
algorithm.insights.cancel(symbols)
```

When you cancel an active insight, it's `close_time_utc` property is set to one second into the past.

Add Insights to Self-Managed Insight Collections

To add insights to the `InsightManager` , return a list of `Insight` objects from the update method of your Alpha model or call the `emit_insights` method. If you manage an `InsightCollection` that's seperate from the `InsightManager` , there are some methods to add `Insight` objects to it.

To add an insight to an `InsightCollection` , call the `add` method.

```
# You can manually add an Insight to an InsightCollection object to organize, fetch, or cancel insights an alpha has generated.
self.insight_collection.add(insight)
```

To add a list of insights, call the `add_range` method.

```
# You can manually add a list of Insights to an InsightCollection object to organize, fetch, or cancel insights an alpha has generated.
self.insight_collection.add_range(insights)
```

Preserve Insights Between Deployments

Follow these steps to use the Object Store to preserve the algorithm state across live deployments:

1. Create an algorithm that defines a storage key and adds insights to the Insight Manager .

```
class ObjectStoreChartingAlgorithm(QCAlgorithm):
    def initialize(self):
        self.insight_key = f"{self.project_id}/insights"
        self.set_universe_selection(ManualUniverseSelectionModel([ Symbol.create("SPY", SecurityType.EQUITY, Market.USA) ]))
        self.set_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(5), 0.025, None))
```

2. At the top of the algorithm file, add the following imports:

```
from Newtonsoft.Json import JsonConvert
from System.Collections.Generic import List
```

   `Insight` objects are C# objects, so you need the preceding C# libraries to serialize and deserialize them.

3. In the on_end_of_algorithm event handler of the algorithm, get the Insight objects and save them in the Object Store as a JSON object.

```
def on_end_of_algorithm(self):
    insights = self.insights.get_insights(lambda x: x.is_active(self.utc_time))
    content = ','.join([JsonConvert.SerializeObject(x) for x in insights])
    self.object_store.save(self.insight_key, f'[{content}]')
```

4. At the bottom of the `initialize` method, read the Insight objects from the Object Store and add them to the Insight Manager .

```
if self.object_store.contains_key(self.insight_key):
    insights = JsonConvert.DeserializeObject[List[Insight]](
        self.object_store.read(self.insights_key)
    )
    self.insights.add_range(insights)
```

The following algorithm provides a full example of preserving the Insight state between deployments:

```
from Newtonsoft.Json import JsonConvert
from System.Collections.Generic import List

class ObjectStoreInsightsAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.universe_settings.resolution = Resolution.DAILY

        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        self.insights_key = f"{self.project_id}/insights"

        # Read the file with the insights
        if self.object_store.contains_key(self.insights_key):
            # Load cached JSON key value pair from object store, then add to algorithm insights.
            insights = JsonConvert.DeserializeObject[List[Insight]](
                self.object_store.read(self.insights_key)
            )
            self.log(f"Read {len(insights)} insight(s) from the Object Store")
            self.insights.add_range(insights)

            # Delete the key to reuse it
            self.object_store.delete(self.insights_key)

        self.set_universe_selection(ManualUniverseSelectionModel([ Symbol.create("SPY", SecurityType.EQUITY, Market.USA) ]))
        self.set_alpha(ConstantAlphaModel(InsightType.PRICE, InsightDirection.UP, timedelta(5), 0.025, None))
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel(Resolution.DAILY))

    def on_end_of_algorithm(self) -> None:
        # Get all active insights.
        insights = self.insights.get_insights(lambda x: x.is_active(self.utc_time))
        # If we want to save all insights (expired and active), we can use
        # insights = self.insights.get_insights(lambda x: True)
        self.log(f"Save {len(insights)} insight(s) to the Object Store.")
        content = ','.join([JsonConvert.SerializeObject(x) for x in insights])
        self.object_store.save(self.insights_key, f'[{content}]')
```

Properties

The `InsightManager` has the following properties:

Examples

The following examples demonstrate some common practices for using insight manager.

Example 1: Cancel Insight

If the risk management model only submits the `PortfolioTarget` to liquidate the security, it will be re-ordered immediately due to the active insight. Hence, we also need to add logic to cancel the insight in the `manage_risk` method of the risk management model. The below example only permits 1-day holding time per each insight through a custom risk management model.

PY

```
class FrameworkInsightManagerAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 11, 15)
        self.set_cash(1000000)
        # Seed the price of each asset with its last known price to avoid trading errors.
        self.settings.seed_initial_prices = True
        # Add a universe of the most liquid stocks since their trend is more capital-supported.
        self.add_universe_selection(QC500UniverseSelectionModel())
        # Emit insights on EMA cross, indicating the trend changes. We use short-term versus medium-term for more trade opportunities.
        self.add_alpha(EmaCrossAlphaModel(20, 60, Resolution.DAILY))
        # Equal weighting on each insight to dissipate capital risk evenly.
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

        # Add a risk management model that controls maximum holding time.
        self.add_risk_management(MaximumHoldingTimeRiskManagementModel(timedelta(5)))

class MaximumHoldingTimeRiskManagementModel(RiskManagementModel):
    def __init__(self, maximum_holding_time: timedelta) -> None:
        self.maximum_holding_time = maximum_holding_time
        # A dictionary to hold the holding time of each position.
        self.holding_time = {}

    def manage_risk(self, algorithm: QCAlgorithm, targets: List[PortfolioTarget]) -> List[PortfolioTarget]:
        targets = []

        for symbol, holding in algorithm.portfolio.items():
            if holding.invested:
                if symbol not in self.holding_time:
                    # For newly open positions, save the entry time.
                    self.holding_time[symbol] = algorithm.time
                elif algorithm.time - self.holding_time[symbol] > self.maximum_holding_time:
                    # Liquidate the position if the holding time exceeds the permitted level.
                    targets.append(PortfolioTarget(symbol, 0))
                    # Cancel the insight to avoid repeated re-ordering.
                    algorithm.insights.cancel([symbol])
                    # Remove from the dictionary.
                    self.holding_time.pop(symbol)

        return targets
```

Charting

Introduction

We provide a powerful charting API that you can use to build many chart types.

Charts

Charts contain a collection of series, which display data on the chart. To add a chart to an algorithm, create a `Chart` object and then call the `add_chart` method.

```py
chart = Chart("<chartName>")
self.add_chart(chart)
```

The `Chart` constructor expects a name argument. The following chart names are reserved:

- Assets Sales Volume
- Exposure
- Portfolio Margin

Series

A chart series displays data on the chart. To add a series to a chart, create a `Series` object and then call the `add_series` method.

```py
series = Series("<seriesName>")
chart.add_series(series)
```

Arguments

There are several other headers for the `Series` constructor.

```
Series(name, type)
Series(name, type, index)
Series(name, type, index, unit)
Series(name, type, unit)
Series(name, type, unit, color)
Series(name, type, unit, color, symbol)
```

The following table describes the constructor arguments:

Argument	Data Type	Description
`name`	`str`	Name of the series
`type`	`SeriesType`	Type of the series
`index`	`int`	Index position on the chart of the series
`unit`	`str`	Unit for the series axis
`color`	`Color`	Color of the series
`symbol`	`ScatterMarkerSymbol`	Symbol for the marker in a scatter plot series

The default `Series` is a line chart with a "$" unit on index 0.

Names

The `Series` constructor expects a name argument. If you add a series to one of the default charts, some series names may be reserved. The following table shows the reserved series name for the default charts:

Chart Name	Reserved Series Names
Strategy Equity	Equity, Return
Capacity	Strategy Capacity
Drawdown	Equity Drawdown
Benchmark	Benchmark
Portfolio Turnover	Portfolio Turnover

Types

The `SeriesType` enumeration has the following members:

A `Line` series connects plotted values with a continuous line. This is the default series type.

```
chart.add_series(Series("EMA", SeriesType.LINE, "$", Color.ORANGE))
```

A `Scatter` series plots individual data points without connecting lines. Use the `ScatterMarkerSymbol` parameter to set the marker shape.

```
chart.add_series(Series("Signal", SeriesType.SCATTER, "$", Color.GREEN, ScatterMarkerSymbol.TRIANGLE))
```

A `Candle` series displays OHLC data as candlesticks. Use the `CandlestickSeries` helper class and plot a `TradeBar` to populate all four values.

```
chart.add_series(CandlestickSeries("SPY", "$"))
```

A `Bar` series draws vertical bars for each plotted value, which is useful for volume or count data.

```
chart.add_series(Series("Volume", SeriesType.BAR, "", Color.GRAY))
```

To create a `StackedArea` chart, add multiple series to the same chart. Each series contributes an area band that stacks on top of the others.

```
chart.add_series(Series("Stocks", SeriesType.STACKED_AREA, "%"))
chart.add_series(Series("Bonds", SeriesType.STACKED_AREA, "%"))
```

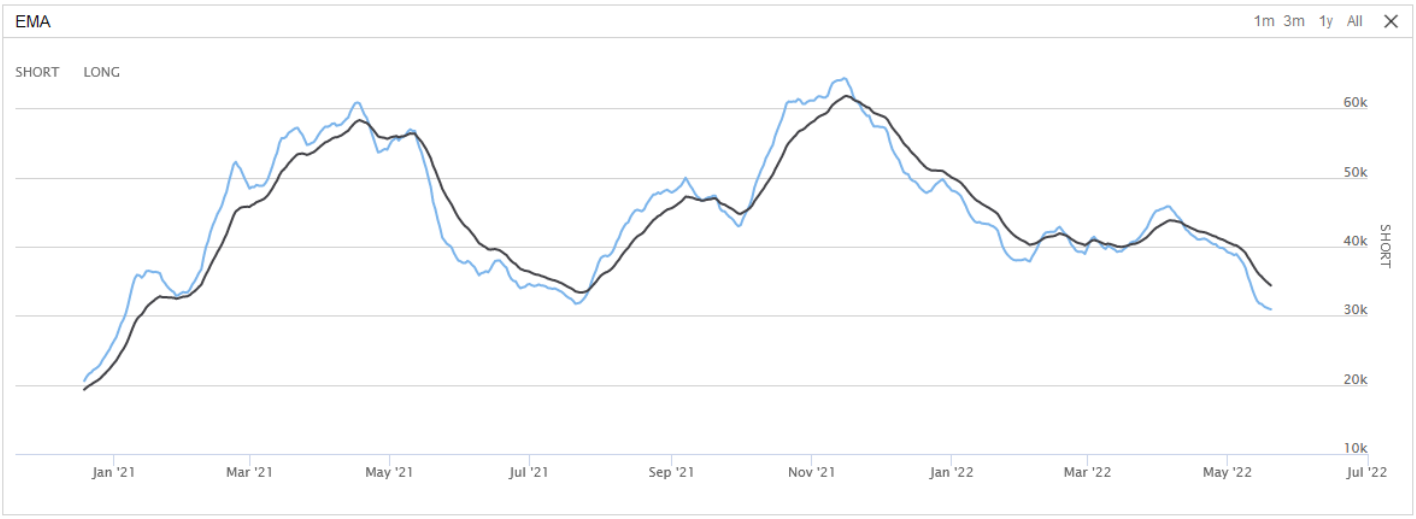
To create a `Treemap` chart, add multiple series to the same chart. Each series becomes a tile and its plotted value determines the tile size.

```
chart.add_series(Series("SPY", SeriesType.TREEMAP, "$"))
chart.add_series(Series("AAPL", SeriesType.TREEMAP, "$"))
```

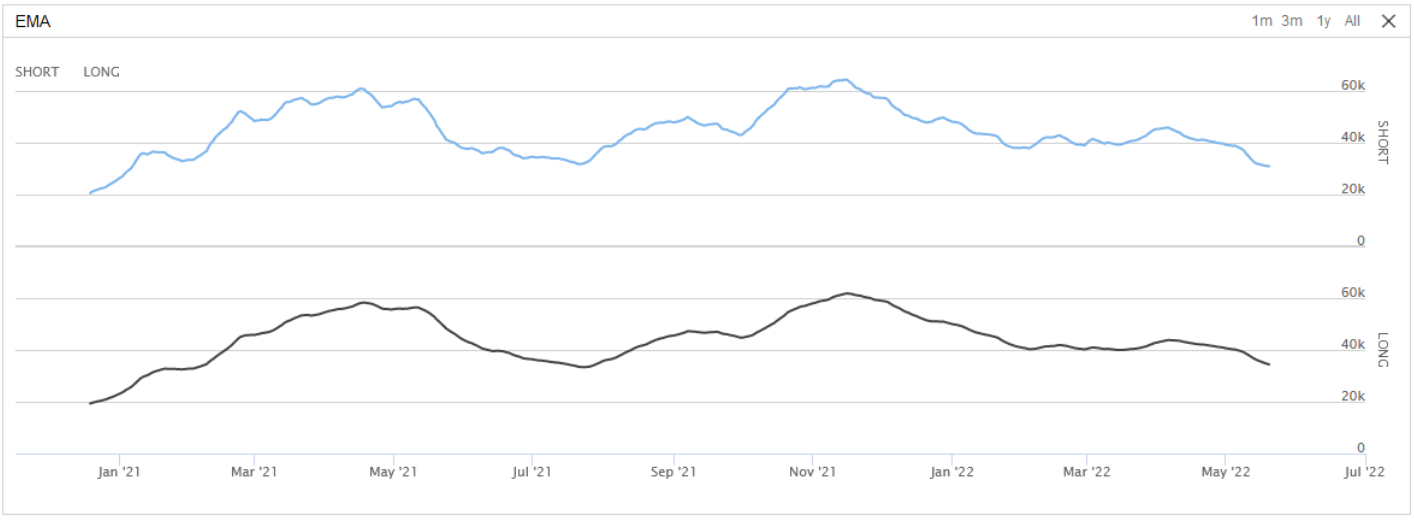
For a full example that demonstrates all series types, see Examples .

Index

The series index refers to its position in the chart. If all the series are at index 0, they lay on top of each other. If each series has its own index, each series will be separate on the chart. The following image shows an EMA cross chart with both EMA series set to the same index:



The following image shows the same EMA series, but with the short EMA on index 0 and the long EMA on index 1:



Colors

To view the available `Color` options, see the Color Struct Properties in the .NET documentation.

Scatter Marker Symbols

The `ScatterMarkerSymbol` enumeration has the following members:

Candlestick Series

A chart candlestick series displays candlesticks on the chart. To add a candlestick series to a chart, create a `CandlestickSeries` object and then call the `add_series` method.

```py
candlestick_series = CandlestickSeries("<seriesName>")
chart.add_series(candlestick_series)
```

There are several other headers for the `CandlestickSeries` constructor.

```
CandlestickSeries(name)
CandlestickSeries(name, index)
CandlestickSeries(name, index, unit)
CandlestickSeries(name, unit)
```

The following table describes the constructor arguments:

Argument	Data Type	Description
`name`	`str`	Name of the series
`index`	`int`	Index position on the chart of the series
`unit`	`str`	Unit for the series axis

The default `CandlestickSeries` has 0 index and "$" unit.

Plot Series

To add a data point to a chart series, call the `plot` method. If you haven't already created a chart and series with the names you pass to the `plot` method, the chart and/or series is automatically created.

```
PY
self.plot("<chartName>", "<seriesName>", value)
```

The `value` argument can be an integer or decimal number. If the chart is a time series, the value is added to the chart using the algorithm time as the x-coordinate.

To plot the current value of indicators, call the `plot` method. The method accepts up to four indicators.

```
PY
# In Initialize
symbol = self.add_equity("SPY")
sma_short = self.sma(symbol, 10)
sma_long = self.sma(symbol, 20)

# In OnData
self.plot("<chartName>", sma_short, sma_long)
```

To plot all of the values of some indicators, in the `initialize` method, call the `plot_indicator` method. The method plots each indicator value as the indicator updates. The method accepts up to four indicators.

```
PY
symbol = self.add_equity("SPY")
sma_short = self.sma(symbol, 10)
sma_long = self.sma(symbol, 20)
self.plot_indicator("<chartName>", sma_short, sma_long)
```

Plot Candlestick

To add a sample of open, high, low, and close values to a candlestick series, call the `plot` method with the data points. If you haven't already created a chart and series with the names you pass to the `plot` method, the chart and/or series is automatically created.

```
PY
self.plot("<chartName>", "<seriesName>", open, high, low, close)
```

The `open` , `high` , `low` , and `close` arguments can be an integer for decimal number. If the chart is a time series, the values are added to the chart using the algorithm time as the x-coordinate.

To plot the current trade bar, call the `plot` method with a `TradeBar` argument in the `on_data` method.

```
PY
# In Initialize
equity = self.add_equity("SPY")
forex = self.add_forex("EURUSD")

# In OnData
trade_bar = slice.bars["SPY"];
collapsed = slice.quote_bars["EURUSD"].collapse()   # Collapses QuoteBar into TradeBar object
self.plot("<chartName>", "<seriesName>", trade_bar)
self.plot("<chartName>", "<seriesName>", collapsed)
```

To plot consolidated bars, call the `plot` method with a `TradeBar` argument in the consolidation handler.

```py
# In Initialize
equity = self.add_equity("SPY")
self.consolidate(equity.symbol, timedelta(minutes=10), self._consolidation_handler)

# Define the consolidation handler
def _consolidation_handler(self, consolidated_bar: TradeBar) -> None:
    self.plot("<chartName>", "<seriesName>", consolidated_bar)
```

Plot Asset Data

Asset plots display the trade prices of an asset and the following order events you have for the asset:

Order Event	Icon
Submissions	Gray circle
Updates	Blue circle
Cancellations	Gray square
Fills and partial fills	Green (buys) or red (sells) arrows

The following image shows an example asset plot for AAPL:

The order submission icons aren't visible by default.

For more information about these charts, including how to view them in QC Cloud, see Asset Plots for backtests or live trading .

View Charts

The following table describes where you can access your charts, depending on how to deploy your algorithms:

Location	Algorithm Lab Algorithms	CLI Cloud Algorithms	CLI Local Algorithms
Backtest results page	✓	✓	
Live results page	✓	✓	
/backtests/read endpoint	✓	✓	
/live/read endpoint	✓	✓	
ReadBacktest method	✓	✓	
ReadLiveAlgorithm method	✓	✓	
Local JSON file in your <projectName> / backtests / <timestamp> or <projectName> / live / <timestamp> directory		✓	✓

Quotas

When you run backtests, you must stay within the plotting quotas to avoid errors.

Cloud Quotas

Intensive charting requires hundreds of megabytes of data, which is too much to stream online or display in a web browser. The number of series and the number of data points per series you can plot depends on your organization tier . The following table shows the quotas:

Tier	Max Series	Max Data Points per Series
Free	10	4,000
Quant Researcher	10	8,000
Team	25	16,000
Trading Firm	25	32,000
Institution	100	96,000

If you exceed the series quota, your algorithm stops executing and the following message displays:

Exceeded maximum chart series count, new series will be ignored. Limit is currently set at <quota>.

If you exceed the data points per series quota, the following message displays:

Exceeded maximum points per chart, data skipped

If your plotting needs exceed the preceding quotas, create the plots in the Research Environment instead .

Local Quotas

If you execute local backtests, the charting quotas are set by the `maximum-chart-series` and `maximum-data-points-per-chart-series` configuration settings .

Examples

The following example demonstrates the `Line` , `Scatter` , `Candle` , `Bar` , `StackedArea` , and `Treemap` series types. The algorithm trades a three-asset portfolio and plots EMA crossover signals, candlestick prices, volume bars, portfolio allocation as a stacked area, and sales volume as a treemap.

```py
class AllSeriesTypesAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 1, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.settings.automatic_indicator_warm_up = True

        tickers = ["AAPL", "MSFT", "GOOG"]
        self._symbols = []
        self._ema_fast = {}
        self._ema_slow = {}
        for ticker in tickers:
            symbol = self.add_equity(ticker, Resolution.DAILY).symbol
            self._symbols.append(symbol)
            self._ema_fast[symbol] = self.ema(symbol, 10)
            self._ema_slow[symbol] = self.ema(symbol, 50)

        # Line and Scatter chart: EMA values with crossover markers.
        price_chart = Chart("EMA Crossover")
        self.add_chart(price_chart)
        price_chart.add_series(Series("EMA Fast", SeriesType.LINE, "$", Color.ORANGE))
        price_chart.add_series(Series("EMA Slow", SeriesType.LINE, "$", Color.BLUE))
        price_chart.add_series(Series("Cross Up", SeriesType.SCATTER, "$",
            Color.GREEN, ScatterMarkerSymbol.TRIANGLE))
        price_chart.add_series(Series("Cross Down", SeriesType.SCATTER, "$",
            Color.RED, ScatterMarkerSymbol.TRIANGLE_DOWN))

        # Bar chart: daily volume.
        volume_chart = Chart("Volume")
        self.add_chart(volume_chart)
        volume_chart.add_series(Series("Volume", SeriesType.BAR, "", Color.GRAY))

        # Candlestick chart: daily OHLC for the first symbol.
        candle_chart = Chart("Candlestick")
        self.add_chart(candle_chart)
```

```
        candle_chart.add_series(CandlestickSeries(self._symbols[0].value, "$"))

        # Stacked area chart: portfolio allocation by asset over time.
        allocation_chart = Chart("Allocation")
        self.add_chart(allocation_chart)
        for symbol in self._symbols:
            allocation_chart.add_series(Series(symbol.value, SeriesType.STACKED_AREA, "%"))

        # Treemap chart: total sales volume per asset.
        treemap_chart = Chart("Sales Volume")
        self.add_chart(treemap_chart)
        for symbol in self._symbols:
            treemap_chart.add_series(Series(symbol.value, SeriesType.TREEMAP, "$"))

    def on_data(self, slice: Slice) -> None:
        # Trade on EMA crossovers for the first symbol.
        symbol = self._symbols[0]
        if not self._ema_fast[symbol].is_ready:
            return

        if (self._ema_fast[symbol].current.value > self._ema_slow[symbol].current.value and
                self._ema_fast[symbol][1] < self._ema_slow[symbol][1]):
            self.set_holdings(symbol, 0.4)
            self.set_holdings(self._symbols[1], 0.3)
            self.set_holdings(self._symbols[2], 0.3)
        elif (self._ema_fast[symbol].current.value < self._ema_slow[symbol].current.value and

            self.liquidate()

    def on_end_of_day(self, symbol: Symbol) -> None:
        if symbol != self._symbols[0]:
            return

        # Plot EMA line and scatter crossover markers.
        self.plot("EMA Crossover", "EMA Fast", self._ema_fast[symbol].current.value)
        self.plot("EMA Crossover", "EMA Slow", self._ema_slow[symbol].current.value)
        if self._ema_fast[symbol].is_ready and self._ema_fast[symbol][1] != 0:
            if (self._ema_fast[symbol].current.value > self._ema_slow[symbol].current.value and
                    self._ema_fast[symbol][1] < self._ema_slow[symbol][1]):
                self.plot("EMA Crossover", "Cross Up", self.securities[symbol].price)
            elif (self._ema_fast[symbol].current.value < self._ema_slow[symbol].current.value and
                    self._ema_fast[symbol][1] > self._ema_slow[symbol][1]):
                self.plot("EMA Crossover", "Cross Down", self.securities[symbol].price)

        # Plot candlestick and volume bar.
        data = self.securities[symbol].get_last_data()
        if data:
            self.plot("Candlestick", symbol.value, data)
            self.plot("Volume", "Volume", data.volume)

        # Plot allocation and treemap.
        total_value = self.portfolio.total_portfolio_value
        if total_value > 0:
            for s in self._symbols:
                weight = 100 * self.portfolio[s].holdings_value / total_value
                self.plot("Allocation", s.value, weight)
                self.plot("Sales Volume", s.value, self.portfolio[s].total_sale_volume)
```

Logging

Introduction

Algorithms can record string messages ('log statements') to a file for analysis after a backtest is complete, or as a live algorithm is running. These records can assist in debugging logical flow errors in the project code. Consider adding them in the code block of an `if` statement to signify an error has been caught.

It's good practice to add logging statements to live algorithms so you can understand its behavior and keep records to compare against backtest results. If you don't add logging statements to a live algorithm and the algorithm doesn't trade as you expect, it's difficult to evaluate the underlying problem.

Log Messages

Log statements are added to the log file while your algorithm continues executing. Logging dataset information is not permitted. Use `log` method statements to debug your backtests and live trading algorithms.

If you execute algorithms in QuantConnect Cloud, log length is capped by organization tier . If your organization hits the daily limit, contact us .

If you log the same content multiple times, only the first instance is added to the log file. To bypass this rate-limit, add a timestamp to your log messages.

For live trading, the log files of each cloud project can store up to 100,000 lines for up to one year. If you log more than 100,000 lines or some lines become older than one year, we remove the oldest lines in the files so your project stays within the quota.

To record the algorithm state when the algorithm stops executing, add log statements to the `on_end_of_algorithm` event handler.

```
self.log("My log message")
```

Debug Messages

Debug statements are the same as log statements, but `debug` method statements are orange in the Cloud Terminal. Use these statements when you want to give more attention to a message in the Cloud Terminal. Debug messages can be up to 200 characters in length. If you send multiple debug statements within 1 second, your messages are rate-limited to avoid crashing your browser.

```
self.debug("My debug message")
```

Error Messages

Error statements are the same as log statements, but `error` method statements are displayed in red text in the Cloud Terminal. Use these statements when you want to give the most attention to a message in the Cloud Terminal. Error statements are rate-limited like debug statements.

```
self.error("My error message")
```

Quit Messages

Quit statements cause your project to stop running and may log some data to the log file and Cloud Terminal. These statements are orange in the Cloud Terminal. When you call the `quit` method method, the program continues executing until the end of the method definition. If you want to quit execution immediately, `return` after you call `quit` method.

```
self.quit("My quit message")
```

Get Logs

The following tables describe how to access the logs of your backtests and live algorithms:

Deployment Target	Execution Mode	Access Tools
QuantConnect Cloud	Backtest	• Backtest results page in the Algorithm Lab • Backtest results page on Local Platform
QuantConnect Cloud	Live Trading	• Live results page in the Algorithm Lab • Live results page on Local Platform • /live/read/log endpoint
Local	Backtest	• Backtest results page on Local Platform • <organizationWorkspace> / <projectName> / backtests / <unixTimestamp> / <algorithmId>-log.txt • lean logs CLI command
Local	Live Trading	• Live results page on Local Platform • <organizationWorkspace> / <projectName> / live / <timeStamp> / / L-<deploymentId>-log.txt • lean logs CLI command

Example

The following examples demonstrate some common practices for logging.

Example 1: On Events And Trading Logic

The following example trades a simple EMA cross trend-following strategy on SPY. We log or debug messages in event handlers and trading logic changes to get information on any event flow.

PY

```
class LoggingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 12)
        self.set_end_date(2024, 10, 1)
        self.set_cash(1000000)

        # Request SPY data to trade.
        self.spy = self.add_equity("SPY").symbol
        # Create an EMA indicator to generate trade signals.
        self._ema = self.ema(self.spy, 20, Resolution.DAILY)

        # Warm up the algorithm for indicator readiness.
        self.set_warm_up(20, Resolution.DAILY)

    def on_warmup_finished(self) -> None:
        # Signals on warm-up finished.
        self.log("Warm up finished")

    def on_data(self, slice: Slice) -> None:
        bar = None if self.is_warming_up else slice.bars.get(self.spy)
        if bar:
            # Trend-following strategy using price and EMA.
            # If the price is above EMA, SPY is in an uptrend, and we buy it.
            if bar.close > self._ema.current.value and not self.portfolio[self.spy].is_long:
                self.debug("Trend changes to upwards")
                self.set_holdings(self.spy, 1)
            elif bar.close < self._ema.current.value and not self.portfolio[self.spy].is_short:
                self.debug("Trend changes to downwards")
                self.set_holdings(self.spy, -1)

    def on_order_event(self, order_event: OrderEvent) -> None:
        if order_event.status == OrderStatus.FILLED:
            # Log the order details if being filled.
            self.log(f"Order filled - Quantity: {order_event.quantity}")
```

Statistics

LEAN automatically monitors a set of statistics as your algorithms execute. You can even create custom statistics for further analysis.

Statistics

Algorithm Statistics

Introduction

The `StatisticsResults` object tracks all the statistics of your algorithm. You can access the statistics anywhere in your algorithm where you have a reference to the algorithm class. Some of these statistics are a function of the risk free interest rate and the number of trading days per year .

Properties

The `StatisticsResults` object has the following properties:

Add Statistics

To add custom statistics to the `StatisticsResults` object, call the `set_summary_statistic` method with the statistic name and value.

```
self.set_summary_statistic("name", value)
```

Get Values

To get the `StatisticsResults` , use the `statistics` member of the algorithm class.

```
sharpe = self.statistics.total_performance.portfolio_statistics.sharpe_ratio
```

To get the value of a custom statistic while your algorithm runs, index the `summary` member with the statistic name. The values in the `summary` dictionary are strings, so you may need to cast the value that returns to a different data type.

```
value = self.statistics.summary["name"]
```

The following table describe other ways to get the statistics after your backtest completes:

Deployment Target	Access Tools
QuantConnect Cloud	• Backtest results page in the Algorithm Lab • Backtest results page on Local Platform • ReadBacktest API method • /backtests/read endpoint
Local	• Backtest results page on Local Platform • <organizationWorkspace> / <projectName> / backtests / <unixTimestamp> / <algorithmId>.json

Examples

The following examples demonstrate common practices for getting algorithm statistics.

Example 1: Portfolio Statistics

To evaluate the algorithm's best domain or regime, we can log the portfolio statistics daily along the backtest to analyze. To do so, we log the Sharpe Ratio, Beta, and 95% Value-at-Risk at the end of each day, storing them in the object store for assessment later.

```py
class AlgorithmStatisticsAlgorithm(QCAlgorithm):
    _statistics = ["Time,Sharpe,Beta,95VaR"]

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 12)
        self.set_end_date(2024, 10, 1)
        self.set_cash(1000000)

        # Request SPY data to trade.
        self.spy = self.add_equity("SPY").symbol
        # Create an EMA indicator to generate trade signals.
        self._ema = self.ema(self.spy, 20, Resolution.DAILY)
        # Warm-up indicator for immediate readiness.
        self.warm_up_indicator(self.spy, self._ema, Resolution.DAILY)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self.spy)
        if bar:
            # Trend-following strategy using price above or below EMA.
            # If the price is above EMA, SPY is in an uptrend, and we buy it.
            if bar.close > self._ema.current.value and not self.portfolio[self.spy].is_long:
                self.set_holdings(self.spy, 1)
            elif bar.close < self._ema.current.value and not self.portfolio[self.spy].is_short:
                self.set_holdings(self.spy, -1)

    def on_end_of_day(self, symbol: Symbol) -> None:
        # Obtain the algorithm statistics interested.
        sharpe = self.statistics.total_performance.portfolio_statistics.sharpe_ratio
        b = self.statistics.total_performance.portfolio_statistics.beta
        var = self.statistics.total_performance.portfolio_statistics.value_at_risk_95

        # Plot the statistics.
        self.plot("Statistics", "Sharpe", sharpe)
        self.plot("Statistics", "Beta", b)
        self.plot("Statistics", "Value-at-Risk", var)

        # Write to save the statistics.
        self._statistics.append(f'{self.time.strftime("%Y%m%d")},{sharpe},{b},{var}')

    def on_end_of_algorithm(self) -> None:
        # Save the logged statistics for later access in the object store.
        self.object_store.save(f'{self.project_id}/algorithm-statistics', '\n'.join(self._statistics))
```

Statistics

Runtime Statistics

Introduction

Runtime statistics show the performace of your algorithm at a single moment in time. Some of these statistics are a function of the risk free interest rate and the number of trading days per year .

Default Statistics

The following table describes the default runtime statistics:

Statistic	Description
Equity	The total portfolio value if all of the holdings were sold at current market rates. Equity equals the sum of cash and the market value of all open positions.
Fees	The total quantity of fees paid for all the transactions during the algorithm's trading period. Total fees include brokerage commissions, exchange fees, and other transaction costs.
Holdings	The absolute sum of the items in the portfolio. Holdings represent the total market value of all positions, regardless of whether they are long or short.
Net Profit	The dollar-value return across the entire trading period.
PSR	The probability that the estimated Sharpe ratio of an algorithm is greater than a benchmark.
Return	The rate of return across the entire trading period.
Unrealized	The amount of profit a portfolio would capture if it liquidated all open positions and paid the fees for transacting and crossing the spread. Unrealized profit becomes realized profit when the positions are closed.
Volume	The total value of assets traded for all of an algorithm's transactions during the trading period.

Add Statistics

To add a custom runtime statistic, call the `set_runtime_statistic` method with a `name` and `value` . The `value` argument can be a `string` or a number.

```
self.set_runtime_statistic(name, value)
```

Don't try to set a value for any of the preceding default runtime statistics. LEAN overwrites the value that you try to set.

Get Values

To get the value of a runtime statistic in an algorithm, index the `runtime_statistics` member of the algorithm class with the statistic name. The values of the `runtime_statistics` dictionary are strings, so you may need to cast the result to a different data type.

```
value = self.runtime_statistics[name]
```

The following table describe other ways to get the runtime statistics of your backtests and live algorithms:

Deployment Target	Execution Mode	Access Tools
QuantConnect Cloud	Backtest	• Backtest results page in the Algorithm Lab • Backtest results page on Local Platform • ReadBacktest API method • /backtests/read endpoint
QuantConnect Cloud	Live Trading	• Live results page in the Algorithm Lab • Live results page on Local Platform • ReadLiveAlgorithm API method • /live/read endpoint
Local	Backtest	• Backtest results page on Local Platform • <organizationWorkspace> / <projectName> / backtests / <unixTimestamp> / <algorithmId>.json
Local	Live Trading	• Live results page on Local Platform • <organizationWorkspace> / <projectName> / live / <timeStamp> / / L-<deploymentId>.json

Examples

The following examples demonstrate common practices for setting runtime statistics.

Example 1: Display Banner

The following algorithm demonstrates how to put calculated runtime statistics of interest in the top display banner in the backtest interface and plot the data for analysis.

PY

```
class RuntimeStatisticsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 12)
        self.set_end_date(2024, 10, 1)
        self.set_cash(1000000)

        # Request SPY data to trade.
        self.spy = self.add_equity("SPY").symbol
        # Create an EMA indicator to generate trade signals.
        self._ema = self.ema(self.spy, 20, Resolution.DAILY)
        # Warms up indicator for immediate readiness.
        self.warm_up_indicator(self.spy, self._ema, Resolution.DAILY)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self.spy)
        if bar:
            # Trend-following strategy using price and EMA.
            # If the price is above the EMA, SPY is in an uptrend, and we buy it.
            if bar.close > self._ema.current.value and not self.portfolio[self.spy].is_long:
                self.set_holdings(self.spy, 1)
            elif bar.close < self._ema.current.value and not self.portfolio[self.spy].is_short:
                self.set_holdings(self.spy, -1)

    def on_end_of_day(self, symbol: Symbol) -> None:
        # Set the 95VaR and fee-to-profit ratio to the display banner.
        var = self.statistics.total_performance.portfolio_statistics.value_at_risk_95
        self.set_runtime_statistic("95VaR", var)
        fee_to_profit = self.statistics.total_performance.trade_statistics.total_fees /\
            self.statistics.total_performance.trade_statistics.total_profit_loss \
            if self.statistics.total_performance.trade_statistics.total_profit_loss != 0 else 0
        self.set_runtime_statistic("Fee-to-Profit", fee_to_profit)

        # Plot the calculated statistics.
        self.plot("Statistics", "95VaR", var)
        self.plot("Statistics", "fee-to-profit", fee_to_profit)

    def on_end_of_algorithm(self) -> None:
        # Log the 95VaR when the algorithm stops
        value_at_risk_95 = self.runtime_statistics["95VaR"]
        self.log(f'Final {value_at_risk_95=}')
```

Statistics

Trade Statistics

Introduction

The `TradeBuilder` tracks the trades of your algorithm and calculates some statistics. Some of these statistics are a function of the risk free interest rate and the number of trading days per year . You can adjust how the `TradeBuilder` defines a trade and how it matches offsetting order fills.

Set Trade Builder

To set the `TradeBuilder` , in the `initialize` method, call the `set_trade_builder` method.

```
self.set_trade_builder(TradeBuilder(grouping_method, matching_method))
```

The following table describes the arguments the `TradeBuilder` constructor accepts:

Argument	Data Type	Description	Default Value
`grouping_method`	`FillGroupingMethod`	The method used to group order fills into trades	
`matching_method`	`FillMatchingMethod`	The method used to match offsetting order fills	

The `FillGroupingMethod` enumeration has the following members:

The `FillMatchingMethod` enumeration has the following members:

Default Behavior

The default `TradeBuilder` uses `FillGroupingMethod.FILL_TO_FILL` and `FillMatchingMethod.FIFO` .

Check Open Positions

To check if you have a position open for a security as defined by the `FillGroupingMethod` , call the `has_open_position` method.

```
# Check if the trade builder has recorded any active trades (unclosed positions)
# for a security.
has_open_position = self.trade_builder.has_open_position(self._symbol)
```

Get Closed Trades

To get your closed trades, use the `closed_trades` property.

```
trades = self.trade_builder.closed_trades
```

This property returns a list of `Trade` objects, which have the following attributes:

Examples

The following examples demonstrate common practices for using trade statistics.

Example 1: Kelly Criterion Sizing Using Previous Trades

The following algorithm uses the previous trades to update the win probability and expected return of each trade of the EMA cross strategy of SPY, by the concept of Bayes Theorem. The updated figures are used for position sizing through Kelly Criterion.

PY

```
class TradeStatisticsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 12)
        self.set_end_date(2024, 10, 1)
        self.set_cash(1000000)

        # Request SPY data to trade.
        self.spy = self.add_equity("SPY").symbol
        # Create an EMA indicator to generate trade signals.
        self._ema = self.ema(self.spy, 20, Resolution.DAILY)
        # Warm-up indicator for immediate readiness.
        self.warm_up_indicator(self.spy, self._ema, Resolution.DAILY)

        # Set up a trade builder to track the trade statistics; we are interested in open-to-close round trade.
        self.set_trade_builder(TradeBuilder(FillGroupingMethod.FLAT_TO_FLAT, FillMatchingMethod.FIFO))

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self.spy)
        if not bar:
            return
        # Trend-following strategy using price and EMA.
        # If the price is above EMA, SPY is in an uptrend, and we buy it.
        sign = 0
        if bar.close > self._ema.current.value and not self.portfolio[self.spy].is_long:
            sign = 1
        elif bar.close < self._ema.current.value and not self.portfolio[self.spy].is_short:
            sign = -1
        else:
            return

        size = 1
        trades = self.trade_builder.closed_trades

        if len(trades) > 4:
            # Use the trade builder to obtain the win rate and % return of the last five trades to calculate position size.
            last_five_trades = sorted(trades, key=lambda x: x.exit_time)[-5:]
            prob_win = len([x for x in last_five_trades if x.is_win]) / 5
            win_size = np.mean([x.profit_loss / x.entry_price for x in last_five_trades])
            # Use the Kelly Criterion to calculate the order size.
            size = max(0, prob_win - (1 - prob_win) / win_size)

        self.set_holdings(self.spy, size * sign)
```

Live Trading

QuantConnect enables you to run your algorithms in live mode with real-time market data. You can use the same algorithm for backtesting and live trading with different brokerages and data providers.

Live Trading

Key Concepts

Introduction

Algorithms should generally work seamlessly shifting from backtesting to live trading with no changes required. In backtesting algorithm events are triggered as fast as possible, whereas in live trading events are triggered in realtime.

Algorithm Portfolio

The live trading algorithm portfolio is loaded from the brokerage holdings, including open orders. When there are unsupported asset types in the portfolio the live trading strategy is stopped as we cannot be sure how to model the asset.

In paper trading the algorithm starts from no portfolio, and attempts to remember the previous portfolio state from the last time the portfolio was deployed.

Your algorithm should not assume it starts from an empty portfolio as you may have holdings from previous deployments.

Stateful Strategies

There is no automatic state management of live strategies in QuantConnect. We recommend algorithms reconstruct state or indicator needs using the WarmUp and History methods.

Once the algorithm has warmed up some objects you can use the Object Store to save the data for the next algorithm restart.

In the event the algorithm is terminated unexpectedly, you should review the live algorithm portfolio at the brokerage to confirm it will behave as expected.

Data Delivery Times

Most data is available at the same time as in backtesting, with the exception of daily data which is often delayed by 4-8 hours (4am - 8am).

US Equities universe selection data is processed at 7-8am ET.

Latency

Live data takes time to travel from the source to your algorithm. The QuantConnect latencies vary depending on the data provider, but for US Equities, we have a latency of 5-40 milliseconds. A much more significant source of latency is the round trip order times from brokers, which can vary from 100ms to 5 seconds. QuantConnect is not intended for high-frequency trading, but we have integrations to high-speed brokers if you need.

Other Brokerages

If we do not support your brokerage reach out to let us and we can attempt to add them to the roadmap. With enough community requests we can build and open-source the brokerage integration.

Live Trading

Brokerages

Introduction

Brokerages provide you with a connection to the market so you can fill trades. To avoid placing invalid orders for execution in live trading, LEAN validates your orders before sending them to the real brokerage. To view all of the integrated brokerages, see Brokerages .

Portfolio

In live trading, LEAN populates the `portfolio` object with your account holdings and the `transactions` object with your open positions. If you don't manually subscribe to the assets in your account, LEAN subscribes to them with the lowest resolution of the subscriptions in your algorithm. For example, say you hold AAPL shares in your account and create the following subscriptions in your algorithm:

```
self.add_equity("SPY", Resolution.HOUR)
self.add_equity("MSFT", Resolution.SECOND)
```

In this case, LEAN subscribes to second-resolution data for AAPL since the lowest resolution in your algorithm is

`Resolution.SECOND` .

Deposits and Withdrawals

You can deposit and withdraw cash from your brokerage account while you run an algorithm that's connected to the account. We sync the algorithm's cash holdings with the cash holdings in your brokerage account every day at 7:45 AM Eastern Time (ET).

Monitor the Brokerage Connection

We notify your algorithm when your brokerage connection disconnects and reconnects.

Lost Connections

If the brokerage connection breaks, we notify your algorithm through the `on_brokerage_disconnect` event handler.

```
def on_brokerage_disconnect(self) -> None:
    self.debug("Brokerage connection lost")
```

Restored Connections

When the brokerage connection restores after it disconnects, we notify your algorithm through the `on_brokerage_reconnect` event handler.

```
def on_brokerage_reconnect(self) -> None:
    self.debug("Brokerage connection restored")
```

When LEAN reconnects with your brokerage, it synchronizes the state of your live orders. For example, say the brokerage fills your limit order during the period of disconnection. When the connection restores, LEAN updates the state of your portfolio and orders to reflect the filled order, but you won't receive an order event .

Example Algorithm

For a full example algorithm that implements the `on_brokerage_disconnect` and `on_brokerage_reconnect` methods, see the BrokerageActivityEventHandlingAlgorithm in the LEAN GitHub repository.

Monitor Brokerage Messages

When your brokerage sends you a message, we notify your algorithm through the `on_brokerage_message` event handler.

```py
def on_brokerage_message(self, message_event: BrokerageMessageEvent) -> None:
    self.debug(f"Brokerage message received: {message_event.message}")
```

`BrokerageMessageEvent` objects have the following attributes:

For a full example algorithm that implements the `on_brokerage_message` method, see the BrokerageActivityEventHandlingAlgorithm in the LEAN GitHub repository.

To handle brokerage messages outside of your algorithm class, create and set a `BrokerageMessageHandler` . For a more information example, see the Reality Modeling > Brokerage Message Handler .

Brokerage Models

Brokerage features and limitations are realistically modelled with Brokerage Models. These reality models set the supported order and asset types for the brokerage. To learn how to set your specific brokerage, see Supported Models .

Examples

The following examples demonstrate common practices for handling live brokerage messages.

Example 1: Pre-Open Order Error

The following algorithm simulate extended market hour trading on Tradier Brokerage . We place a market-on-open order at 7:30am and expect the order cannot submit to the broker since it is not supported, resulting into an error.

```py
class OrderErrorsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Simulate Tradier brokerage, which does not support the market-on-open orders.
        self.set_brokerage_model(BrokerageName.TRADIER_BROKERAGE, AccountType.CASH)

        # Request extended market hour SPY data for trading.
        self.spy = self.add_equity("SPY", extended_market_hours=True).symbol

        # Set a scheduled event to trade 2 hours pre-open to place the market-on-open-order.
        self.schedule.on(
            self.date_rules.every_day(self.spy),
            self.time_rules.before_market_open(self.spy, 120),
            self.open_position
        )

    def open_position(self) -> None:
        # Buy on market open will result in an error since Tradier does not support it.
        self.market_on_open_order(self.spy, 10)

    # It will be triggered on live trading.
    def on_brokerage_message(self, message: BrokerageMessageEvent) -> None:
        if message.type == BrokerageMessageType.ERROR:
            self.log(f"{self.time}: {message.type}: Message: {message.message}")
```

Live Trading

Data Providers

Introduction

Data providers provide a stream of asset prices and quotes delivered to your trading algorithm during live execution. You need live data provider to inject data into your algorithm so that you can make real-time trading decisions and so that the values of the securities in your portfolio update in real-time. You can source data from QuantConnect, brokerage, or a third-party source. To view the available data providers you can use in QuantConnect cloud, see Datasets . To view the available data providers you can use with local algorithms, see the Data Providers .

Data Providers

You can source data from QuantConnect, your brokerage, or third-party providers. The following table lists the data providers:

Data Provider	Cloud	Local
QuantConnect	✓	
Alpaca	✓	✓
Alpha Vantage		✓
Binance	✓	✓
Bitfinex	✓	✓
Bybit	✓	✓
Charles Schwab	✓	✓
Coinbase	✓	✓
FactSet		✓
Interactive Brokers	✓	✓
IQFeed		✓
Kraken	✓	✓
Polygon	✓	✓
Samco	✓	✓
Theta Data		✓
TradeStation	✓	✓
Terminal Link		✓
Tradier	✓	✓
Zerodha	✓	✓

Bar Building

We aggregate ticks to build bars.

In live trading, bars are built using the exchange timestamps with microsecond accuracy. This microsecond-by-microsecond processing of the ticks can mean that the individual bars between live trading and backtesting can have slightly different ticks. As a result, it's possible for a tick to be

counted in different bars between backtesting and live trading, which can lead to bars having slightly different open, high, low, close, and volume values.

Latency

Live data takes time to travel from the source to your algorithm. The QuantConnect latencies vary depending on the data provider, but for US Equities, we have a latency of 5-40 milliseconds. A much more significant source of latency is the round trip order times from brokers, which can vary from 100ms to 5 seconds. QuantConnect is not intended for high-frequency trading, but we have integrations to high-speed brokers if you need.

History Requests

In live trading, if you make a history request for minute data at noon and the history period covers the start of the previous day to the present moment, the data from the previous day will be backtest data. The data of the current day will be live data that we collected throughout the morning. If you make this history request in a backtest, you might get slightly different data for the current day because of post-processing from the data vendor.

In cloud deployments, QuantConnect is the default data provider. If you remove it and use a different data provider, you won't get any price data from QuantConnect. However, we provide the following datasets:

- US Equity Security Master
- US Futures Security Master
- US Equity Option Universe
- US Index Option Universe
- Universe selection datasets
- Non-streaming alternative datasets

Warm Up Periods

LEAN supports an automated fast-forward system called "Warm Up". It simulates winding back the date you deployed your algorithm by a specific time period. In backtests, it changes the start date of your algorithm to an earlier time. In live trading, it fetches data from before your deployment and fast forwards through your strategy up to the present day. Warm Up is a great way to prepare your algorithm and its indicators for trading. You can't place trades during the warm-up period because the data feed is replaying historical data for setting algorithm state.

Live Trading

Trading and Orders

Introduction

LEAN has dozens of methods to create, update, and cancel orders. You can place orders automatically with helper methods or manually through methods on the algorithm API. You can fetch, update, and cancel manual orders with order tickets . As the state of your orders change, LEAN creates events that notify your algorithm.

In backtesting, LEAN simulates order fills with historical data, but you can create your own fill, fee, slippage, and margin models via plugin points. You control how optimistic or pessimistic order fills are with transaction model classes. For more information about these types of models, see Reality Modeling .

In live trading, orders fill asynchronously. We send your order to the API of your brokerage and wait for their response to update the state of your algorithm and portfolio. The timing of live order fills doesn't depend on the resolution of your security subscriptions. When your order fills, the fill price and fee is set by your brokerage. You can add event handlers to your algorithm to monitor the brokerage connection and brokerage messages .

In backtesting, the trade fill timing depends on the resolution of your security subscription. For example, if you subscribe to a security with minute resolution data, the algorithm only receives data in one-minute time slices . As a result, the fill model can only evaluate if the order should fill on a minute-by-minute frequency.

Order Life Cycle

When you call one of the order methods to place an order, LEAN performs pre-order checks to ensure that the order meets some requirements and uses the last known price to check you have enough capital . To see the requirements of each order, see the Requirements section of the documentation for the order types and the Orders section of your brokerage model . If you can place the order, LEAN creates `Order` and OrderTicket objects. The order ticket is sent to your brokerage. As the brokerage processes your order, it returns another order ticket and it's compared against the order to see if the order is satisfied. Orders fill asynchronously in live trading, so if you want to change an order, you must request it with the order ticket. Order changes are not guaranteed since your order may fill by the time brokerage receives the request.

When you create an order ticket, LEAN validates it to avoid sending orders that will be rejected by your brokerage. If the order is invalid, it's status is set to `OrderStatus.Invalid` . Otherwise, LEAN sets the order status to `OrderStatus.New` , sends the order to your brokerage, and waits for the brokerage message. If your brokerage accepts the order, the order status becomes `OrderStatus.Submitted` . Otherwise, it becomes `OrderStatus.Canceled` .

You can update orders until they fill or the brokerage prevents modifications. If you place an order update request, LEAN validates it to avoid sending orders that will be rejected by you brokerage. If the order update is valid, LEAN sends the update request and waits for the brokerage message. If your brokerage accepts the update, the order status becomes `OrderStatus.UpdateSubmitted` . Otherwise, it becomes `OrderStatus.Canceled` .

The brokerage notifies LEAN when you order fills (`OrderStatus.FILLED`), partially fills (`OrderStatus.PartiallyFilled`) or is canceled (`OrderStatus.Canceled`). The brokerage can cancel your order before it completely fills. For example, if you place a market on open and the asset price moves before the market open to where you can't afford the quantity of the order, the brokerage rejects your order. The brokerage can also cancel your market on open order after partial fills if there is no shares left to trade.

Transaction Manager

LEAN doesn't save orders and order tickets across live deployments.

When you deploy your algorithm, LEAN fetches the open orders from your brokerage and populate the algorithm transactions manager (`SecurityTransactionManager`).

Disable Buying Power

You can disable order margin checks and opt to let your brokerage decide to accept or reject the trades. This is helpful in live trading if you have a more permissive brokerage margin allowance that what LEAN models. The default position group buying power models are helpful for Option trading

strategies. However, it can be counterproductive if it's not a supported Option strategy . To disable the validations of the default position group buying power model, use the `NullSecurityPositionGroupModel` . To set the `NullSecurityPositionGroupModel` for the portfolio, during initialization , call the `set_positions` method with the `SecurityPositionGroupModel. NULL` argument.

```py
self.portfolio.set_positions(SecurityPositionGroupModel.NULL)
```

To disable the validations of the default buying power model , use the `NullBuyingPowerModel` . To set the `NullBuyingPowerModel` for a security subscription, call the `set_buying_power_model` method with the `BuyingPowerModel. NULL` argument.

```py
def initialize(self) -> None:
    equity = self.add_equity("SPY")
    # To disable any buying power of the selected security
    equity.set_buying_power_model(BuyingPowerModel.NULL)
    # Alias:
    # equity.set_margin_model(SecurityMarginModel.NULL)
```

You can also set the `NullBuyingPowerModel` in a security initializer . If your algorithm has a universe, use the security initializer technique. To set the buying power of securities in the security initializer, set the brokerage model , set the security initializer , and then create security subscriptions.

```py
class AddSecurityInitializerExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the security initializer to set models of assets.
        self.add_security_initializer(self._custom_security_initializer)

    def _custom_security_initializer(self, security: Security) -> None:
        # Overwrite the security buying power
        security.set_buying_power_model(BuyingPowerModel.NULL)
```

Trading and Orders

Financial Advisors

Introduction

Financial Advisor accounts enable certified professionals to use a single trading algorithm to manage several client accounts. Our Interactive Brokers integration enables you to place FA group orders if your IB account code starts with F, FA, or I.

Group Routing

To place trades using a subset of client accounts, create Account Groups in Trader Workstation and then define the `InteractiveBrokersOrderProperties` when you create orders.

```py
self.default_order_properties = InteractiveBrokersOrderProperties()
self.default_order_properties.fa_group = "TestGroupEQ"
self.default_order_properties.fa_method = "Equal"
self.default_order_properties.account = "DU123456"
```

SecurityHolding objects aggregate your positions across all the account groups. If you have two groups where group A has 10 shares of SPY and group B has -10 shares of SPY, then `self.portfolio["SPY"].quantity` is zero.

Allocation Methods

LEAN supports several allocation methods for FA group orders. If you intend to use the same group allocation method for every order, set the `default_order_properties` of your algorithm, which sets the order properties for all of your orders.

```py
def initialize(self) -> None:
    # Set the default order properties
    self.default_order_properties = InteractiveBrokersOrderProperties()
    self.default_order_properties.fa_group = "TestGroupEQ"
    self.default_order_properties.fa_method = "Equal"
    self.default_order_properties.account = "DU123456"

def on_data(self, slice: Slice) -> None:
    # Use default order order properties
    LimitOrder(_symbol, quantity, limitPrice);
```

To adjust the order properties of an order, change the `default_order_properties` or pass an order properties object to the order method . The following sections explain the FA group allocation methods.

Equal

This group allocation method distributes shares equally between all accounts in the group. When you use this method, you need to specify an order quantity.

For example, say your Account Group includes four accounts and you place an order to buy 400 shares of a stock. In this case, each account receives 100 shares. If your Account Group includes six accounts, each account receives 66 shares, and then 1 share is allocated to each account until all are distributed. After you submit the order, your algorithm receives order events to track the order progress. When all the shares are bought, the order status is `OrderStatus.FILLED` . If one of the accounts in the group can't afford 10 of the shares it needs to buy, 10 shares are cancelled and you'll only end up buying 390 shares in total.

```py
order_properties = InteractiveBrokersOrderProperties()
order_properties.fa_method = "Equal"
self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Net Liquidation Value

This group allocation method distributes shares based on the net liquidation value of each account. The system calculates ratios based on the net

liquidation value in each account and allocates shares based on these ratios. When you use this method, you need to specify an order quantity.

For example, say your account group includes three accounts, A, B and C with Net Liquidation values of 25,000, 50,000 and $100,000, respectively. In this case, the system calculates a ratio of 1:2:4. If you place an order for 700 shares of a stock, it allocates 100 shares to Client A, 200 shares to Client B, and 400 shares to Client C.

```py
order_properties = InteractiveBrokersOrderProperties()
order_properties.fa_method = "NetLiq"
self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Available Equity

This group allocation method distributes shares based on the amount of available equity in each account. The system calculates ratios based on the available equity in each account and allocates shares based on these ratios. When you use this method, you need to specify an order quantity.

For example, say your account group includes three accounts, A, B and C with available equity of 25,000, 50,000 and $100,000, respectively. In this case, the system calculates a ratio of 1:2:4. If you place an order for 700 shares of a stock, it allocates 100 shares to Client A, 200 shares to Client B, and 400 shares to Client C.

```py
order_properties = InteractiveBrokersOrderProperties()
order_properties.fa_method = "AvailableEquity"
self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Subscription Requirements

To use FA group orders through our Interactive Brokers integration, you need to connect as a member of a Trading Firm and Institution organization. If you aren't currently on either of these tiers, upgrade your organization .

Live Trading

Reconciliation

Introduction

Algorithms usually perform differently between backtesting and live trading over the same time period. Backtests are simulations where we model reality as close as possible, but the modeling isn't always perfect. To measure the performance differences, we run an out-of-sample (OSS) backtest in parallel to all of your live trading deployments. The live results page displays the live equity curve and the OOS backtest equity curve of your algorithms.

If your algorithm is perfectly reconciled, it has an exact overlap between its live and OOS backtest equity curves. Deviations mean that the performance of your algorithm has differed between the two execution modes. Several factors can contribute to the deviations.

To generate the OOS reconciliation curve for a live deployment and overlay live vs. backtest equity and order fills from the Research Environment, see Live Reconciliation .

Differences From Data

The data that your algorithm uses can cause differences between backtesting and live trading performance.

Data Providers

QuantConnect provides high-quality historical data for all supported asset classes . However, our live data provider lacks data feeds for equity options, index options, and futures options. If your algorithm trades these asset classes, you must rely on brokerage or third-party data feeds.

Look-Ahead Bias

The Time Frontier minimizes the risk of look-ahead bias in backtests, but it does not completely eliminate the risk of look-ahead bias. For instance, if you use a custom dataset that contains look-ahead bias, your algorithm's live and backtest equity curves may deviate. To avoid look-ahead bias with custom datasets, set a `period` on your custom data points so that your algorithm receives the data points after the `time + period` .

Discrete Time Steps

In backtests, we inject data into your algorithm at predictable times, according to the data resolution. In live trading, we inject data into your algorithm when new data is available. Therefore, if your algorithm has a condition with a specific time (i.e. time is 9:30:15), the condition may work in backtests but it will always fail in live trading since live data has microsecond precision. To avoid issues, either use a time range in your condition (i.e. 9:30:10 < time < 9:30:20), use a rounded time, or use a Scheduled Event.

Custom Data Emission Times

Custom data is often timestamped to midnight, but the data point may not be available in reality until several days after that point. If your custom dataset is prone to this delay, your backtest may not fetch the same data at the same time or frequency that your live trading algorithm receives the data, leading to deviations between backtesting and live trading. To avoid issues, ensure the timestamps of your custom dataset are the times when the data points would be available in reality.

In backtesting, LEAN and custom data are perfectly synchonized. In live trading, daily and hourly data from a custom data source are not because of the frequency that LEAN checks the data source depends on the `resolution` argument. The following table shows the polling frequency of each resolution:

Resolution	Update Frequency
Daily	Every 30 minutes
Hour	Every 30 minutes
Minute	Every minute
Second	Every second
Tick	Constantly checks for new data

Split Adjustment of Indicators

Backtests use adjusted price data by default. Therefore, if you don't change the data normalization mode , the indicators in your backtests are updated with adjusted price data. In contrast, if a split or dividend occurs in live trading, your indicators will temporarily contain price data from before the corporate event and price data from after the corporate event. If this occurs, your indicators will produce different signals in your backtests compared to your live trading deployment. To avoid issues, reset and warm up your indicators when your algorithm receives a corporate event.

Tick Slice Sizes

In backtesting, we collect ticks into slices that span 1 millisecond before injecting them into your algorithm. In live trading, we collect ticks into slices that span up to 70 milliseconds before injecting them into your algorithm. This difference in slice sizes can cause deviations between your algorithm's live and OOS backtest equity curves. To avoid issues, ensure your strategy logic is compatible with both slice sizes.

Opening and Closing Auctions

The opening and closing price of the day is set by very specific opening and closing auction ticks. When a stock like Apple is listed, it’s listed on Nasdaq. The open auction tick on Nasdaq is the price that’s used as the official open of the day. NYSE, BATS, and other exchanges also have opening auctions, but the only official opening price for Apple is the opening auction on the exchange where it was listed.

We set the opening and closing prices of the first and last bars of the day to the official auction prices. This process is used for second, minute, hour, and daily bars for the 9:30 AM and 4:00 PM Eastern Time (ET) prices. In contrast, other platforms might not be using the correct opening and closing prices.

The official auction prices are usually emitted 2-30 seconds after the market open and close. We do our best to use the official opening and closing prices in the bars we build, but the delay can be so large that there isn't enough time to update the opening and closing price of the bar before it's injected into your algorithms. For example, if you subscribe to second resolution data, we wait until the end of the second for the opening price but most second resolution data won’t get the official opening price. If you subscribe to minute resolution data, we wait until the end of the minute for the opening auction price. Most of the time, you’ll get the actual opening auction price with minute resolution data, but there are always exceptions. Nasdaq and NYSE can have delays in publishing the opening auction price, but we don’t have control over those issues and we have to emit the data on time so that you get the bar you are expecting.

Data Updates

Data issues are incorrect or missing values in a dataset. These issues are generally a result of human error or from mistakes in the data collection process. Data issues can be reported by any QuantConnect member. When data issues are reported and verified, our Data Team works to quickly resolve them. Thanks to the communal efforts of the QuantConnect members, the QuantConnect data is reviewed and fixed by over 250,000 people, giving you a very high-quality source of data.

Data updates change backtest results and, consequently, cause differences between backtesting running with fixed data and live trading. For more information on common data issues, please refer to the data issues documentation .

Differences From Modeling

The modeling that your algorithm uses can cause differences between backtesting and live trading performance.

Reality Modeling Error

We provide brokerage models to model fees, slippage, and order fills in backtests. However, these model predictions may not always match the fees that your live algorithm incurs, leading to deviations between backtesting and live trading. You can adjust the reality models that your algorithm uses to more accurately reflect the specific assets that you're trading. For more information about reality models, see Reality Modeling .

Market Impact

We don't currently model market impact. So, if you are trading large orders, your fill prices can be better during backtesting than live trading, causing deviations between backtesting and live trading. To avoid issues, implement a custom fill model in your backtests that incorporates market impact.

Fills

In backtests, orders fill immediately. In live trading, they are sent to your brokerage and take about half a second to execute. If you fill an order in a backtest with stale data, deviations between backtesting and live trading can occur because the order is filled at a price that is likely different from the real market price. Stale order fills commonly occur in backtests when you create a Scheduled Event with an incompatible data resolution. For instance, if you subscribe to hourly data, place a Scheduled Event for 11:15 AM, and fill an order during the Scheduled Event, the order will fill at a stale price because the data between 11:00 AM and 11:15 AM is missing. To avoid stale fills, only place orders when your algorithm receives price data.

In live trading, your brokerage provides the fill price of your orders. Since the backtesting brokerage models do not know the price at which live orders are filled, the fill price of backtest orders is based on the best price available in the current backtesting data. Similarly, limit orders can fill at different prices between backtesting and live trading. In backtesting, limit orders fill as soon as the limit price is hit. In live trading, your brokerage may fill the same limit order at a different price or fail to fill the order, depending on the position of your order in their order book.

Borrowing Costs

By default, LEAN doesn't simulate the cost of borrowing shorts in backtests, but you can enable them by setting a margin interest model.

Differences From Brokerage

The brokerage that your algorithm uses can cause differences between backtesting and live trading performance.

Portfolio Allocations on Small Accounts

If you trade a small portfolio, it's difficult to achieve accurate portfolio allocations because shares are usually sold in whole numbers. For instance, you likely can't allocate exactly 10% of your portfolio to a security. You can use fractional shares to achieve accurate portfolio allocations, but not all brokerages support fractional shares. To get the closest results when backtesting and live trading over the same period, ensure both algorithms have the same starting cash balance.

Different Backtest Parameters

If you don't start your backtest and live deployment on the same date with the same holdings, deviations can occur between backtesting and live trading. To avoid issues, ensure your backtest parameters are the same as your live deployment.

Non-deterministic State From Algorithm Restarts

If you stop and redeploy your live trading algorithm, it needs to restart in a stateful way or else deviations can occur between backtesting and live trading. To avoid issues, redeploy your algorithm in a stateful way using the `set_warm_up` and `history` methods. Furthermore, use the Object Store to save state information between your live trading deployments.

Existing Portfolio Securities

If you deploy your algorithm to live trading with a brokerage account that has existing holdings, your live trading equity curve reflects your existing positions, but the backtesting curve won't. Therefore, if you have existing positions in your brokerage account when you deploy your algorithm to live trading, deviations will occur between backtesting and live trading. To avoid issues, deploy your algorithm to live trading using a separate brokerage account or subaccount that does not have existing positions.

Brokerage Limitations

We provide brokerage models that support specific order types and model your buying power. In backtesting, we simulate your orders with the brokerage model you select. In live trading, we send your orders to your brokerage for execution. If the brokerage model that you use in backtesting is not the same brokerage that you use in live trading, deviations may occur between backtesting and live trading. The deviations can occur if your live brokerage doesn't support the order types that you use or if the backtesting brokerage models your buying power with a different methodology than the real brokerage. To avoid brokerage model issues, set the brokerage model in your backtest to the same brokerage that you use in live trading.

Differences From Third-Party Indicators

The values of our indicators can sometimes produce different results than the indicators on other platforms. There can be several reasons for these discrepancies.

Price Differences

If you find differences in indicator values, compare the prices that are fed into the indicator on each platform. If the input data is slightly different, the indicator values will be different. To test if it's a difference in price data, feed in the data from the third-party platform into our indicators. We validate the indicators against third-party sources and when the values are the same, the indicator values are similar too.

Timestamp Differences

We timestamp our data to the time when the period ends. Many other platforms timestamp to the beginning of the candle.

Implementation Differences

Some indicators can have slightly different default arguments for their implementation. A common difference across platforms is to use a different `MovingAverageType` for the indicators. To view the default arguments for all our indicators, see Supported Indicators . To view the full implementation of our indicators, see the LEAN GitHub repository .

Warm Up Period Differences

Some platforms use all of the historical data to warm up their indicators while LEAN indicators have a fixed number of bars they need to warm up. As a result, indicators with long memory like the Exponential Moving Average can have slightly different values across platforms.

Risk Free Interest Rate Differences

Some indicators, like Sharpe ratios and Sortino ratios , are a function of the risk free interest rate . LEAN provides several different ways to define the interest rate, which can lead to different indicator values compared to other platforms.

Differences From Real-time Scheduled Events

In live trading, Scheduled Events execute in a parallel thread based on a real-time clock. If you set a Scheduled Event to fire at 10:00 AM, it executes at exactly 10:00 AM. In backtesting, Scheduled Events are part of the main algorithm manager loop, so they may not execute exactly when you set them. For example, if your algorithm subscribes to minute resolution US Equity data with regular trading hours and you set a Scheduled Event to occur at 2:00 AM, your Scheduled Event will execute at 9:31 AM when the next bar is fed into your algorithm.

The difference between live trading and backtesting is important to note because it can affect your algorithm's behavior. There are two common scenarios to consider.

Execution Timing and Backtest Timeouts

Take the following scenario:

- You set Scheduled Events for 2:00 AM, 3:00 AM, and 4:00 AM each day.
- Each Scheduled Event takes eight minutes to execute.
- Your algorithm only subscribes to US Equity securities without extended market hours (9:30 AM - 4:00 PM).

In this scenario, the Scheduled Events each fire at the correct time and execute without error in live trading. In backtesting, all of the Scheduled Events execute at 9:31 AM when your algorithm receives the first bar of the trading day. Since all the Scheduled Events take eight minutes to execute, the algorithm tries to execute all the Scheduled Events but reaches the 10-minute timeout and the backtest stops execution.

Live Data Delays

In backtests, your algorithm receives data at perfect timing. If you request minute resolution data, your algorithm receives the bars at the top of each minute. In live trading, bars have a slight delay, so you may receive them milliseconds after the top of each minute. Take the following scenario:

- You subscribe to minute resolution data
- You set a Scheduled Event for 10:00 AM
- The Scheduled Event checks the current asset price

In live trading, the Scheduled Event executes at exactly 10:00 AM but your algorithm may receive the 9:59-10:00 AM bar at 10:00:00.01 AM. Therefore, when you check the price in the Scheduled Event, the price from the 9:58-9:59 AM bar is the latest price. In backtesting, the Scheduled Event gets the price from the 9:59-10:00 AM bar since your algorithm receives the bar at perfect timing.

Live Trading

Notifications

Introduction

Set up some live trading notifications so that you are notified of market events and your algorithm's performance. QuantConnect Cloud supports email, SMS, webhooks, and Telegram notifications for live trading algorithms. If you run local algorithm with LEAN or the LEAN CLI, the notification services aren't available. To view the number of notification you can send for free in QuantConnect Cloud, see the Live Trading Notification Quotas . Notifications are different from commands because notifications enable you to send information out of your algorithm while commands enable you to manually call methods in your algorithm as it runs.

Email

Email notifications can include up to 10KB of text content in the message body. These notifications can be slow since they go through your email provider. If you don't receive an email notification that you're expecting, check your junk folders.

To send email notifications in your code files, run:

```
PY
message = "2023-07-13T12:20:00.2033226Z,EURUSD,1.11853,89187,Market,Filled,99758.33511"
self.notify.email(address="quant@office.com", subject="Last Trade", message=message)
```

You can include an attachment and set its name.

```
PY
attachment = "2023-07-13T12:20:00.2033226Z,EURUSD,1.11853,89187,Market,Filled,99758.33511"
headers = { "filename": "trades.csv" }
self.notify.email(address="quant@office.com", subject="Last Trade", message="See attachment", data=attachment, headers=headers)
```

If you don't provide headers, the attachment name is attachment.txt .

FTP

FTP notifications send files to your FTP server. You can use password and SSH authentication.

To send a file to your FTP server in your code files, run:

```
PY
file_content = "2023-07-13T12:20:00.2033226Z,EURUSD,1.11853,89187,Market,Filled,99758.33511"
self.notify.ftp(hostname="myftpserver.com", username="admin", password="12345", file_path="trades.csv", file_content=file_content,
port=21)
```

To send a file to your SFTP server in your code files, run:

```
PY
file_content = "2023-07-13T12:20:00.2033226Z,EURUSD,1.11853,89187,Market,Filled,99758.33511"
self.notify.sftp(hostname="mysftpserver.com", username="admin", password="12345", file_path="trades.csv", file_content=file_content,
port=21)
```

You can use password authentication over SFTP using SSH keys.

```
PY
file_content = "2023-07-13T12:20:00.2033226Z,EURUSD,1.11853,89187,Market,Filled,99758.33511"
self.notify.sftp(hostname="mysftpserver.com", username="admin", private_key="12345", private_key_passphrase="67890",
file_path="trades.csv", file_content=file_content, port=21)
```

The `file_path` parameter is path to file on the FTP server. The `port` parameter is optional.

SMS

SMS notifications are the only type of notification that you don't need an internet connection to receive. They can include up to 1,600 characters of text content in the message body.

To send SMS notifications in your code files, run:

```py
message = "2023-07-13T12:20:00.2033226Z,EURUSD,1.11853,89187,Market,Filled,99758.33511"
self.notify.sms(phone_number="+100503016366", message=message)
```

Telegram

Telegram notifications are automated messages to a Telegram group.

To send Telegram notifications in your code files, run:

```py
message = "2023-07-13T12:20:00.2033226Z,EURUSD,1.11853,89187,Market,Filled,99758.33511"
self.notify.telegram(id="-503016366", message=message, token="1234")
```

The `id` argument is your Telegram group Id. Your group Id is in the URL when you open your group chat in the Telegram web interface. For example, the group Id of web.telegram.org/z/#-503016366 is -503016366.

The `token` optional argument is a token of a bot you must add to your Telegram group. To create a bot, chat with @BotFather and follow its instructions. If you want to use our bot, the username is @quantconnect_notifications_bot.

To add emoticons to your `message` , convert the emoticon character to UTF-32 with the Unicode Converter on the Branah website. For example, the rocket emoji is `0001f680` in UTF-32 format, so use `\U001f680` in your message.

Webhooks

Webhook notifications are an HTTP-POST request to a URL you provide. The request is sent with a timeout of 300s. You can process these notifications on your web server however you want. For instance, you can inject the content of the notifications into your server's database or use it to create other notifications on your own server.

To send webhook notifications in your code files, run:

```py
data = ""
headers = { 'Authorization': 'Basic XXXXX' }
self.notify.web(address="http://api.myserver.com", data=data, headers=headers)
```

The `data` argument can be a `string` , `float` , or `int` object .

To send a webhook to a Discord server, generate a webhook URL (for instructions, see Intro to Webhooks in the Discord Help Center) and serialize the data in a dictionary with a `content` key.

```py
discord_url = "https://discord.com/api/webhooks/.../..."
self.notify.web(discord_url, json.dumps({'content': 'Hello world!'}))
```

Receive Notifications

To receive external notification in your algorithm, see Commands .

Terms of Use

The notification system can't be used for data distribution.

Examples

The following examples demonstrate common practices for sending notifications in live algorithms.

Example 1: Pre-Open Order Error

The following algorithm simulate extended market hour trading on Tradier Brokerage . We place a market-on-open order at 7:30am and expect the

order cannot submit to the broker since it is not supported, resulting into an error.

```py
class OrderErrorsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Simulate Tradier brokerage, which does not support the market-on-open orders.
        self.set_brokerage_model(BrokerageName.TRADIER_BROKERAGE, AccountType.CASH)

        # Request extended market hour SPY data for trading.
        self.spy = self.add_equity("SPY", extended_market_hours=True).symbol

        # Set a scheduled event to trade 2 hours pre-open to place the market-on-open-order.
        self.schedule.on(
            self.date_rules.every_day(self.spy),
            self.time_rules.before_market_open(self.spy, 120),
            self.open_position
        )

    def open_position(self) -> None:
        # Buy on market open will result in an error since Tradier does not support it.
        self.market_on_open_order(self.spy, 10)

    # It will be triggered on live trading.
    def on_brokerage_message(self, message: BrokerageMessageEvent) -> None:
        if message.type == BrokerageMessageType.ERROR:
            self.log(f"{self.time}: {message.type}: Message: {message.message}")
```

Other Examples

For more examples, see the following algorithms:

Demonstration Algorithm
LiveFeaturesAlgorithm.py Python

Live Trading

Commands

Introduction

Commands enable you to manually call methods in your live algorithm as it runs. You can command live projects to update your algorithm state, place orders, or run any other logic. Commands are different from notifications because notifications enable you to send information *out* of your algorithm while commands enable you to send information *into* your algorithm.

Basic Usage

To receive and handle generic commands in your algorithm, define the `on_command` method. This method receives the data you want to inject into your algorithm and returns a boolean that represents if the command was successful.

```
PY
class BasicCommandAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_benchmark(lambda x: 1) # So the algorithm needs no asset data.

    def on_command(self, data):
        self.log(f'Got command at {self.time} with data: {data}')
        return True
```

To invoke the `on_command` event handler, send a payload (for example, `{"ticker": "AAPL", "quantity": 1}`) through the QuantConnect REST API or LEAN CLI . The keys of the payload become the members of the `data` object.

Encapsulate Event Handlers

To encapsulate the command handler logic, define isolated classes. Command classes should extend the `Command` class. Extensions of the `Command` class must implement a `run` method, which receives the payload you send and returns a boolean that represents if the command was successful. To add the command to your algorithm, call the `add_command` method.

```
PY
class EncapsulatedCommandAlgorithm(QCAlgorithm):

    def initialize(self):
        MyCommand.ALGORITHM = self
        self.add_command(MyCommand)
        self.set_benchmark(lambda x: 1) # So the algorithm doesn’t need asset data.

    def do_something(self):
        self.log('Something was done!')

class MyCommand(Command):
    ALGORITHM = None
    ticker = None
    quantity = None
    parameters = {}

    def run(self, algorithm):
     if not MyCommand.ALGORITHM:
            algorithm.log('Please set the static reference to the ALGORITHM attribute in the initialize method: `MyCommand.ALGORITHM =
self`')
            return False
        algorithm.log(f"ticker: {self.ticker}; quantity: {self.quantity}; parameters: {self.parameters}")
        MyCommand.ALGORITHM.do_something()
        return True
```

To invoke the `run` method of the class you define, send a payload with a `$type` key (for example, `{"ticker": "AAPL", "quantity": 1, "$type": "MyCommand"}`). The value of the `$type` key must be the `Command` class you define. The other keys of the payload set the members of the class. If you don’t provide a `$type` key, LEAN runs the `on_command` method instead of the `run` method in your custom `Command` class.

To access your algorithm's attributes, you need to create a global static variable , and assign the reference to the global variable in the algorithm's `initialize` . Then, in the `run` merhod, you can acess your algorithm's attributes through the global.

Send Command Link

You can create the command in your algorithm and then send yourself an email notification with a link inside it. When you click the link, it then executes the event handler in your algorithm. To create the link, call the `link` method. The following algorithm demonstrates how send command requests for the `on_command` event handler:

```
PY
class BasicLinkedCommandAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_benchmark(lambda x: 1) # So the algorithm needs no asset data.
        link = self.link({"ticker": "AAPL", "quantity": 1})
        self.notify.email("email@address.com", "Run Command?", f"Click here to run: {link}")

    def on_command(self, data):
        self.log(f'Got command at {self.time} with data: {data}')
        return True
```

The following algorithm demonstrates how to send command requests for an event handler you encapsulate in a class:

```
PY
class EncapsulatedAndLinkedCommandAlgorithm(QCAlgorithm):

    def initialize(self):
        self.add_command(MyCommand)
        self.set_benchmark(lambda x: 1) # So the algorithm doesn't need asset data.
        potential_command = MyCommand()
        potential_command.ticker = 'AAPL'
        potential_command.quantity = 1
        potential_command.parameters = {"tag": "Signal X"}
        link = self.link(potential_command)
        self.notify.email("email@address.com", "Run Command?", f"Click here to run: {link}")

class MyCommand(Command):
    ticker = None
    quantity = None
    parameters = {}

    def run(self, algorithm):
        algorithm.log(f"ticker: {self.ticker}; quantity: {self.quantity}; parameters: {self.parameters}")
        return True
```

Broadcast Command

You can create the command in your algorithm and then broadcast it to all live algorithms in your organization, except the source algorithm and commands of unregisted type name. The following algorithm demonstrates how broadcast a command to the `on_command` event handler in all your live algorithms:

```
PY
class BasicBroadcastCommandAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_benchmark(lambda x: 1) # So the algorithm needs no asset data.
        link = self.broadcast_command({"ticker": "AAPL", "quantity": 1})

    def on_command(self, data):
        self.log(f'Got command at {self.time} with data: {data}')
        return True
```

You can control the command data by encapsulating the event handler in a class. The following algorithm demonstrates how to broadcast a command for an event handler you encapsulate in a class:

```
class EncapsulatedAndBroadcastCommandAlgorithm(QCAlgorithm):

    def initialize(self):
        self.add_command(MyCommand)
        self.set_benchmark(lambda x: 1) # So the algorithm doesn't need asset data.
        potential_command = MyCommand()
        potential_command.ticker = 'AAPL'
        potential_command.quantity = 1
        potential_command.parameters = {"tag": "Signal X"}
        broadcast_result = self.broadcast_command(potential_command)

class MyCommand(Command):
    ticker = None
    quantity = None
    parameters = {}

    def run(self, algorithm):
        algorithm.log(f"ticker: {self.ticker}; quantity: {self.quantity}; parameters: {self.parameters}")
        return True
```

Send Commands by API

To send a command to your algorithm, send a payload through the QuantConnect REST API or LEAN CLI . Follow these steps to send a command from the command line. In this case, the script calls the `on_command` method.

1. Install the `requests` library, if you haven't already.

```
pip install requests
```

2. Save the following code as `send_command.py` .

```
from base64 import b64encode
from hashlib import sha256
from time import time
from sys import argv
from requests import post

# Edit these values:
USER_ID = 0
API_TOKEN = '_____'
PROJECT_ID = <project_id>

BASE_URL = 'https://www.quantconnect.com/api/v2/'

def get_headers():
    # Get timestamp
    timestamp = f'{int(time())}'
    time_stamped_token = f'{API_TOKEN}:{timestamp}'.encode('utf-8')

    # Get hased API token
    hashed_token = sha256(time_stamped_token).hexdigest()
    authentication = f'{USER_ID}:{hashed_token}'.encode('utf-8')
    authentication = b64encode(authentication).decode('ascii')

    # Create headers dictionary.
    return {
        'Authorization': f'Basic {authentication}',
        'Timestamp': timestamp
    }

def create_command(project_id, command):
    return post(
        f'{BASE_URL}/live/commands/create',
        headers=get_headers(),
        json={"projectId": project_id, "command": command}
    ).json()

# Read the ticker, quantity, and (optional) command type from the command line:
ticker = argv[1]
quantity = int(argv[2])
command = {'ticker': ticker, 'quantity': quantity}
if len(argv) > 3:
    command['$type'] = argv[3]
print(create_command(PROJECT_ID, command))
```

3. Replace the placeholder values at the top of the file with your user Id, API token, and project Id.
4. Run the script, passing the ticker and quantity as arguments. The first form below calls the `on_command` method; the second adds an optional third argument that sets the `$type` key to route to an encapsulated `Command` subclass handler.

```
python send_command.py AAPL 1
python send_command.py AAPL 1 MyCommand
```

To get your user Id and API token, see Request API Token .

Broadcast Commands by API

To broadcast a command to your live algorithms, send a payload through the QuantConnect REST API or LEAN CLI . Follow these steps to broadcast a command to all projects in your organization from the command line.

1. Install the `requests` library, if you haven't already.

```
pip install requests
```

2. Save the following code as `broadcast_command.py` .

```
from base64 import b64encode
from hashlib import sha256
from time import time
from sys import argv
from requests import post

# Edit these values:
USER_ID = 0
API_TOKEN = '_____'
ORGANIZATION_ID = '_____'

BASE_URL = 'https://www.quantconnect.com/api/v2/'

def get_headers():
    # Get timestamp
    timestamp = f'{int(time())}'
    time_stamped_token = f'{API_TOKEN}:{timestamp}'.encode('utf-8')

    # Get hased API token
    hashed_token = sha256(time_stamped_token).hexdigest()
    authentication = f'{USER_ID}:{hashed_token}'.encode('utf-8')
    authentication = b64encode(authentication).decode('ascii')

    # Create headers dictionary.
    return {
        'Authorization': f'Basic {authentication}',
        'Timestamp': timestamp
    }

def broadcast_command(command):
    return post(
        f'{BASE_URL}/live/commands/broadcast',
        headers=get_headers(),
        json={"organizationId": ORGANIZATION_ID, "command": command}
    ).json()

# Read the ticker, quantity, and (optional) command type from the command line:
ticker = argv[1]
quantity = int(argv[2])
command = {'ticker': ticker, 'quantity': quantity}
if len(argv) > 3:
    command['$type'] = argv[3]
print(broadcast_command(command))
```

3. Replace the placeholder values at the top of the file with your user Id, API token, and organization Id.
4. Run the script, passing the ticker and quantity as arguments. The first form below calls the `on_command` method; the second adds an optional third argument that sets the `$type` key to route to an encapsulated `Command` subclass handler.

```
python broadcast_command.py AAPL 1
python broadcast_command.py AAPL 1 MyCommand
```

To get your user Id, API token, and organization Id, see Request API Token and Get Organization Id .

Examples

The following examples demonstrate common practices for implementing live commands.

Example 1: Grey Box

The following algorithm trades a simple EMA cross strategy on SPY. However, instead of direct ordering by the algorithm as a "black box", it sends an email to ask for clicking a confirmation link before ordering, making each order decision an informed manual decision. The algorithm is called a "grey box".

```py
class LiveCommandAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 12)
        self.set_end_date(2024, 10, 1)
        self.set_cash(1000000)

        # Request SPY data to trade.
        self.spy = self.add_equity("SPY").symbol
        # Create an EMA indicator to generate trade signals.
        self._ema = self.ema(self.spy, 20, Resolution.DAILY)
        # Warm-up indicator for immediate readiness.
        self.warm_up_indicator(self.spy, self._ema, Resolution.DAILY)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self.spy)
        if bar and self.live_mode:
            # Trend-following strategy using price and EMA.
            # If the price is above EMA, SPY is in an uptrend, and we buy it.
            # We sent a link to our email address and await confirmation.
            if bar.close > self._ema.current.value and not self.portfolio[self.spy].is_long:
                link = self.link({"ticker": "SPY", "size": 1})
                self.notify.email("email@address.com", "Trade Confirmation Needed", f"Click here to run: {link}")
            elif bar.close < self._ema.current.value and not self.portfolio[self.spy].is_short:
                link = self.link({"ticker": "SPY", "size": -1})
                self.notify.email("email@address.com", "Trade Confirmation Needed", f"Click here to run: {link}")

    def on_command(self, data: DynamicData) -> Optional[bool]:
        # The algorithm will place the order if we click the email link to confirm the trade.
        self.set_holdings(data["ticker"], data["size"])
        return True
```

Example 2: Parent-Child Communication

Parent algorithm

The parent algorithm is connected to a brokerage. It receives commands from other algorithms and places market orders based on those commands.

```py
class ParentAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100_000)

        # Remove benchmark so doesn't need asset data.
        self.set_benchmark(lambda x: 1)

        # Seed each asset with it's price to trade right away.
        self.settings.seed_initial_prices = True

    def on_command(self, payload):
        self.log(f'{self.time} - Execute on_command(): {payload}')
        equity = self.add_equity(payload.ticker)

        if payload.email:
            self.notify.email(address=payload.email, subject=f"Order Executed from {payload.source}", message=f"{equity.symbol},
{payload.quantity}, {payload.source}")

        self.market_order(equity.symbol, payload.quantity, asynchronous=True, tag=payload.source)
        return True
```

Child algorithm

The child algorithm is connected to a paper trading account. It contains the trading logic and sends commands to the parent algorithm for execution.

```py
class ChildAlgorithm (QCAlgorithm):
    def initialize(self):
        # Set the initials to identify the sender and the cash this algorithm will use.
        self._initials = 'C1'
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(10_000)

    def on_order_event(self, order_event: OrderEvent):
        # When an order is filled, we send a command to the parent algorithm with the order details.
        if order_event.status == OrderStatus.FILLED:
            self.log(f'{self.time} - Sending command')
            response = send(self, order_event.symbol.value, order_event.fill_quantity, self._initials)
            self.log(f'{self.time} - Command response {response}')

def send(algorithm, ticker, quantity, name):
    if not algorithm.live_mode:
        return ''
    # Set the project ID with the ID of your parent algorithm.
    algorithm.project_id = 30123456
    # Generate the command link with the desired data payload, and execute with download_data.
    link = algorithm.link({'ticker': ticker, 'quantity': quantity, 'name': name})
    return Extensions.download_data(link)
```

Live Trading

Arbitrage

Introduction

Arbitrage is the practice of taking advantage of a price difference between two or more markets. QuantConnect supports arbitrage strategies by allowing you to run multiple live algorithms deployments simultaneously and communicate between them using commands .

Basic Implementation

You can broadcast a command from and execute the event handler in another project. Add the project ID to the command data to identify the source of the command:

```py
class BasicBroadcastCommandAlgorithm(QCAlgorithm):
    def initialize(self):
        self.set_benchmark(lambda x: 0) # So the algorithm needs no asset data.
        broadcast_result = self.broadcast_command({"sender": self.project_id, "ticker": "AAPL", "quantity": 1})

    def on_command(self, data):
        # Receive the command from the other algorithm
        self.log(f'Got command at {self.time} with data: {data}')
        return True
```

Examples

The following examples demonstrate common practices for implementing arbitrage algorithms.

Example 1: Long-short Bitcoin in two exchanges

The following algorithms trade an arbitrage strategy with BTCUSDT.

Primary algorithm

The primary algorithm trades a simple EMA cross strategy on BTCUSDT in Kraken. It broadcasts a command with the order filled quantity to all live deployments, and logs the command data it receives from the secondary algorithm.

```py
class CryptoArbitrageA(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_account_currency('USDT', 100000)

        # Set the brokerage model to trade on Kraken.
        self.set_brokerage_model(BrokerageName.KRAKEN, AccountType.MARGIN)
        # Request BTCUSDT data to trade.
        self._btc = self.add_crypto("BTCUSDT").symbol
        # Create an EMA indicator to generate trade signals.
        self._ema = self.ema(self._btc, 22)
        # Warm-up indicator for immediate readiness.
        self.warm_up_indicator(self._btc, self._ema)
        # Trade when the EMA is updated.
        self._ema.updated += self.trade
        # Set a threshold value for the EMA cross.
        self._threshold = 0.005

    def trade(self, _, current: IndicatorDataPoint) -> None:
        ema = current.value
        holdings = self.portfolio[self._btc]
        price = holdings.security.price

        # Trend-following strategy using price and EMA.
        # If the price is above EMA, SPY is in an uptrend, and we buy it.
        if not holdings.is_long and price > ema * (1+self._threshold):
            self.set_holdings(self._btc, 1)
        elif not holdings.is_short and price < ema * (1-self._threshold):
            self.set_holdings(self._btc, -1)

    def on_command(self, data: DynamicData) -> Optional[bool]:
        # The algorithm will log the command data from the secondary algorithm.
        self.log(f'Got command at {self.time} with data: {data}')
        return True

    def on_order_event(self, order_event: OrderEvent) -> None:
        # If an order is filled, we call the broadcast_command method to send a command to all live deployments.
        # You can add the project ID to the command data to identigy the sender.
        if not self.live_mode or order_event.status != OrderStatus.FILLED:
            return
        broadcast_result = self.broadcast_command({"sender": self.project_id, "ticker": f"{order_event.symbol.value}", "quantity":
self.portfolio[order_event.symbol].quantity})
```

Secondary algorithm

The secondary algorithm trades the opposite direction of the primary in Bybit using the command it receives from the primary algorithm. It broadcasts a command with the order filled quantity to all live deployments.

```py
class CryptoArbitrageB(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_account_currency('USDT', 100000)

        # Set the brokerage model to trade on Bybit.
        self.set_brokerage_model(BrokerageName.BYBIT, AccountType.MARGIN)
        # Request BTCUSDT data to trade.
        self._btc = self.add_crypto("BTCUSDT").symbol

    def on_command(self, data: DynamicData) -> Optional[bool]:
        # The algorithm will trade the opposite direction of the primary algorithm.
        self.log(f'Got command at {self.time} with data: {data}')
        quantity = -(self.portfolio[self._btc].quantity + float(data.quantity))
        if quantity != 0:
            self.market_order(self._btc, quantity, tag=str(data))
        return True

    def on_order_event(self, order_event: OrderEvent) -> None:
        # If an order is filled, we call the broadcast_command method to send a command to all live deployments.
        # You can add the project ID to the command data to identify the sender.
        if not self.live_mode or order_event.status != OrderStatus.FILLED:
            return
        broadcast_result = self.broadcast_command({"sender": self.project_id, "ticker": f"{order_event.symbol.value}", "quantity":
self.portfolio[order_event.symbol].quantity})
```

Live Trading

Charting and Logging

Introduction

The live results page shows your algorithm's live trading performance. You can add custom charts and logs to the results page.

Charting

Charts are sampled every one and ten minutes. If you create 1-minute resolution custom charts, the IDE charting will downgrade the granularity and display the 10-minutes sampling after a certain amount of samples. There are not quotas in live trading.

Logging

Algorithms can record string messages ('log statements') to a file for analysis after a backtest is complete, or as a live algorithm is running. These records can assist in debugging logical flow errors in the project code. Consider adding them in the code block of an `if` statement to signify an error has been caught.

It's good practice to add logging statements to live algorithms so you can understand its behavior and keep records to compare against backtest results. If you don't add logging statements to a live algorithm and the algorithm doesn't trade as you expect, it's difficult to evaluate the underlying problem.

If you run algorithms on QuantConnect, you must stay within the log quota . To only log when your algorithm is live, use the `live_mode` property.

```
PY
if self.live_mode:
    self.log("My log message")
```

Runtime Statistics

Runtime statistics show the performace of your algorithm at a single moment in time.

The following table describes the default runtime statistics:

Statistic	Description
Equity	The total portfolio value if all of the holdings were sold at current market rates. Equity equals the sum of cash and the market value of all open positions.
Fees	The total quantity of fees paid for all the transactions during the algorithm's trading period. Total fees include brokerage commissions, exchange fees, and other transaction costs.
Holdings	The absolute sum of the items in the portfolio. Holdings represent the total market value of all positions, regardless of whether they are long or short.
Net Profit	The dollar-value return across the entire trading period.
PSR	The probability that the estimated Sharpe ratio of an algorithm is greater than a benchmark.
Return	The rate of return across the entire trading period.
Unrealized	The amount of profit a portfolio would capture if it liquidated all open positions and paid the fees for transacting and crossing the spread. Unrealized profit becomes realized profit when the positions are closed.
Volume	The total value of assets traded for all of an algorithm's transactions during the trading period.

For more information about runtime statistics, see Runtime Statistics .

Examples

The following examples demonstrate some common practices for logging in live algorithm.

Example 1: On Events And Trading Logic

The following example trades a simple EMA cross trend-following strategy on SPY. We log or debug messages in event handlers and trading logic changes to get information on any event flow.

```py
class LoggingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 12)
        self.set_end_date(2024, 10, 1)
        self.set_cash(1000000)

        # Request SPY data to trade.
        self.spy = self.add_equity("SPY").symbol
        # Create an EMA indicator to generate trade signals.
        self._ema = self.ema(self.spy, 20, Resolution.DAILY)

        # Warm up the algorithm for indicator readiness.
        self.set_warm_up(20, Resolution.DAILY)

    def on_warmup_finished(self) -> None:
        # Signals on warm-up finished.
        self.log("Warm up finished")

    def on_data(self, slice: Slice) -> None:
        bar = None if self.is_warming_up else slice.bars.get(self.spy)
        if bar:
            # Trend-following strategy using price and EMA.
            # If the price is above EMA, SPY is in an uptrend, and we buy it.
            if bar.close > self._ema.current.value and not self.portfolio[self.spy].is_long:
                self.debug("Trend changes to upwards")
                self.set_holdings(self.spy, 1)
            elif bar.close < self._ema.current.value and not self.portfolio[self.spy].is_short:
                self.debug("Trend changes to downwards")
                self.set_holdings(self.spy, -1)

    def on_order_event(self, order_event: OrderEvent) -> None:
        if order_event.status == OrderStatus.FILLED:
            # Log the order details if being filled.
            self.log(f"Order filled - Quantity: {order_event.quantity}")
```

Signal Exports

Key Concepts

Introduction

QuantConnect Signal Exports allows you to transmit the state of an algorithm's trading and portfolio positions to your fund or a third-party service. QuantConnect implements two signal services out of the box: Collective2 and Numerai . To send portfolio targets to your fund, you need to create a custom Signal Export implementation.

Add Providers

To export signals to a signal provider, during initialization , add a signal export provider.

```
self.signal_export.add_signal_export_provider(CustomSignalExport())
```

You can add multiple signal export providers to a single algorithm.

Send Portfolio Targets

The signal export manager automatically sends signals when your portfolio holdings change to your fund or a third-party service. By default, it waits five seconds after an order is filled to aggregate all the state changes into a single post. Set the `automatic_export_time_span` property to change the waiting time.

```
self.signal_export.automatic_export_time_span = timedelta(seconds=1)
```

To send targets that aren't based on your portfolio holdings, see Manual Exports .

To disable automatic exports, set the `automatic_export_time_span` property to `None` .

```
self.signal_export.automatic_export_time_span = None
```

Custom Signal Exports

Signal export providers must implement the `ISignalExportTarget` interface. Extensions of the `ISignalExportTarget` interface must define the `send` and the `dispose` methods.

The `send` receives a `SignalExportTargetParameters` object with a list of `PortfolioTarget` objects you can use to create the API request payload.

The `dispose` method is called when the algorithm is disposed. You can use this method to release unmanaged resources such as HTTP Clients.

```py
class CustomSignalExportExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the custom signal export provider
        self.add_equity("SPY")
        self.signal_export.add_signal_export_providers(CustomSignalExport())

    def on_data(self, slice: Slice) -> None:
        # Buy the SPY ETF when the algorithm is not invested
        if not self.portfolio.invested:
            self.set_holdings("SPY", 0.1)

# Define the custom signal export provider
from requests import post
class CustomSignalExport:
    def send(self, parameters: SignalExportTargetParameters) -> bool:
        # Create the request payload using the PortfolioTarget objects in the parameters
        # You can use the PortfolioTarget.Percent to calculate the target quantity
        # from the target percentage
        # The Tag property can be used to send additional information about the target
        # It's only available when you create the PortfolioTarget object with the tag parameter
        # See the Manual Exports documentation for more information
        targets = [PortfolioTarget.percent(parameters.algorithm, x.symbol, x.quantity, x.tag)
           for x in parameters.targets]
        data = [ {'symbol' : x.symbol.value, 'quantity': x.quantity, 'tag': x.tag} for x in targets ]

        # Send the request to your custom endpoint
        request_uri = "https://your-custom-endpoint.com/api/signal-export"
        response = post(request_uri, json = data)
        result = response.json()

        # Log the result of the request for debugging purposes
        success = result.get('success', False)
        parameters.algorithm.log(f"Send #{len(parameters.targets)} targets. Success: {success}")
        return success

    def dispose(self) -> None:
        pass
```

Manual Exports

In some cases, you may need to send signals to your fund or a third-party manually. For example, the signal export manager sends signals after a fill event and you need to submit signals when the market is closed or your signals aren't based on your portfolio holdings.

To do this, pass a `PortfolioTarget` object or a list of `PortfolioTarget` objects to the `set_target_portfolio` method. The method returns a boolean that represents if the targets were successfully sent to its destination. In this situation, the number you pass to the `PortfolioTarget` constructor represents the portfolio weight. Don't use the `PortfolioTarget.percent` method.

```py
target = PortfolioTarget(self._symbol, weight, tag="My tag")
success = self.signal_export.set_target_portfolio(target)
```

If you use a margin account, you can send your current portfolio holdings by calling the `set_target_portfolio_from_portfolio` method.

```py
success = self.signal_export.set_target_portfolio_from_portfolio()
```

Signal Exports

Collective2

Introduction

Collective2 is a service that connects strategy developers and capital allocators. With our Collective2 integration, you can send trading signals from your live algorithms to Collective2 .

Add Providers

To export signals to Collective2 from your algorithm, during initialization , add a Collective2 signal export provider.

```
self.signal_export.add_signal_export_provider(Collective2SignalExport(api_key, system_id, use_white_label_api))
```

The `Collective2SignalExport` constructor accepts the following arguments:

Argument: `api_key` Your Collective2 API key. To get your API key, see Where can I find my API key? on the Collective2 website. Data Type: `str`
Argument: `system_id` Your Collective2 strategy Id. To get your strategy Id, see How do I find my strategy ID? on the Collective2 website. Data Type: `int`
Argument: `use_white_label_api` Whether to use the white-label API instead of the general one. Data Type: `bool` | Default Value: `False`

You can add multiple signal export providers to a single algorithm.

Asset Classes

Our Collective2 integration supports signals for the following asset classes:

- US Equity
- Equity Options
- Forex
- Futures
- Index Options

Send Portfolio Targets

The signal export manager automatically sends signals when your portfolio holdings change to Collective2. By default, it waits five seconds after an order is filled to aggregate all the state changes into a single post. Set the `automatic_export_time_span` property to change the waiting time.

```
self.signal_export.automatic_export_time_span = timedelta(seconds=1)
```

To send targets that aren't based on your portfolio holdings, see Manual Exports .

To disable automatic exports, set the `automatic_export_time_span` property to `None` .

```
self.signal_export.automatic_export_time_span = None
```

Signal Exports

Numerai

Introduction

Numerai is a platform where you can earn rewards by uploading unique live trading signals for a universe of US Equities. The regular Numerai Tournament is built around a free dataset they provide , but with Numerai Signals , you can now use any dataset to generate your trading signals. Through our Numerai integration, you can use our rich library of alternative datasets or your own custom datasets to create and automate your Numerai Signal submissions.

Add Providers

To export signals to Numerai from your algorithm, during initialization , add a Numerai signal export provider.

```
self.signal_export.add_signal_export_provider(NumeraiSignalExport(public_id, secret_id, model_id, file_name))
```

The `NumeraiSignalExport` constructor accepts the following arguments:

Argument: `public_id` Your Numerai API key. To create and view your API keys, see the Automation section of your Account page on the Numerai website. Data Type: `str` | Default Value: `None`
Argument: `secret_id` Your Numerai API secret. You get your API secret when you create a new API key. Data Type: `str` | Default Value: `None`
Argument: `model_id` The Id of the Numerai model. Follow these steps to get the model Id: 1. Open the Models page on the Numerai website. 2. In the Models section, click the three dots next to a model. 3. Click Copy Model ID . Data Type: `str` | Default Value: `""`
Argument: `file_name` The name for the signal file. If you use a file name that already exists, the new file overwrites the old one. Data Type: `str` | Default Value: `"predictions.csv"`

You can add multiple signal export providers to a single algorithm.

Asset Classes

Our Numerai integration supports signals for US Equities .

Universe Selection

The Numerai Signals stock market universe covers roughly the top 5,000 largest stocks in the world. The universe available on QuantConnect that's the closest match to the Numerai Signals universe is the CRSP US Total Market Index, which represents approximately 100% of the investable US Equity market regularly traded on the New York Stock Exchange and Nasdaq. This Index doesn't contain all of the stocks in the Numerai Signals universe, but you don't need to submit signals for all the stocks in the Numerai Signals universe.

To get the constituents of the CRSP US Total Market Index, add an ETF constituents universe for the Vanguard Total Stock Market ETF, VTI.

```py
self.universe_settings.asynchronous = True
self.etf_symbol = self.add_equity("VTI").symbol
self.add_universe(self.universe.etf(self.etf_symbol))
```

Schedule Submissions

Every Tuesday, Wednesday, Thursday, Friday, and Saturday of the week, a new round is open for you to submit signals. Saturday rounds open at 18:00 UTC, and the submission window is open until Monday 14:30 UTC. Weekday rounds open at 13:00 UTC, and the submission window is open for 1 hour. For more information about the competition rounds, see Rounds in the Numerai documentation.

To schedule your submissions, you can set a Scheduled Event during initialization.

```py
self.schedule.on(
    self.date_rules.every_day(self.etf_symbol),
    self.time_rules.at(13, 0, TimeZones.UTC),
    self.submit_signals)
```

Send Portfolio Targets

To send targets, pass a list of `PortfolioTarget` objects to the `set_target_portfolio` method. The method returns a boolean that represents if the targets were successfully sent to Numerai Signals. In this situation, the number you pass to the `PortfolioTarget` constructor represents the portfolio weight. Don't use the `PortfolioTarget.percent` method.

```py
success = self.signal_export.set_target_portfolio(targets)
```

Signal Requirements

When you submit signals to Numerai, abide by the following rules:

- All signals must have a quantity between 0 and 1 (exclusive)
- You must submit at least 10 different signals per submission
- At least one of the weights in every batch of signals must be unique

Signal Exports

vBase

Introduction

validityBase enables you to create a globally credible, independently verifiable audit trail for trading track records, models and signals. This ensures anyone viewing your results can confirm that your results are point-in-time, complete, free from cherry-picking and fully out-of-sample.

QuantConnect users can use validityBase to publish live, verifiable, indices of their trading strategies and signals - increasing their credibility with allocators, clients and potential employers, and significantly increasing their commercial value. Integration is simple. With a single function call from your QuantConnect code, you can automatically build an immutable blockchain-backed audit trail for your signals and models.

Add Providers

To export signals to vBase from your algorithm, during initialization , add a vBase signal export provider.

```
self.signal_export.add_signal_export_provider(VBaseSignalExport(api_key, collection_name, store_stamped_file=True, idempotent=False))
```

The `VBaseSignalExport` constructor accepts the following arguments:

Argument: `api_key` Your vBase API key. You can find it in your profile Account Settings tab. Data Type: `str`
Argument: `collection_name` The name of the vBase collection to which the signals will be sent. You can create and manage collections in the vBase app Collections tab. Think of a collection like a strategy or dataset name. Data Type: `str`
Argument: `store_stamped_file` Whether to store a stamped copy of the signal in vBase. **Important** if this is marked "no", then you will be responsible for maintaining an exact copy of your stamped data. Losing or accidentally modifying stamped outputs will prevent your work from being verifiable. Data Type: `bool` | Default Value: `True`
Argument: `idempotent` Whether to make the signal export idempotent. If true, sending the same signal multiple times will only create one record in vBase. Data Type: `bool` | Default Value: `False`

You can add multiple signal export providers to a single algorithm.

Asset Classes

Our vBase integration supports all asset classes.

Send Portfolio Targets

To send targets, pass a list of `PortfolioTarget` objects to the `set_target_portfolio` method. The method returns a boolean value indicating whether the targets were successfully sent to vBase.

What gets stamped? The provider builds a `sym,wt` (symbol-weight) CSV directly from your portfolio targets. Each target's `Quantity` value is treated as the portfolio weight (percentage of holdings), so you should pass percentage-based targets (e.g., 0.25 for 25% of the portfolio). Default behavior can be customized by overriding the `BuildCsv` method of the `VBaseSignalExport` class.

```py
success = self.signal_export.set_target_portfolio(targets)
```

Strategy Name
CAPM Alpha Ranking Strategy on Dow 30 Companies Applies CAPM model to rank Dow Jones 30 companies.
Combining Mean Reversion and Momentum in Forex Market Combines momentum and mean reversion techniques in the forex markets.
Pairs Trading-Copula vs Cointegration Applies Copula and Cointergration method to pairs trading.
The Dynamic Breakout II Strategy A demonstration of dynamic breakout II strategy.
Dual Thrust Trading Algorithm A demontration of Dual Thrust Intraday strategy.
Can Crude Oil Predict Equity Returns Applies regression method to predict the return from the stock market and compare it to the short-term U.S. T-bill rate.
Intraday Dynamic Pairs Trading using Correlation and Cointegration Approach A high frequency pairs trading algorithm based on cointegration.
The Momentum Strategy Based on the Low Frequency Component of Forex Market Applies high frequency filter to the momentum strategy.
Stock Selection Strategy Based on Fundamental Factors MorningStar Fundamental factors universe selection algorithm.
Short-Term Reversal Strategy in Stocks A short term reversal algorithm which gives the opposite signal by analyzing recent period price action.

Fundamental Factor Long Short Strategy

A basic monthly rebalance long short algorithm based on fundamental factors.

Asset Class Trend Following

Selects ETFs over ten-month moving average and assigns an equally weighted allocation.

Source: Quantpedia

Asset Class Momentum

Selects ETFs in different asset classes with the highest momentum and assigns an equally weighted allocation.

Source: Quantpedia

Residual Momentum

Constructs a long/short portfolio based on trailing residual momentum normalized by its standard deviation

Source: Quantpedia

Sector Momentum

Selects ETFs in different sectors with the highest momentum and assigns an equally weighted allocation.

Source: Quantpedia

Overnight Anomaly

Buy SPY ETF at its closing price and sell it at the opening each day.

Source: Quantpedia

Forex Carry Trade

Goes long the currency with the highest central bank interest rate and goes short the currency with the lowest interest rate.

Source: Quantpedia

Volatility Effect in Stocks

Constructs equally weighted portfolios by selecting stocks with the lowest volatility in the past one year.

Source: Quantpedia

Forex Momentum

Goes long currencies with strongest 12 month momentum against USD and goes short currencies with the lowest 12 month momentum against USD.

Source: Quantpedia

Pairs Trading with Stocks

Looks for the security that minimizes the sum of squared deviations and long-short position is opened when pair prices have diverged by multiple of standard deviations.

Source: Quantpedia

Short Term Reversal

Goes long stocks with the lowest return in the previous month and goes short stocks with the greatest return from the previous month.

Source: Quantpedia

Momentum Effect in Stocks

Goes long stocks with the best 12-month momentum in the large-cap universe.

Source: Quantpedia

Momentum Effect in Country Equity Indexes

Goes long stocks with the best 12-month momentum in the country equity indexes ETFs.

Source: Quantpedia

Mean Reversion Effect in Country Equity Indexes

Goes long country equity indexes ETFs with the worst 36-month return and short ETFs with the best 36-month return.

Source: Quantpedia

Liquidity Effect in Stocks

Goes long stocks with the lowest turnover and short on stocks with the highest turnover from the lowest market-cap quartile.

Source: Quantpedia

Volatility Risk Premium Effect

Sells at-the-money straddle with one month until maturity and buys an offsetting 15% out-of-the-money puts each month.

Source: Quantpedia

Momentum Effect in Commodities Futures

Goes long commodity futures with the highest momentum and short on futures with the lowest momentum.

Source: Quantpedia

Small Capitalization Stocks Premium Anomaly

Goes long stocks with the lowest market capitalization and rebalances the portfolio once a year.

Source: Quantpedia

Paired Switching

Goes long asset with better performance over the last period and rebalances portfolio every quarter.

Source: Quantpedia

Term Structure Effect in Commodities

Buys each month the 20% of commodities with the highest roll-returns and shorts the 20% of commodities with the lowest roll-returns and holds the long-short positions for one month.

Source: Quantpedia

Momentum Effect Combined with Term Structure in Commodities

Portfolios are formed based on roll returns and the algorithm goes long and short contracts with the highest and lowest one-month performance.

Source: Quantpedia

Book-to-Market Value Anomaly

Quintile portfolios are formed based on the Book-to-Market ratio and the highest quintile is held for one year.

Source: Quantpedia

Gold Market Timing

Goes long gold when the Fed model shows that the market is undervalued (the earnings yield is higher than the bond yield and their ratio is at least 2).

Source: Quantpedia

Turn of the Month in Equity Indexes

Buys SPY the day before the end of the month and liquidates position on 3rd trading day of new month.

Source: Quantpedia

Momentum - Short Term Reversal Strategy

Goes long stocks with the decreasing return from the winner group and short stocks with the increasing return from the loser group.

Source: Quantpedia

Pairs Trading with Country ETFs

Identifies the price divergence from two highly correlated country ETFs and takes a market neutral position.

Source: Quantpedia

Sentiment and Style Rotation Effect in Stocks

Creates long-short positions of growth and value stocks based on the investment sentiment.

Source: Quantpedia

Asset Growth Effect

Creates long-short positions of stocks based on the annual change of their total assets.

Source: Quantpedia

Momentum and State of Market Filters

Goes long and short stocks with the highest and lowest six-month momentum respectively if the previous 12 months return on the broad market index was positive.

Source: Quantpedia

Accrual Anomaly

Decile portfolios are formed based on balance sheet based accruals and highest decile is shorted while lowest decile is bought for a year.

Source: Quantpedia

Momentum in Mutual Fund Returns

Forms a long-short portfolio of asset management firms based on trailing rate of change and nearness to trailing high.

Source: Quantpedia

Momentum and Style Rotation Effect

Goes long style index ETF with the highest 12-month momentum and short ETF with the lowest 12-month momentum.

Source: Quantpedia

Trading with WTI BRENT Spread

Goes long the spread if the spread is below 20-day moving average and short if the spread is above 20-day moving average.

Source: Quantpedia

Momentum Effect in REITs

Tercile portfolios are formed based on momentum and the best performing portfolio is held.

Source: Quantpedia

Option Expiration Week Effect

Goes long S&P 100 index ETF during option expiration week and stays in cash during other days.

Source: Quantpedia

Earnings Quality Factor

Goes long stocks with high earnings quality and short stocks with low earnings quality based on composite factor score.

Source: Quantpedia

January Effect in Stocks

Invests into small cap stocks at the beginning of each January and stays invested in large cap stocks for rest of the year.

Source: Quantpedia

Momentum and Reversal Combined with Volatility Effect in Stocks

Goes long on stocks from the highest performing quintile from the highest volatility group and short on stocks from the lowest performing quintile from the highest volatility group.

Source: Quantpedia

ROA Effect within Stocks

Goes long on stocks with highest ROA and short stocks with the lowest ROA from each market capitalization group.

Source: Quantpedia

January Barometer

Invested in equity market with ETF only if January return is positive otherwise switch investments to T-Bills.

Source: Quantpedia

Lunar Cycle in Equity Market

Goes long in emerging market index ETF 7 days before the new moon and switch to a short position on emerging market index ETF 7 days before the full moon.

Source: Quantpedia

VIX Predicts Stock Index Returns

Goes long on equity index ETF if the VIX is in the highest percentile short if VIX is in the lowest percentile in the last two-year history.

Source: Quantpedia

Combining Momentum Effect with Volume

Goes long stocks with the highest volume from the top momentum decile and short stocks with the highest volume from the bottom momentum decile.

Source: Quantpedia

Short Term Reversal with Futures

Goes long (short) on futures from the high-volume, low-open interest group with the lowest (greatest) returns in the previous week.

Source: Quantpedia

Pre-holiday Effect

Invests in equity market 2 days preceding holiday days and stays in cash during the other trading days.

Source: Quantpedia

Beta Factors in Stocks

Goes long stocks with the bottom beta and short stocks with the top beta, securities are weighted by the ranked betas.

Source: Quantpedia

Exploiting Term Structure of VIX Futures

Buys or sells the nearest VIX futures based on the daily roll and hedge against the open positions with E-mini S&P500 futures.

Source: Quantpedia

12 Month Cycle in Cross-Section of Stocks Returns

Reviews the returns from last January, going long on the top 10% winners and short the bottom 10%.

Source: Quantpedia

Momentum Effect in Stocks in Small Portfolios

Goes long in the 10 stocks with the highest performance and goes short in the 10 stocks with the lowest performance in the previous one year.

Source: Quantpedia

Value Effect within Countries

Invests in the cheapest 33% of country ETFs according to CAPE ratios.

Source: Quantpedia

Beta Factor in Country Equity Indexes

Goes long on the low-beta portfolio and short on the high-beta portfolio in country indexes ETFs.

Source: Quantpedia

Price to Earnings Anomaly

Invests in stocks with low P/E ratio.

API Reference

The QuantConnect API Reference is a comprehensive technical document that details every class, method, property, and event available in the LEAN algorithmic trading framework. It serves as the definitive source for understanding how to interact with LEAN, helping you quickly look up syntax and explore available features. The LEAN engine is written in C#, but you can create algorithms with either C# or Python since LEAN uses Python.Net to bridge between your Python code and the underlying C# engine. For your convenience, we provide an API Reference for both languages.

Python

C#

Migrations

Migrations

Zipline

The following pages explain how to migrate trading algorithms from Zipline to LEAN:

Initialization

Using Data

Ordering

Logging and Plotting

Quick Reference

Zipline

Initialization

Initializing State

On QuantConnect, algorithm initialization behavior is equivalent to Quantopian's `initialize` method. `initialize` is the method equivalent, and it is only ran once at the start of the algorithm. It is responsible for initially adding data to the algorithm, adding a universe, setting the brokerage, setting the algorithm's start and end date, etc.

The algorithm structure in QuantConnect differs from Quantopian's as well. On QuantConnect, we create a class that derives from `QCAlgorithm` and define our overrides/algorithm functionality there. An example of an algorithm with initialization is provided.

Quantopian

```
def initialize(context):
    # Adds AAPL sid to `context` for use later in `handle_data(...)`
    context.aapl = sid(24)
```

QuantConnect

```
class MyAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # Adds minutely AAPL data to the algorithm
        self.aapl = self.add_equity("AAPL", Resolution.MINUTE)
```

On QuantConnect, the `self` parameter is the equivalent of the `context` parameter in Quantopian algorithms. You can use `self` to access algorithm resources, such as the Portfolio, Orders, Order Tickets, Securities, place orders in your algorithm, and much more.

You can read more about algorithm initialization at the Initializion documentation page.

Attaching Pipelines

The functional equivalent of Pipelines on QuantConnect are Universes. Universes can be used to dynamically select assets your algorithm wants to trade or request data from. To add a universe to your algorithm, you can call the `AddUniverse()` method and provide the required Coarse and Fine universe selection functions.

Coarse Universe selection is the first step of universe selection. It provides a means to filter data in a lightweight fashion before proceeding to Fine Universe selection. Coarse universe will allow you to filter assets based off top-level fundamental factors, such as Dollar Volume for the day, if a company has fundamental data, and market of the asset.

Fine Universe selection is the second step of universe selection. It provides fundamental data to your user-defined function, and can be used to filter in greater detail based on an asset's fundamental data, such as earnings, EPS, etc.

An example of coarse and fine universe selection to filter assets in our algorithm is provided. Adding universes can be used as an alternative to using `add_equity` if you prefer dynamic asset selection.

```
class MyUniverseAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2020, 1, 1)
        self.set_end_date(2020, 2, 1)

        self.universe_settings.resolution = Resolution.MINUTE
        self.add_universe(self._coarse_selection_function, self._fine_selection_function)

    def _coarse_selection_function(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
        return [i.symbol for i in coarse if i.dollar_volume > 500000 and i.has_fundamental_data]

    def _fine_selection_function(self, fine: List[FineFundamental]) -> List[Symbol]:
        return [i.symbol for i in fine if i.earning_reports.basic_eps.one_month > 0]
```

PY

You can configure universe settings by modifying the existing `UniverseSettings` attribute of the algorithm.

```
class MyUniverseAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.universe_settings.resolution = Resolution.MINUTE
        self.universe_settings.data_normalization_mode = DataNormalizationMode.ADJUSTED
        self.universe_settings.leverage = 1.0
        self.universe_settings.extended_market_hours = False
```

PY

You can read more about universe selection at the Universe documentation page.

Scheduling Functions

Scheduled Events on QuantConnect are the equivalent of `schedule_function()` from Quantopian. Examples are provided comparing the Scheduled Events functionality between QuantConnect and Quantopian.

Quantopian

```
import quantopian.algorithm as algo

def my_scheduled_function(context, data):
    pass

def initialize(context):
    # Runs a function every day 60 minutes before U.S. Equities market close
    algo.schedule_function(
        func=my_scheduled_function,
        date_rule=algo.date_rules.every_day(),
        time_rule=algo.time_rules.market_close(minutes=60),
        calendar=algo.calendars.US_EQUITIES
    )
```

PY

QuantConnect

```
class MyAlgorithm(QCAlgorithm):
    def my_scheduled_function(self):
        pass

    # Runs a function every day 60 minutes before SPY ETF's market close
    def initialize(self) -> None:
        self.schedule.on(
            self.date_rules.every_day(),
            self.time_rules.before_market_close("SPY", 60),
            self.my_scheduled_function
       )
```

PY

You can read more about scheduled events at the Scheduled Events documentation page.

Setting Slippage and Commissions

QuantConnect supports applying slippage and commissions per individual security.

To add a slippage model to a security, we must set the `SlippageModel` property of the `Security` object to our model. A `Security` is returned when data is added to the algorithm. Examples of setting slippage in an algorithm is provided below for both Quantopian and QuantConnect.

Quantopian

```
PY
import quantopian.algorithm as algorithm
from zipline.finance.slippage import FixedSlippage

    def initialize(context):
        # This will set slippage for all U.S. equities
        algorithm.set_slippage(us_equities=FixedSlippage(0.01))
```

QuantConnect

```
PY
class MyAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        spy = self.add_equity("SPY", Resolution.MINUTE)
        # `ConstantSlippageModel` is the same as `FixedSlippage` on Quantopian.
        # This will set slippage only for the "SPY" security.
        spy.slippage_model = ConstantSlippageModel(0.01)
```

Commissions

To add a fee model (otherwise known as Commissions on Quantopian) to a security, we must set the `FeeModel` property of the `Security` object to our model. Examples are provided below for Quantopian and QuantConnect.

Quantopian

```
PY
import quantopian.algorithm as algorithm
from zipline.finance.commission import PerShare

    def initialize(context):
        # Approximates Interactive Brokers' equities trading commissions.
        algorithm.set_commission(us_equities=Pershare(cost=0.0075))
```

QuantConnect

```
PY
class MyAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
       aapl = self.add_equity("AAPL", Resolution.MINUTE)
       spy = self.add_equity("SPY", Resolution.MINUTE)

       # Sets the fee model to the IB fee model, which simulates
       # the fees we would encounter in live trading.
       spy.fee_model = InteractiveBrokersFeeModel()

       # Sets the fee model to a constant fee model
       aapl.fee_model = ConstantFeeModel(0.01, "USD")
```

You can read more about Securities and their attributes at the Securities and Portfolio and Reality Modeling documentation pages.

Manual Asset Lookup

On QuantConnect, we provide the `Symbol` class to reference a security across time with a changing ticker. This is similar to Quantopian's `symbol()` function, which enables the same functionality.

When you add data to your algorithm, a `Security` object is returned. The `Symbol` is accessible from the `Security` as shown below.

```
PY
class MyAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2000, 1, 1)
        self.set_end_date(2020, 1, 1)
        # TWX will change to AOL when backtesting in the early 2000s, and will
        # change to TWX as the backtest advances past the date it was renamed.
        twx_security = self.add_equity("TWX", Resolution.MINUTE)
        twx_symbol = twx_security.symbol
```

To manually create a reference to an old equity, you can use the `Symbol.create()` method.

You can read more about Symbols and Security Identifiers (SID) at the Security Identifiers documentation page.

Zipline

Using Data

Pipeline in Algorithms

As covered in the Initialization section, Pipelines can be replicated using Universe Selection in QuantConnect, albeit with some additional steps in between and a performance impact.

In this section, we will construct and define an equivalent pipeline model using universe selection in QuantConnect. We will filter our data set in Coarse and Fine, and apply an additional filter to historical data with a rolling window.

We first create a skeleton algorithm definition to begin setting up our Pipeline. Note that this algorithm will allow all equities through, which will have a substantial performance impact on our algorithm.

```py
class MyPipelineAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2020, 1, 1)
        self.set_end_date(2020, 10, 20)

        self.add_universe(self.coarse_selection_function, self.fine_selection_function)

    def coarse_selection_function(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
        # Allows all Symbols through, no filtering applied
        return [coarse_data.symbol for coarse_data in coarse]

    def fine_selection_function(self, fine: List[FineFundamental]) -> List[Symbol]:
        # Allows all Symbols through, no filtering applied
        return [fine_data.symbol for fine_data in fine]
```

The skeleton algorithm is the equivalent of the Pipeline call below.

```py
from quantopian.pipeline import Pipeline
from quantopian.pipeline.domain import US_EQUITIES
from quantopian.research import run_pipeline

pipe = Pipeline(columns={}, domain=US_EQUITIES)
run_pipeline(pipe, '2020-01-01', '2020-10-20')
```

The equivalent of `Pipeline(screen=...)` resolves to the filter applied at the Coarse and Fine stages of universe selection. Let's define a filter of stocks with a dollar volume greater than $50000000 USD, as well as a rolling thirty day return greater than 2%. Once we've initially filtered the Symbols in Coarse Universe Selection, let's define a final filter only allowing stocks with EPS greater than 0. Beware of making `History()` calls with many Symbols. It could potentially cause your algorithm to run out of system resources (i.e. RAM) and reduce performance of your algorithm on universe selection.

```py
from datetime import datetime, timedelta

class MyPipelineAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2020, 1, 1)
        self.set_end_date(2020, 10, 20)

        self.add_universe(self._coarse_selection_function, self._fine_selection_function)

    def _coarse_selection_function(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
        # Allows all Symbols through, no filtering applied
        dollar_volume_filter_symbols = [coarse_data.symbol for coarse_data in coarse if coarse_data.dollar_volume > 50000000]

        # Make a history call to calculate the 30 day rolling returns
        df = self.history(dollar_volume_filter_symbols, self.time - timedelta(days=60), self.time, Resolution.DAILY)

        # Compute the rolling 30 day returns
        df = df['close'].groupby(level=0).filter(lambda x: len(x) >= 30).groupby(level=0).apply(lambda x: (x.iloc[-1] - x.iloc[-30]) /
x.iloc[-30])

        # Finally, apply our filter
        dataframe_screen = df[df > 0.02]

        # Filters out any Symbol that is not in the DataFrame
        return [s for s in dollar_volume_filter_symbols if str(s) in dataframe_screen]

    def _fine_selection_function(self, fine: List[FineFundamental]) -> List[Symbol]:
        # We receive the filtered symbols from before, and we filter by EPS > 0 in this step
       return [s.symbol for s in fine if s.earning_reports.basic_eps.three_months > 0]
```

This class definition is now roughly equivalent to the following `CustomFactor` and Pipeline call in Quantopian, excluding the EPS filtering.

```py
from quantopian.pipeline.filters import QTradableStocksUS
from quantopian.pipeline.factors import AverageDollarVolume

class PercentageChange(CustomFactor):
    def compute(self, today, assets, out, values):
        out[:] = (values[-1] - values[0]) / values[0]

    dollar_volume = AverageDollarVolume(window_length=5)
    dollar_volume_filter = (dollar_volume > 50000000)

    pipe = Pipeline(
        columns={
            "percent_change": PercentageChange(inputs=[USEquityPricing.close], window_length=30)
        },
        screen=(QTradableStocksUS() & dollar_volume_filter)
    )
```

An example of the shape of the DataFrame returned from History is shown below. The DataFrame has a MultiIndex, with `level=0` being the Symbol, and `level=1` being the Time for that point of data. You can index the Symbol/ `level=0` index by using either the SecurityIdentifier string (e.g. `df.loc["AAPL R735QTJ8XC9X"]`) or with the ticker of the Symbol (e.g. `df.loc["AAPL"]`)

		close	high	low	open	volume
symbol	time					
IBM	2019-04-26	138.62	139.82	137.70	139.82	1419038.0
	2019-04-27	139.44	139.89	138.81	139.28	1275702.0
AAPL	2019-04-26	205.24	207.76	205.12	206.84	10105760.0
	2019-04-27	204.29	205.00	202.12	204.83	9984854.0

BarData Lookup

Similar but different, the Quantopian `BarData` object, and the QuantConnect `Slice` object both provide data to the user's algorithm as point-in-time data.

In Quantopian, data is handled via the `handle_data(context, data)` function. In QuantConnect, data is handled via the `OnData(self, slice)` method. Both of these functions accept data whenever new data exists for a given point in time. Although these two functions share the same method signature, the handling of the data is different.

`BarData` vs. `Slice`

`BarData` is the primary mechanism to retrieve the point-in-time data, as well as requesting history for any given securities in Quantopian. The

following code retrieves daily historical data from 30 days into the past, as well as getting the most recent data for AAPL at the current point-in-time.

Quantopian

```py
def initialize(context):
    context.aapl = sid(24)

def handle_data(context, data):
    # Gets a DataFrame of AAPL history going back 30 days
    aapl_history = data.history(context.aapl, fields=["open", "high", "low", "close", "volume"], 30, "1d")
    # Gets a pandas Series of the most recent AAPL data
    aapl_current = data.current(context.aapl, fields=["open", "high", "low", "close", "volume"])
```

QuantConnect

```py
from datetime import timedelta

class MyHistoryAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.aapl = self.add_equity("AAPL", Resolution.DAILY)

    def on_data(self, slice: Slice) -> None:
        # Gets a DataFrame of AAPL history going back 30 days
        aapl_history = self.history([self.aapl.symbol], timedelta(days=30), Resolution.DAILY)

        # Gets the most recent AAPL Trade data (OHLCV)
        aapl_current = slice.bars[self.aapl.symbol]
```

`Slice` represents a single point in time, and does not provide the functionality to access historical data itself. To access historical data in an algorithm, use the algorithm's `self.History()` call to request a pandas DataFrame of historical data. In `Slice` , the data that is accessed is not a pandas DataFrame, but rather a single object containing data for a single point in time.

The `TradeBar` class, for example, only contains scalar values of OHLCV, rather than return a DataFrame of OHLCV values. Since the data `Slice` contains is point-in-time, there will be only a single trade/quote bar per Symbol whenever `OnData(self, data)` is called.

QuantConnect provides Quote (NBBO) data for use in your algorithm, otherwise known as a `QuoteBar` . Quote data is only accessible when an algorithm is set to consume Tick, Second, or Minutely data.

You can access Trade (OHLCV) data by accessing the `Bars` attribute of `Slice` . You can access Quote (Bid(OHLCV), Ask(OHLCV)) data by accessing the `QuoteBars` attribute of `Slice` .

Both of the `Bars` and `QuoteBars` attributes are similar to Python dictionaries, and can be used as such. To check to see if there exists a new piece of data for a given security, you can use Python's `in` operator on `Bars` and or `QuoteBars` . You can also choose to iterate on all data received by calling the `Values` attribute of the `Bars` or `QuoteBars` attributes, which will return either a list of `TradeBar` or `QuoteBar` objects.

The `TradeBar` object contains the `Open` , `High` , `Low` , `Close` , `Volume` , `time` , `end_time` , and `Symbol` attributes. The `QuoteBar` object contains the following attributes:

- `Bid.Open` , `Bid.High` , `Bid.Low` , `Bid.Close` , `LastBidSize`
- `Ask.Open` , `Ask.High` , `Ask.Low` , `Ask.Close` , `LastAskSize`
- `time` , `end_time` , and `Symbol` .

Note that the `Bid` and `Ask` attributes can potentially be `None` if no bid/ask data exists at a given point-in-time.

The example below shows the different ways to access `TradeBar` and `QuoteBar` data, as well as requesting 30 days of AAPL historical data.

PY

```
from datetime import datetime, timedelta

class MyDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.aapl_security = self.add_equity("AAPL", Resolution.DAILY)
        self.aapl_symbol = self.aapl_security.symbol

    def on_data(self, slice: Slice) -> None:
        # Gets 30 days of AAPL history
        aapl_history = self.history([self.aapl_symbol], timedelta(days=30), Resolution.DAILY)

        # We must first check to make sure we have AAPL data, since this point-in-time
        # might not have had any trades for AAPL (this is in case you trade a low
        # liquidity asset. The data can potentially be missing for a point-in-time).
        if self.aapl_symbol in slice.bars:
            aapl_current_trade = slice.bars[self.aapl_symbol]
            self.log(f"{self.time} :: TRADE :: {self.aapl_symbol} - O: {aapl_current_trade.open} H: {aapl_current_trade.high} L:
{aapl_current_trade.low} C: {aapl_current_trade.close} V: {aapl_current_trade.volume}")

        # Check to make sure we have AAPL data first, since there might not have
        # been any quote updates since the previous for AAPL (this is in case you trade
        # a low liquidity asset. The data can potentially be missing for a point-in-time).
        if self.aapl_symbol in slice.quote_bars:
            aapl_current_quote = slice.quote_bars[self.aapl_symbol]
            if aapl_current_quote.bid is not None:
                bid = aapl_current_quote.bid
                self.log(f"{self.time} :: QUOTE :: {self.aapl_symbol} - Bid O: {bid.open} Bid H: {bid.high} Bid L: {bid.low} Bid C:
{bid.close} Bid size: {aapl_current_quote.last_bid_size}")

            if aapl_current_quote.ask is not None:
                ask = aapl_current_quote.ask
                self.log(f"{self.time} :: QUOTE :: {self.aapl_symbol} - Ask O: {ask.open} Ask H: {ask.high} Ask L: {ask.low} Ask C:
{ask.close} Ask size: {aapl_current_quote.last_ask_size}")
```

Zipline

Ordering

Placing Orders

Both Quantopian and QuantConnect offer several methods for placing orders. Both platforms have `MarketOrder` , `LimitOrder` , `StopOrder` , and `stop_limit_order` classes to create specific order types, although the `StopOrder` order is named `StopMarketOrder` on our platform. On Quantopian, creating these orders is done by passing a `style` argument to the `order` method.

```py
from zipline.finance.execution import (
    LimitOrder,
    MarketOrder,
    StopLimitOrder,
    StopOrder,
)

def initialize(context):
    context.stock = sid(8554)
    context.ordered = False

def handle_data(context, data):
    if not context.ordered:
        close = data.current(context.stock, 'close')
        order(context.stock, 10, style=MarketOrder())
        order(context.stock, 10, style=LimitOrder(limit_price=close * 0.9))
        order(context.stock, -10, style=StopOrder(stop_price=close * 0.85))
        order(context.stock, -10, style=StopLimitOrder(limit_price=close * 0.75, stop_price=close * 0.85))
        context.ordered = True
```

On QuantConnect, the same orders can be created with

```py
class MyAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2020, 3, 1)
        self.set_cash(100000)
        self._symbol = self.add_equity("SPY", Resolution.MINUTE).symbol
        self.ordered = False

    def on_data(self, slice: Slice) -> None:
        if not self.ordered and slice.contains_key(self._symbol):
            close = slice[self._symbol].close
            self.market_order(self._symbol, 10)
            self.limit_order(self._symbol, 10, close * 0.9)
            self.stop_market_order(self._symbol, -10, close * 0.85)
            self.stop_limit_order(self._symbol, -10, close * 0.85, close * 0.75)
            self.ordered = True
```

In addition to the order types above, QuantConnect has several other order types available. Refer to our Trading and Orders documentation for a comprehensive list.

Quantopian's `order_optimal_portfolio` method computes the optimal portfolio weights using an objective and constraints, then places the orders to achieve the desired portfolio. For example, the code below uses the Quantopian API to create an equal-weighted dollar-neutral portfolio.

```py
import quantopian.algorithm as algo
import quantopian.optimize as opt

objective = opt.TargetWeights(weights)
constraints = [
    opt.MaxGrossExposure(1.0),
    opt.DollarNeutral()
]
algo.order_optimal_portfolio(objective, constraints)
```

To acheive the same functionality with QuantConnect, we utilize portfolio construction models . For instance, to create an equal-weighted dollar-neutral portfolio, we could define the following portfolio construction model and attach it to the algorithm.

```
class MyAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2020, 5, 1)
        self.set_cash(100000)

        self.set_portfolio_construction(EqualWeightedDollarNeutralPortfolioConstructionModel())

class EqualWeightedDollarNeutralPortfolioConstructionModel(PortfolioConstructionModel):

    def determine_target_percent(self, activeInsights: List[Insight]):
        result = {}

        longs = 0
        shorts = 0
        for insight in activeInsights:
            if insight.direction == InsightDirection.UP:
                longs += 1
            elif insight.direction == InsightDirection.DOWN:
                shorts += 1
            result[insight] = 0

        if longs == 0 or shorts == 0:
            return result

        for insight in activeInsights:
            if insight.direction == InsightDirection.UP:
                result[insight] = 0.5 / longs
            elif insight.direction == InsightDirection.DOWN:
                result[insight] = -0.5 / shorts
        return result
```

When algorithms require manual control of their orders, both Quantopian and QuantConnect have lower-level ordering methods. Quantopian's `order` method, which places an order for a fixed number of shares, directly maps to our `Order` method. Additionally, Quantopian's `order_target_percent` method places an order to adjust a position to a target percent of the current portfolio value. Here's an example use case of these methods on the Quantopian platform.

```
order_target_percent(sid(8554), 10) # Allocate 10% of portfolio
order(sid(8554), 10) # Order 10 shares
```

On QuantConnect, these same orders can be placed using the `set_holdings` and `Order` methods.

```
self.set_holdings(symbol, 0.1) # Allocate 10% of portfolio
self.order(symbol, 10) # Order 10 shares
```

Quantopian and QuantConnect don't have equivalents for all the ordering techniques, although we can create a workaround for most situations. For instance, Quantopian's `order_percent` method places an order in the specified asset corresponding to the given percent of the current portfolio value.

```
order_percent(sid(8554), 10) # Allocate 10% more of portfolio
```

To accomplish this on QuantConnect, we can determine the weight of the asset in the `portfolio` , then manually determine the new target percent to pass to `set_holdings` .

```
current_weight = self.portfolio[symbol].holdings_value / self.portfolio.total_portfolio_value
self.set_holdings(symbol, current_weight + 0.1) # Allocate 10% more of portfolio
```

The Porfolio Object

Quantopian's `portfolio` class provides read-only access to the current portfolio state. The state includes starting cash, current cash, portfolio value, and positions. The `portfolio` object is accessed through the `context` object, as seen below.

```py
context.portfolio.starting_cash     # Amount of cash in the portfolio at the start of the backtest
                 .cash              # Amount of cash currently held in portfolio
                 .portfolio_value   # Current liquidation value of the portfolio's holdings
                 .positions         # Dict-like object for currently-held positions
```

All of this information, and more, is attainable on QuantConnect by using our `portfolio` object. Listed below is an example of doing so. Although there isn't a property for starting cash, this value can be saved during Initialization to be referenced later.

```py
self.portfolio.cash                 # Sum of all currencies in account (only settled cash)
              .total_portfolio_value   # Portfolio equity
              .keys                 # Collection of Symbol objects in the portfolio
              .values               # Collection of SecurityHolding objects in the portfolio
```

On Quantopian, by iterating through the `positions` dictionary, we can access information about currently-held positions. This includes the number of shares held, the last traded price & date of the asset, and the position's cost basis.

```py
for sid, position in context.portfolio.positions.iteritems():
    position.amount           # Number of shares in the position
            .cost_basis       # Volume weighted average price paid per share
            .last_sale_price  # Price at last sale of the asset on the exchange
            .last_sale_date   # Date of last sale of the asset on the exchange
```

Since the `portfolio` on QuantConnect is a `Dictionary<Symbol, SecurityHolding>` , we can get information on current positions by indexing the `portfolio` object with a `Symbol` or ticker. The `SecurityHolding` object that is returned contains information related to a single security in the portfolio. For instance, we have

```py
self.portfolio[symbol].quantity                # Number of shares held
                      .average_price            # Average price of shares held (aka cost basis)
                      .price                   # Last traded price of the security
```

For more information on our `portfolio` object refer to the Securities and Portfolio documentation.

Zipline

Logging and Plotting

Logging

In QuantConnect, the `self.Debug()` method is the equivalent of the `log.info()` function in Quantopian. Debug output is viewable via the QuantConnect Terminal Console.

Output to the console via `self.Debug()` is rate-limited. If you need long-term storage of your logs and don't want to overflow the console, consider using `self.Log()` instead. An example comparing logging between Quantopian and QuantConnect is shown below.

Quantopian

```
def initialize(context):
    log.info("Hello, console!")
```

PY

QuantConnect

```
class MyLoggingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.debug("Hello, console!")
        self.log("Hello, backtesting logs!")
```

PY

Logging via `self.Log()` has daily limits in QuantConnect. On the free tier, users are limited to 10KB of logs per day for your account/organization. To increase this limit, you can upgrade your account to a different tier. Calls to `self.Debug()` will also count towards the 10KB log limit, but are always outputted to the Terminal Console regardless of your daily log limit.

To view pricing and upgrade your account, visit the Organization Pricing page.

You can view the logs generated via `self.Log()` for a backtest by first accessing a backtest, and clicking the "Logs" tab near the bottom of the page. To download the logs, you can click the "Download Logs" link to download a text file containing your backtest's logs.

Plotting

In Quantopian, plotting/charting is done with the `record(series1_name=scalar_value, series2_name=scalar_value, ...)` function. In QuantConnect, plotting is accessible via the `self.plot("chart name", "series name", scalar_value)` method.

Plotting multiple series in one function call is possible in Quantopian. However, in QuantConnect, a separate call is needed for each series requiring an update. All series with the same chart name will appear on the same window/pane. New charts can be created by calling `self.plot()` method with a unique chart name.

An example of plotting in Quantopian vs. QuantConnect is shown below. The QuantConnect code will create two charts, one named "Chart1" with two series of data, and another named "Chart2" with one series of data. Note that you can also use `self.plot("series name", value)` to place the custom series on the same chart as the equity curve.

Quantopian

```py
import numpy as np
from quantopian.algorithm import record

    def initialize(context):
        context.i = 0

    def handle_data(context, data):
        context.i += 0.25

        record(
            series1=np.sin(context.i),
            Series2=np.cos(context.i),
            Series3=np.tan(context.i)
        )
```

QuantConnect

```py
import numpy as np

class Algorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.i = 0

    def on_data(self, slice: Slice) -> None:
        self.i += 0.25

        self.plot('Chart1', 'Series1', np.sin(self.i))
        self.plot('Chart1', 'Series2', np.cos(self.i))
        self.plot('Chart2', 'Chart2 Series1', np.tan(self.i))
```

For more information on plotting in QuantConnect, visit the Charting documentation page.

Zipline

Quick Reference

User-Implemented Functions

The following table describes functions that are treated specially when defined in the IDE.

Algorithms are required to implement one method: Initialize(self).

An optional scheduled event can be defined to behave like before_trading_start(). OnData() is also optional but is treated especially if defined.

Quantopian	**QuantConnect**
`initialize` (context)	`Initialize` (self)
Required function called once at the start of a backtest.	
`before_trading_start` (context, data)	`self.Schedule.On(self.DateRules.EveryDay(), self.TimeRules.AfterMarketOpen(symbol, 10), self.before_trading_start)`
Optional function called prior to market open on every trading day.	
`handle_data` (context, data)	`OnData` (self, slice)
Optional function called at the end of each market minute.	

Interface Classes

The following table describes classes that are passed to `initialize()` , `handle_data()` , `before_trading_start()` and any scheduled with `schedule_function()` .

In QuantConnect/Lean, the portfolio state and the positions are class attributes of QCAlgorithm, available via self keyword. The scheduled function is parameterless and can algorithms can self.CurrentSlice.

Quantopian	**QuantConnect**
`quantopian.algorithm.interface.AlgorithmContext`	`QCAlgorithm`
Shared object for storing custom state.	
`quantopian.algorithm.interface.BarData`	`Slice`
Provides methods for accessing minutely and daily price/volume data from Algorithm API functions.	
`quantopian.algorithm.interface.Portfolio`	`self.Portfolio`
Object providing read-only access to current portfolio state.	
`quantopian.algorithm.interface.Positions`	`self.Transactions`
A dict-like object containing the algorithm's current positions.	

The features from the BarData methods are found in the Slice object (current data), History method (past data) and class attribute Securities.

Quantopian	QuantConnect
`quantopian.algorithm.interface.BarData.current`	`Slice[symbol]`
Returns the "current" value of the given fields for the given assets at the current simulation time.	
`quantopian.algorithm.interface.BarData.history`	`self.History(symbols, bar_count)`
Returns a trailing window of length `bar_count` containing data for the given assets, fields, and frequency.	
`quantopian.algorithm.interface.BarData.can_trade`	`self.Securities[symbol].IsTradable`
For the given asset or iterable of assets, returns True if all of the following are true:	
`quantopian.algorithm.interface.BarData.is_stale`	`not Slice[symbol].IsFillForward`
For the given asset or iterable of assets, returns True if the asset is alive and there is no trade data for the current simulation time.	

Pipeline

The following table describes functions used to schedule and retrieve results of Universe selection. For more information on the Universe Selection API, see the Univeres API Reference.

Quantopian	QuantConnect
`quantopian.algorithm.attach_pipeline` (...)	`universe = self.AddUniverse` (...) name = universe.Configuration.Symbol
Register a pipeline to be computed at the start of each day.	
`quantopian.algorithm.pipeline_output` (name)	`self.UniverseManager` [name]
Get results of the pipeline attached by with `name` .	

Scheduling Functions

The following tables describes functions that can be used to schedule functions to run periodically during your algorithm.

Quantopian	QuantConnect
`quantopian.algorithm.schedule_function` (func)	`self.Schedule.On(IDateRule, ITimeRule, func)`
Schedule a function to be called repeatedly in the future.	

Date Rules

The following table contains functions that can be used with the `date_rule` parameter of `schedule_function()` .

Quantopian	QuantConnect
`quantopian.algorithm.date_rules.every_day` ()	`self.DateRules.EveryDay(symbol)`
Create a rule that triggers every day.	
`quantopian.algorithm.date_rules.month_start` ([...])	`self.DateRules.MonthStart(symbol, daysOffset)`
Create a rule that triggers a fixed number of trading days after the start of each month.	
`quantopian.algorithm.date_rules.month_end` ([...])	`self.DateRules.MonthEnd(symbol, daysOffset)`
Create a rule that triggers a fixed number of trading days before the end of each month.	
`quantopian.algorithm.date_rules.week_start` ([...])	`self.DateRules.WeekStart(symbol, daysOffset)`
Create a rule that triggers a fixed number of trading days after the start of each week.	
`quantopian.algorithm.date_rules.week_end` ([...])	`self.DateRules.WeekEnd(symbol, daysOffset)`
Create a rule that triggers a fixed number of trading days before the end of each week.	

Time Rules

The following table contains functions that can be used with the `time_rule` parameter of `schedule_function()` .

Quantopian	QuantConnect
`quantopian.algorithm.time_rules.market_open` ([...])	`self.TimeRules.AfterMarketOpen(symbol, minutes_after_open = 0)`
Create a rule that triggers at a fixed offset from market open.	
`quantopian.algorithm.time_rules.market_close` ([...])	`self.TimeRules.BeforeMarketClose(symbol, minutes_before_close = 0)`
Create a rule that triggers at a fixed offset from market close.	

Ordering

There are several ways to place orders from an algorithm. For most use-cases, we recommend using SetHoldings method which correctly accounts the porfolio buying power model and fees. At the moment, there is no equivalent for `order_optimal_portfolio()` . However a similar behavior can be replicated with a Portfolio Construction Model.

Algorithms that require explicit manual control of their orders can use the lower-level ordering functions.

Placing Orders

Quantopian	QuantConnect
`quantopian.algorithm.order_optimal_portfolio` (...)	`N/A`
Calculate an optimal portfolio and place orders toward that portfolio.	
`quantopian.algorithm.order` (asset, amount[, ...])	`self.Order(symbol, amount)`
Place an order for a fixed number of shares.	
`quantopian.algorithm.order_value` (asset, value)	`N/A`
Place an order for a fixed amount of money.	
`quantopian.algorithm.order_percent` (asset, ...)	`self.SetHoldings(symbol, percent)`
Place an order in the specified asset corresponding to the given percent of the current portfolio value.	
`quantopian.algorithm.order_target` (asset, target)	`N/A`
Place an order to adjust a position to a target number of shares.	
`quantopian.algorithm.order_target_value` (...)	`N/A`
Place an order to adjust a position to a target value.	
`quantopian.algorithm.order_target_percent` (...)	`self.SetHoldings(symbol, percent)`
Place an order to adjust a position to a target percent of the current portfolio value.	

Controlling Order Execution

Quantopian	QuantConnect
`zipline.finance.execution.ExecutionStyle`	`FillModel`
Base class for order execution styles.	
`zipline.finance.execution.MarketOrder` ([exchange])	`self.MarketOrder` (symbol, quantity)
Execution style for orders to be filled at current market price.	
`zipline.finance.execution.LimitOrder` (limit_price)	`self.LimitOrder` (symbol, quantity, limit_price)
Execution style for orders to be filled at a price equal to or better than a specified limit price.	
`zipline.finance.execution.StopOrder` (stop_price)	`self.StopMarketOrder` (symbol, quantity, stop_price)
Execution style representing a market order to be placed if market price reaches a threshold.	
`zipline.finance.execution.StopLimitOrder` (...)	`self.StopLimitOrder` (symbol, quantity, stop_price, limit_price)
Execution style representing a limit order to be placed if market price reaches a threshold.	

Managing Existing Orders

Quantopian	QuantConnect
`quantopian.algorithm.get_order` (order_id)	`self.Transactions.GetOrderById` (order_id)
Lookup an order based on the order Id returned from one of the order functions.	
`quantopian.algorithm.get_open_orders` ([asset])	`self.Transactions.GetOpenOrders` (symbol)
Retrieve all of the current open orders.	
`quantopian.algorithm.cancel_order` (order_param)	`self.Transactions.CancelOpenOrders` (symbol)
Cancel an open order.	

Customizing the Simulation

Slippage

Algorithms can customize the simulation of order fills by calling SetSlippageModel() with a ISlippageModel which is any class that implements GetSlippageApproximation method. Unlike Quantopian, the slippage model is a security attribute, not a global attribute. Different securities can have different slippage models.

The default slippage model on QuantConnect is a constant slippage model with zero slippage percent (no slippage).

Quantopian	QuantConnect
`quantopian.algorithm.set_slippage` ([...])	`self.Securities[symbol].SetSlippageModel(ISlippageModel)`
Set the slippage models for the simulation.	
`zipline.finance.slippage.SlippageModel` ()	`N/A (class must implement GetSlippageApproximation method)`
Abstract base class for slippage models.	
`zipline.finance.slippage.FixedBasisPointsSlippage` ([...])	`ConstantSlippageModel(slippage_percent)`
Model slippage as a fixed percentage difference from historical minutely close price, limiting the size of fills to a fixed percentage of historical minutely volume.	
`zipline.finance.slippage.NoSlippage` ()	`NullSlippageModel.Instance`
A slippage model where all orders fill immediately and completely at the current close price.	
`zipline.finance.slippage.FixedSlippage` ([spread])	`N/A`
Simple model assuming a fixed-size spread for all assets.	
`zipline.finance.slippage.VolumeShareSlippage` ([...])	`N/A`
Model slippage as a quadratic function of percentage of historical volume.	

Commissions

Algorithms can customize the simulation of order fees by calling SetFeeModel() with a IFeeModel which is any class that implements GetOrderFee method. Unlike Quantopian, the fee model is a security attribute, not a global attribute. Different securities can have different fee models.

The default fee model on QuantConnect depends on the security type and the brokerage. For instance, the default fee model for equity is the Interactive Brokers fee model.

Quantopian	QuantConnect
`quantopian.algorithm.set_commission` ([...])	`self.Securities[symbol].SetFeeModel(IFeeModel)`
Sets the commission models for the simulation.	
`zipline.finance.commission.CommissionModel`	`N/A (class must implement GetOrderFee method)`
Abstract base class for commission models.	
`zipline.finance.commission.PerShare` ([cost, ...])	`N/A`
Calculates a commission for a transaction based on a per share cost with an optional minimum cost per trade.	
`zipline.finance.commission.PerTrade` ([cost])	`N/A`
Calculates a commission for a transaction based on a per trade cost.	
`zipline.finance.commission.PerDollar` ([cost])	`N/A`
Model commissions by applying a fixed cost per dollar transacted.	
`zipline.finance.commission.NoCommission`	`FeeModel()`
Model commissions as free.	

Benchmark

The default benchmark is SPY.

Quantopian	QuantConnect
`quantopian.algorithm.set_benchmark` (benchmark)	`self.SetBenchmark` (benchmark)
Set the benchmark asset.
