        self.set_end_date(2021, 1, 1)
        self.set_cash(100000)

        self.aapl = self.add_equity("AAPL", Resolution.MINUTE).symbol
        self.intention_symbol = self.add_data(SmartInsiderIntention, self.aapl).symbol
        self.transaction_symbol = self.add_data(SmartInsiderTransaction, self.aapl).symbol
```

Accessing Data

To get the current Corporate Buybacks data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.intention_symbol):
        data_point = slice[self.intention_symbol]
        self.log(f"{self.intention_symbol} intention amount at {slice.time}: {data_point.amount}")

    if slice.contains_key(self.transaction_symbol):
        data_point = slice[self.transaction_symbol]
        self.log(f"{self.transaction_symbol} transaction amount at {slice.time}: {data_point.amount}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.get(SmartInsiderIntention).items():
        self.log(f"{dataset_symbol} intention amount at {slice.time}: {data_point.amount}")

    for dataset_symbol, data_point in slice.get(SmartInsiderTransaction).items():
        self.log(f"{dataset_symbol} transaction amount at {slice.time}: {data_point.amount}")
```

Historical Data

To get historical Corporate Buybacks data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
# DataFrames
intention_history_df = self.history(self.intention_symbol, 100, Resolution.DAILY)
transaction_history_df = self.history(self.transaction_symbol, 100, Resolution.DAILY)
history_df = self.history([self.intention_symbol, self.transaction_symbol], 100, Resolution.DAILY)

# Dataset objects
intention_history_bars = self.history[SmartInsiderIntention](self.intention_symbol, 100, Resolution.DAILY)
transaction_history_bars = self.history[SmartInsiderTransaction](self.transaction_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on Corporate Buybacks data, call the `add_universe` method with the `SmartInsiderIntentionUniverse` class or the `SmartInsiderTransactionUniverse` and a selection function.

```
def initialize(self) -> None:
    self.intention_universe = self.add_universe(SmartInsiderIntentionUniverse, self.intention_selection)
    self.transaction_universe = self.add_universe(SmartInsiderTransactionUniverse, self.transaction_selection)

def intention_selection(self, alt_coarse: List[SmartInsiderIntentionUniverse]) -> List[Symbol]:
    return [d.symbol for d in alt_coarse \
                if d.percentage > 0.005 \
                and d.usd_market_cap > 100000000]

def transaction_selection(self, alt_coarse: List[SmartInsiderTransactionUniverse]) -> List[Symbol]:
    return [d.symbol for d in alt_coarse \
                if d.buyback_percentage > 0.005 \
                and d.usd_market_cap > 100000000]
```

For more information about dynamic universes, see Universes .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `history` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```
# DataFrame example where the columns are the SmartInsiderIntentionUniverse attributes:
intention_history_df = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series example where the values are lists of SmartInsiderIntentionUniverse objects:
intention_universe_history = self.history(self.intention_universe, 30, Resolution.DAILY)
for (_, time), intentions in intention_universe_history.items():
    for intention in intentions:
        self.log(f"{intention.symbol.value} amount value at {intention.end_time}: {intention.amount_value}")

# DataFrame example where the columns are the SmartInsiderTransactionUniverse attributes:
transaction_history_df = self.history(self._universe, 30, Resolution.DAILY, flatten=True)

# Series example where the values are lists of SmartInsiderTransactionUniverse objects:
transaction_universe_history = self.history(self.transaction_universe, 30, Resolution.DAILY)
for (_, time), transactions in transaction_universe_history.items():
    for transaction in transactions:
        self.log(f"{transaction.symbol.value} amount at {intention.end_time}: {intention.amount}")
```

Historical Universe Data in Research

To get historical universe data in research, call the `universe_history` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```
# DataFrame example where the columns are the SmartInsiderIntentionUniverse attributes:
intention_history_df = qb.universe_history(universe, qb.time-timedelta(30), qb.time, flatten=True)

# Series example where the values are lists of SmartInsiderIntentionUniverse objects:
intention_universe_history = qb.universe_history(intention_universe, qb.time-timedelta(30), qb.time)
for (_, time), intentions in intention_universe_history.items():
    for intention in intentions:
        print(f"{intention.symbol.value} amount value at {intention.end_time}: {intention.amount_value}")

# DataFrame example where the columns are the SmartInsiderTransactionUniverse attributes:
transaction_history_df = qb.universe_history(universe, qb.time-timedelta(30), qb.time, flatten=True)

# Series example where the values are lists of SmartInsiderTransactionUniverse objects:
transaction_universe_history = qb.universe_history(transaction_universe, qb.time-timedelta(30), qb.time)
for (_, time), transactions in transaction_universe_history.items():
    for transaction in transactions:
        print(f"{transaction.symbol.value} amount at {transaction.end_time}: {transaction.amount}")
```

You can call the `history` method in Research.

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
self.remove_security(self.intention_symbol)
self.remove_security(self.transaction_symbol)
```

If you subscribe to Corporate Buybacks data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Corporate Buybacks dataset enables you to design strategies using information on company buyback programs. Examples include the following strategies:

- Buying securities when the company announces an upcoming share buyback on the premise that the reduction in supply (shares outstanding) will drive up the remaining shares' price
- Buying securities when the company executes an upcoming share buyback on the premise that the reduction in supply (shares outstanding) will drive up the remaining shares' price

Classic Algorithm Example

The following example algorithm buys Apple stock when there is a buyback intention or transaction and then it sells the stock 3 days later:

```
from AlgorithmImports import *

class CorporateBuybacksDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        self.aapl = self.add_equity("AAPL", Resolution.MINUTE).symbol

        # Requesting insider trade intention news and actual trades to estimate the return, since insiders may have better information of
the future confidence
        self.smart_insider_intention = self.add_data(SmartInsiderIntention, self.aapl).symbol
        self.smart_insider_transaction = self.add_data(SmartInsiderTransaction, self.aapl).symbol

        # Historical data
        history = self.history(self.smart_insider_intention, 365, Resolution.DAILY)
        self.debug(f"We got {len(history)} items from our history request for intentions")

        history = self.history(self.smart_insider_transaction, 365, Resolution.DAILY)
        self.debug(f"We got {len(history)} items from our history request for transactions")

    def on_data(self, slice: Slice) -> None:
        # Buy Apple whenever we receive a buyback intention or transaction notification, given the insiders may have confidence in the
future to buy more
        # This news may stimulate market popularity
        if slice.contains_key(self.smart_insider_intention) or slice.contains_key(self.smart_insider_transaction):
            self.set_holdings(self.aapl, 1)
            self.entry_time = self.time

        # Liquidate holdings 3 days after the latest entry
        # The market popularity and possible overbrought is cooled
        if self.portfolio.invested and self.time >= self.entry_time + timedelta(days=3):
            self.liquidate()
```

Framework Algorithm Example

The following example algorithm buys Apple stock when there is a buyback intention or transaction and then it sells the stock 3 days later:

```
from AlgorithmImports import *

class CorporateBuybacksDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Only interest in AAPL's insider trades information
        symbols = [Symbol.create("AAPL", SecurityType.EQUITY, Market.USA)]
        self.add_universe_selection(ManualUniverseSelectionModel(symbols))
        self.add_alpha(CorporateBuybacksAlphaModel())
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

class CorporateBuybacksAlphaModel(AlphaModel):

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        # Buy Apple whenever we receive a buyback intention or transaction notification, given the insiders may have confidence in the
future to buy more
        # This news may stimulate market popularity, so we hold for 3 days
        if slice.contains_key(self.smart_insider_intention) or slice.contains_key(self.smart_insider_transaction):
            return [Insight.price(self.aapl, timedelta(days=3), InsightDirection.UP)]
        return []

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            self.aapl = security.symbol

            # Requesting insider trade intention news and actual trades to estimate the return, since insiders may have better
information of the future confidence
            self.smart_insider_intention = algorithm.add_data(SmartInsiderIntention, self.aapl).symbol
            self.smart_insider_transaction = algorithm.add_data(SmartInsiderTransaction, self.aapl).symbol

            # Historical data
            history = algorithm.history(self.smart_insider_intention, 365, Resolution.DAILY)
            algorithm.debug(f"We got {len(history)} items from our history request for intentions")

            history = algorithm.history(self.smart_insider_transaction, 365, Resolution.DAILY)
            algorithm.debug(f"We got {len(history)} items from our history request for transactions")
```

Research Example

The following example lists US Equities with the highest buyback amount.

```
PY
```

```python
from math import isnan
qb = QuantBook()

# Requesting Data
symbol = qb.AddEquity("AAPL").Symbol
intention_symbol = qb.AddData(SmartInsiderIntention, symbol).Symbol
transaction_symbol = qb.AddData(SmartInsiderTransaction, symbol).Symbol

# Historical data
intention_history = qb.History(SmartInsiderIntention, intention_symbol, 300, Resolution.Daily)
for (symbol, time), row in intention_history.iterrows():
    if isnan(row['amountvalue']): continue
    print(f"{symbol} amount value at {time}: {row['amountvalue']}")

transaction_history = qb.History(SmartInsiderTransaction, transaction_symbol, 300, Resolution.Daily)
for (symbol, time), row in transaction_history.iterrows():
    if isnan(row['amount']): continue
    print(f"{symbol} amount at {time}: {row['amount']}")

# Add Universe Selection for SmartInsiderIntention
def IntentionSelection(alt_coarse: List[SmartInsiderIntentionUniverse]) -> List[Symbol]:
    return [d.Symbol for d in sorted([x for x in alt_coarse if x.AmountValue],
        key=lambda x: x.AmountValue, reverse=True)[:10]]

intention_universe  = qb.AddUniverse(SmartInsiderIntentionUniverse, IntentionSelection)

# Historical Universe data
intention_universe_history = qb.UniverseHistory(intention_universe, qb.Time-timedelta(10), qb.Time)
for (_, time), intentions in intention_universe_history.items():
    for intention in intentions:
        print(f"{intention.Symbol.Value} amount value at {intention.EndTime}: {intention.AmountValue}")

# Add Universe Selection for SmartInsiderTransaction
def IntentionSelection(alt_coarse: List[SmartInsiderTransactionUniverse]) -> List[Symbol]:
    return [d.Symbol for d in sorted([x for x in alt_coarse if x.Amount],
        key=lambda x: x.Amount, reverse=True)[:10]]

transaction_universe  = qb.AddUniverse(SmartInsiderTransactionUniverse, IntentionSelection)

# Historical Universe data
transaction_universe_history = qb.UniverseHistory(transaction_universe, qb.Time-timedelta(10), qb.Time)
for (_, time), transactions in transaction_universe_history.items():
    for transaction in transactions:
        print(f"{transaction.Symbol.Value} amount at {transaction.EndTime}: {transaction.Amount}")
```

Data Point Attributes

The Corporate Buybacks dataset provides `SmartInsiderIntention`, `SmartInsiderIntentionUniverse`, `SmartInsiderTransaction`, and `SmartInsiderTransactionUniverse` objects.

SmartInsiderIntention Attributes

`SmartInsiderIntention` objects have the following attributes:

SmartInsiderIntentionUniverse Attributes

`SmartInsiderIntentionUniverse` objects have the following attributes:

SmartInsiderTransaction Attributes

`SmartInsiderTransaction` objects have the following attributes:

SmartInsiderTransactionUniverse Attributes

`SmartInsiderTransactionUniverse` objects have the following attributes:

Datasets

Tiingo

Tiingo was founded by Rishi Singh in 2014. Tiingo goes beyond traditional news sources and focuses on finding rich, quality content written by knowledgeable writers. Their proprietary algorithms scan unstructured, non-traditional news and other information sources while tagging companies, topics, and assets. This refined system is backed by over ten years of research and development, and is written by former institutional quant traders. Because of this dedicated approach, Tiingo's News API is a trusted tool used by quant funds, hedge funds, pension funds, social media companies, and tech companies around the world.

Tiingo News Feed

Tiingo

Tiingo News Feed

Introduction

The Tiingo News Feed dataset by Tiingo tracks US Equity news releases. The data covers 10,000 US Equities, starts in January 2014, and is delivered on a second frequency. This dataset is creating by Tiingo integrating over 120 different news providers into their platform.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Tiingo News Feed dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Tiingo was founded by Rishi Singh in 2014. Tiingo goes beyond traditional news sources and focuses on finding rich, quality content written by knowledgeable writers. Their proprietary algorithms scan unstructured, non-traditional news and other information sources while tagging companies, topics, and assets. This refined system is backed by over ten years of research and development, and is written by former institutional quant traders. Because of this dedicated approach, Tiingo's News API is a trusted tool used by quant funds, hedge funds, pension funds, social media companies, and tech companies around the world.

Getting Started

The following snippet demonstrates how to request data from the Tiingo News Feed dataset:

```
self.aapl = self.add_equity("AAPL", Resolution.MINUTE).symbol
self.dataset_symbol = self.add_data(TiingoNews, self.aapl).symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2014
Asset Coverage	10,000 US Equities
Data Density	Sparse
Resolution	Second
Timezone	UTC

Requesting Data

To add Tiingo News Feed data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
class TiingoNewsDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2021, 1, 1)
        self.set_end_date(2021, 6, 1)
        self.set_cash(100000)

        self.aapl = self.add_equity("AAPL", Resolution.MINUTE).symbol
        self.dataset_symbol = self.add_data(TiingoNews, self.aapl).symbol
```

Accessing Data

To get the current Tiingo News Feed data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
PY
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        article = slice[self.dataset_symbol]
        self.log(f"{self.dataset_symbol} article description at {slice.time}: {article.description}")
```

To iterate through all of the articles in the current `Slice` , call the `get` method.

```
PY
def on_data(self, slice: Slice) -> None:
    for dataset_symbol, article in slice.get(TiingoNews).items():
        self.log(f"{dataset_symbol} article description at {slice.time}: {article.description}")
```

Historical Data

To get historical Tiingo News Feed data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.history(self.dataset_symbol, 100, Resolution.DAILY)

# Dataset objects
self.history[TiingoNews](self.dataset_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
PY
self.remove_security(self.dataset_symbol)
```

If you subscribe to Tiingo News Feed data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Tiingo News Feed enables you to accurately design strategies harnessing news articles on the companies you're trading. Examples include the following strategies:

- Creating a dictionary of sentiment scores for various words and assigning a sentiment score to the content of each news release
- Calculating the sentiment of news releases with Natural Language Processing (NLP)
- Trading securities when their news releases are tagged by Tiingo with current buzzwords
- Detecting impactful news in ETF constituents

Classic Algorithm Example

The following example algorithm assigns a sentiment score to each news article that's released for Apple. When the sentiment score is positive, the algorithm buys Apple stock. When the sentiment score is negative, it short sells Apple stock.

```py
from AlgorithmImports import *

class TiingoNewsDataAlgorithm(QCAlgorithm):

    current_holdings = 0
    target_holdings = 0
    # Custom word-score map to assign score for each word in article
    word_scores = {'good': 1, 'great': 1, 'best': 1, 'growth': 1,
                   'bad': -1, 'terrible': -1, 'worst': -1, 'loss': -1}

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Requesting Tiingo news data to obtain the updated news articles to calculate the sentiment score
        self.aapl = self.add_equity("AAPL", Resolution.MINUTE).symbol
        self.tiingo_symbol = self.add_data(TiingoNews, self.aapl).symbol

        # Historical data
        history = self.history(self.tiingo_symbol, 14, Resolution.DAILY)
        self.debug(f"We got {len(history)} items from our history request")

    def on_data(self, slice: Slice) -> None:
        if slice.contains_key(self.tiingo_symbol):
            # Assign a sentiment score to the news article by the word-score map
            title_words = slice[self.tiingo_symbol].description.lower()
            score = 0
            for word, word_score in self.word_scores.items():
                if word in title_words:
                    score += word_score

            # Buy if aggregated sentiment score shows positive sentiment, sell vice versa
            if score > 0:
                self.target_holdings = 1
            elif score < 0:
                self.target_holdings = -1

        # Buy or short sell if the sentiment has changed from our current holdings
        if slice.contains_key(self.aapl) and self.current_holdings != self.target_holdings:
            self.set_holdings(self.aapl, self.target_holdings)
            self.current_holdings = self.target_holdings
```

Framework Algorithm Example

The following example algorithm assigns a sentiment score to each news article that's released for Apple. When the sentiment score is positive, the algorithm buys Apple stock. When the sentiment score is negative, it short sells Apple stock. The algorithm holds positions for 14 days.

```py
from AlgorithmImports import *

class TiingoNewsDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        symbols = [Symbol.create("AAPL", SecurityType.EQUITY, Market.USA)]
        self.add_universe_selection(ManualUniverseSelectionModel(symbols))
        self.add_alpha(TiingoNewsAlphaModel())
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

class TiingoNewsAlphaModel(AlphaModel):

    current_holdings = 0
    target_holdings = 0
    # Custom word-score map to assign score for each word in article
    word_scores = {'good': 1, 'great': 1, 'best': 1, 'growth': 1,
                   'bad': -1, 'terrible': -1, 'worst': -1, 'loss': -1}

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        if slice.contains_key(self.tiingo_symbol):
            # Assign a sentiment score to the news article by the word-score map
            title_words = slice[self.tiingo_symbol].description.lower()
            score = 0
            for word, word_score in self.word_scores.items():
                if word in title_words:
                    score += word_score

            # Buy if aggregated sentiment score shows positive sentiment, sell vice versa
            if score > 0:
                self.target_holdings = 1
            elif score < 0:
                self.target_holdings = -1

        # Buy or short sell if the sentiment has changed from our current holdings
        if slice.contains_key(self.aapl) and self.current_holdings != self.target_holdings:
            self.current_holdings = self.target_holdings
            direction = InsightDirection.UP if self.target_holdings == 1 else InsightDirection.DOWN
            return [Insight.price(self.aapl, timedelta(days=14), direction)]

        return []

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            self.aapl = security.symbol

            # Requesting Tiingo news data to obtain the updated news articles to calculate the sentiment score
            self.tiingo_symbol = algorithm.add_data(TiingoNews, self.aapl).symbol

            # Historical data
            history = algorithm.history(self.tiingo_symbol, 14, Resolution.DAILY)
            algorithm.debug(f"We got {len(history)} items from our history request")
```

Data Point Attributes

The Tiingo News Feed dataset provides `TiingoNews` objects, which have the following attributes:

Datasets

Treasury Department

The Treasury Department is the executive agency responsible for promoting economic prosperity and ensuring the financial security of the United States. The Department is responsible for a wide range of activities such as advising the President on economic and financial issues, encouraging sustainable economic growth, and fostering improved governance in financial institutions. The Department of the Treasury operates and maintains systems that are critical to the nation's financial infrastructure, such as the production of coin and currency, the disbursement of payments to the American public, revenue collection, and the borrowing of funds necessary to run the federal government.

US Treasury Yield Curve

Treasury Department

US Treasury Yield Curve

Introduction

The US Treasury Yield Curve datasets tracks the yield curve rate from the US Department of the Treasury. The data starts in January 1990 and is delivered on a daily frequency. This dataset is calculated from composites of indicative, bid-side market quotations (not actual transactions) obtained by the Federal Reserve Bank of New York at or near 3:30 PM Eastern Time (ET) each trading day.

For more information about the US Treasury Yield Curve dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

The Treasury Department is the executive agency responsible for promoting economic prosperity and ensuring the financial security of the United States. The Department is responsible for a wide range of activities such as advising the President on economic and financial issues, encouraging sustainable economic growth, and fostering improved governance in financial institutions. The Department of the Treasury operates and maintains systems that are critical to the nation's financial infrastructure, such as the production of coin and currency, the disbursement of payments to the American public, revenue collection, and the borrowing of funds necessary to run the federal government.

Getting Started

The following snippet demonstrates how to request data from the US Treasury Yield Curve dataset:

```py
self.dataset_symbol = self.add_data(USTreasuryYieldCurveRate, "USTYCR").symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1990
Coverage	1 Dataset
Data Density	Sparse

Timezone	New York

Requesting Data

To add US Treasury Yield Curve data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```py
class QuiverCongressDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2019, 1, 1)
        self.set_end_date(2020, 6, 1)
        self.set_cash(100000)

        self.dataset_symbol = self.add_data(USTreasuryYieldCurveRate, "USTYCR").symbol
```

Accessing Data

To get the current US Treasury Yield Curve data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the

data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.log(f"{self.dataset_symbol} one month value at {slice.time}: {data_point.one_month}")
```

Historical Data

To get historical US Treasury Yield Curve data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.history(self.dataset_symbol, 100, Resolution.DAILY)

# Dataset objects
history_bars = self.history[USTreasuryYieldCurveRate](self.dataset_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove your subscription to US Treasury Yield Curve data, call the `remove_security` method.

```
self.remove_security(self.dataset_symbol)
```

Example Applications

The US Treasury Yield Curve dataset enables you to monitor the yields of bonds with numerous maturities in your strategies. Examples include the following strategies:

- Short selling SPY when the yield curve inverts
- Buying short-term Treasuries and short selling long-term Treasuries when the yield curve becomes steeper (aka curve steepener trade)

Classic Algorithm Example

The following example algorithm short sells SPY for two years when the yield curve inverts:

```py
from AlgorithmImports import *

class USTreasuryDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:

        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Request SPY as the market representative for trading
        self.spy_symbol = self.add_equity("SPY", Resolution.HOUR).symbol

        # Requesting yield curve data for trade signal generation (inversion)
        self.yield_curve_symbol = self.add_data(USTreasuryYieldCurveRate, "USTYCR").symbol

        # Historical data
        history = self.history(USTreasuryYieldCurveRate, self.yield_curve_symbol, 60, Resolution.DAILY)
        self.debug(f"We got {len(history)} items from our history request")

        self.last_inversion = datetime.min

    def on_data(self, slice: Slice) -> None:
        # Trade only based on updated yield curve data
        if not slice.contains_key(self.yield_curve_symbol):
            return
        rates = slice[self.yield_curve_symbol]

        # Only advance if a year has gone by, since the inversion signal indicates longer term market regime that will not revert in a
short period
        if (self.time - self.last_inversion < timedelta(days=365)):
            return

        # Normally, 10y yield should be greater than 2y yield due to default risk accumulation
        # But if an inversion occurs, it means the market expects a recession in short term such that the near-expiry bond is more likely
to default
        # if there is a yield curve inversion after not having one for a year, short sell SPY for two years for the expected down market
        if (not self.portfolio.invested and rates.two_year > rates.ten_year):
            self.debug(f"{self.time} - Yield curve inversion! Shorting the market for two years")
            self.set_holdings(self.spy_symbol, -0.5)
            self.last_inversion = self.time
            return

        # If two years have passed, liquidate our position in SPY assuming the market starts resilience
        if (self.time - self.last_inversion >= timedelta(days=365 * 2)):
            self.liquidate(self.spy_symbol)
```

Framework Algorithm Example

The following example algorithm short sells SPY for two years when the yield curve inverts:

```py
from AlgorithmImports import *

class USTreasuryDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        self.universe_settings.resolution = Resolution.HOUR
        # Universe only have SPY as the market representative for trading
        symbols = [Symbol.create("SPY", SecurityType.EQUITY, Market.USA)]
        self.add_universe_selection(ManualUniverseSelectionModel(symbols))
        # Custom alpha model that emit insight according to US Treasury data
        self.add_alpha(USTreasuryAlphaModel(self))
        # Use insight weighting PCM to limit the size of investment, reduce the fluctuation of the portfolio value
        self.set_portfolio_construction(InsightWeightingPortfolioConstructionModel(lambda time: None))

class USTreasuryAlphaModel(AlphaModel):

    spy_symbol = None
    last_inversion = datetime.min

    def __init__(self, algorithm: QCAlgorithm) -> None:
        # Requesting yield curve data for trade signal generation (inversion)
        self.yield_curve_symbol = algorithm.add_data(USTreasuryYieldCurveRate, "USTYCR").symbol

        # Historical data
        history = algorithm.history(self.yield_curve_symbol, 60, Resolution.DAILY)
        algorithm.debug(f"We got {len(history)} items from our history request")

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        # Trade only based on updated yield curve data
        if not (slice.contains_key(self.yield_curve_symbol) and self.spy_symbol is not None):
            return []
        rates = slice[self.yield_curve_symbol]

        # Only advance if a year has gone by, since the inversion signal indicates longer term market regime that will not revert in a
short period
        if (slice.time - self.last_inversion < timedelta(days=365)):
            return []

        # Normally, 10y yield should be greater than 2y yield due to default risk accumulation
        # But if an inversion occurs, it means the market expects a recession in short term such that the near-expiry bond is more likely
to default
        # if there is a yield curve inversion after not having one for a year, short sell SPY for two years for the expected down market
        if (not algorithm.portfolio.invested and rates.two_year > rates.ten_year):
            algorithm.debug(f"{slice.time} - Yield curve inversion! Shorting the market for two years")
            self.last_inversion = slice.time
            return [Insight.price(self.spy_symbol, slice.time + timedelta(days=2*365), InsightDirection.DOWN, None, None, None, 0.5)]
        return []

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.added_securities:
            self.spy_symbol = security.symbol
```

Data Point Attributes

The US Treasury Yield Curve dataset provides `USTreasuryYieldCurveRate` objects, which have the following attributes:

Datasets

US Department of Agriculture

The Economic Research Service (ERS) is a federal statistical agency of the U.S. Department of Agriculture (USDA) dedicated to conducting objective economic research that informs public and private decision-making across agriculture, food, the environment, and rural America. ERS serves policymakers at all levels of government, Congress, and industry groups by providing high-quality analysis on topics ranging from farm sector performance and food security to global trade and rural economic development. The USDA Economic Research Service (ERS) publishes retail price data for fruits and vegetables across multiple forms: Fresh, Canned, Frozen, Dried, and Juice.

USDA Fruit And Vegetables

US Department of Agriculture

USDA Fruit And Vegetables

Introduction

The USDA Fruit And Vegetables dataset by the U.S. Department of Agriculture (USDA) tracks retail price estimates for 75+ commonly consumed fresh and processed fruits and vegetables. Includes price per pound/pint and normalized price per edible cup equivalent.

For more information about the USDA Fruit And Vegetables dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

The Economic Research Service (ERS) is a federal statistical agency of the U.S. Department of Agriculture (USDA) dedicated to conducting objective economic research that informs public and private decision-making across agriculture, food, the environment, and rural America. ERS serves policymakers at all levels of government, Congress, and industry groups by providing high-quality analysis on topics ranging from farm sector performance and food security to global trade and rural economic development. The USDA Economic Research Service (ERS) publishes retail price data for fruits and vegetables across multiple forms: Fresh, Canned, Frozen, Dried, and Juice.

Getting Started

The following snippet demonstrates how to request data from the USDA Fruit and Vegetables dataset:

```
self.dataset_symbol = self.add_data(USDAFruitAndVegetables,
    USDAFruitAndVegetable.Symbols.Apples, Resolution.DAILY)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2013
Asset Coverage	75 Fruits and Vegetables
Resolution	Annual
Data Density	Sparse
Timezone	New York

Requesting Data

To add USDA Fruit And Vegetables data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
class USDAFruitAndVegetablesAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2013, 1, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.dataset_symbol = self.add_data(USDAFruitAndVegetables, USDAFruitAndVegetable.Symbols.Apples, Resolution.DAILY)
```

Accessing Data

To get the current USDA Fruit And Vegetables data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        collection = slice[self.dataset_symbol]
        for data in collection.data:
            self.log(f"{symbol} [{data.form}]: ${data.price_per_cup_equivalent}")
```

To iterate through all of the dataset objects in the current `Slice` , call the `get` method.

```
def on_data(self, slice: Slice) -> None:
    for symbol, collection in slice.get(USDAFruitAndVegetables).items():
        # Iterate over all forms in the collection
        for data in collection.data:
            self.log(f"{symbol} [{data.form}]: ${data.price_per_cup_equivalent}")
```

Historical Data

To get historical USDA Fruit And Vegetables data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
history_df = self.history(self.dataset_symbol, datetime(2013, 1, 1), self.time, Resolution.DAILY)
```

Remove Subscriptions

To remove a subscription, call the `remove_security` method.

```
self.remove_security(self.dataset_symbol)
```

Supported Assets

The USDA Fruit And Vegetable dataset lists data for the following agricultural products:

Example Applications

The USDA Fruit and Vegetable dataset provides insights into the agricultural sector. Examples include the following strategies:

- Compare the prices across sub-products (fresh vs frozen)
- Compare the price trends across products (strawberry vs orange)
- Understand how the agricultural market correlates with the stock market

Classic Algorithm Example

The following example algorithm compares the price difference between fresh and frozen strawberries:

```py
from AlgorithmImports import *

class FreshVsFrozenAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2018, 1, 1)
        self.set_end_date(2023, 12, 31)

        # Single subscription gets both Fresh and Frozen forms
        self.strawberries = self.add_data(USDAFruitAndVegetables, USDAFruitAndVegetable.Symbols.Strawberries).symbol

        history = self.history(USDAFruitAndVegetables, self.strawberries, datetime(2013,1,1), self.time, flatten=True)

    def on_data(self, slice):
        if slice.contains_key(self.strawberries):
            collection = slice[self.strawberries]

            # Find Fresh and Frozen forms in the collection
            fresh_price = None
            frozen_price = None

            for data in collection.data:
                if data.form == "Fresh":
                    fresh_price = data.value
                elif data.form == "Frozen":
                    frozen_price = data.value

            if fresh_price and frozen_price:
                diff_pct = ((fresh_price / frozen_price) - 1) * 100
                self.log(f"{self.time.year}: Fresh ${fresh_price:.2f} vs Frozen ${frozen_price:.2f} ({diff_pct:+.1f}%)")
```

Data Point Attributes

The USDA Fruit And Vegetable dataset provides `USDAFruitAndVegetables` and `USDAFruitAndVegetable` objects, which have the following attributes:

Datasets

VIX Central

VIX Central was founded by Eli Mintz in 2012 with goal of displaying historical VIX term structures in a simple and intuitive interface. VIX Central provides access to real-time and historical VIX data for individual investors.

VIX Central Contango

VIX Central

VIX Central Contango

Introduction

The VIX Central Contango dataset by VIX Central tracks VIX Futures (VX) contango data. The data covers 12 Futures contracts closest to expiry/maturity, starts in June 2010, and is delivered on a daily frequency. The dataset is created by QuantConnect downloading data from VIX Central website, which collects and analyses VIX and VX (VIX Futures) data.

Contango and Backwardation are terms used to describe if participants in the Futures market are overpaying or underpaying relative to the "spot" price of the underlying commodity when trading a Futures contract ("spot" price is the price of the actual commodity/asset at a given moment in time). Contango and backwardation can be used to determine forward-looking expectations of the commodity's spot price by the time the Future has expired/matured and is set to be delivered by participants of the Futures market. As Futures near their expiration/maturity date, contango and backwardation curves tend to converge on the spot price of the commodity at the time of expiration.

For more information about the VIX Central Contango dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

VIX Central was founded by Eli Mintz in 2012 with goal of displaying historical VIX term structures in a simple and intuitive interface. VIX Central provides access to real-time and historical VIX data for individual investors.

Getting Started

The following snippet demonstrates how to request data from the VIX Central Contango dataset:

```
self.dataset_symbol = self.add_data(VIXCentralContango, "VIX", Resolution.DAILY).symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	June 2010
Asset Coverage	1 Futures Chain with 12 contracts
Data Density	Regular
Resolution	Daily
Timezone	New York

Requesting Data

To add VIX Central Contango data to your algorithm, call the `add_data` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
class VixCentralContangoAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2014, 1, 1)
        self.set_end_date(2018, 1, 1)
        self.set_cash(25000)

        self.dataset_symbol = self.add_data(VIXCentralContango, "VX", Resolution.DAILY).symbol
```

Accessing Data

To get the current VIX Central Contango data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
def on_data(self, slice: Slice) -> None:
    if slice.contains_key(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.log(f"{self.dataset_symbol} front month at {slice.time}: {data_point.front_month}")
```

Historical Data

To get historical VIX Central Contango data, call the `history` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.history(self.dataset_symbol, 100, Resolution.DAILY)

# Dataset objects
history_bars = self.history[VIXCentralContango](self.dataset_symbol, 100, Resolution.DAILY)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove your subscription to VIX Central Contango data, call the `remove_security` method.

```
self.remove_security(self.dataset_symbol)
```

Example Applications

The VIX Central Contango dataset enables you to explore VIX Future contracts pricing data. Examples include the following strategies:

- Determining forward-looking expectations by Futures market participants of the underlying commodity's spot price by the time of expiration/maturity
- Creating cash-and-carry arbitrage strategies by trading the spread/convergence of the contango/backwardation curves as a Future nears expiration/maturity

Classic Algorithm Design

The following example algorithm buys SPY when the percentage change between contract F2 and F1 (`Contango_F2_Minus_F1`) is positive. Otherwise, it remains in cash.

```py
from AlgorithmImports import *

class VixCentralContangoAlgorithm (QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(25000)
        # SPY as market representative for macroeconomy indicator trading
        self.spy = self.add_equity("SPY", Resolution.DAILY).symbol
        # Request VIX Contango data for trade signal generation
        self.contango = self.add_data(VIXCentralContango, "VX", Resolution.DAILY).symbol

    def on_data(self, slice: Slice) -> None:
        # Trade base on the updated VIX contango data
        if self.contango not in slice:
            return
        contango_data = slice.get(VIXCentralContango, self.contango)
        ratio = contango_data.contango_f_2_minus_f_1 if contango_data else 0

        # Bet the market will go up if F2 - F1 price percentage change is positive, meaning the near-term market volatility is expected
to be low
        if not self.portfolio.invested and ratio > 0:
            self.set_holdings(self.spy, 1)
        # Liqudiate otherwise to avoid excessive market volatility
        elif ratio < 0:
            self.liquidate()
```

Framework Algorithm Design

The following example algorithm buys SPY when the percentage change between contract F2 and F1 (`Contango_F2_Minus_F1`) is positive. Otherwise, it remains in cash.

```py
from AlgorithmImports import *

class VixCentralContangoAlgorithm (QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(25000)

        self.universe_settings.resolution = Resolution.DAILY
        # Include SPY as market representative for macroeconomy indicator trading
        symbols = [Symbol.create("SPY", SecurityType.EQUITY, Market.USA)]
        self.add_universe_selection(ManualUniverseSelectionModel(symbols))
        # Custom alpha model that emit insights base on VIX contango data
        self.add_alpha(ContangoAlphaModel(self))
        # Equal weighting investment to evenly dissipate the capital concentration risk on non-systematic risky event
        self.set_portfolio_construction(EqualWeightingPortfolioConstructionModel())

class ContangoAlphaModel(AlphaModel):

    def __init__(self, algorithm: QCAlgorithm) -> None:
        self.symbols = []
        # Request VIX Contango data for trade signal generation
        self.contango = algorithm.add_data(VIXCentralContango, "VX", Resolution.DAILY).symbol

        # Historical data
        history = algorithm.history(VIXCentralContango, self.contango, 60, Resolution.DAILY)
        algorithm.debug(f"We got {len(history.index)} items from our history request")

    def update(self, algorithm: QCAlgorithm, slice: Slice) -> List[Insight]:
        insights = []

        if self.contango not in slice:
            return []
        contango_data = slice.get(VIXCentralContango, self.contango)
        ratio = contango_data.contango_f_2_minus_f_1 if contango_data else 0

        # Bet the market will go up if F2 - F1 price percentage change is positive, meaning the near-term market volatility is expected
to be low
        if not algorithm.portfolio.invested and ratio > 0:
            for symbol in self.symbols:
                insights += [Insight.price(symbol, Expiry.ONE_MONTH, InsightDirection.UP)]
        # Liqudiate otherwise to avoid excessive market volatility
        elif ratio < 0:
            for symbol in self.symbols:
                insights += [Insight.price(symbol, Expiry.ONE_MONTH, InsightDirection.FLAT)]

        return insights

    def on_securities_changed(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for symbol in [x.symbol for x in changes.removed_securities]:
            if symbol in self.symbols:
                self.symbols.pop(symbol)

        self.symbols += [x.symbol for x in changes.added_securities]
```

Data Point Attributes

The VIX Central Contango dataset provides `VIXCentralContango` objects, which have the following attributes:

Importing Data

Importing Data

Key Concepts

Introduction

Custom data is your own external data that's not from the Dataset Market. You can use custom data to inform trading decisions and to simulate trades on unsupported securities. To get custom data into your algorithms, you download the entire file at once or read it line-by-line with a custom data reader. If you use a custom data reader, LEAN sends the data to the `on_data` method in your algorithm.

File Providers

The most common file providers to use are the Object Store , Dropbox, GitHub, and Google Sheets.

Object Store

The Object Store is the fastest file provider. If you import files from remote providers, you will be restricted by their rate limits and your download speed.

Dropbox

If you store your custom data in Dropbox, you need to create a link to the file and add `?dl=1` to the end of the file URL. To create file links, see How to share files or folders in the Dropbox documentation. The `?dl=1` parameter lets you download the direct file link, not the HTML page of the file.

GitHub

If you store your custom data in GitHub, you can use public or private repositories. When you download the data, use the raw file (for example, https://raw.githubusercontent.com/<organization>/<repo>/<path>). For instructions on accessing the raw file, see Viewing or copying the raw file content in the GitHub documentation.

Google Sheets

If you store your custom data in Google Sheets, you need to create a link to the file. To create file links, see Make Google Docs, Sheets, Slides & Forms public in the Google Docs documentation. Choose the CSV format to find `/pub?gid={SHEET_ID}&single=true&output=csv` parameter on the end of the link. Google Sheets don't support exporting data in JSON format.

Stream Custom Data

To receive your custom data in the `on_data` method, create a custom type and then create a data subscription. The custom data type tells LEAN where to get your data and how to read it.

All custom data types must extend the `PythonData` class and override the `get_source` and `reader` methods

```py
class MyCustomDataType(PythonData):
    def get_source(self,
         config: SubscriptionDataConfig,
         date: datetime,
         is_live: bool) -> SubscriptionDataSource:
        return SubscriptionDataSource("<sourceURL>", SubscriptionTransportMedium.REMOTE_FILE)

    def reader(self,
         config: SubscriptionDataConfig,
         line: str,
         date: datetime,
         is_live: bool) -> BaseData:

         if not (line.strip() and line[0].isdigit()):
            return None

         data = line.split(',')

        custom = MyCustomDataType()
        custom.time = datetime.strptime(data[0], '%Y%m%d')
        custom.end_time = custom.time + timedelta(1)
        custom.value = float(data[1])
        custom["Property1"] = float(data[2])
        return custom
```

For more information about custom data types, see Streaming Data .

Download Bulk Data

The `download` method downloads the content served from a local file or URL and then returns it as a string.

```py
content = self.download("<filePathOrURL>")
```

For more information about bulk downloads, see Bulk Downloads .

File Quotas

There are no limits to the number of files you can load from the Object Store during a single backtest or Research Environment session in QuantConnect Cloud.

The following table shows the number of remote files you can download during a single backtest or Research Environment session in QuantConnect Cloud:

Organization Tier	File Quota
Free	25
Quant Researcher	100

Remote files can be up to 200 MB in size and can have names up to 200 characters long.

Rate Limits

We do not impose a rate limit on file downloads but often external providers do. Dropbox caps download speeds to 10 kb/s after 3-4 download requests. To ensure your algorithms run fast, only use a small number of small custom data files or use the Object Store.

Timeouts

In cloud algorithms, the download methods have a 10-second timeout period. If the methods don't download the data within 10 seconds, LEAN throws an error.

Importing Data

Streaming Data

Streaming Data

Key Concepts

Introduction

There are two techniques to import data into your algorithm. You can either manually import the entire file or stream the file line-by-line into your algorithm's `on_data` event. This page explores streaming a file's contents into your algorithm line-by-line. The data you import can be from a remote server or the Object Store .

Data Formats

Common data formats are CSV , JSON , XML , and ZIP but you can use any file type that can be read over the internet. For Excel files, double check the raw data format for parsing in the data reader, since data will be formatted for convenient visualization in Excel application view. To avoid confusion of data format, save the spreadsheet as a CSV file and open it in a text editor to confirm the raw data format.

If you import from a remote file provider , each request has a one-second overhead, so package your custom data to minimize requests. Bundle dates together where possible to speed up execution. The Object Store file provider gives you the fastest execution because you don't need to download the files on every execution.

Point-In-Time Tickers

Tickers are a string shortcode representation for an asset. Some examples of popular tickers include "AAPL" for Apple Corporation and "IBM" for International Business Machines Corporation. These tickers often change when the company rebrands or they undergo a merger or reverse merger.

The ticker of an asset is not the same as the `Symbol` . `Symbol` objects are permanent and track the underlying entity. When a company rebrands or changes its name, the `Symbol` object remains constant, giving algorithms a way to reliably track assets over time.

Tickers are also often reused by different brokerages. For example Coinbase, a leading US Crypto Brokerage lists the "BTCUSD" ticker for trading. Its competitor, Bitfinex, also lists "BTCUSD". You can trade both tickers with LEAN. `Symbol` objects allow LEAN to identify which market you reference in your algorithms.

To create a `Symbol` object for a point-in-time ticker, call the `generate_equity` method to create the security identifier and then call the `Symbol` constructor. For example, Heliogen, Inc. changed their ticker from ATHN to HLGN on December 31, 2021. To convert the ATHN ticker to the Equity `Symbol` , type:

```
# Generate an Equity security identifier for a ticker and then create a symbol with it.
ticker = "ATHN"
security_id = SecurityIdentifier.generate_equity(ticker, Market.USA, mapping_resolve_date=datetime(2021, 12, 1))
symbol = Symbol(security_id, ticker)
```

In the preceding code snippet, the `mapping_resolve_date` must be a date when the point-in-time ticker was trading.

For examples of point-in-time tickers in custom data types, refer to the CSV Format Example and JSON Format Example .

Set Data Sources

The `get_source` method in your custom data class instructs LEAN where to find the data.

```
class MyCustomDataType(PythonData):
    def get_source(self,
         config: SubscriptionDataConfig,
         date: datetime,
         is_live_mode: bool) -> SubscriptionDataSource:

         if is_live_mode:
            return SubscriptionDataSource("https://www.bitstamp.net/api/ticker/", SubscriptionTransportMedium.REST)

        source = f"http://my-ftp-server.com/{config.symbol.value}/{date:%Y%M%d}.csv"
        return SubscriptionDataSource(source, SubscriptionTransportMedium.REMOTE_FILE)

        # Example of loading from the Object Store:
        # return SubscriptionDataSource(Bitstamp.KEY, SubscriptionTransportMedium.OBJECT_STORE)

        # Example of loading a remote zip file:
        # return SubscriptionDataSource(
        #     "https://cdn.quantconnect.com/uploads/multi_csv_zipped_file.zip",
        #     SubscriptionTransportMedium.REMOTE_FILE,
        #     FileFormat.ZIP_ENTRY_NAME
        # )

        # Example of loading a remote zip file and accessing a CSV file inside it:
        # return SubscriptionDataSource(
        #     "https://cdn.quantconnect.com/uploads/multi_csv_zipped_file.zip#csv_file_10.csv",
        #     SubscriptionTransportMedium.REMOTE_FILE,
        #     FileFormat.ZIP_ENTRY_NAME
        # )

        # Example of loading a remote file with Basic authentication headers:
        # import base64
        # user = "username"
        # password = "12345"
        # byte_key = base64.b64encode(f"{user}:{password}".encode("ascii"))
        # authorization_headers = {
        #     "Authorization": f"Basic {byte_key.decode('ascii')}"
        # }
        # return SubscriptionDataSource(source, SubscriptionTransportMedium.REMOTE_FILE, FileFormat.CSV, authorization_headers)
```

The following table describes the arguments the `get_source` method accepts:

Argument	Data Type	Description
`config`	`SubscriptionDataConfig`	The subscription configuration
`date`	`datetime`	Date of this source file
`is_live_mode`	`bool`	`True` if algorithm is running in live mode

You can use these arguments to create `SubscriptionDataSource` objects representing different locations and formats. The following table describes the arguments the `SubscriptionDataSource` accepts:

Argument	Data Type	Description	Default Value
`source`	`str`	Data source location	
`transport_medium`	`SubscriptionTransportMedium`	The transport medium to be used to retrieve data from the source	
`format`	`FileFormat`	The format of the data within the source	`FileFormat.Csv`
`headers`	`dict[str, str]`	The headers to be used for this source. In cloud algorithms, each of the key-value pairs can consist of up to 1,000 characters.	`None`

The `FileFormat` enumeration has the following members:

The `SubscriptionTransportMedium` enumeration has the following members:

Member	Description	Example
`LOCAL_FILE`	The data comes from disk	Lean.DataSource.CBOE
`REMOTE_FILE`	The data is downloaded from a remote source	`Custom Securities Examples`
`REST`	The data comes from a rest call that is polled and returns a single line/data point of information	`live_mode` case of Demonstration Algorithm
`OBJECT_STORE`	The data comes from the object store	Example of Custom Data

Parse Custom Data

The `reader` method of your custom data class takes one line of data from the source location and parses it into one of your custom objects. You can add as many properties to your custom data objects as you need, but the following table describes the properties you must set. When there is no useable data in a line, the method should return `None` . LEAN repeatedly calls the `reader` method until the date/time advances or it reaches the end of the file.

Property	Description
`symbol`	You can set this property to `config.symbol` .
`time`	The time when the data sample starts.
`end_time`	The time when the data sample ends and when LEAN should add the sample to a Slice .
`value`	The default data point value (`float`).

The following table describes the arguments the `reader` method accepts:

Argument	Data Type	Description
`config`	`SubscriptionDataConfig`	The subscription configuration
`line`	`str`	Content from the requested data source
`date`	`datetime`	Date of this source file
`is_live_mode`	`bool`	`True` if algorithm is running in live mode

You can use these arguments to create `BaseData` objects from different sources.

```py
class MyCustomDataType(PythonData):
    def reader(self,
         config: SubscriptionDataConfig,
         line: str,
         date: datetime,
         is_live_mode: bool) -> BaseData:

        if not line.strip():
            return None

        custom = MyCustomDataType()
        custom.symbol = config.symbol

        if is_live_mode:
            data = json.loads(line)
            custom.end_time =  Extensions.convert_from_utc(datetime.utcnow(), config.exchange_time_zone)
            custom.value = data["value"]
            return custom

        if not line[0].isdigit():
            return None

        data = line.split(',')
        custom.end_time = datetime.strptime(data[0], '%Y%m%d') + timedelta(1)
        custom.value = float(data[1])
        return custom
```

Unsorted Data

By default, LEAN expects the data in chronological order. If the data is unsorted, set the `sort` property of the `SubscriptionDataSource` object to `True`.

```py
class MyCustomDataType(PythonData):
    def get_source(self,
            config: SubscriptionDataConfig,
            date: datetime,
            is_live_mode: bool) -> SubscriptionDataSource:

        source = f"http://my-ftp-server.com/{config.symbol.value}/{date:%Y%M%d}.csv"
        subscription = SubscriptionDataSource(source, SubscriptionTransportMedium.REMOTE_FILE)
        subscription.sort = True
        return subscription
```

LEAN uses `end_time` property of your custom data to sort it.

Object Store

The Object Store file provider gives you the fastest execution because you don't need to download the files on every execution. To upload the data files into the Object Store, use the Algorithm Lab , CLI , or Research Environment . To then pull the data from the Object Store into an algorithm, set the custom data source to read from the file in Object Store and parse the data in the `reader` method.

```py
class MyCustomDataType(PythonData):
    def get_source(self,
            config: SubscriptionDataConfig,
            date: datetime,
            is_live_mode: bool) -> SubscriptionDataSource:

        return SubscriptionDataSource("<your_csv_key>", SubscriptionTransportMedium.OBJECT_STORE, FileFormat.CSV)
        # return new SubscriptionDataSource("<your_json_key>", SubscriptionTransportMedium.ObjectStore, FileFormat.UNFOLDING_COLLECTION);
```

Set Properties

To set the Symbol Properties of the custom data, provide a `SymbolProperties` object when you subscribe to the dataset. The ticker you pass to the `SymbolProperties` constructor and the `add_data` method must be the same.

To set the Exchange Hours of the custom data, provide a `SecurityExchangeHours` object when you subscribe to the dataset. The default hours are for the market to be open 24/7.

```
ticker = "ABC"
properties = SymbolProperties("description", "USD", 1, 0.01, 0.01, ticker)
hours = MarketHoursDatabase.get_entry(Market.USA, "SPY", SecurityType.EQUITY).exchange_hours
self.add_data(CustomData, ticker, properties, hours)
```

PY

Live Trading Considerations

In live trading, we pass custom data to your algorithm as soon as it arrives. The time it arrives may not align with the time of other slices . Design your algorithm to handle unsychronized data so that you don't run into issues.

Demonstration Algorithm

The following example algorithm implements a custom data source for the Bitstamp API.

PY

```
class CustomDataBitstampAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2020, 9, 1)
        self.set_end_date(2020, 12, 31)
        self.set_cash(100000)
        # Define the symbol and "type" of our generic data:
        self._custom_data_symbol = self.add_data(Bitstamp, "BTC").symbol
        # Get some historical data.
        history = self.history(
            Bitstamp, self._custom_data_symbol, 200, Resolution.DAILY
        )

    def on_data(self, slice):
        # Get the data of the current day.
        data = slice.get(self._custom_data_symbol)
        if not data:
            return
        self.plot(self._custom_data_symbol, 'Price', data.close)

class Bitstamp(PythonData):

    def get_source(self, config, date, is_live_mode):
        if is_live_mode:
            return SubscriptionDataSource(
                'https://www.bitstamp.net/api/ticker/',
                SubscriptionTransportMedium.REST
            )
        return SubscriptionDataSource(
            "https://raw.githubusercontent.com/QuantConnect/Documentation/master/Resources/datasets/custom-data/bitstampusd.csv",
            SubscriptionTransportMedium.REMOTE_FILE
        )

    def reader(self, config, line, date, is_live_mode):
        if not line.strip():
            return None
        coin = Bitstamp()
        coin.symbol = config.symbol
        # In live trading, parse the JSON file.
        if is_live_mode:
            # Example Line Format:
            # {"high": "441.00", "last": "421.86", "timestamp": "1411606877", "bid": "421.96", "vwap": "428.58", "volume":
"14120.40683975", "low": "418.83", "ask": "421.99"}
            live_btc = json.loads(line)
            # If value is zero, return None
            coin.value = float(live_btc["last"])
            if coin.value == 0:
                return None
            coin.end_time =  Extensions.convert_from_utc(
                datetime.utcnow(), config.exchange_time_zone
            )
            coin.time = coin.end_time - timedelta(1)
            coin["Open"] = float(live_btc["open"])
            coin["High"] = float(live_btc["high"])
            coin["Low"] = float(live_btc["low"])
            coin["Close"] = coin.value
            coin["Ask"] = float(live_btc["ask"])
            coin["Bid"] = float(live_btc["bid"])
            coin["VolumeBTC"] = float(live_btc["volume"])
            coin["WeightedPrice"] = float(live_btc["vwap"])
            return coin

        # In backtests, parse the CSV file.
        # Example Line Format:
        # Date      Open   High    Low     Close   Volume (BTC)    Volume (Currency)   Weighted Price
        # 2011-09-13 5.8    6.0     5.65    5.97    58.37138238,    346.0973893944      5.929230648356
        if not line[0].isdigit():
            return None
        data = line.split(',')
        # If value is zero, return None
        coin.value = float(data[4])
        if coin.value == 0:
            return None
        coin.time = datetime.strptime(data[0], "%Y-%m-%d")
        coin.end_time = coin.time + timedelta(1)
        coin["Open"] = float(data[1])
        coin["High"] = float(data[2])
        coin["Low"] = float(data[3])
        coin["Close"] = coin.value
        coin["VolumeBTC"] = float(data[5])
        coin["VolumeUSD"] = float(data[6])
        coin["WeightedPrice"] = float(data[7])
        return coin
```

Streaming Data

Custom Securities

Custom Securities

Key Concepts

Introduction

To receive your custom data in the `on_data` method instead of in a bulk download, create a custom type and then create a data subscription. The custom data type tells LEAN where to get your data and how to read it. All custom data types must extend from `PythonData` and override the `reader` and `get_source` methods.

Unlike custom data, native QC data gets the full benefit of security modeling like splits and dividends. Custom data is ignorant of everything about the actual market. Things like market hours, delistings, and mergers don't work with custom data.

Create Subscriptions

After you define the custom data class, in the `initialize` method of your algorithm, call the `add_data` method. This method gives LEAN the type factory to create the objects, the name of the data, and the resolution at which to poll the data source for updates.

```py
class MyAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_data(MyCustomDataType, "<name>", Resolution.DAILY).symbol
```

The `resolution` argument should match the resolution of your custom dataset. The lowest reasonable resolution is every minute. Anything more frequent than every minute is very slow to execute. The frequency that LEAN checks the data source depends on the `resolution` argument. The following table shows the polling frequency of each resolution:

Resolution	Update Frequency
Daily	Every 30 minutes
Hour	Every 30 minutes
Minute	Every minute
Second	Every second
Tick	Constantly checks for new data

There are several other signatures for the `add_data` method.

```
self.add_data(type, ticker, resolution)
self.add_data(type, ticker, resolution, time_zone, fill_forward, leverage)
self.add_data(type, ticker, properties, exchange_hours, resolution, fill_forward, leverage)
```

Receive Custom Data

As your data reader reads your custom data file, LEAN adds the data points in the `Slice` it passes to your algorithm's `on_data` method. To collect the custom data, use the `symbol` or name of your custom data subscription. You can access the `value` and custom properties of your custom data class from the `Slice` . To access the custom properties, pass the property name to the `get_property` method .

```py
class MyAlgorithm(QCAlgorithm):
    def on_data(self, slice: Slice) -> None:
        if slice.contains_key(self._symbol):
            custom_data = slice[self._symbol]
            value = custom_data.value
            property1 = custom_data.property1
```

Debugging

In backtests, you can use the IDE debugging capabilities to inspect the variables to understand the internal state of the custom data implementation. For more information about backtest debugging, see the Debugging documentation for Cloud Platform , Local Platform , or the CLI .

In live trading, consider adding logging statements to help with debugging since the debugger isn't available. To log information from inside your custom data class, set a class member that references the algorithm.

```py
class MyCustomDataTypeAlgorithm(QCAlgorithm):
    def initialize(self):
        MyCustomDataType.ALGORITHM = self
        self._symbol = self.add_data(MyCustomDataType, "<name>", Resolution.DAILY).Symbol

class MyCustomDataType(PythonData):
    def reader(self, config: SubscriptionDataConfig, line: str, date: datetime, is_live_mode: bool) -> BaseData:
        data = line.split(',')
        custom = MyCustomDataType()
        custom.symbol = config.symbol
        if not line[0].isdigit():
            # Display the line with the header
            MyCustomDataType.ALGORITHM.Debug(f"HEADER: {line}")
            return custom
        custom.end_time = datetime.strptime(data[0], '%Y%m%d') + timedelta(1)
        custom.value = float(data[1])
        return custom
```

Set the Benchmark

To set your custom data source as the benchmark, in the `initialize` method, call the `set_benchmark` method with the `Symbol` of your custom data subscription.

```py
self._symbol = self.add_data(MyCustomDataType, "<name>", Resolution.DAILY).symbol
self.set_benchmark(self._symbol)
```

Avoid Look-Ahead Bias

Look-ahead bias occurs when you make decisions with information that wouldn't be available until some time in the future. In backtesting, look-ahead bias occurs when you receive data earlier than it would actually be available in reality. If look-ahead bias seeps into your algorithm, it will perform differently between live trading and backtesting.

To avoid look-ahead bias, set the timestamp of data points to the time when the data would actually be available. A lot of external sources apply timestamps to data differently than we do. For instance, on some platforms, daily bars are displayed with the date that they opened. We display daily bars with the date they closed. If you set the `end_time` to the start of the bar, you'll receive the bar earlier in backtests than you would in live trading.

Time Modeling

Data types classes in LEAN inherit from the `BaseData` class that defines the `time` and `end_time` properties. These properties represent the time period of which the data was built. If the data type occurs in a singular point in time, they have no period, so `time` and `end_time` are the same. Regardless of the period, LEAN uses the time when the data sample ends, `end_time` , to add the sample to a `Slice` .

Historical Data

To get historical data points for a custom dataset, call the `history` method with the dataset `Symbol` . For more information about historical data, see Data Points .

Market Hours

The default market hours for custom securities is to be always open. To set the market hours, pass an `exchange_hours` argument to the `add_data` method.

```
symbol = Symbol.create('SPY', SecurityType.EQUITY, Market.USA)
symbol_properties = self.symbol_properties_database.get_symbol_properties(symbol.id.market, symbol, SecurityType.EQUITY, 'USD')
security_exchange_hours = self.market_hours_database.get_exchange_hours(symbol.id.market, symbol, SecurityType.EQUITY)
security = self.add_data(CustomType, contract, symbol_properties, security_exchange_hours, Resolution.HOUR)
```

Custom Securities

CSV Format Example

Introduction

This page explains how to import custom data of a single security sourced in CSV format.

Data Format

The following snippet shows an example CSV file:

```
Date,Open,High,Low,Close,SharesTraded,Tur11er(Rs.Cr)
1997-01-01,905.2,941.4,905.2,939.55,38948210,978.21
1997-01-02,941.95,944,925.05,927.05,49118380,1150.42
1997-01-03,924.3,932.6,919.55,931.65,35263845,866.74
...
2014-07-24,7796.25,7835.65,7771.65,7830.6,117608370,6271.45
2014-07-25,7828.2,7840.95,7748.6,7790.45,153936037,7827.61
2014-07-28,7792.9,7799.9,7722.65,7748.7,116534670,6107.78
```

The data in the file must be in chronological order.

Define Custom Types

To define a custom data type, inherit the `PythonData` class and override the GetSource and Reader methods.

PY

```
class MyCustomDataType(PythonData):

    def get_source(self,
         config: SubscriptionDataConfig,
         date: datetime,
         is_live: bool) -> SubscriptionDataSource:

        if not is_live:
            return SubscriptionDataSource("<custom_data_key>", SubscriptionTransportMedium.OBJECT_STORE, FileFormat.CSV)
        return SubscriptionDataSource("https://raw.githubusercontent.com/QuantConnect/Documentation/master/Resources/datasets/custom-
data/csv-data-example.csv", SubscriptionTransportMedium.REMOTE_FILE)

    def reader(self,
         config: SubscriptionDataConfig,
         line: str,
         date: datetime,
         is_live: bool) -> BaseData:

        if not (line.strip()):
            return None

        index = MyCustomDataType()
        index.symbol = config.symbol

        try:
            data = line.split(',')
            index.time = datetime.strptime(data[0], "%Y-%m-%d")
            index.end_time = index.time + timedelta(days=1)
            index.value = data[4]
            index["open"] = float(data[1])
            index["high"] = float(data[2])
            index["low"] = float(data[3])
            index["close"] = float(data[4])

        except ValueError:
            # Do nothing
            return None

        return index
```

Create Subscriptions

To create a subscription for the custom type, in the `initialize` method, call the `add_data` method. The `add_data` method returns a `Security` object, which contains a `Symbol` . Save a reference to the `symbol` so you can use it in `on_data` to access the security data in the `Slice` .

```
class MyAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_data(MyCustomDataType, "MyCustomDataType", Resolution.DAILY).symbol
```

The `add_data` method creates a subscription for a single custom data asset and adds it to your user-defined universe.

Receive Custom Data

As your data reader reads your custom data file, LEAN adds the data points in the `Slice` it passes to your algorithm's `on_data` method. To collect the custom data, use the `symbol` or name of your custom data subscription. You can access the `value` and custom properties of your custom data class from the `Slice` . To access the custom properties, pass the property name to the `get_property` method .

```
class MyAlgorithm(QCAlgorithm):
    def on_data(self, slice: Slice) -> None:
        if slice.contains_key(self._symbol):
            custom_data = slice[self._symbol]
            close = custom_data.close
```

If you add custom properties to your data object in the `reader` method, LEAN adds them as members to the data object in the `Slice` . To ensure the property names you add in the `reader` method follow the convention of member names, LEAN applies the following changes to the property names you provide in the `reader` method:

1. `-` and `.` characters are replaced with whitespace.
2. The first letter is capitalized.
3. Whitespace characters are removed.

For example, if you set a property name in the `reader` method to `['some-property.name']` , you can access it in the `on_data` method through the `Somepropertyname` member of your data object.

Custom Securities

JSON Format Example

Introduction

This page explains how to import custom data of a single security sourced in JSON format.

Data Format

The following code snippet shows an example JSON file

```
[
    {
      "Date": "1997-01-01",
      "Open": 905.2,
      "High": 941.4,
      "Low": 905.2,
      "Close": 939.55,
      "SharesTraded": 38948210,
      "Turller(Rs.Cr)": 978.21
    },
    {
      "Date": "1997-01-02",
      "Open": 941.95,
      "High": 944,
      "Low": 925.05,
      "Close": 927.05,
      "SharesTraded": 49118380,
      "Turller(Rs.Cr)": 1150.42
    },
    ...
    {
      "Date": "2014-07-25",
      "Open": 7828.2,
      "High": 7840.95,
      "Low": 7748.6,
      "Close": 7790.45,
      "SharesTraded": 153936037,
      "Turller(Rs.Cr)": 7827.61
    },
    {
      "Date": "2014-07-28",
      "Open": 7792.9,
      "High": 7799.9,
      "Low": 7722.65,
      "Close": 7748.7,
      "SharesTraded": 116534670,
      "Turller(Rs.Cr)": 6107.78
    }
]
```

The data in the file must be in chronological order.

Define Custom Types

To define a custom data type, inherit the `PythonData` class and override the GetSource and Reader methods.

If you need to create multiple objects in your `reader` method from a single `line` , follow these steps:

1. In the `get_source` method, pass `FileFormat.UNFOLDING_COLLECTION` as the third argument to the `SubscriptionDataSource` constructor.
2. In the `reader` method, order the objects by their timestamp and then return a `BaseDataCollection(end_time, config.symbol, objects)` where `objects` is a list of your custom data objects.

```
class MyCustomDataType(PythonData):
    def get_source(self,
         config: SubscriptionDataConfig,
         date: datetime,
         is_live: bool) -> SubscriptionDataSource:
        if not is_live:
            return SubscriptionDataSource("<custom_data_key>", SubscriptionTransportMedium.OBJECT_STORE, FileFormat.UNFOLDING_COLLECTION)
        return SubscriptionDataSource("https://raw.githubusercontent.com/QuantConnect/Documentation/master/Resources/datasets/custom-
data/unfolding-collection-example.json", SubscriptionTransportMedium.REMOTE_FILE, FileFormat.UNFOLDING_COLLECTION)

    def reader(self,
         config: SubscriptionDataConfig,
         line: str,
         date: datetime,
         is_live: bool) -> BaseData:

        if not (line.strip()):
            return None

        objects = []
        data = json.loads(line)

        for datum in data:
            index = MyCustomDataType()
            index.symbol = config.symbol
            index.time = datetime.strptime(datum["Date"], "%Y-%m-%d")
            index.end_time = index.time + timedelta(1)
            index["Open"] = float(datum["Open"])
            index["High"] = float(datum["High"])
            index["Low"] = float(datum["Low"])
            index["Close"] = float(datum["Close"])
            index.value = index["Close"]
            objects.append(index)

        return BaseDataCollection(objects[-1].end_time, config.symbol, objects)
```

Create Subscriptions

To create a subscription for the custom type, in the `initialize` method, call the `add_data` method. The `add_data` method returns a `Security` object, which contains a `Symbol` . Save a reference to the `symbol` so you can use it in `on_data` to access the security data in the `Slice` .

```
class MyAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_data(MyCustomDataType, "MyCustomDataType", Resolution.DAILY).symbol
```

The `add_data` method creates a subscription for a single custom data asset and adds it to your user-defined universe.

Receive Custom Data

As your data reader reads your custom data file, LEAN adds the data points in the `Slice` it passes to your algorithm's `on_data` method. To collect the custom data, use the `symbol` or name of your custom data subscription. You can access the `value` and custom properties of your custom data class from the `Slice` . To access the custom properties, pass the property name to the `get_property` method .

```
class MyAlgorithm(QCAlgorithm):
    def on_data(self, slice: Slice) -> None:
        if slice.contains_key(self._symbol):
            custom_data = slice[self._symbol]
            close = custom_data.close
```

If you add custom properties to your data object in the `reader` method, LEAN adds them as members to the data object in the `Slice` . To ensure the property names you add in the `reader` method follow the convention of member names, LEAN applies the following changes to the property names you provide in the `reader` method:

1. `-` and `.` characters are replaced with whitespace.
2. The first letter is capitalized.
3. Whitespace characters are removed.

For example, if you set a property name in the `reader` method to `['some-property.name']` , you can access it in the `on_data` method through the `Somepropertyname` member of your data object.

Custom Universes

Custom Universes

Key Concepts

Introduction

A custom universe lets you select a basket of assets from a custom dataset.

Initialize Universes

To add a custom universe to your algorithm, in the `initialize` method, pass your universe type and a selector function to the `add_universe` method.

```
self.add_universe(MyCustomUniverseDataClass, self._selector_function)
```

Receive Custom Data

The universe selector function receives a list of your custom objects and must return a list of `Symbol` objects. In the selector function definition, you can use any of the properties of your custom data type. The `Symbol` objects that you return from the selector function set the constituents of the universe.

```
class MyCustomUniverseAlgorithm(QCAlgorithm):
 def _selector_function(self, data: List[MyCustomUniverseDataClass]) -> List[Symbol]:
     sorted_data = sorted([ x for x in data if x["CustomAttribute1"] > 0 ],
                          key=lambda x: x["CustomAttribute2"],
                          reverse=True)
     return [x.symbol for x in sorted_data[:5]]
```

Historical Data

To get historical data for a custom data universe , call the `history` method with the `Universe` object. For more information about historical data, see Universes .

Custom Universes

CSV Format Example

Introduction

This page explains how to import custom data for universe selection sourced in CSV format.

Data Format

You must create a file with data in CSV format. Ensure the data in the file is in chronological order.

```
20170704,SPY,QQQ,FB,AAPL,IWM
20170706,QQQ,AAPL,IWM,FB,GOOGL
20170707,IWM,AAPL,FB,BAC,GOOGL
...
20170729,SPY,QQQ,FB,AAPL,IWM
20170801,QQQ,FB,AAPL,IWM,GOOGL
20170802,QQQ,IWM,FB,BAC,GOOGL
```

Define Custom Types

To define a custom data type, inherit the `PythonData` class and override the GetSource and Reader methods.

PY

```
class StockDataSource(PythonData):
    def get_source(self, config: SubscriptionDataConfig, date: datetime, is_live: bool) -> SubscriptionDataSource:
        if not is_live:
            return SubscriptionDataSource("csv-universe-example.csv", SubscriptionTransportMedium.OBJECT_STORE, FileFormat.CSV)
        return SubscriptionDataSource("https://raw.githubusercontent.com/QuantConnect/Documentation/master/Resources/datasets/custom-
data/csv-universe-example.csv", SubscriptionTransportMedium.REMOTE_FILE, FileFormat.CSV)

    def reader(self, config: SubscriptionDataConfig, line: str, date: datetime, is_live: bool) -> BaseData:
        csv = line.split(',')
        stocks = StockDataSource()
        stocks.symbol = config.symbol
        stocks.line = line
        try:
            stocks.time = Extensions.convert_from_utc(datetime.utcnow(), config.data_time_zone) \
                if is_live else datetime.strptime(csv[0], "%Y%m%d")
            def point_in_time(ticker):
                # The tickers are point-in-time. We generate its security identifier for a given date
                # Then we create a Symbol where the value is the ticker
                sid = SecurityIdentifier.generate_equity(ticker, Market.USA, mapping_resolve_date=stocks.time)
                return Symbol(sid, ticker)
            stocks.symbols = [point_in_time (ticker) for ticker in csv[1:]]
        except:
            pass
        return stocks
```

Initialize Universe

To perform a universe selection with custom data, in the `initialize` method, call the `add_universe` method.

PY

```
class MyAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.add_universe(StockDataSource, self._filter_function)
```

Receive Custom Data

As your data reader reads your custom data file, LEAN adds the data points into a `List[StockDataSource])` object it passes to your algorithm's filter function. Your filter function needs to return a list of `Symbol` or `str` object. LEAN automatically subscribes to these new assets and adds them to your algorithm.

```
class MyAlgorithm(QCAlgorithm):
    def _filter_function(self, data: list[BaseData]) -> list[str]:
        symbols = []
        for item in data:
            symbols.extend(item.symbols)
        return symbols

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        self.debug(str(changes))
```

If you add custom properties to your data object in the `reader` method, LEAN adds them as members to the data object in your filter method. To ensure the property names you add in the `reader` method follow the convention of member names, LEAN applies the following changes to the property names you provide in the `reader` method:

1. `-` and `.` characters are replaced with whitespace.
2. The first letter is capitalized.
3. Whitespace characters are removed.

For example, if you set a property name in the `reader` method to `['some-property.name']`, you can access it in your filter method through the `Somepropertyname` member of your data object.

Custom Universes

JSON Format Example

Introduction

This page explains how to import custom data for universe selection sourced in JSON format.

Data Format

You must create a file with data in JSON format. Ensure the data in the file is in chronological order.

```
[
    {
      "Date": "20170704",
      "Symbols": ["SPY", "QQQ", "FB", "AAPL", "IWM"]
    },
    {
      "Date": "20170706",
      "Symbols": ["QQQ", "AAPL", "IWM", "FB", "GOOGL"]
    },
    ...
    {
      "Date": "20170801",
      "Symbols": ["QQQ", "FB", "AAPL", "IWM", "GOOGL"]
    },
    {
      "Date": "20170802",
      "Symbols": ["QQQ", "IWM", "FB", "BAC", "GOOGL"]
    }
]
```

Define Custom Types

To define a custom data type, inherit the `PythonData` class and override the GetSource and Reader methods.

If you need to create multiple objects in your `reader` method from a single `line` , follow these steps:

1. In the `get_source` method, pass `FileFormat.UNFOLDING_COLLECTION` as the third argument to the `SubscriptionDataSource` constructor.
2. In the `reader` method, order the objects by their timestamp and then return a `BaseDataCollection(end_time, config.symbol, objects)` where `objects` is a list of your custom data objects.

PY

```
class StockDataSource(PythonData):
    def get_source(self, config: SubscriptionDataConfig, date: datetime, is_live: bool) -> SubscriptionDataSource:
        if not is_live:
            return SubscriptionDataSource("universe-example.json", SubscriptionTransportMedium.OBJECT_STORE,
FileFormat.UNFOLDING_COLLECTION)
        return SubscriptionDataSource("https://raw.githubusercontent.com/QuantConnect/Documentation/master/Resources/datasets/custom-
data/universe-example.json", SubscriptionTransportMedium.REMOTE_FILE, FileFormat.UNFOLDING_COLLECTION)

    def reader(self, config: SubscriptionDataConfig, line: str, date: datetime, is_live: bool) -> BaseData:
        def convert(obj):
            stocks = StockDataSource()
            stocks.time = datetime.strptime(obj["Date"], "%Y%m%d")
            def point_in_time(ticker):
                # The tickers are point-in-time. We generate its security identifier for a given date
                # Then we create a Symbol where the value is the ticker
                sid = SecurityIdentifier.generate_equity(ticker, Market.USA, mapping_resolve_date=stocks.time)
                return Symbol(sid, ticker)
            stocks.symbols = [point_in_time (ticker) for ticker in obj["Symbols"]]
            return stocks

        objects = [convert(obj) for obj in json.loads(line)]

        return BaseDataCollection(objects[-1].end_time, config.symbol, objects)
```

Initialize Universe

To perform a universe selection with custom data, in the `initialize` method, call the `add_universe` method.

```py
class MyAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.add_universe(StockDataSource, self._filter_function)
```

Receive Custom Data

As your data reader reads your custom data file, LEAN adds the data points into a `List[StockDataSource])` object it passes to your algorithm's filter function. Your filter function needs to return a list of `Symbol` or `str` object. LEAN automatically subscribes to these new assets and adds them to your algorithm.

```py
class MyAlgorithm(QCAlgorithm):
    def _filter_function(self, data: list[BaseData]) -> list[str]:
        symbols = []
        for item in data:
            symbols.extend(item.symbols)
        return symbols

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        self.debug(str(changes))
```

If you add custom properties to your data object in the `reader` method, LEAN adds them as members to the data object in your filter method. To ensure the property names you add in the `reader` method follow the convention of member names, LEAN applies the following changes to the property names you provide in the `reader` method:

1. `-` and `.` characters are replaced with whitespace.
2. The first letter is capitalized.
3. Whitespace characters are removed.

For example, if you set a property name in the `reader` method to `['some-property.name']`, you can access it in your filter method through the `Somepropertyname` member of your data object.

Streaming Data

Precomputed ML Predictions

Introduction

QuantConnect's point-in-time backtesting engine is one of its greatest strengths: in machine-learning strategies , it forces every feature and prediction to be calculated using only the data available on that exact historical day. This delivers unmatched realism and eliminates look-ahead bias. At the same time, there are clear trade-offs. The same rigorous point-in-time discipline means that every small change to portfolio rules normally triggers a full rerun of the feature-engineering and model-inference pipeline inside the backtest engine.

To avoid re-running the entire feature-engineering and model-inference pipeline for every small change, you can precompute machine learning predictions in the Research Environment and then stream them into an algorithm as a custom universe dataset . This two-file pattern separates expensive feature engineering and model training from the algorithm, which becomes a pure portfolio engine. It provides the following benefits:

- **Speed** - Backtests run much faster because they skip feature calculation and model inference.
- **Iteration speed** - Test many thresholds or risk overlays without rerunning the ML pipeline.
- **Reproducibility** - Predictions are frozen in the Object Store, so there is no drift between backtest runs.

This page explains how to implement a project for precomputing machine learning predictions in the Research Environment and streaming them into a backtest as a custom universe dataset.

Create ML Predictions

In a Research Environment, gather universe and price history , calculate factors and labels, train a model, and export daily predictions as JSON to the Object Store . When you define factors in the notebook, strictly use trailing data as inputs. If you use future data, you may introduce look-ahead bias into the backtest.

PY

```
from sklearn.ensemble import GradientBoostingRegressor

# Define the training and validation periods.
validation_end = datetime(2026, 3, 12)  # or datetime.now()
validation_start = validation_end - timedelta(30)
train_end = validation_start
train_start = train_end - timedelta(90)

# Get the SP500 constituents history.
qb = QuantBook()
spy = qb.add_equity('SPY')
universe = qb.add_universe(qb.universe.etf(spy))
universe_history = qb.universe_history(universe, train_start, validation_end)
symbols_by_date = {
    time: [constituent.symbol for constituent in constituents]  # Timestamps are midnight Tuesday-Saturday
    for (_, time), constituents in universe_history.items()
}

# Get price history for all the assets in the universe.
symbols = list(set().union(*symbols_by_date.values()))
start_buffer = timedelta(40) # Add buffers to warm-up factors and labels
end_buffer = timedelta(5)
history = qb.history(symbols, train_start-start_buffer, validation_end+end_buffer, Resolution.DAILY)

# Calculate the feature and labels.
def add_features_and_label(asset_history):
    open_ = asset_history["open"]
    close = asset_history["close"]
    volume = asset_history["volume"]
    daily_return = close.pct_change()
    dataset = pd.DataFrame()
    # Feature 1: 10-day momentum
    dataset["momentum_10d"] = close / close.shift(10) - 1
    # Feature 2: 20-day volatility
    dataset["volatility_20d"] = daily_return.rolling(window=20).std()
    # Feature 3: Relative volume
    dataset["relative_volume"] = volume / volume.rolling(window=20).mean()
    # Label: return from next open to following open
    # The rebalancing logic in the algorithm uses market-on-open orders.
    # The opening auction is the earliest possible time to trade after
    # the factors update at market close.
    dataset["label"] = open_.shift(-2) / open_.shift(-1) - 1
    return dataset

dataset = history.groupby(level='symbol').apply(add_features_and_label).droplevel(0)
```

```
# Remove rows from the dataset for when the asset wouldn't have been in the universe.
indices = []
rows = []
for universe_dt, symbols in symbols_by_date.items():
    previous_close_dt = spy.exchange.hours.get_next_market_close(universe_dt - timedelta(1), False)
    for symbol in symbols:
        indices.append((universe_dt, symbol))
        rows.append(dataset.loc[(symbol, previous_close_dt)])
cleaned_dataset = pd.DataFrame(rows, index=pd.MultiIndex.from_tuples(indices, names=['time', 'symbol']))

# Split the dataset into train and validation subsets (and drop NaN rows).
t = cleaned_dataset.index.get_level_values("time")
train_data = cleaned_dataset[(train_start <= t) & (t < validation_start)].dropna()
validation_data = cleaned_dataset[(validation_start <= t) & (t <= validation_end)].dropna()
X_train = train_data.drop('label', axis=1)
y_train = train_data['label']
X_val = validation_data.drop('label', axis=1)
y_val = validation_data['label']

# Train the model.
model = GradientBoostingRegressor(
    n_estimators=100,
    learning_rate=0.1,
    max_depth=3,
    random_state=42
)
model.fit(X_train, y_train)

# Calculate predictions on the validation set.
predictions = pd.Series(model.predict(X_val), index=X_val.index)

# Convert the predictions Series into a JSON object.
df = predictions.rename("prediction").reset_index()
df['symbol'] = df['symbol'].apply(str)
df['time'] = df['time'].dt.strftime('%Y-%m-%d')
predictions_json = [
    {
        'date': date,
        'prediction_by_symbol': group.set_index('symbol')['prediction'].to_dict()
    }
    for date, group in df.groupby('time')
]
# Save the predictions JSON to the Object Store.
key = 'research-to-backtest-factors.json'
qb.object_store.save(key, json.dumps(predictions_json))
```

Define A Custom Universe

In the main.py file of your project, define a custom data type that reads the JSON predictions from the Object Store.

```
PY
class PredictionUniverse(PythonData):

    def get_source(self, config, date, is_live_mode):
        # Read from the JSON file we saved in the Object Store.
        return SubscriptionDataSource(
            'research-to-backtest-factors.json',
            SubscriptionTransportMedium.OBJECT_STORE,
            FileFormat.UNFOLDING_COLLECTION
        )

    def reader(self, config, line, date, is_live):
        objects = []
        # Iterate through each day.
        for obj in json.loads(line):
            end_time = datetime.strptime(obj["date"], "%Y-%m-%d")
            # Iterate through each stock on this day.
            for symbol, prediction in obj['prediction_by_symbol'].items():
                stock = PredictionUniverse()
                stock.symbol = Symbol(SecurityIdentifier.parse(symbol), "")
                stock.end_time = end_time
                stock.value = prediction
                objects.append(stock)
        # The BaseDataCollection contains multiple PredictionUniverse objects
        # for each day. Set its `time` to match the `end_time` of one of the objects.
        # We pack the collection and timestamp it with the last timestamp (-1) to signal
        # that the collection has data prior to (or including) that timestamp.
        return BaseDataCollection(objects[-1].end_time, config.symbol, objects)
```

Stream Predictions in Backtests

In the main.py file of your project, subscribe to the custom universe type you defined in the preceding step. To rebalance the portfolio on each new set of daily predictions, add a Scheduled Event .

PY

```
class PredictionUniverseAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2026, 2, 10)
        self.set_cash(100_000)
        self.settings.seed_initial_prices = True
        self._return_prediction_threshold = 0
        # Add the universe of custom data.
        self.universe_settings.resolution = Resolution.DAILY
        self._universe = self.add_universe(PredictionUniverse, self._select_assets)
        # Add a Scheduled Event to rebalance the portfolio every day.
        self.schedule.on(self.date_rules.every_day('SPY'), self.time_rules.at(8, 0), self._rebalance)

    def _select_assets(self, data):
        # Select the assets with a return prediction above some threshold.
        return [stock.symbol for stock in data if stock.value > self._return_prediction_threshold]

    def _rebalance(self):
        # Form an equal-weighted portfolio with the assets in the universe.
        symbols = self._universe.selected
        if not symbols:
            return
        targets = [PortfolioTarget(symbol, 1/len(symbols)) for symbol in symbols]
        self.set_holdings(targets, True)
```

Bulk Downloads

Introduction

There are two techniques to import data into your algorithm. You can either manually import the entire file or stream the file line-by-line into your algorithm's `on_data` event. This page explores importing an entire file for manual use.

Instead of downloading the file from a remote file provider, you can upload the file to the Object Store (with the Algorithm Lab or with the CLI) for faster execution.

Recommended Use Cases

The batch import technique is outside of the LEAN's awareness or control, so it can't enforce good practices. However, the batch import technique is good for the loading the following datasets:

- Loading data into the Object Store
- Trained AI Models
- Well-defined historical price datasets
- Parameters and setting imports such as `Symbol` lists

Download Files

The `download` method downloads the content served from a local file or URL and then returns it as a string.

Basic Usage

```py
file = self.download("<filePathOrURL>")

# If your file is in CSV format, convert it to a DataFrame with the `read_csv` method.
from io import StringIO
import pandas as pd
df = pd.read_csv(StringIO(file))

# If your file is in JSON format, parse it with the `loads` method.
import json
data = json.loads(file)

# If your file is in XML format, parse it with the `fromstring` method.
import xml.etree.ElementTree as ET
root = ET.fromstring(file)
```

Download Method Arguments

The `download` method can accept header settings, a username, and a password for authentication.

Argument	Data Type	Description	Default Value
`address`	`str`	A string containing the URI to download	
`headers`	`Dict[str,str]`	Defines header values to add to the request	`dict()`
`user_name`	`str`	The user name associated with the credentials	`None`
`password`	`str`	The password for the user name associated with the credentials	`None`

Download Request Headers

```
header = { "1": "1" }
self.download(address, headers)
self.download(address, headers, user_name, password)
```

Save Files

When you download a remote file, save it into the Object Store so that you don't have to download the file again. If you need to import the file multiple times, it's faster to import it from the Object Store rather than repeatedly downloading the file from the remote file provider.

Transport Binary Data

Follow these steps to transport binary files with `joblib` :

1. Add the following imports to your local program:

```
import joblib
from io import BytesIO
from base64 import b64encode, b64decode
```

2. Serialize your object and save it to a file. This Base64 serialization is necessary because the default `joblib.dump` serialization produces a binary file that the `download` method can't read without data corruption.

```
buffer = BytesIO()
joblib.dump(my_object, buffer)
base64_str = b64encode(buffer.getvalue()).decode('ascii')
with open("my_model.b64", "w") as f:
    f.write(base64_str)
```

3. Save the file to one of the supported sources . For example, save the file to Dropbox.
4. Download the remote file into your project.

```
base64_str = self.download("<fileURL>")
```

5. Restore the object.

```
model_bytes = b64decode(base64_str.encode('ascii'))
restored_model = joblib.load(BytesIO(model_bytes))
```

Follow these steps to transport binary files with `pickle` :

1. Add the following imports to your local program:

```
import pickle
from base64 import b64encode, b64decode
```

2. Serialize your object and save it to a file.

```
pickle_bytes = pickle.dumps(my_object)
base64_str = b64encode(pickle_bytes).decode('ascii')
with open("my_model.b64", "w") as f:
    f.write(base64_str)
```

3. Save the file to one of the supported sources . For example, save the file to Dropbox.
4. Download the remote file into your project.

```
base64_str = self.download("<fileURL>")
```

5. Restore the object.

```
PY
model_bytes = b64decode(base64_str.encode('ascii'))
restored_model = pickle.loads(model_bytes)
```

Examples

The following examples demonstrate common practices for bulk downloading data.

Example 1: Download Machine Learning Model

The following algorithm makes use of a Scikit-Learn machine learning model to predict SPY price changes and place orders according to the prediction. To obtain the model, we either retrieve it from the Object Store if there exists any or download it from a Dropbox link using the `download` method.

```
PY
import joblib
from io import BytesIO
from base64 import b64decode, b64encode
from sklearn.svm import SVR
from sklearn.model_selection import GridSearchCV

class BulkDownloadExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        # Request SPY data for model training, prediction, and trading.
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol

        # 2-year data to train the model.
        training_length = 252*2
        self.training_data = RollingWindow(training_length)
        # Warm up the training dataset to train the model immediately.
        history = self.history[TradeBar](self._symbol, training_length, Resolution.DAILY)
        for trade_bar in history:
            self.training_data.add(trade_bar)

Consolidating Data

Consolidating Data

Getting Started

Introduction

Consolidating data allows you to create bars of any length from smaller bars. Consolidation is commonly used to combine one-minute price bars into longer bars such as 10-20 minute bars. Consolidated bars are helpful because price movement over a longer period can sometimes contain less noise and bars of exotic length are less researched than standard bars, so they may present more opportunities to capture alpha.

To consolidate data, create a `Consolidator` object and register it for data. The built-in consolidators make it easy to create consolidated bars without introducing bugs. In the following sections, we will introduce the different types of consolidators and show you how to shape data into any form.

Basic Usage

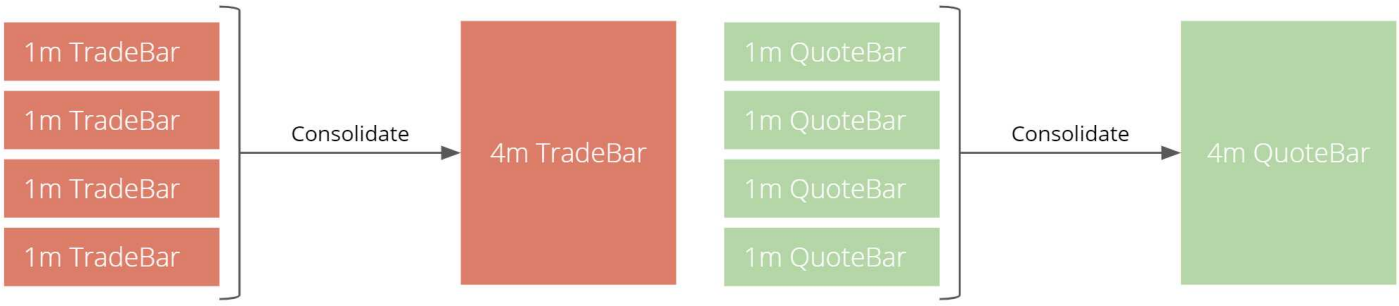
The following code snippet demonstrates a simple consolidator that aggregates 1-minute bars into 10-minutes bars:

```
# In Initialize, subscribe to a security, create the consolidator, and register it for automatic updates
self._symbol = self.add_equity("SPY", Resolution.MINUTE).symbol
self._consolidator = self.consolidate(self._symbol, timedelta(minutes=10), self._consolidation_handler)

# Define the consolidation handler
def _consolidation_handler(self, consolidated_bar: TradeBar) -> None:
    pass
```

Data Shapes and Sizes

Consolidators usually produce output data that is the same format as the input data. They aggregate small `TradeBar` objects into a large `TradeBar` , small `QuoteBar` objects into a large `QuoteBar` , and `Tick` objects into either a `TradeBar` or `QuoteBar` .



Many asset classes in QuantConnect have data for both trades and quotes. By default, consolidators aggregate data into `TradeBar` objects. Forex data is the only exception, which consolidators aggregate into `QuoteBar` objects since Forex data doesn't have `TradeBar` objects.

Consolidator Types

There are many different types of consolidators you can create. The process to create and update the consolidator depends on the input data format, output data format, and the consolidation technique.

Time Period Consolidators

Time period consolidators aggregate data based on a period of time like a number of seconds, minutes, or days. If a time period consolidator aggregates data over multiple days, the multi-day aggregation cycle starts and repeats based on the time stamp of the first data point you use to update the consolidator.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
`TradeBar`	`TradeBar`	TradeBarConsolidator
`QuoteBar`	`QuoteBar`	QuoteBarConsolidator
`Tick`	`TradeBar`	TickConsolidator
`Tick`	`QuoteBar`	TickQuoteBarConsolidator

Calendar Consolidators

Calendar consolidators aggregate data based on specific periods of time like a weekly basis, quarterly basis, or any schedule with specific start and end times. In contrast to time period consolidators, the bars that calendar consolidators produce always end on the same schedule, regardless of the first data point the consolidator receives.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
`TradeBar`	`TradeBar`	TradeBarConsolidator
`QuoteBar`	`QuoteBar`	QuoteBarConsolidator
`Tick`	`TradeBar`	TickConsolidator
`Tick`	`QuoteBar`	TickQuoteBarConsolidator

Count Consolidators

Count consolidators aggregate data based on a number of bars or ticks. This type of consolidator aggregates n samples together, regardless of the time period the samples cover. Managing count consolidators is similiar to managing time period consolidators , except you create count consolidators with an integer argument instead of a time-based argument.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
`TradeBar`	`TradeBar`	TradeBarConsolidator
`QuoteBar`	`QuoteBar`	QuoteBarConsolidator
`Tick`	`TradeBar`	TickConsolidator
`Tick`	`QuoteBar`	TickQuoteBarConsolidator

Mixed-Mode Consolidators

Mixed-mode consolidators are a combination of count consolidators and time period consolidators. This type of consolidator aggregates n samples together or aggregates samples over a specific time period, whichever happens first.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
TradeBar	TradeBar	TradeBarConsolidator
QuoteBar	QuoteBar	QuoteBarConsolidator
Tick	TradeBar	TickConsolidator
Tick	QuoteBar	TickQuoteBarConsolidator

Renko Consolidators

Most Renko consolidators aggregate bars based on a fixed price movement. The RenkoConsolidator produces Renko bars by their traditional definition. In the case of a $1 bar size, the RenkoConsolidator produces bars that have a body spanning 1. The opening price of the first bar is set to the closest 1 multiple of the first trade. When the price moves by at least 1, the first bar closes. If a bar is a rising bar, the following bar closes when the price moves 1 above the closing price of the previous bar or 1 below the opening price of the previous bar. If a bar is a falling bar, the following bar closes when the price moves 1 below the closing price of the previous bar or $1 above the opening price of the previous bar. If the price jumps multiple dollars in a single tick, the RenkoConsolidator produces multiple $1 bars in a single time step.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
TradeBar	TradeBar	RenkoConsolidator
QuoteBar	QuoteBar	RenkoConsolidator
Tick	TradeBar	RenkoConsolidator
Tick	QuoteBar	RenkoConsolidator

Classic Renko Consolidators

Most Renko consolidators aggregate bars based on a fixed price movement. The ClassicRenkoConsolidator produces a different type of Renko bars than the RenkoConsolidator . A ClassicRenkoConsolidator with a bar size of 1 produces a new bar that spans 1 every time an asset closes $1 away from the close of the previous bar. If the price jumps multiple dollars in a single tick, the ClassicRenkoConsolidator only produces one bar per time step where the open of each bar matches the close of the previous bar.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
TradeBar	TradeBar	ClassicRenkoConsolidator
QuoteBar	QuoteBar	ClassicRenkoConsolidator
Tick	TradeBar	ClassicRenkoConsolidator
Tick	QuoteBar	ClassicRenkoConsolidator

Volume Renko Consolidators

Volume Renko consolidators aggregate bars based on a fixed trading volume. These types of bars are commonly known as volume bars. A VolumeRenkoConsolidator with a bar size of 10,000 produces a new bar every time 10,000 units of the security trades in the market. If the trading volume of a single time step exceeds two step sizes (i.e. >20,000), the VolumeRenkoConsolidator produces multiple bars in a single time step.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
`TradeBar`	`TradeBar`	VolumeRenkoConsolidator
`Tick`	`TradeBar`	VolumeRenkoConsolidator

Range Consolidators

Most Range consolidators aggregate bars based on a fixed price movement. It is very much like a Renko Bar, but instead of consolidating a fix movement from the opening price, a Range Bar would fix the range of the whole bar, i.e. High - Low. A new bar is formed when the range of the whole bar reached a preset value, thus it completely neglects the time effect and focuses on the variance/information carried by the price movement.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
`TradeBar`	`TradeBar`	RangeConsolidator
`QuoteBar`	`QuoteBar`	RangeConsolidator
`Tick`	`TradeBar`	RangeConsolidator
`Tick`	`QuoteBar`	RangeConsolidator

Sequential Consolidators

Sequential consolidators wire two internal consolidators together such that the output of the first consolidator is the input to the second consolidator and the output of the second consolidator is the output of the sequential consolidator.

For more information about sequential consolidators, see Combining Consolidators .

Identity Consolidators

Identity consolidators are data pass through. This type of consolidator does not aggregate samples but instead passes each data point through as-is. You can use this consolidator to register indicators that require every data point without any aggregation or sequential consolidators.

Filtered Identity consolidators are a particular type that allows filtering the data. For example, you can filter out unwanted data points before they reach your indicators.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
`TradeBar`	`TradeBar`	IdentityDataConsolidator[TradeBar]
`QuoteBar`	`QuoteBar`	IdentityDataConsolidator[QuoteBar]
`Tick`	`TradeBar`	FilteredIdentityDataConsolidator.for_tick_type(Ti
`Tick`	`QuoteBar`	FilteredIdentityDataConsolidator.for_tick_type(Ti

Execution Sequence

The algorithm manager calls events in the following order:

1. Scheduled Events
2. Consolidation event handlers
3. `on_data` event handler

This event flow is important to note. For instance, if your consolidation handlers or `on_data` event handler appends data to a `RollingWindow` and you use that `RollingWindow` in your Scheduled Event, when the Scheduled Event executes, the `RollingWindow` won't contain the most recent data.

The consolidators are called in the order that they are updated. If you register them for automatic updates, they are updated in the order that you register them.

Plot Consolidated Data

To plot consolidated bars, call the `plot` method with a `TradeBar` argument in the consolidation handler.

```
# In Initialize
equity = self.add_equity("SPY")
self.consolidate(equity.symbol, timedelta(minutes=10), self._consolidation_handler)

# Define the consolidation handler
def _consolidation_handler(self, consolidated_bar: TradeBar) -> None:
    self.plot("<chartName>", "<seriesName>", consolidated_bar)
```

Reset Consolidators

To reset a consolidator, call its `reset` method.

```
self._consolidator.reset()
```

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your consolidators when splits and dividends occur. When a split or dividend occurs while the consolidator is in the process of building a bar, the open, high, and low may reflect prices from before the split or dividend. To avoid issues, call the consolidator's `reset` method and then warm it up with `SCALED_RAW` data from a history request .

```
def on_data(self, data: Slice):
    # When a split or dividend occurs...
    if (data.splits.contains_key(self._symbol) and data.splits[self._symbol].type == SplitType.SPLIT_OCCURRED or
        data.dividends.contains_key(self._symbol)):
        # If the consolidator is working on a bar...
        if self._consolidator.working_data:
            # Get adjusted prices for the time period of the working bar.
            history = self.history[TradeBar](self._symbol, self._consolidator.working_data.time, self.time,
data_normalization_mode=DataNormalizationMode.SCALED_RAW)
            # Reset the consolidator.
            self._consolidator.reset()
            # Warm-up the consolidator with the adjusted price data.
            for bar in history:
                self._consolidator.update(bar)
```

Consolidating Data

Consolidator Types

Consolidator Types

Time Period Consolidators

Introduction

Time period consolidators aggregate data based on a period of time like a number of seconds, minutes, or days. If a time period consolidator aggregates data over multiple days, the multi-day aggregation cycle starts and repeats based on the time stamp of the first data point you use to update the consolidator.

Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `TradeBar` objects of the same size or larger. Follow these steps to create and manage a `TradeBar` consolidator based on a period of time:

1. Create the consolidator.

   To set the time period for the consolidator, you can use either a `timedelta` or `Resolution` object. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

   - `timedelta` Periods

     ```
     self._consolidator = TradeBarConsolidator(timedelta(days=1))
     # Aliases:
     # self._consolidator = self.create_consolidator(timedelta(days=1), TradeBar)
     # self._consolidator = self.resolve_consolidator(self._symbol, timedelta(days=1))
     ```

     The time period is relative to the exchange time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

     Use the `start_time` parameter of the TradeBarConsolidator type constructor to define a custom start time.

     ```
     self._consolidator = TradeBarConsolidator(timedelta(days=1),
         start_time=timedelta(hours=9, minutes=30))
     ```

   - `Resolution` Periods

     The `Resolution` enumeration has the following members:

     ```
     self._consolidator = TradeBarConsolidator.from_resolution(Resolution.DAILY)
     # Alias:
     # self._consolidator = self.resolve_consolidator(self._symbol, Resolution.DAILY)
     ```

   If the security subscription in your algorithm provides `TradeBar` and `QuoteBar` data, `resolve_consolidator` returns a `TradeBarConsolidator` .

   If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET. To change this behavior, set the `start_time` parameter of the TradeBarConsolidator type constructor to `timedelta(hours=9, minutes=30)`

2. Add an event handler to the consolidator.

```
self._consolidator.data_consolidated += self._consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: TradeBar) -> None:
    pass
```

The consolidation event handler receives bars when the consolidated bar closes based on the exchange time zone . If you subscribe to minute resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to minute resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars at market close or midnight, depending on your `daily_precise_end_time` setting .

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

  ```
  self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

  ```
  # Example 1: Update the consolidator with data from the Slice object
  def on_data(self, slice: Slice) -> None:
      trade_bar = slice.bars[self._symbol]
      self._consolidator.update(trade_bar)

  # Example 2: Update the consolidator with data from a history request
  history = self.history[TradeBar](self._symbol, 30, Resolution.MINUTE)
  for trade_bar in history:
      self._consolidator.update(trade_bar)
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create period consolidators and register them for automatic updates. With just one line of code,

you can create data in any time period based on a `timedelta` or `Resolution` object:

- `timedelta` Periods

```
self._consolidator = self.consolidate(self._symbol, timedelta(days=1), self._consolidation_handler)
```

- `Resolution` Periods

```
self._consolidator = self.consolidate(self._symbol, Resolution.DAILY, self._consolidation_handler)
```

If you use the `consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
def _consolidation_handler(self, consolidated_bar: TradeBar) -> None:
    pass
```

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `QuoteBar` objects of the same size or larger. Follow these steps to create and manage a `QuoteBar` consolidator based on a period of time:

1. Create the consolidator.

   To set the time period for the consolidator, you can use either a `timedelta` or `Resolution` object. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

   - `timedelta` Periods

     ```
     self._consolidator = QuoteBarConsolidator(timedelta(days=1))
     # Aliases:
     # self._consolidator = self.create_consolidator(timedelta(days=1), QuoteBar)
     # self._consolidator = self.resolve_consolidator(self._symbol, timedelta(days=1))
     ```

     The time period is relative to the exchange time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

     Use the `start_time` parameter of the QuoteBarConsolidator type constructor to define a custom start time.

     ```
     self._consolidator = QuoteBarConsolidator(timedelta(days=1),
         start_time=timedelta(hours=9, minutes=30))
     ```

   - `Resolution` Periods

     The `Resolution` enumeration has the following members:

     ```
     self._consolidator = self.resolve_consolidator(self._symbol, Resolution.DAILY)
     ```

   If the security subscription in your algorithm provides `TradeBar` and `QuoteBar` data, `resolve_consolidator` returns a `TradeBarConsolidator` .

   If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET. To change this behavior, set the `start_time` parameter of the QuoteBarConsolidator type constructor to `timedelta(hours=9, minutes=30)`

2. Add an event handler to the consolidator.

```
self._consolidator.data_consolidated += self._consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: QuoteBar) -> None:
    pass
```

The consolidation event handler receives bars when the consolidated bar closes based on the exchange time zone . If you subscribe to minute resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to minute resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars at market close or midnight, depending on your `daily_precise_end_time` setting .

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

     ```
     self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `QuoteBar` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

     ```
     # Example 1: Update the consolidator with data from the Slice object
     def on_data(self, slice: Slice) -> None:
         quote_bar = slice.quote_bars[self._symbol]
         self._consolidator.update(quote_bar)

     # Example 2: Update the consolidator with data from a history request
     history = self.history[QuoteBar](self._symbol, 30, Resolution.MINUTE)
     for quote_bar in history:
         self._consolidator.update(quote_bar)
     ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create period consolidators and register them for automatic updates. With just one line of code, you can create data in any time period based on a `timedelta` or `Resolution` object:

- `timedelta` Periods

```
self._consolidator = self.consolidate(self._symbol, timedelta(days=1), TickType.Quote, self._consolidation_handler)
```

- `Resolution` Periods

```
self._consolidator = self.consolidate(self._symbol, Resolution.DAILY, TickType.Quote, self._consolidation_handler)
```

If you use the `consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
def _consolidation_handler(self, consolidated_bar: QuoteBar) -> None:
    pass
```

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `TradeBar` objects. Follow these steps to create and manage a `Tick` consolidator based on a period of time:

1. Create the consolidator.

   To set the time period for the consolidator, you can use either a `timedelta` or `Resolution` object. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

   - `timedelta` Periods

     ```
     self._consolidator = TickConsolidator(timedelta(milliseconds=100))
     # Aliases:
     # self._consolidator = self.create_consolidator(timedelta(milliseconds=100), Tick)
     # self._consolidator = self.resolve_consolidator(self._symbol, timedelta(milliseconds=100))
     ```

     The time period is relative to the exchange time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

     Use the `start_time` parameter of the TickConsolidator type constructor to define a custom start time.

     ```
     self._consolidator = TickConsolidator(timedelta(milliseconds=100),
         start_time=timedelta(hours=9, minutes=30))
     ```

   - `Resolution` Periods

     The `Resolution` enumeration has the following members:

     ```
     self._consolidator = self.resolve_consolidator(self._symbol, Resolution.SECOND)
     ```

   If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET. To change this behavior, set the `start_time` parameter of the TickConsolidator type constructor to `timedelta(hours=9, minutes=30)`

2. Add an event handler to the consolidator.

```
self._consolidator.data_consolidated += self._consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: TradeBar) -> None:
    pass
```

The consolidation event handler receives bars when the consolidated bar closes based on the exchange time zone . If you subscribe to tick resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to tick resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars at market close or midnight, depending on your `daily_precise_end_time` setting .

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

```
self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def on_data(self, slice: Slice) -> None:
    ticks = slice.ticks[self._symbol]
    for tick in ticks:
        self._consolidator.update(tick)

# Example 2: Update the consolidator with data from a history request
ticks = self.history[Tick](self._symbol, timedelta(minutes=3), Resolution.TICK)
for tick in ticks:
    self._consolidator.update(tick)
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create period consolidators and register them for automatic updates. With just one line of code, you can create data in any time period based on a `timedelta` or `Resolution` object:

- `timedelta` Periods

```
self._consolidator = self.consolidate(self._symbol, timedelta(milliseconds=100), self._consolidation_handler)
```

- `Resolution` Periods

```
self._consolidator = self.consolidate(self._symbol, Resolution.SECOND, self._consolidation_handler)
```

If you use the `consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
def _consolidation_handler(self, consolidated_bar: TradeBar) -> None:
    pass
```

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `QuoteBar` objects. Follow these steps to create and manage a `Tick` quote bar consolidator based on a period of time:

1. Create the consolidator.

   To set the time period for the consolidator, you can use either a `timedelta` or `Resolution` object. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

   - `timedelta` Periods

     ```
     self._consolidator = TickQuoteBarConsolidator(timedelta(milliseconds=100))
     # Aliases:
     # self._consolidator = self.create_consolidator(timedelta(milliseconds=100), Tick, TickType.QUOTE)
     # self._consolidator = self.resolve_consolidator(self._symbol, timedelta(milliseconds=100))
     ```

     The time period is relative to the exchange time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

     Use the `start_time` parameter of the TickQuoteBarConsolidator type constructor to define a custom start time.

     ```
     self._consolidator = TickQuoteBarConsolidator(timedelta(milliseconds=100),
         start_time=timedelta(hours=9, minutes=30))
     ```

   - `Resolution` Periods

     The `Resolution` enumeration has the following members:

     ```
     self._consolidator = self.resolve_consolidator(self._symbol, Resolution.SECOND)
     ```

   If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET. To change this behavior, set the `start_time` parameter of the TickQuoteBarConsolidator type constructor to `timedelta(hours=9, minutes=30)`

2. Add an event handler to the consolidator.

   ```
   self._consolidator.data_consolidated += self._consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method

executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: QuoteBar) -> None:
    pass
```

The consolidation event handler receives bars when the consolidated bar closes based on the exchange time zone . If you subscribe to tick resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to tick resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars at market close or midnight, depending on your `daily_precise_end_time` setting .

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

```
self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def on_data(self, slice: Slice) -> None:
    ticks = slice.ticks[self._symbol]
    for tick in ticks:
        self._consolidator.update(tick)

# Example 2: Update the consolidator with data from a history request
ticks = self.history[Tick](self._symbol, timedelta(minutes=3), Resolution.TICK)
for tick in ticks:
    self._consolidator.update(tick)
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create period consolidators and register them for automatic updates. With just one line of code, you can create data in any time period based on a `timedelta` or `Resolution` object:

- `timedelta` Periods

```
self._consolidator = self.consolidate(self._symbol, timedelta(milliseconds=100), TickType.Quote, self._consolidation_handler)
```

- `Resolution` Periods

```
self._consolidator = self.consolidate(self._symbol, Resolution.SECOND, TickType.Quote, self._consolidation_handler)
```

If you use the `consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
def _consolidation_handler(self, consolidated_bar: QuoteBar) -> None:
    pass
```

Consolidate Other Data

`<dataType>` consolidators aggregate various types of data objects into `<dataType>` objects of the same size or larger. If you consolidate custom data or alternative datasets, check the definition of the data class to see its data type. Follow these steps to create and manage a `<dataType>` consolidator based on a period of time:

1. Create the consolidator.

   To set the time period for the consolidator, you can use either a `timedelta` or `Resolution` object. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

   - `timedelta` Periods

     ```
     self._consolidator = DynamicDataConsolidator(timedelta(days=1))
     # Aliases:
     # self._consolidator = self.create_consolidator(timedelta(days=1), <dataType>)
     # self._consolidator = self.resolve_consolidator(self._symbol, timedelta(days=1))
     ```

     The time period is relative to the exchange time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

     Use the `start_time` parameter of the DynamicDataConsolidator type constructor to define a custom start time.

     ```
     self._consolidator = DynamicDataConsolidator(timedelta(days=1),
         start_time=timedelta(hours=9, minutes=30))
     ```

   - `Resolution` Periods

     The `Resolution` enumeration has the following members:

     ```
     self._consolidator = self.resolve_consolidator(self._symbol, Resolution.DAILY)
     ```

   If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET. To change this behavior, set the `start_time` parameter of the DynamicDataConsolidator type constructor to `timedelta(hours=9, minutes=30)`

2. Add an event handler to the consolidator.

   ```
   self._consolidator.data_consolidated += self._consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: <dataType>) -> None:
    pass
```

   The consolidation event handler receives bars when the consolidated bar closes based on the exchange time zone .

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the data subscription, call the `add_consolidator` method of the Subscription Manager.

     ```
     self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `<dataType>` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

     ```
     # Example 1: Update the consolidator with data from the Slice object
     def on_data(self, slice: Slice) -> None:
         if self._symbol in slice:
             self._consolidator.update(slice[self._symbol])

     # Example 2: Update the consolidator with data from a history request
     history = self.history[<dataType>](self._symbol, 30, Resolution.DAILY)
     for data in history:
         self._consolidator.update(data)
     ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create period consolidators and register them for automatic updates. With just one line of code, you can create data in any time period based on a `timedelta` or `Resolution` object:

- `timedelta` Periods

  ```
  self._consolidator = self.consolidate(self._symbol, timedelta(days=1), self._consolidation_handler)
  ```

- `Resolution` Periods

  ```
  self._consolidator = self.consolidate(self._symbol, Resolution.DAILY, self._consolidation_handler)
  ```

If you use the `consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
def _consolidation_handler(self, consolidated_bar: <dataType>) -> None:
    pass
```

Reset Consolidators

To reset a consolidator, call its `reset` method.

```
self._consolidator.reset()
```

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your consolidators when splits and dividends occur. When a split or dividend occurs while the consolidator is in the process of building a bar, the open, high, and low may reflect prices from before the split or dividend. To avoid issues, call the consolidator's `reset` method and then warm it up with `SCALED_RAW` data from a history request .

```
def on_data(self, data: Slice):
    # When a split or dividend occurs...
    if (data.splits.contains_key(self._symbol) and data.splits[self._symbol].type == SplitType.SPLIT_OCCURRED or
        data.dividends.contains_key(self._symbol)):
        # If the consolidator is working on a bar...
        if self._consolidator.working_data:
            # Get adjusted prices for the time period of the working bar.
            history = self.history[TradeBar](self._symbol, self._consolidator.working_data.time, self.time,
data_normalization_mode=DataNormalizationMode.SCALED_RAW)
            # Reset the consolidator.
            self._consolidator.reset()
            # Warm-up the consolidator with the adjusted price data.
            for bar in history:
                self._consolidator.update(bar)
```

Examples

The following examples demonstrate common practices for implementing time-period consolidators.

Example 1: RSI-MACD Trading

The following algorithm utilizes a 5-minute trade bar consolidator to feed the smoothed trade bar to an RSI indicator and a 15-minute quote bar consolidator to feed the smoothed quote bar to a MACD indicator, generating trade entry signals during an uptrend and oversold conditions while exiting when the trend turns down.

```py
class UniverseSettingsAlgorithm(QCAlgorithm):
    # Create RSI and MACD indicators for trade signal generation.
    _rsi = RelativeStrengthIndex(14)
    _macd = MovingAverageConvergenceDivergence(12, 26, 9)

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Request SPY data to feed to indicators and trade.
        self.spy = self.add_equity("SPY").symbol

        # Create a 5-minute trade bar consolidator to feed the smoothed bar to the RSI indicator for the price action entry signal.
        rsi_consolidator = TradeBarConsolidator(timedelta(minutes=5))
        # Create a 15-minute quote bar consolidator to feed the smoothed bar to the MACD consolidator for trend entry/exit signal.
        macd_consolidator = QuoteBarConsolidator(timedelta(minutes=15))

        # Subscribe the consolidators to SPY data to automatically update the indicators.
        self.register_indicator(self.spy, self._rsi, rsi_consolidator)
        self.register_indicator(self.spy, self._macd, macd_consolidator)

        # Warm up the indicators by updating the consolidators with historical data.
        trade_bars = self.history[TradeBar](self.spy, 5 * self._rsi.warm_up_period, Resolution.MINUTE)
        for bar in trade_bars:
            rsi_consolidator.update(bar)
        quote_bars = self.history[QuoteBar](self.spy, 15 * self._macd.warm_up_period, Resolution.MINUTE)
        for bar in quote_bars:
            macd_consolidator.update(bar)

    def on_data(self, slice: Slice) -> None:
        # Entry rule: MACD histogram is positive (positive trend) and RSI is below 30 (oversold) to maximize return.
        if self._rsi.current.value < 30 and self._macd.histogram.current.value > 0 and not self.portfolio[self.spy].is_long:
            self.set_holdings(self.spy, 0.5)
        # Exit rule: MACD histogram is below 0 (negative trend)
        elif self._macd.histogram.current.value < 0 and self.portfolio[self.spy].is_long:
            self.liquidate(self.spy)
```

Example 2: Create Daily `QuoteBar` Objects That Start at 5 PM

The following algorithm consolidates minute resolution Forex data into daily `QuoteBar` objects that open and close at 5 PM Eastern Time.

```py
class CustomStartTimeConsolidatorExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add the USDJPY Forex pair.
        self._pair = self.add_forex("USDJPY")
        # Create an EMA indicator for the pair.
        self._pair.ema = ExponentialMovingAverage(10)
        # Create a QuoteBar consolidator with a custom start time.
        consolidator = QuoteBarConsolidator(timedelta(1), timedelta(hours=17))
        # Attach a consolidation handler that will receive the consolidated bars.
        consolidator.data_consolidated += self._consolidation_handler
        # Subscribe the consolidator for automatic updates with the prices of the pair.
        self.subscription_manager.add_consolidator(self._pair.symbol, consolidator)
        # Register the indicator for automatic updates with the consolidated bars.
        self.register_indicator(self._pair.symbol, self._pair.ema, consolidator)
        # Warm up the consolidator and indicator.
        history = self.history[QuoteBar](self._pair.symbol, 29000, Resolution.MINUTE)
        for bar in history:
            consolidator.update(bar)

    def _consolidation_handler(self, sender: object, consolidated_bar: QuoteBar) -> None:
        # Wait until the indicator is ready and the algorithm is running.
        if not self._pair.ema.is_ready or self.is_warming_up:
            return
        # Plot the closing price and the EMA.
        self.plot(consolidated_bar.symbol.value, 'Close', consolidated_bar.close)
        self.plot(consolidated_bar.symbol.value, 'EMA', self._pair.ema.current.value)

        if not self._pair.holdings.is_long and consolidated_bar.close > self._pair.ema.current.value:
            self.set_holdings(self._pair.symbol, 1)
        if consolidated_bar.close < self._pair.ema.current.value:
            self.liquidate()
```

Consolidator Types

Calendar Consolidators

Introduction

Calendar consolidators aggregate data based on specific periods of time like a weekly basis, quarterly basis, or any schedule with specific start and end times. In contrast to time period consolidators, the bars that calendar consolidators produce always end on the same schedule, regardless of the first data point the consolidator receives.

Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `TradeBar` objects of the same size or larger. Follow these steps to create and manage a `TradeBar` consolidator based on custom start and end periods:

1. Create the consolidator.

   To set the time period for the consolidator, you can use the built-in `CalendarInfo` objects or create your own. The following list describes each technique:

   - Standard Periods

     The following table describes the helper methods that the `Calendar` class provides to create the built-in `CalendarInfo` objects:

Method	Description
`Calendar.WEEKLY`	Computes the start of week (previous Monday) of the given date/time
`Calendar.MONTHLY`	Computes the start of month (1st of the current month) of the given date/time
`Calendar.QUARTERLY`	Computes the start of quarter (1st of the starting month of the current quarter) of the given date/time
`Calendar.YEARLY`	Computes the start of year (1st of the current year) of the given date/time

     ```
     self._consolidator = TradeBarConsolidator(Calendar.WEEKLY)
     # Alias:
     # self._consolidator = self.create_consolidator(Calendar.WEEKLY, TradeBar)
     ```

     PY

   - Custom Periods

     If you need something more specific than the preceding time periods, define a method to set the start time and period of the consolidated bars. The method should receive a `datetime` object that's based in the exchange time zone and should return a `CalendarInfo` object, which contains the start time of the bar in the exchange time zone and the duration of the consolidation period. The following example demonstrates how to create a custom consolidator for weekly bars:

```
# Define a consolidation period method
def _consolidation_period(self, dt: datetime) -> CalendarInfo:
    period = timedelta(7)

    dt = dt.replace(hour=17, minute=0, second=0, microsecond=0)
    delta = 1+dt.weekday()
    if delta > 6:
        delta = 0
    start = dt-timedelta(delta)

    return CalendarInfo(start, period)

# Create the consolidator with the consolidation period method
self._consolidator = TradeBarConsolidator(self._consolidation_period)
```

2. Add an event handler to the consolidator.

```
self._consolidator.data_consolidated += self._consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: TradeBar) -> None:
    pass
```

If you use a custom consolidation period method, LEAN passes the consolidated bar to the consolidation handler when the consolidation period ends. The `time` and `end_time` properties of the consolidated bar reflect the exchange time zone, but the `time` property of the algorithm still reflects the algorithm time zone .

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

  ```
  self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

  ```
  # Example 1: Update the consolidator with data from the Slice object
  def on_data(self, slice: Slice) -> None:
      trade_bar = slice.bars[self._symbol]
      self._consolidator.update(trade_bar)

  # Example 2: Update the consolidator with data from a history request
  history = self.history[TradeBar](self._symbol, 30, Resolution.MINUTE)
  for trade_bar in history:
      self._consolidator.update(trade_bar)
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the

security leaves the universe.

```
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `consolidate` helper method to create calendar consolidators and register them for automatic updates.

```
self._consolidator = self.consolidate(self._symbol, Calendar.WEEKLY, self._consolidation_handler)
```

If you use the `consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
def _consolidation_handler(self, consolidated_bar: TradeBar) -> None:
    pass
```

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `QuoteBar` objects of the same size or larger. Follow these steps to create and manage a `QuoteBar` consolidator based on custom start and end periods:

1. Create the consolidator.

   To set the time period for the consolidator, you can use the built-in `CalendarInfo` objects or create your own. The following list describes each technique:

   - Standard Periods

     The following table describes the helper methods that the `Calendar` class provides to create the built-in `CalendarInfo` objects:

Method	Description
`Calendar.WEEKLY`	Computes the start of week (previous Monday) of the given date/time
`Calendar.MONTHLY`	Computes the start of month (1st of the current month) of the given date/time
`Calendar.QUARTERLY`	Computes the start of quarter (1st of the starting month of the current quarter) of the given date/time
`Calendar.YEARLY`	Computes the start of year (1st of the current year) of the given date/time

     ```
     self._consolidator = QuoteBarConsolidator(Calendar.WEEKLY)
     # Alias:
     # self._consolidator = self.create_consolidator(Calendar.WEEKLY, QuoteBar)
     ```

   - Custom Periods

     If you need something more specific than the preceding time periods, define a method to set the start time and period of the consolidated bars. The method should receive a `datetime` object that's based in the exchange time zone and should return a `CalendarInfo` object, which contains the start time of the bar in the exchange time zone and the duration of the consolidation period. The following example demonstrates how to create a custom consolidator for weekly bars:

```
# Define a consolidation period method
def _consolidation_period(self, dt: datetime) -> CalendarInfo:
    period = timedelta(7)

    dt = dt.replace(hour=17, minute=0, second=0, microsecond=0)
    delta = 1+dt.weekday()
    if delta > 6:
        delta = 0
    start = dt-timedelta(delta)

    return CalendarInfo(start, period)

# Create the consolidator with the consolidation period method
self._consolidator = QuoteBarConsolidator(self._consolidation_period)
```

2. Add an event handler to the consolidator.

```
self._consolidator.data_consolidated += self._consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: QuoteBar) -> None:
    pass
```

If you use a custom consolidation period method, LEAN passes the consolidated bar to the consolidation handler when the consolidation period ends. The `time` and `end_time` properties of the consolidated bar reflect the exchange time zone, but the `time` property of the algorithm still reflects the algorithm time zone .

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

  ```
  self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `QuoteBar` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

  ```
  # Example 1: Update the consolidator with data from the Slice object
  def on_data(self, slice: Slice) -> None:
      quote_bar = slice.quote_bars[self._symbol]
      self._consolidator.update(quote_bar)

  # Example 2: Update the consolidator with data from a history request
  history = self.history[QuoteBar](self._symbol, 30, Resolution.MINUTE)
  for quote_bar in history:
      self._consolidator.update(quote_bar)
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the

security leaves the universe.

```
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `consolidate` helper method to create calendar consolidators and register them for automatic updates.

```
self._consolidator = self.consolidate(self._symbol, Calendar.WEEKLY, TickType.QUOTE, self._consolidation_handler)
```

If you use the `consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
def _consolidation_handler(self, consolidated_bar: QuoteBar) -> None:
    pass
```

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `TradeBar` objects. Follow these steps to create and manage a `Tick` consolidator based on custom start and end periods:

1. Create the consolidator.

   To set the time period for the consolidator, you can use the built-in `CalendarInfo` objects or create your own. The following list describes each technique:

   - Standard Periods

     The following table describes the helper methods that the `Calendar` class provides to create the built-in `CalendarInfo` objects:

Method	Description
`Calendar.WEEKLY`	Computes the start of week (previous Monday) of the given date/time
`Calendar.MONTHLY`	Computes the start of month (1st of the current month) of the given date/time
`Calendar.QUARTERLY`	Computes the start of quarter (1st of the starting month of the current quarter) of the given date/time
`Calendar.YEARLY`	Computes the start of year (1st of the current year) of the given date/time

     ```
     self._consolidator = TickConsolidator(Calendar.WEEKLY)
     # Alias:
     # self._consolidator = self.create_consolidator(Calendar.WEEKLY, Tick)
     ```

   - Custom Periods

     If you need something more specific than the preceding time periods, define a method to set the start time and period of the consolidated bars. The method should receive a `datetime` object that's based in the exchange time zone and should return a `CalendarInfo` object, which contains the start time of the bar in the exchange time zone and the duration of the consolidation period. The following example demonstrates how to create a custom consolidator for weekly bars:

```
# Define a consolidation period method
def _consolidation_period(self, dt: datetime) -> CalendarInfo:
    period = timedelta(7)

    dt = dt.replace(hour=17, minute=0, second=0, microsecond=0)
    delta = 1+dt.weekday()
    if delta > 6:
        delta = 0
    start = dt-timedelta(delta)

    return CalendarInfo(start, period)

# Create the consolidator with the consolidation period method
self._consolidator = TickConsolidator(self._consolidation_period)
```

2. Add an event handler to the consolidator.

```
self._consolidator.data_consolidated += self._consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: TradeBar) -> None:
    pass
```

If you use a custom consolidation period method, LEAN passes the consolidated bar to the consolidation handler when the consolidation period ends. The `time` and `end_time` properties of the consolidated bar reflect the exchange time zone, but the `time` property of the algorithm still reflects the algorithm time zone .

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

  ```
  self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

  ```
  # Example 1: Update the consolidator with data from the Slice object
  def on_data(self, slice: Slice) -> None:
      ticks = slice.ticks[self._symbol]
      for tick in ticks:
          self._consolidator.update(tick)

  # Example 2: Update the consolidator with data from a history request
  ticks = self.history[Tick](self._symbol, timedelta(minutes=3), Resolution.TICK)
  for tick in ticks:
      self._consolidator.update(tick)
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `consolidate` helper method to create calendar consolidators and register them for automatic updates.

```
self._consolidator = self.consolidate(self._symbol, Calendar.WEEKLY, self._consolidation_handler)
```

If you use the `consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
def _consolidation_handler(self, consolidated_bar: TradeBar) -> None:
    pass
```

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `QuoteBar` objects. Follow these steps to create and manage a `Tick` quote bar consolidator based on custom start and end periods:

1. Create the consolidator.

   To set the time period for the consolidator, you can use the built-in `CalendarInfo` objects or create your own. The following list describes each technique:

   - Standard Periods

     The following table describes the helper methods that the `Calendar` class provides to create the built-in `CalendarInfo` objects:

Method	Description
`Calendar.WEEKLY`	Computes the start of week (previous Monday) of the given date/time
`Calendar.MONTHLY`	Computes the start of month (1st of the current month) of the given date/time
`Calendar.QUARTERLY`	Computes the start of quarter (1st of the starting month of the current quarter) of the given date/time
`Calendar.YEARLY`	Computes the start of year (1st of the current year) of the given date/time

     ```
     self._consolidator = TickQuoteBarConsolidator(Calendar.WEEKLY)
     # Alias:
     # self._consolidator = self.create_consolidator(Calendar.WEEKLY, Tick, TickType.QUOTE)
     ```

   - Custom Periods

     If you need something more specific than the preceding time periods, define a method to set the start time and period of the consolidated bars. The method should receive a `datetime` object that's based in the exchange time zone and should return a `CalendarInfo` object, which contains the start time of the bar in the exchange time zone and the duration of the consolidation period. The following example demonstrates how to create a custom consolidator for weekly bars:

```
# Define a consolidation period method
def _consolidation_period(self, dt: datetime) -> CalendarInfo:
    period = timedelta(7)

    dt = dt.replace(hour=17, minute=0, second=0, microsecond=0)
    delta = 1+dt.weekday()
    if delta > 6:
        delta = 0
    start = dt-timedelta(delta)

    return CalendarInfo(start, period)

# Create the consolidator with the consolidation period method
self._consolidator = TickQuoteBarConsolidator(self._consolidation_period)
```

2. Add an event handler to the consolidator.

```
self._consolidator.data_consolidated += self._consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: QuoteBar) -> None:
    pass
```

If you use a custom consolidation period method, LEAN passes the consolidated bar to the consolidation handler when the consolidation period ends. The `time` and `end_time` properties of the consolidated bar reflect the exchange time zone, but the `time` property of the algorithm still reflects the algorithm time zone .

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

  ```
  self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

  ```
  # Example 1: Update the consolidator with data from the Slice object
  def on_data(self, slice: Slice) -> None:
      ticks = slice.ticks[self._symbol]
      for tick in ticks:
          self._consolidator.update(tick)

  # Example 2: Update the consolidator with data from a history request
  ticks = self.history[Tick](self._symbol, timedelta(minutes=3), Resolution.TICK)
  for tick in ticks:
      self._consolidator.update(tick)
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `consolidate` helper method to create calendar consolidators and register them for automatic updates.

```
self._consolidator = self.consolidate(self._symbol, Calendar.WEEKLY, TickType.QUOTE, self._consolidation_handler)
```

If you use the `consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
def _consolidation_handler(self, consolidated_bar: QuoteBar) -> None:
    pass
```

Consolidate Other Data

`<dataType>` consolidators aggregate various types of data objects into `<dataType>` objects of the same size or larger. If you consolidate custom data or alternative datasets, check the definition of the data class to see its data type. Follow these steps to create and manage a `<dataType>` consolidator based on custom start and end periods:

1. Create the consolidator.

   To set the time period for the consolidator, you can use the built-in `CalendarInfo` objects or create your own. The following list describes each technique:

   - Standard Periods

     The following table describes the helper methods that the `Calendar` class provides to create the built-in `CalendarInfo` objects:

Method	Description
`Calendar.WEEKLY`	Computes the start of week (previous Monday) of the given date/time
`Calendar.MONTHLY`	Computes the start of month (1st of the current month) of the given date/time
`Calendar.QUARTERLY`	Computes the start of quarter (1st of the starting month of the current quarter) of the given date/time
`Calendar.YEARLY`	Computes the start of year (1st of the current year) of the given date/time

     ```
     self._consolidator = DynamicDataConsolidator(Calendar.WEEKLY)
     # Alias:
     # self._consolidator = self.create_consolidator(Calendar.WEEKLY, <dataType>)
     ```

   - Custom Periods

     If you need something more specific than the preceding time periods, define a method to set the start time and period of the consolidated bars. The method should receive a `datetime` object that's based in the exchange time zone and should return a `CalendarInfo` object, which contains the start time of the bar in the exchange time zone and the duration of the consolidation period. The following example demonstrates how to create a custom consolidator for weekly bars:

```
# Define a consolidation period method
def _consolidation_period(self, dt: datetime) -> CalendarInfo:
    period = timedelta(7)

    dt = dt.replace(hour=17, minute=0, second=0, microsecond=0)
    delta = 1+dt.weekday()
    if delta > 6:
        delta = 0
    start = dt-timedelta(delta)

    return CalendarInfo(start, period)

# Create the consolidator with the consolidation period method
self._consolidator = DynamicDataConsolidator(self._consolidation_period)
```

2. Add an event handler to the consolidator.

```
self._consolidator.data_consolidated += self._consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: <dataType>) -> None:
    pass
```

If you use a custom consolidation period method, LEAN passes the consolidated bar to the consolidation handler when the consolidation period ends. The `time` and `end_time` properties of the consolidated bar reflect the exchange time zone, but the `time` property of the algorithm still reflects the algorithm time zone .

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the data subscription, call the `add_consolidator` method of the Subscription Manager.

  ```
  self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `<dataType>` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

  ```
  # Example 1: Update the consolidator with data from the Slice object
  def on_data(self, slice: Slice) -> None:
      if self._symbol in slice:
          self._consolidator.update(slice[self._symbol])

  # Example 2: Update the consolidator with data from a history request
  history = self.history[<dataType>](self._symbol, 30, Resolution.DAILY)
  for data in history:
      self._consolidator.update(data)
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the

security leaves the universe.

```
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `consolidate` helper method to create calendar consolidators and register them for automatic updates.

```
self._consolidator = self.consolidate(self._symbol, Calendar.WEEKLY, self._consolidation_handler)
```

If you use the `consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
def _consolidation_handler(self, consolidated_bar: <dataType>) -> None:
    pass
```

Reset Consolidators

To reset a consolidator, call its `reset` method.

```
self._consolidator.reset()
```

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your consolidators when splits and dividends occur. When a split or dividend occurs while the consolidator is in the process of building a bar, the open, high, and low may reflect prices from before the split or dividend. To avoid issues, call the consolidator's `reset` method and then warm it up with `SCALED_RAW` data from a history request .

```
def on_data(self, data: Slice):
    # When a split or dividend occurs...
    if (data.splits.contains_key(self._symbol) and data.splits[self._symbol].type == SplitType.SPLIT_OCCURRED or
        data.dividends.contains_key(self._symbol)):
        # If the consolidator is working on a bar...
        if self._consolidator.working_data:
            # Get adjusted prices for the time period of the working bar.
            history = self.history[TradeBar](self._symbol, self._consolidator.working_data.time, self.time,
data_normalization_mode=DataNormalizationMode.SCALED_RAW)
            # Reset the consolidator.
            self._consolidator.reset()
            # Warm-up the consolidator with the adjusted price data.
            for bar in history:
                self._consolidator.update(bar)
```

Examples

The following examples demonstrate some common practices for calendar consolidators.

Example 1: Daily Futures Bars

Daily bars from the CME and Yahoo Finance represent the price action from 5 PM Central Time (CT) to 4 PM CT on the following day. In contrast, the regular daily resolution bars on QuantConnect represent the price action from 12 AM Eastern Time (ET) to 12 AM ET the following day. To create daily bars that represent the same period of time as the daily bars from the CME, the following algorithm consolidates minute bars (during regular and extended market hours) into daily bars that span from 5 PM CT to 4 PM CT on the following day. The algorithm then uses these consolidated daily bars to place take profit and stop loss orders as a function of the daily Average True Range .

```py
class CalendarConsolidatorExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Create an ATR indicator to set take profit and stop loss levels.
        self._atr = AverageTrueRange(10)
        # Create a day tracker to avoid overtrading.
        self._day = -1
        # Add ES Futures data and configure the continuous contract settings
        # so you can update the ATR with a smooth feed of prices.
        self._future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            extended_market_hours=True,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            contract_depth_offset=0
        )
        # Create a calendar consolidator to generate daily ES Futures bars
        # since market starts at 6pm EST to 5pm EST next day.
        consolidator = TradeBarConsolidator(self._future_trading_hour)
        consolidator.data_consolidated += self._on_consolidated
        # Warm up the consolidator and ATR indicator.
        history = self.history[TradeBar](self._future.symbol, 14500, Resolution.MINUTE)
        for bar in history:
            consolidator.update(bar)
        # Subscribe the consolidator for automatic updates with ES data.
        self.subscription_manager.add_consolidator(self._future.symbol, consolidator)

    def _future_trading_hour(self, dt: datetime) -> CalendarInfo:
        # Set the open time of the bar to be 6 PM EST.
        start = dt.replace(hour=0, minute=0, second=0, microsecond=0)
        if dt.hour < 18:
            start -= timedelta(hours=6)
        else:
            start += timedelta(hours=18)
        # Set the close time of the bar to be 5 PM EST the next day, which is 23 hours later.
        return CalendarInfo(start, timedelta(hours=23))

    def _on_consolidated(self, sender: object, bar: TradeBar) -> None:
        # Update the ATR indicator since we want the daily ATR to set the stop price.
        self._atr.update(bar)
        # Set the daily take profit and stop price levels as a function of the previous
        # close price and the ATR.
        self._take_profit_price = bar.close + self._atr.current.value * 2
        self._stop_loss_price = bar.close - self._atr.current.value * 2

    def on_data(self, slice: Slice) -> None:
        # Liquidate the current contract in the continuous contract series
        # when it's about to expire.
        changed_event = slice.symbol_changed_events.get(self._future.symbol)
        if changed_event:
            self.liquidate(changed_event.old_symbol)

        # If we're not invested, buy the current contract in the continuous contract series.
        if (not self.portfolio.invested and
            self.securities[self._future.mapped].price and
            self._day != slice.time.day):
            self.market_order(self._future.mapped, 1)
        # If we're already invested, check if we've hit the TP/SL level.
        elif self.portfolio.invested and self._future.symbol in slice.bars:
            current_price = slice.bars[self._future.symbol].close
            # Check if the current price is above profit taker or below stop loss.
            if current_price > self._take_profit_price or current_price < self._stop_loss_price:
                # Exit the position.
                self.liquidate()

        # Update the daily tracker so we only update our position once per day.
        self._day = slice.time.day
```

Example 2: Create Daily `QuoteBar` Objects That Start at 5 PM

The following algorithm consolidates minute resolution Forex data into daily `QuoteBar` objects that open and close at 5 PM Eastern Time.

```py
class CalendarConsolidatorExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add the USDJPY Forex pair.
        self._pair = self.add_forex("USDJPY")
        # Create an EMA indicator for the pair.
        self._pair.ema = ExponentialMovingAverage(10)
        # Create a QuoteBar consolidator with a custom consolidation period.
        consolidator = QuoteBarConsolidator(self._daily_forex_consolidation_period)
        # Attach a consolidation handler that will receive the consolidated bars.
        consolidator.data_consolidated += self._consolidation_handler
        # Subscribe the consolidator for automatic updates with the prices of the pair.
        self.subscription_manager.add_consolidator(self._pair.symbol, consolidator)
        # Register the indicator for automatic updates with the consolidated bars.
        self.register_indicator(self._pair.symbol, self._pair.ema, consolidator)
        # Warm up the consolidator and indicator.
        history = self.history[QuoteBar](self._pair.symbol, 29000, Resolution.MINUTE)
        for bar in history:
            consolidator.update(bar)

    # Define the consolidation period.
    def _daily_forex_consolidation_period(self, dt: datetime) -> CalendarInfo:
        # Set the start of the bar to be 5 PM ET.
        start = dt.replace(hour=0, minute=0, second=0, microsecond=0)
        if dt.hour < 17:
            start -= timedelta(hours=7)
        else:
            start += timedelta(hours=17)
        # Set the end of the bar to be 5 PM ET the next day.
        return CalendarInfo(start, timedelta(1))

    def _consolidation_handler(self, sender: object, consolidated_bar: QuoteBar) -> None:
        # Wait until the indicator is ready and the algorithm is running.
        if not self._pair.ema.is_ready or self.is_warming_up:
            return
        # Plot the closing price and the EMA.
        self.plot(str(consolidated_bar.symbol), 'Close', consolidated_bar.close)
        self.plot(str(consolidated_bar.symbol), 'EMA', self._pair.ema.current.value)
```

For a version of this algorithm with Time Period Consolidators, see Time Period Consolidators > Examples .

Example 3: Monthly Candlesticks

The following algorithm consolidates minute-resolution data into monthly `TradeBar` objects and then plots them as candlesticks .

```py
from dateutil.relativedelta import relativedelta

class CalendarConsolidatorExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add an asset.
        symbol = self.add_equity("SPY").symbol
        # Create a consolidator that produces monthly TradeBar objects.
        # This is the stardard way:
        #consolidator = TradeBarConsolidator(Calendar.MONTHLY)
        # However, you can acomplish the same thing with a custom period:
        consolidator = TradeBarConsolidator(self._custom_monthly)
        # Add a consolidation handler that plots the monthly bars as candlesticks.
        consolidator.data_consolidated += lambda _, bar: self.plot(
            "Monthly Candlestick", symbol.value, bar.open, bar.high, bar.low, bar.close
        )
        # Register the consolidator for automatic updates.
        self.subscription_manager.add_consolidator(symbol, consolidator)

    def _custom_monthly(self, dt: datetime) -> CalendarInfo:
        # Set the start time to the beginning of the month.
        start = dt.replace(day=1).date()
        # Set the end time to the beginning of next month.
        end = start + relativedelta(months=1)
        return CalendarInfo(start, end - start)
```

Consolidator Types

Count Consolidators

Introduction

Count consolidators aggregate data based on a number of bars or ticks. This type of consolidator aggregates n samples together, regardless of the time period the samples cover. Managing count consolidators is similiar to managing time period consolidators , except you create count consolidators with an integer argument instead of a time-based argument.

Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `TradeBar` objects of the same size or larger. Follow these steps to create and manage a `TradeBar` consolidator based on a number of samples:

1. Create the consolidator.

   To create a count consolidator, pass the number of samples to the consolidator constructor.

   ```
   self._consolidator = TradeBarConsolidator(10)
   ```

2. Add an event handler to the consolidator.

   ```
   self._consolidator.data_consolidated += self._consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

   ```
   def _consolidation_handler(self, sender: object, consolidated_bar: TradeBar) -> None:
       pass
   ```

   When the consolidator receives the n -th data point, it passes the consolidated bar to the event handler.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

     ```
     self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def on_data(self, slice: Slice) -> None:
    trade_bar = slice.bars[self._symbol]
    self._consolidator.update(trade_bar)

# Example 2: Update the consolidator with data from a history request
history = self.history[TradeBar](self._symbol, 30, Resolution.MINUTE)
for trade_bar in history:
    self._consolidator.update(trade_bar)
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `QuoteBar` objects of the same size or larger. Follow these steps to create and manage a `QuoteBar` consolidator based on a number of samples:

1. Create the consolidator.

   To create a count consolidator, pass the number of samples to the consolidator constructor.

```
self._consolidator = QuoteBarConsolidator(10)
```

2. Add an event handler to the consolidator.

```
self._consolidator.data_consolidated += self._consolidation_handler
```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: QuoteBar) -> None:
    pass
```

   When the consolidator receives the n -th data point, it passes the consolidated bar to the event handler.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

```
self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `QuoteBar` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

  ```
  # Example 1: Update the consolidator with data from the Slice object
  def on_data(self, slice: Slice) -> None:
      quote_bar = slice.quote_bars[self._symbol]
      self._consolidator.update(quote_bar)

  # Example 2: Update the consolidator with data from a history request
  history = self.history[QuoteBar](self._symbol, 30, Resolution.MINUTE)
  for quote_bar in history:
      self._consolidator.update(quote_bar)
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `TradeBar` objects. Follow these steps to create and manage a `Tick` consolidator based on a number of samples:

1. Create the consolidator.

   To create a count consolidator, pass the number of samples to the consolidator constructor.

   ```
   self._consolidator = TickConsolidator(10)
   ```

2. Add an event handler to the consolidator.

   ```
   self._consolidator.data_consolidated += self._consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

   ```
   def _consolidation_handler(self, sender: object, consolidated_bar: TradeBar) -> None:
       pass
   ```

   When the consolidator receives the n -th data point, it passes the consolidated bar to the event handler.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

```
self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
```

- Manual Updates

Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def on_data(self, slice: Slice) -> None:
    ticks = slice.ticks[self._symbol]
    for tick in ticks:
        self._consolidator.update(tick)

# Example 2: Update the consolidator with data from a history request
ticks = self.history[Tick](self._symbol, timedelta(minutes=3), Resolution.TICK)
for tick in ticks:
    self._consolidator.update(tick)
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `QuoteBar` objects. Follow these steps to create and manage a `Tick` quote bar consolidator based on a number of samples:

1. Create the consolidator.

To create a count consolidator, pass the number of samples to the consolidator constructor.

```
self._consolidator = TickQuoteBarConsolidator(10)
```

2. Add an event handler to the consolidator.

```
self._consolidator.data_consolidated += self._consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: QuoteBar) -> None:
    pass
```

When the consolidator receives the n -th data point, it passes the consolidated bar to the event handler.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

     ```
     self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

     ```
     # Example 1: Update the consolidator with data from the Slice object
     def on_data(self, slice: Slice) -> None:
         ticks = slice.ticks[self._symbol]
         for tick in ticks:
             self._consolidator.update(tick)

     # Example 2: Update the consolidator with data from a history request
     ticks = self.history[Tick](self._symbol, timedelta(minutes=3), Resolution.TICK)
     for tick in ticks:
         self._consolidator.update(tick)
     ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Other Data

`<dataType>` consolidators aggregate various types of data objects into `<dataType>` objects of the same size or larger. If you consolidate custom data or alternative datasets, check the definition of the data class to see its data type. Follow these steps to create and manage a `<dataType>` consolidator based on a number of samples:

1. Create the consolidator.

   To create a count consolidator, pass the number of samples to the consolidator constructor.

   ```
   self._consolidator = DynamicDataConsolidator(10)
   ```

2. Add an event handler to the consolidator.

   ```
   self._consolidator.data_consolidated += self._consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method

executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: <dataType>) -> None:
    pass
```

When the consolidator receives the n -th data point, it passes the consolidated bar to the event handler.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

To automatically update a consolidator with data from the data subscription, call the `add_consolidator` method of the Subscription Manager.

```
self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
```

- Manual Updates

Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `<dataType>` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def on_data(self, slice: Slice) -> None:
    if self._symbol in slice:
        self._consolidator.update(slice[self._symbol])

# Example 2: Update the consolidator with data from a history request
history = self.history[<dataType>](self._symbol, 30, Resolution.DAILY)
for data in history:
    self._consolidator.update(data)
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Reset Consolidators

To reset a consolidator, call its `reset` method.

```
self._consolidator.reset()
```

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your consolidators when splits and dividends occur. When a split or dividend occurs while the consolidator is in the process of building a bar, the open, high, and low may reflect prices from before the split or dividend. To avoid issues, call the consolidator's `reset` method and then warm it up with `SCALED_RAW` data from a history request .

```
def on_data(self, data: Slice):
    # When a split or dividend occurs...
    if (data.splits.contains_key(self._symbol) and data.splits[self._symbol].type == SplitType.SPLIT_OCCURRED or
        data.dividends.contains_key(self._symbol)):
        # If the consolidator is working on a bar...
        if self._consolidator.working_data:
            # Get adjusted prices for the time period of the working bar.
            history = self.history[TradeBar](self._symbol, self._consolidator.working_data.time, self.time,
data_normalization_mode=DataNormalizationMode.SCALED_RAW)
            # Reset the consolidator.
            self._consolidator.reset()
            # Warm-up the consolidator with the adjusted price data.
            for bar in history:
                self._consolidator.update(bar)
```

Examples

The following examples demonstrate common practices for implementing count consolidator.

Example 1: Tick Count Consolidator

```
class CountConsolidatorAlgorithm(QCAlgorithm):
    # Create EMA indicators for trade signal generation.
    _ema = ExponentialMovingAverage(14)
    # The _day variable controls trade daily when open.
    _day = -1

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 4)
        self.set_end_date(2024, 9, 5)

        # Request SPY data to feed to indicators and trade.
        self.spy = self.add_equity("SPY", Resolution.TICK).symbol

        # Create a 10000 trade tick consolidator to feed the "volume" bar to the EMA indicator for trend entry/exit signal.
        tick_consolidator = TickConsolidator(10000)

        # Subscribe the consolidators to SPY data to automatically update the indicators.
        self.register_indicator(self.spy, self._ema, tick_consolidator)

        self.set_warm_up(120)

    def on_data(self, slice: Slice) -> None:
        ticks = slice.ticks.get(self.spy)
        if self._ema.is_ready and ticks and self._day != slice.time.day:
            # Obtain the latest quote price from the latest tick.
            last_tick = sorted(ticks, key=lambda x: x.end_time, reverse=True)[0]

            ema = self._ema.current.value

            # Trade the trend by EMA crosses.
            if last_tick.price > ema and not self.portfolio[self.spy].is_long:
                self.set_holdings(self.spy, 0.5)
            elif last_tick.price < ema and not self.portfolio[self.spy].is_short:
                self.set_holdings(self.spy, -0.5)

            self._day = slice.time.day
```

Consolidator Types

Mixed-Mode Consolidators

Introduction

Mixed-mode consolidators are a combination of count consolidators and time period consolidators. This type of consolidator aggregates n samples together or aggregates samples over a specific time period, whichever happens first.

Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `TradeBar` objects of the same size or larger. Follow these steps to create and manage a `TradeBar` consolidator based on a period of time or a number of samples, whichever occurs first:

1. Create the consolidator.

   To create a mixed-mode consolidator, pass a `timedelta` object and an integer to the consolidator constructor. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

   ```
   self._consolidator = TradeBarConsolidator(10, timedelta(days=1))
   ```
   PY

   The time period is relative to the exchange time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

   If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET. To change this behavior, set the `start_time` parameter of the type constructor to `timedelta( timeDeltaStartTime?>)`

2. Add an event handler to the consolidator.

   ```
   self._consolidator.data_consolidated += self._consolidation_handler
   ```
   PY

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

   ```
   def _consolidation_handler(self, sender: object, consolidated_bar: TradeBar) -> None:
       pass
   ```
   PY

   The consolidation event handler receives bars when the consolidated bar closes based on the exchange time zone or the number of samples, whichever occurs first. If you subscribe to minute resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to minute resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars at market close or midnight, depending on your `daily_precise_end_time` setting .

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription

Manager.

```
self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

  ```
  # Example 1: Update the consolidator with data from the Slice object
  def on_data(self, slice: Slice) -> None:
      trade_bar = slice.bars[self._symbol]
      self._consolidator.update(trade_bar)

  # Example 2: Update the consolidator with data from a history request
  history = self.history[TradeBar](self._symbol, 30, Resolution.MINUTE)
  for trade_bar in history:
      self._consolidator.update(trade_bar)
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `QuoteBar` objects of the same size or larger. Follow these steps to create and manage a `QuoteBar` consolidator based on a period of time or a number of samples, whichever occurs first:

1. Create the consolidator.

   To create a mixed-mode consolidator, pass a `timedelta` object and an integer to the consolidator constructor. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

   ```
   self._consolidator = QuoteBarConsolidator(10, timedelta(days=1))
   ```

   The time period is relative to the exchange time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

   If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET. To change this behavior, set the `start_time` parameter of the type constructor to `timedelta( timeDeltaStartTime?>)`

2. Add an event handler to the consolidator.

   ```
   self._consolidator.data_consolidated += self._consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event

system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: QuoteBar) -> None:
    pass
```

The consolidation event handler receives bars when the consolidated bar closes based on the exchange time zone or the number of samples, whichever occurs first. If you subscribe to minute resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to minute resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars at market close or midnight, depending on your `daily_precise_end_time` setting .

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

```
self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
```

- Manual Updates

Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `QuoteBar` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def on_data(self, slice: Slice) -> None:
    quote_bar = slice.quote_bars[self._symbol]
    self._consolidator.update(quote_bar)

# Example 2: Update the consolidator with data from a history request
history = self.history[QuoteBar](self._symbol, 30, Resolution.MINUTE)
for quote_bar in history:
    self._consolidator.update(quote_bar)
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `TradeBar` objects. Follow these steps to create and manage a `Tick` consolidator based on a period of time or a number of samples, whichever occurs first:

1. Create the consolidator.

To create a mixed-mode consolidator, pass a `timedelta` object and an integer to the consolidator constructor. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

```
self._consolidator = TickConsolidator(10, timedelta(milliseconds=100))
```

The time period is relative to the exchange time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET. To change this behavior, set the `start_time` parameter of the type constructor to `timedelta( timeDeltaStartTime?>)`

2. Add an event handler to the consolidator.

```
self._consolidator.data_consolidated += self._consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: TradeBar) -> None:
    pass
```

The consolidation event handler receives bars when the consolidated bar closes based on the exchange time zone or the number of samples, whichever occurs first. If you subscribe to tick resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to tick resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars at market close or midnight, depending on your `daily_precise_end_time` setting .

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

  ```
  self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

  ```
  # Example 1: Update the consolidator with data from the Slice object
  def on_data(self, slice: Slice) -> None:
      ticks = slice.ticks[self._symbol]
      for tick in ticks:
          self._consolidator.update(tick)

  # Example 2: Update the consolidator with data from a history request
  ticks = self.history[Tick](self._symbol, timedelta(minutes=3), Resolution.TICK)
  for tick in ticks:
      self._consolidator.update(tick)
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the

security leaves the universe.

```
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `QuoteBar` objects. Follow these steps to create and manage a `Tick` quote bar consolidator based on a period of time or a number of samples, whichever occurs first:

1. Create the consolidator.

   To create a mixed-mode consolidator, pass a `timedelta` object and an integer to the consolidator constructor. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

   ```
   self._consolidator = TickQuoteBarConsolidator(10, timedelta(milliseconds=100))
   ```

   The time period is relative to the exchange time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

   If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET. To change this behavior, set the `start_time` parameter of the type constructor to `timedelta( timeDeltaStartTime?>)`

2. Add an event handler to the consolidator.

   ```
   self._consolidator.data_consolidated += self._consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

   ```
   def _consolidation_handler(self, sender: object, consolidated_bar: QuoteBar) -> None:
       pass
   ```

   The consolidation event handler receives bars when the consolidated bar closes based on the exchange time zone or the number of samples, whichever occurs first. If you subscribe to tick resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to tick resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars at market close or midnight, depending on your `daily_precise_end_time` setting .

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

```
self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

  ```
  # Example 1: Update the consolidator with data from the Slice object
  def on_data(self, slice: Slice) -> None:
      ticks = slice.ticks[self._symbol]
      for tick in ticks:
          self._consolidator.update(tick)

  # Example 2: Update the consolidator with data from a history request
  ticks = self.history[Tick](self._symbol, timedelta(minutes=3), Resolution.TICK)
  for tick in ticks:
      self._consolidator.update(tick)
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Other Data

`<dataType>` consolidators aggregate various types of data objects into `<dataType>` objects of the same size or larger. If you consolidate custom data or alternative datasets, check the definition of the data class to see its data type. Follow these steps to create and manage a `<dataType>` consolidator based on a period of time or a number of samples, whichever occurs first:

1. Create the consolidator.

   To create a mixed-mode consolidator, pass a `timedelta` object and an integer to the consolidator constructor. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

   ```
   self._consolidator = DynamicDataConsolidator(10, timedelta(days=1))
   ```

   The time period is relative to the exchange time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

   If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET. To change this behavior, set the `start_time` parameter of the type constructor to `timedelta( timeDeltaStartTime?>)`

2. Add an event handler to the consolidator.

   ```
   self._consolidator.data_consolidated += self._consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event

system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: <dataType>) -> None:
    pass
```

The consolidation event handler receives bars when the consolidated bar closes based on the exchange time zone or the number of samples, whichever occurs first.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

To automatically update a consolidator with data from the data subscription, call the `add_consolidator` method of the Subscription Manager.

```
self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
```

- Manual Updates

Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `<dataType>` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def on_data(self, slice: Slice) -> None:
    if self._symbol in slice:
        self._consolidator.update(slice[self._symbol])

# Example 2: Update the consolidator with data from a history request
history = self.history[<dataType>](self._symbol, 30, Resolution.DAILY)
for data in history:
    self._consolidator.update(data)
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Reset Consolidators

To reset a consolidator, call its `reset` method.

```
self._consolidator.reset()
```

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your consolidators when splits and dividends occur. When a split or dividend occurs while the consolidator is in the process of building a bar, the open, high, and low may reflect prices from before the split or dividend. To avoid issues, call the consolidator's `reset` method and then warm it up with `SCALED_RAW` data from a history request .

```
def on_data(self, data: Slice):
    # When a split or dividend occurs...
    if (data.splits.contains_key(self._symbol) and data.splits[self._symbol].type == SplitType.SPLIT_OCCURRED or
        data.dividends.contains_key(self._symbol)):
        # If the consolidator is working on a bar...
        if self._consolidator.working_data:
            # Get adjusted prices for the time period of the working bar.
            history = self.history[TradeBar](self._symbol, self._consolidator.working_data.time, self.time,
data_normalization_mode=DataNormalizationMode.SCALED_RAW)
            # Reset the consolidator.
            self._consolidator.reset()
            # Warm-up the consolidator with the adjusted price data.
            for bar in history:
                self._consolidator.update(bar)
```

Examples

The following examples demonstrate common practices for implementing mixed-mode consolidators.

Example 1: Opening Range Breakout

The following algorithm demonstrates an opening range breakout strategy for BJK (a Gaming ETF). We create a 15-count/30-minute trade bar as the opening range for signal generation. If the close price at 10 am is higher than the high price of the aggregated opening bar, we long BJK and exit by a 2% trailing stop loss.

```
class MixedModeConsolidatorAlgorithm(QCAlgorithm):
    _high_price = 0

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Request CARZ data to feed to the consolidators and trade.
        self._equity = self.add_equity("CARZ", Resolution.MINUTE).symbol

        # Create a 10-count-or-20-minute trade bar consolidator to create the opening range for trade signal generation.
        # CARZ is a less liquid ETF, we use a mixed-mode consolidator.
        self._consolidator = TradeBarConsolidator(10, timedelta(minutes=20))

        # Subscribe the consolidators to CARZ data for automatic updating.
        self.subscription_manager.add_consolidator(self._equity, self._consolidator)

        # We check if the entry condition is attained 30 minutes after the market opens.
        self.schedule.on(
            self.date_rules.every_day(self._equity),
            self.time_rules.after_market_open(self._equity, 30),
            self.entry
        )

        self.set_warm_up(1)

    def entry(self) -> None:
        # Check if the entry condition is met: the current price is higher than the high price of the open range.
        current = self.securities[self._equity].close
        if current > self._consolidator.consolidated.high:
            self.market_order(self._equity, 20)
            # Cache the current price for trailing stop loss need.
            self._high_price = current

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._equity)
        if bar and self.portfolio.invested:
            # Update the high price if the current high is higher to update the trailing stop price.
            if bar.high > self._high_price:
                self._high_price = bar.high

            # Exit position if the trailing stop loss is hit.
            if bar.close < self._high_price * 0.98:
                self.liquidate()
                self._high_price = 0
```

Consolidator Types

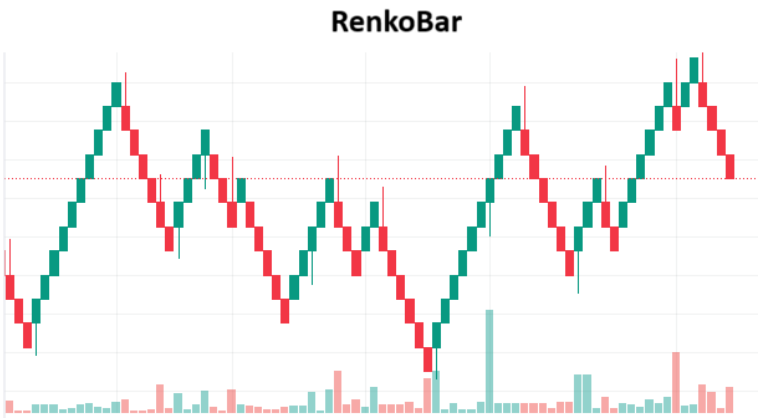
Renko Consolidators

Renko Consolidators

Renko Consolidators

Introduction

Most Renko consolidators aggregate bars based on a fixed price movement. The `RenkoConsolidator` produces Renko bars by their traditional definition. In the case of a $1 bar size, the `RenkoConsolidator` produces bars that have a body spanning 1. The opening price of the first bar is set to the closest 1 multiple of the first trade. When the price moves by at least 1, the first bar closes. If a bar is a rising bar, the following bar closes when the price moves 1 above the closing price of the previous bar or 1 below the opening price of the previous bar. If a bar is a falling bar, the following bar closes when the price moves 1 below the closing price of the previous bar or $1 above the opening price of the previous bar. If the price jumps multiple dollars in a single tick, the `RenkoConsolidator` produces multiple $1 bars in a single time step.



Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `RenkoBar` objects. Follow these steps to create and manage a `TradeBar` consolidator based on the traditional Renko bar rules:

1. Create the consolidator.

   To create a Renko consolidator, pass the bar size to the `RenkoConsolidator` constructor.

   ```
   # Create a Renko consolidator that emits a bar when the price moves $1
   self._consolidator = RenkoConsolidator(1)
   ```

2. Add an event handler to the consolidator.

   ```
   self._consolidator.data_consolidated += self._consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: RenkoBar) -> None:
    pass
```

The consolidation event handler receives bars when the price movement forms a new Renko bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

     ```
     self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

     ```
     # Example 1: Update the consolidator with data from the Slice object
     def on_data(self, slice: Slice) -> None:
         trade_bar = slice.bars[self._symbol]
         self._consolidator.update(trade_bar)

     # Example 2: Update the consolidator with data from a history request
     history = self.history[TradeBar](self._symbol, 30, Resolution.MINUTE)
     for trade_bar in history:
         self._consolidator.update(trade_bar)
     ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `RenkoBar` objects. Follow these steps to create and manage a `QuoteBar` consolidator based on the traditional Renko bar rules:

1. Create the consolidator.

   To create a Renko consolidator, pass the bar size to the `RenkoConsolidator` constructor.

   ```
   # Create a Renko consolidator that emits a bar when the price moves $1
   self._consolidator = RenkoConsolidator(1)
   ```

2. Add an event handler to the consolidator.

   ```
   self._consolidator.data_consolidated += self._consolidation_handler
   ```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
PY
def _consolidation_handler(self, sender: object, consolidated_bar: RenkoBar) -> None:
    pass
```

The consolidation event handler receives bars when the price movement forms a new Renko bar.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

```
PY
self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
```

- Manual Updates

Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `QuoteBar` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

```
PY
# Example 1: Update the consolidator with data from the Slice object
def on_data(self, slice: Slice) -> None:
    quote_bar = slice.quote_bars[self._symbol]
    self._consolidator.update(quote_bar)

# Example 2: Update the consolidator with data from a history request
history = self.history[QuoteBar](self._symbol, 30, Resolution.MINUTE)
for quote_bar in history:
    self._consolidator.update(quote_bar)
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
PY
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `RenkoBar` objects. Follow these steps to create and manage a `Tick` consolidator based on the traditional Renko bar rules:

1. Create the consolidator.

To create a Renko consolidator, pass the bar size to the `RenkoConsolidator` constructor.

```
# Create a Renko consolidator that emits a bar when the price moves $1
self._consolidator = RenkoConsolidator(1)
```

2. Add an event handler to the consolidator.

```
self._consolidator.data_consolidated += self._consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: RenkoBar) -> None:
    pass
```

The consolidation event handler receives bars when the price movement forms a new Renko bar.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

  ```
  self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

  ```
  # Example 1: Update the consolidator with data from the Slice object
  def on_data(self, slice: Slice) -> None:
      ticks = slice.ticks[self._symbol]
      for tick in ticks:
          self._consolidator.update(tick)

  # Example 2: Update the consolidator with data from a history request
  ticks = self.history[Tick](self._symbol, timedelta(minutes=3), Resolution.TICK)
  for tick in ticks:
      self._consolidator.update(tick)
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `RenkoBar` objects. Follow these steps to create and manage a `Tick` quote bar consolidator based on the traditional Renko bar rules:

1. Create the consolidator.

   To create a Renko consolidator, pass the bar size to the `RenkoConsolidator` constructor.

   ```
   # Create a Renko consolidator that emits a bar when the price moves $1
   self._consolidator = RenkoConsolidator(1)
   ```

2. Add an event handler to the consolidator.

   ```
   self._consolidator.data_consolidated += self._consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

   ```
   def _consolidation_handler(self, sender: object, consolidated_bar: RenkoBar) -> None:
       pass
   ```

   The consolidation event handler receives bars when the price movement forms a new Renko bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

     ```
     self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

     ```
     # Example 1: Update the consolidator with data from the Slice object
     def on_data(self, slice: Slice) -> None:
         ticks = slice.ticks[self._symbol]
         for tick in ticks:
             self._consolidator.update(tick)

     # Example 2: Update the consolidator with data from a history request
     ticks = self.history[Tick](self._symbol, timedelta(minutes=3), Resolution.TICK)
     for tick in ticks:
         self._consolidator.update(tick)
     ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Reset Consolidators

To reset a consolidator, call its `reset` method.

```
self._consolidator.reset()
```

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your consolidators when splits and dividends occur. When a split or dividend occurs while the consolidator is in the process of building a bar, the open, high, and low may reflect prices from before the split or dividend. To avoid issues, call the consolidator's `reset` method and then warm it up with `SCALED_RAW` data from a history request .

```
def on_data(self, data: Slice):
    # When a split or dividend occurs...
    if (data.splits.contains_key(self._symbol) and data.splits[self._symbol].type == SplitType.SPLIT_OCCURRED or
        data.dividends.contains_key(self._symbol)):
        # If the consolidator is working on a bar...
        if self._consolidator.working_data:
            # Get adjusted prices for the time period of the working bar.
            history = self.history[TradeBar](self._symbol, self._consolidator.working_data.time, self.time,
data_normalization_mode=DataNormalizationMode.SCALED_RAW)
            # Reset the consolidator.
            self._consolidator.reset()
            # Warm-up the consolidator with the adjusted price data.
            for bar in history:
                self._consolidator.update(bar)
```

Renko Consolidators

Classic Renko Consolidators

Introduction

Most Renko consolidators aggregate bars based on a fixed price movement. The `ClassicRenkoConsolidator` produces a different type of Renko bars than the `RenkoConsolidator` . A `ClassicRenkoConsolidator` with a bar size of `1` produces a new bar that spans `1` every time an asset closes $1 away from the close of the previous bar. If the price jumps multiple dollars in a single tick, the `ClassicRenkoConsolidator` only produces one bar per time step where the open of each bar matches the close of the previous bar.

Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `RenkoBar` objects. Follow these steps to create and manage a `TradeBar` consolidator based on the preceding Renko bar rules:

1. Create the consolidator.

   To create a classic Renko consolidator, pass the bar size to the `ClassicRenkoConsolidator` constructor.

   ```
   PY
   # Create a Classic Renko consolidator that emits a bar when the price moves $1
   self._consolidator = ClassicRenkoConsolidator(1)
   ```

   The `ClassicRenkoConsolidator` has the following default behavior:

   - It uses the `value` property of the `IBaseData` object it receives to build the Renko bars
   - It ignores the volume of the input data
   - It enforces the open and close of each bar to be a multiple of the bar size

   To build the Renko bars with a different property than the `value` of the `IBaseData` object, provide a `selector` argument. The `selector` should be a function that receives the `IBaseData` object and returns a decimal value.

   ```
   PY
   self._consolidator = ClassicRenkoConsolidator(1, selector = lambda data: data.high)
   ```

   To add a non-zero `volume` property to the Renko bars, provide a `volume_selector` argument. The `volume_selector` should be a function that receives the `IBaseData` object and returns a decimal value.

   ```
   PY
   self._consolidator = ClassicRenkoConsolidator(1, volume_selector = lambda data: data.volume)
   ```

   To relax the requirement that the open and close of the Renko bars must be a multiple of bar size, disable the `even_bars` argument. If you disable `even_bars` , the open value of the first Renko bar is set to the first value from the `selector` . The following opening and closing Renko bar values are all multiples of the first value from the `selector`

   ```
   PY
   self._consolidator = ClassicRenkoConsolidator(1, even_bars=False)
   ```

2. Add an event handler to the consolidator.

   ```
   PY
   self._consolidator.data_consolidated += self._consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method

executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
PY
def _consolidation_handler(self, sender: object, consolidated_bar: RenkoBar) -> None:
    pass
```

The consolidation event handler receives bars when the price movement forms a new classic Renko bar.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

```
PY
self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
```

- Manual Updates

Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

```
PY
# Example 1: Update the consolidator with data from the Slice object
def on_data(self, slice: Slice) -> None:
    trade_bar = slice.bars[self._symbol]
    self._consolidator.update(trade_bar)

# Example 2: Update the consolidator with data from a history request
history = self.history[TradeBar](self._symbol, 30, Resolution.MINUTE)
for trade_bar in history:
    self._consolidator.update(trade_bar)
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
PY
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `RenkoBar` objects. Follow these steps to create and manage a `QuoteBar` consolidator based on the preceding Renko bar rules:

1. Create the consolidator.

To create a classic Renko consolidator, pass the bar size to the `ClassicRenkoConsolidator` constructor.

```
PY
# Create a Classic Renko consolidator that emits a bar when the price moves $1
self._consolidator = ClassicRenkoConsolidator(1)
```

The `ClassicRenkoConsolidator` has the following default behavior:

- It uses the `value` property of the `IBaseData` object it receives to build the Renko bars
- It ignores the volume of the input data
- It enforces the open and close of each bar to be a multiple of the bar size

The following arguments enable you to create Renko bars that aggregate the excess liquidity on the bid.

```
self._consolidator = ClassicRenkoConsolidator(10, lambda data: data.value, lambda data: data.last_bid_size - data.last_ask_size)
```

To relax the requirement that the open and close of the Renko bars must be a multiple of bar size, disable the `even_bars` argument. If you disable `even_bars` , the open value of the first Renko bar is set to the first value from the `selector` . The following opening and closing Renko bar values are all multiples of the first value from the `selector`

```
self._consolidator = ClassicRenkoConsolidator(1, even_bars=False)
```

2. Add an event handler to the consolidator.

```
self._consolidator.data_consolidated += self._consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: RenkoBar) -> None:
    pass
```

The consolidation event handler receives bars when the price movement forms a new classic Renko bar.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

  ```
  self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `QuoteBar` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def on_data(self, slice: Slice) -> None:
    quote_bar = slice.quote_bars[self._symbol]
    self._consolidator.update(quote_bar)

# Example 2: Update the consolidator with data from a history request
history = self.history[QuoteBar](self._symbol, 30, Resolution.MINUTE)
for quote_bar in history:
    self._consolidator.update(quote_bar)
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `RenkoBar` objects. Follow these steps to create and manage a `Tick` consolidator based on the preceding Renko bar rules:

1. Create the consolidator.

   To create a classic Renko consolidator, pass the bar size to the `ClassicRenkoConsolidator` constructor.

   ```
   # Create a Classic Renko consolidator that emits a bar when the price moves $1
   self._consolidator = ClassicRenkoConsolidator(1)
   ```

   The `ClassicRenkoConsolidator` has the following default behavior:

   - It uses the `value` property of the `IBaseData` object it receives to build the Renko bars
   - It ignores the volume of the input data
   - It enforces the open and close of each bar to be a multiple of the bar size

   To relax the requirement that the open and close of the Renko bars must be a multiple of bar size, disable the `even_bars` argument. If you disable `even_bars` , the open value of the first Renko bar is set to the first value from the `selector` . The following opening and closing Renko bar values are all multiples of the first value from the `selector`

   ```
   self._consolidator = ClassicRenkoConsolidator(1, even_bars=False)
   ```

2. Add an event handler to the consolidator.

   ```
   self._consolidator.data_consolidated += self._consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

   ```
   def _consolidation_handler(self, sender: object, consolidated_bar: RenkoBar) -> None:
       pass
   ```

The consolidation event handler receives bars when the price movement forms a new classic Renko bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

     ```
     self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

     ```
     # Example 1: Update the consolidator with data from the Slice object
     def on_data(self, slice: Slice) -> None:
         ticks = slice.ticks[self._symbol]
         for tick in ticks:
             self._consolidator.update(tick)

     # Example 2: Update the consolidator with data from a history request
     ticks = self.history[Tick](self._symbol, timedelta(minutes=3), Resolution.TICK)
     for tick in ticks:
         self._consolidator.update(tick)
     ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `RenkoBar` objects. Follow these steps to create and manage a `Tick` quote bar consolidator based on the preceding Renko bar rules:

1. Create the consolidator.

   To create a classic Renko consolidator, pass the bar size to the `ClassicRenkoConsolidator` constructor.

   ```
   # Create a Classic Renko consolidator that emits a bar when the price moves $1
   self._consolidator = ClassicRenkoConsolidator(1)
   ```

   The `ClassicRenkoConsolidator` has the following default behavior:

   - It uses the `value` property of the `IBaseData` object it receives to build the Renko bars
   - It ignores the volume of the input data
   - It enforces the open and close of each bar to be a multiple of the bar size

   To relax the requirement that the open and close of the Renko bars must be a multiple of bar size, disable the `even_bars` argument. If you disable `even_bars` , the open value of the first Renko bar is set to the first value from the `selector` . The following opening and closing Renko

bar values are all multiples of the first value from the `selector`

```
self._consolidator = ClassicRenkoConsolidator(1, even_bars=False)
```

2. Add an event handler to the consolidator.

```
self._consolidator.data_consolidated += self._consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: RenkoBar) -> None:
    pass
```

The consolidation event handler receives bars when the price movement forms a new classic Renko bar.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

  ```
  self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

  ```
  # Example 1: Update the consolidator with data from the Slice object
  def on_data(self, slice: Slice) -> None:
      ticks = slice.ticks[self._symbol]
      for tick in ticks:
          self._consolidator.update(tick)

  # Example 2: Update the consolidator with data from a history request
  ticks = self.history[Tick](self._symbol, timedelta(minutes=3), Resolution.TICK)
  for tick in ticks:
      self._consolidator.update(tick)
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Reset Consolidators

To reset a consolidator, call its `reset` method.

```
self._consolidator.reset()
```

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your consolidators when splits and dividends occur. When a split or dividend occurs while the consolidator is in the process of building a bar, the open, high, and low may reflect prices from before the split or dividend. To avoid issues, call the consolidator's `reset` method and then warm it up with `SCALED_RAW` data from a history request .

```
def on_data(self, data: Slice):
    # When a split or dividend occurs...
    if (data.splits.contains_key(self._symbol) and data.splits[self._symbol].type == SplitType.SPLIT_OCCURRED or
        data.dividends.contains_key(self._symbol)):
        # If the consolidator is working on a bar...
        if self._consolidator.working_data:
            # Get adjusted prices for the time period of the working bar.
            history = self.history[TradeBar](self._symbol, self._consolidator.working_data.time, self.time,
data_normalization_mode=DataNormalizationMode.SCALED_RAW)
            # Reset the consolidator.
            self._consolidator.reset()
            # Warm-up the consolidator with the adjusted price data.
            for bar in history:
                self._consolidator.update(bar)
```

Examples

The following examples demonstrate some common practices for implementing classic renko consolidator.

Example 1: 10 Dollar Bar Range SMA Cross

The following algorithm creates a dollar bar for SPY. Then, for each 10-dollar bar, we find their range (high - low) and feed to an SMA indicator, such that we obtain a trend indicator of the range of SPY. We trade VXX as the proxy of the SPY volatility based on the trend of the range SMA.

```py
class ClassicRenkoBarConsolidatorAlgorithm(QCAlgorithm):
    _high = 0
    _low = 10000
    _count = 0
    _sma = SimpleMovingAverage(10)

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Request SPY data to feed the consolidators and indicators for trade signal generation.
        self._spy = self.add_equity("SPY", Resolution.MINUTE).symbol
        # Request VXX data for trading.
        self._vxx = self.add_equity("VXX", Resolution.MINUTE).symbol

        # Create a dollar bar of SPY to track the volatility.
        self._consolidator = ClassicRenkoConsolidator(1)
        self._consolidator.data_consolidated += self.on_consolidated

        # Subscribe the consolidators to SPY data for automatic updating.
        self.subscription_manager.add_consolidator(self._spy, self._consolidator)

        self._sma.window.size = 2;
        self.set_warm_up(100)

    def on_consolidated(self, sender: object, bar: TradeBar) -> None:
        # Update the SPY range of the current batch.
        self._high = max(self._high, bar.high)
        self._low = min(self._low, bar.low)
        self._count += 1

        # Update SMA of SPY range of the last 10 Renko bars.
        if self._count >= 10:
            self._sma.update(bar.end_time, self._high - self._low)

            # Reset high and low.
            self._high = 0
            self._low = 10000
            self._count = 0

    def on_data(self, slice: Slice) -> None:
        if self._sma.is_ready:
            current = self._sma.current.value
            previous = self._sma.previous.value

            # If the range trend increases, buy VXX as a proxy for the increasing volatility.
            if current > previous and not self.portfolio[self._vxx].is_long:
                self.set_holdings(self._vxx, 0.5)
            # If the range trend decreases, sell VXX as a proxy for decreasing volatility.
            elif current < previous and not self.portfolio[self._vxx].is_short:
                self.set_holdings(self._vxx, -0.5)
```

Renko Consolidators

Volume Renko Consolidators

Introduction

Volume Renko consolidators aggregate bars based on a fixed trading volume. These types of bars are commonly known as volume bars. A `VolumeRenkoConsolidator` with a bar size of 10,000 produces a new bar every time 10,000 units of the security trades in the market. If the trading volume of a single time step exceeds two step sizes (i.e. >20,000), the `VolumeRenkoConsolidator` produces multiple bars in a single time step.

Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `VolumeRenkoBar` objects. Follow these steps to create and manage a `TradeBar` consolidator based on custom set volume traded:

1. Create the consolidator.

   To create a Volume Renko consolidator, pass the bar size to the `VolumeRenkoConsolidator` constructor.

   ```
   # Create a Volume Renko consolidator that emits a bar every time 10,000 units trade
   self._consolidator = VolumeRenkoConsolidator(10000)
   ```

2. Add an event handler to the consolidator.

   ```
   self._consolidator.data_consolidated += self._consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

   ```
   def _consolidation_handler(self, sender: object, consolidated_bar: VolumeRenkoBar) -> None:
       pass
   ```

   The consolidation event handler receives bars when the trading volume forms a new Volume Renko bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

     ```
     self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def on_data(self, slice: Slice) -> None:
    trade_bar = slice.bars[self._symbol]
    self._consolidator.update(trade_bar)

# Example 2: Update the consolidator with data from a history request
history = self.history[TradeBar](self._symbol, 30, Resolution.MINUTE)
for trade_bar in history:
    self._consolidator.update(trade_bar)
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `VolumeRenkoBar` objects. Follow these steps to create and manage a `Tick` consolidator based on custom set volume traded:

1. Create the consolidator.

   To create a Volume Renko consolidator, pass the bar size to the `VolumeRenkoConsolidator` constructor.

   ```
   # Create a Volume Renko consolidator that emits a bar every time 10,000 units trade
   self._consolidator = VolumeRenkoConsolidator(10000)
   ```

2. Add an event handler to the consolidator.

   ```
   self._consolidator.data_consolidated += self._consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

   ```
   def _consolidation_handler(self, sender: object, consolidated_bar: VolumeRenkoBar) -> None:
       pass
   ```

   The consolidation event handler receives bars when the trading volume forms a new Volume Renko bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

     ```
     self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
     ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

  ```
  PY
  # Example 1: Update the consolidator with data from the Slice object
  def on_data(self, slice: Slice) -> None:
      ticks = slice.ticks[self._symbol]
      for tick in ticks:
          self._consolidator.update(tick)

  # Example 2: Update the consolidator with data from a history request
  ticks = self.history[Tick](self._symbol, timedelta(minutes=3), Resolution.TICK)
  for tick in ticks:
      self._consolidator.update(tick)
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   PY
   self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Reset Consolidators

To reset a consolidator, call its `reset` method.

```
PY
self._consolidator.reset()
```

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your consolidators when splits and dividends occur. When a split or dividend occurs while the consolidator is in the process of building a bar, the open, high, and low may reflect prices from before the split or dividend. To avoid issues, call the consolidator's `reset` method and then warm it up with `SCALED_RAW` data from a history request .

```
PY
def on_data(self, data: Slice):
    # When a split or dividend occurs...
    if (data.splits.contains_key(self._symbol) and data.splits[self._symbol].type == SplitType.SPLIT_OCCURRED or
        data.dividends.contains_key(self._symbol)):
        # If the consolidator is working on a bar...
        if self._consolidator.working_data:
            # Get adjusted prices for the time period of the working bar.
            history = self.history[TradeBar](self._symbol, self._consolidator.working_data.time, self.time,
data_normalization_mode=DataNormalizationMode.SCALED_RAW)
            # Reset the consolidator.
            self._consolidator.reset()
            # Warm-up the consolidator with the adjusted price data.
            for bar in history:
                self._consolidator.update(bar)
```

Examples

The following examples demonstrate common practices for implementing volume renko consolidator.

Example 1: Bollinger Bands From Volume Renko Bar

The following algorithm uses 100,000-share volume Renko bars to spot mean reversal opportunities on SPY with Bollinger Bands. Equal volume bars could provide more equal information in each bar, so the standard deviation and trade opportunities are more credible.

PY

```
class VolumeRenkoBarConsolidatorAlgorithm(QCAlgorithm):
    # We use a Bollinger band to signal mean reversal opportunities.
    _bbands = BollingerBands(20, 2, MovingAverageType.EXPONENTIAL)

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Request SPY data to feed for the consolidators, indicators, and trade signal generation.
        self._spy = self.add_equity("SPY", Resolution.MINUTE).symbol

        # Create a 100,000-share bar of SPY to obtain a more equally-informed bar.
        self._consolidator = VolumeRenkoConsolidator(100000)

        # Subscribe the consolidators to SPY data to automatically update the indicator.
        self.register_indicator(self._spy, self._bbands, self._consolidator)

        # Warm up the indicator for immediate use.
        self.set_warm_up(20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._spy) if not self.is_warming_up else None
        if self._bbands.is_ready and bar:
            upper_band = self._bbands.upper_band.current.value
            middle_band = self._bbands.middle_band.current.value
            lower_band = self._bbands.lower_band.current.value

            # Trade the mean reversal by short-selling SPY if the current price exceeds the upper threshold.
            if bar.close > upper_band and not self.portfolio[self._spy].is_long:
                self.set_holdings(self._spy, -0.5)
            # Trade the mean reversal by buying SPY if the price is below the lower threshold.
            elif bar.close < lower_band and not self.portfolio[self._spy].is_short:
                self.set_holdings(self._spy, 0.5)
            # Exit position if the price is mean-reverted that crosses the EMA reference.
            elif (self.portfolio[self._spy].quantity > 0 and bar.close > middle_band)\
            or (self.portfolio[self._spy].quantity < 0 and bar.close < middle_band):
                self.liquidate(self._spy)
```

Consolidator Types

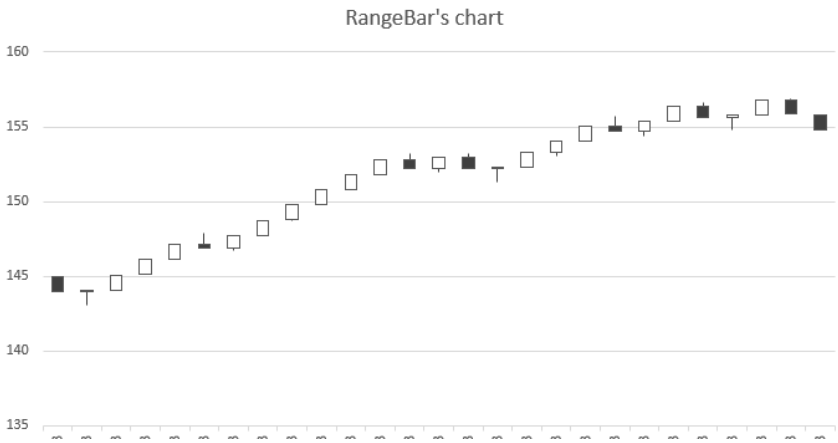
Range Consolidators

Range Consolidators

Range Consolidators

Introduction

Most Range consolidators aggregate bars based on a fixed price movement. It is very much like a Renko Bar, but instead of consolidating a fix movement from the opening price, a Range Bar would fix the range of the whole bar, i.e. High - Low. A new bar is formed when the range of the whole bar reached a preset value, thus it completely neglects the time effect and focuses on the variance/information carried by the price movement.



Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `RangeBar` objects. Follow these steps to create and manage a `TradeBar` consolidator based on the preset range of price movement:

1. Create the consolidator.

   To create a Range consolidator, pass the bar size to the `RangeConsolidator` constructor.

   ```
   # Create a Range consolidator that emits a bar when the high and low differs $1
   self._consolidator = RangeConsolidator(1)
   ```

2. Add an event handler to the consolidator.

   ```
   self._consolidator.data_consolidated += self._consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: RangeBar) -> None:
    pass
```

The consolidation event handler receives bars when the price movement forms a new Range bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

     ```
     self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

     ```
     # Example 1: Update the consolidator with data from the Slice object
     def on_data(self, slice: Slice) -> None:
         trade_bar = slice.bars[self._symbol]
         self._consolidator.update(trade_bar)

     # Example 2: Update the consolidator with data from a history request
     history = self.history[TradeBar](self._symbol, 30, Resolution.MINUTE)
     for trade_bar in history:
         self._consolidator.update(trade_bar)
     ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `RangeBar` objects. Follow these steps to create and manage a `QuoteBar` consolidator based on the preset range of price movement:

1. Create the consolidator.

   To create a Range consolidator, pass the bar size to the `RangeConsolidator` constructor.

   ```
   # Create a Range consolidator that emits a bar when the high and low differs $1
   self._consolidator = RangeConsolidator(1)
   ```

2. Add an event handler to the consolidator.

   ```
   self._consolidator.data_consolidated += self._consolidation_handler
   ```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: RangeBar) -> None:
    pass
```

The consolidation event handler receives bars when the price movement forms a new Range bar.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

```
self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
```

- Manual Updates

Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `QuoteBar` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def on_data(self, slice: Slice) -> None:
    quote_bar = slice.quote_bars[self._symbol]
    self._consolidator.update(quote_bar)

# Example 2: Update the consolidator with data from a history request
history = self.history[QuoteBar](self._symbol, 30, Resolution.MINUTE)
for quote_bar in history:
    self._consolidator.update(quote_bar)
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `RangeBar` objects. Follow these steps to create and manage a `Tick` consolidator based on the preset range of price movement:

1. Create the consolidator.

To create a Range consolidator, pass the bar size to the `RangeConsolidator` constructor.

```
# Create a Range consolidator that emits a bar when the high and low differs $1
self._consolidator = RangeConsolidator(1)
```

2. Add an event handler to the consolidator.

```
self._consolidator.data_consolidated += self._consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: RangeBar) -> None:
    pass
```

The consolidation event handler receives bars when the price movement forms a new Range bar.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

  ```
  self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

  ```
  # Example 1: Update the consolidator with data from the Slice object
  def on_data(self, slice: Slice) -> None:
      ticks = slice.ticks[self._symbol]
      for tick in ticks:
          self._consolidator.update(tick)

  # Example 2: Update the consolidator with data from a history request
  ticks = self.history[Tick](self._symbol, timedelta(minutes=3), Resolution.TICK)
  for tick in ticks:
      self._consolidator.update(tick)
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `RangeBar` objects. Follow these steps to create and manage a `Tick` quote bar consolidator based on the preset range of price movement:

1. Create the consolidator.

   To create a Range consolidator, pass the bar size to the `RangeConsolidator` constructor.

   ```
   # Create a Range consolidator that emits a bar when the high and low differs $1
   self._consolidator = RangeConsolidator(1)
   ```

2. Add an event handler to the consolidator.

   ```
   self._consolidator.data_consolidated += self._consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

   ```
   def _consolidation_handler(self, sender: object, consolidated_bar: RangeBar) -> None:
       pass
   ```

   The consolidation event handler receives bars when the price movement forms a new Range bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

     ```
     self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

     ```
     # Example 1: Update the consolidator with data from the Slice object
     def on_data(self, slice: Slice) -> None:
         ticks = slice.ticks[self._symbol]
         for tick in ticks:
             self._consolidator.update(tick)

     # Example 2: Update the consolidator with data from a history request
     ticks = self.history[Tick](self._symbol, timedelta(minutes=3), Resolution.TICK)
     for tick in ticks:
         self._consolidator.update(tick)
     ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Reset Consolidators

To reset a consolidator, call its `reset` method.

```
self._consolidator.reset()
```

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your consolidators when splits and dividends occur. When a split or dividend occurs while the consolidator is in the process of building a bar, the open, high, and low may reflect prices from before the split or dividend. To avoid issues, call the consolidator's `reset` method and then warm it up with `SCALED_RAW` data from a history request .

```
def on_data(self, data: Slice):
    # When a split or dividend occurs...
    if (data.splits.contains_key(self._symbol) and data.splits[self._symbol].type == SplitType.SPLIT_OCCURRED or
        data.dividends.contains_key(self._symbol)):
        # If the consolidator is working on a bar...
        if self._consolidator.working_data:
            # Get adjusted prices for the time period of the working bar.
            history = self.history[TradeBar](self._symbol, self._consolidator.working_data.time, self.time,
data_normalization_mode=DataNormalizationMode.SCALED_RAW)
            # Reset the consolidator.
            self._consolidator.reset()
            # Warm-up the consolidator with the adjusted price data.
            for bar in history:
                self._consolidator.update(bar)
```

Range Consolidators

Classic Range Consolidators

Introduction

Most Range consolidators aggregate bars based on a fixed price range movement. The `ClassicRangeConsolidator` produces a different type of Range bars than the `RangeConsolidator` . A `ClassicRangeConsolidator` with a bar size of `1` produces a new bar that spans `1` every time an asset's price range moves $1. If the price jumps multiple dollars in a single tick, the `ClassicRangeConsolidator` only produces one bar per time step where the open of each bar matches the close of the previous bar.

Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `RangeBar` objects. Follow these steps to create and manage a `TradeBar` consolidator based on the preceding Range bar rules:

1. Create the consolidator.

   To create a classic Range consolidator, pass the bar size to the `ClassicRangeConsolidator` constructor.

   ```
   # Create a Classic Range consolidator that emits a bar when the price range moves $1
   self._consolidator = ClassicRangeConsolidator(1)
   ```

   The `ClassicRangeConsolidator` has the following default behavior:

   - It uses the `value` property of the `IBaseData` object it receives to build the Range bars
   - It ignores the volume of the input data
   - It enforces the high and low of each bar to be a multiple of the bar size

   To build the Range bars with a different property than the `value` of the `IBaseData` object, provide a `selector` argument. The `selector` should be a function that receives the `IBaseData` object and returns a decimal value.

   ```
   self._consolidator = ClassicRangeConsolidator(1, selector=lambda data: data.high)
   ```

   To add a non-zero `volume` property to the Range bars, provide a `volume_selector` argument. The `volume_selector` should be a function that receives the `IBaseData` object and returns a decimal value.

   ```
   self._consolidator = ClassicRangeConsolidator(1, volume_selector=lambda data: data.volume)
   ```

2. Add an event handler to the consolidator.

   ```
   self._consolidator.data_consolidated += self._consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

   ```
   def _consolidation_handler(self, sender: object, consolidated_bar: RangeBar) -> None:
       pass
   ```

The consolidation event handler receives bars when the price movement forms a new classic Range bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

     ```
     self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

     ```
     # Example 1: Update the consolidator with data from the Slice object
     def on_data(self, slice: Slice) -> None:
         trade_bar = slice.bars[self._symbol]
         self._consolidator.update(trade_bar)

     # Example 2: Update the consolidator with data from a history request
     history = self.history[TradeBar](self._symbol, 30, Resolution.MINUTE)
     for trade_bar in history:
         self._consolidator.update(trade_bar)
     ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `RangeBar` objects. Follow these steps to create and manage a `QuoteBar` consolidator based on the preceding Range bar rules:

1. Create the consolidator.

   To create a classic Range consolidator, pass the bar size to the `ClassicRangeConsolidator` constructor.

   ```
   # Create a Classic Range consolidator that emits a bar when the price range moves $1
   self._consolidator = ClassicRangeConsolidator(1)
   ```

   The `ClassicRangeConsolidator` has the following default behavior:

   - It uses the `value` property of the `IBaseData` object it receives to build the Range bars
   - It ignores the volume of the input data
   - It enforces the high and low of each bar to be a multiple of the bar size

   The following arguments enable you to create Range bars that aggregate the excessive bid-ask spread on the asset. It can help market-making algorithms to track wider spread opportunities.

```
self._consolidator = ClassicRangeConsolidator(10, lambda data: data.value, lambda data: data.last_bid_size - data.last_ask_size)
```

2. Add an event handler to the consolidator.

```
self._consolidator.data_consolidated += self._consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

```
def _consolidation_handler(self, sender: object, consolidated_bar: RangeBar) -> None:
    pass
```

The consolidation event handler receives bars when the price movement forms a new classic Range bar.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

  ```
  self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `QuoteBar` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

  ```
  # Example 1: Update the consolidator with data from the Slice object
  def on_data(self, slice: Slice) -> None:
      quote_bar = slice.quote_bars[self._symbol]
      self._consolidator.update(quote_bar)

  # Example 2: Update the consolidator with data from a history request
  history = self.history[QuoteBar](self._symbol, 30, Resolution.MINUTE)
  for quote_bar in history:
      self._consolidator.update(quote_bar)
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `RangeBar` objects. Follow these steps to create and manage a `Tick` consolidator based on the preceding Range bar rules:

1. Create the consolidator.

   To create a classic Range consolidator, pass the bar size to the `ClassicRangeConsolidator` constructor.

   ```
   # Create a Classic Range consolidator that emits a bar when the price range moves $1
   self._consolidator = ClassicRangeConsolidator(1)
   ```

   The `ClassicRangeConsolidator` has the following default behavior:

   - It uses the `value` property of the `IBaseData` object it receives to build the Range bars
   - It ignores the volume of the input data
   - It enforces the high and low of each bar to be a multiple of the bar size

2. Add an event handler to the consolidator.

   ```
   self._consolidator.data_consolidated += self._consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

   ```
   def _consolidation_handler(self, sender: object, consolidated_bar: RangeBar) -> None:
       pass
   ```

   The consolidation event handler receives bars when the price movement forms a new classic Range bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

     ```
     self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def on_data(self, slice: Slice) -> None:
    ticks = slice.ticks[self._symbol]
    for tick in ticks:
        self._consolidator.update(tick)

# Example 2: Update the consolidator with data from a history request
ticks = self.history[Tick](self._symbol, timedelta(minutes=3), Resolution.TICK)
for tick in ticks:
    self._consolidator.update(tick)
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `RangeBar` objects. Follow these steps to create and manage a `Tick` quote bar consolidator based on the preceding Range bar rules:

1. Create the consolidator.

   To create a classic Range consolidator, pass the bar size to the `ClassicRangeConsolidator` constructor.

   ```
   # Create a Classic Range consolidator that emits a bar when the price range moves $1
   self._consolidator = ClassicRangeConsolidator(1)
   ```

   The `ClassicRangeConsolidator` has the following default behavior:

   - It uses the `value` property of the `IBaseData` object it receives to build the Range bars
   - It ignores the volume of the input data
   - It enforces the high and low of each bar to be a multiple of the bar size

2. Add an event handler to the consolidator.

   ```
   self._consolidator.data_consolidated += self._consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self._consolidation_handler` , not `self._consolidation_handler()` .

3. Define the consolidation handler.

   ```
   def _consolidation_handler(self, sender: object, consolidated_bar: RangeBar) -> None:
       pass
   ```

   The consolidation event handler receives bars when the price movement forms a new classic Range bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

To automatically update a consolidator with data from the security subscription, call the `add_consolidator` method of the Subscription Manager.

```
self.subscription_manager.add_consolidator(self._symbol, self._consolidator)
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `on_data` method or with data from a history request .

  ```
  # Example 1: Update the consolidator with data from the Slice object
  def on_data(self, slice: Slice) -> None:
      ticks = slice.ticks[self._symbol]
      for tick in ticks:
          self._consolidator.update(tick)

  # Example 2: Update the consolidator with data from a history request
  ticks = self.history[Tick](self._symbol, timedelta(minutes=3), Resolution.TICK)
  for tick in ticks:
      self._consolidator.update(tick)
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   self.subscription_manager.remove_consolidator(self._symbol, self._consolidator)
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Reset Consolidators

To reset a consolidator, call its `reset` method.

```
self._consolidator.reset()
```

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your consolidators when splits and dividends occur. When a split or dividend occurs while the consolidator is in the process of building a bar, the open, high, and low may reflect prices from before the split or dividend. To avoid issues, call the consolidator's `reset` method and then warm it up with `SCALED_RAW` data from a history request .

```
def on_data(self, data: Slice):
    # When a split or dividend occurs...
    if (data.splits.contains_key(self._symbol) and data.splits[self._symbol].type == SplitType.SPLIT_OCCURRED or
        data.dividends.contains_key(self._symbol)):
        # If the consolidator is working on a bar...
        if self._consolidator.working_data:
            # Get adjusted prices for the time period of the working bar.
            history = self.history[TradeBar](self._symbol, self._consolidator.working_data.time, self.time,
data_normalization_mode=DataNormalizationMode.SCALED_RAW)
            # Reset the consolidator.
            self._consolidator.reset()
            # Warm-up the consolidator with the adjusted price data.
            for bar in history:
                self._consolidator.update(bar)
```

Consolidator Types

Combining Consolidators

Introduction

Sequential consolidators wire two internal consolidators together such that the output of the first consolidator is the input to the second consolidator and the output of the second consolidator is the output of the sequential consolidator.

Create Consolidators

To create a sequential consolidator, create two consolidators and then pass them to the `SequentialConsolidator` constructor.

```py
# This first consolidator produces a consolidated bar after a day passes
one_day_consolidator = TradeBarConsolidator(timedelta(days=1))

# This second consolidators produces a consolidated bar after it sees 3 samples
three_count_consolidator = TradeBarConsolidator(3)

# This sequential consolidator aggregates three 1-day bars together
self.consolidator = SequentialConsolidator(one_day_consolidator, three_count_consolidator)
```

For more information about each type of consolidator, see Consolidator Types .

Consolidating Data

Consolidator History

Introduction

This page explains how to save and access historical consolidated bars.

Save Consolidated Bars

To access historical bars that were passed to your consolidation handler, save the bars as you receive them. You can use a RollingWindow to save the consolidated bars and easily access them later on in your algorithm.

```
# Create a class member to store the RollingWindow
self._window = RollingWindow(2)

# In the consolidation handler, add consolidated bars to the RollingWindow
def _consolidation_handler(self, sender: object, consolidated_bar: TradeBar) -> None:
    self._window.add(consolidated_bar)
```

Get Historical Bars

If you save consolidated bars in a `RollingWindow`, you can access them by indexing the `RollingWindow`. `RollingWindow` objects operate on a first-in, first-out process to allow for reverse list access semantics with positive and negative indexing. Index 0 refers to the most recent item in the window and the largest index refers to the last item in the window. Index -1 refers to the latest item as well.

```
most_recent_bar = self._window[0]
previous_bar = self._window[1]
oldest_bar = self._window[-1]
```

To get the consolidated bar that was most recently removed from the `RollingWindow`, use the `most_recently_removed` property.

```
removed_bar = self._window.most_recently_removed
```

Examples

The following examples demonstrate some common practices for consolidator history.

Example 1: Price Action

The following algorithm trades breakout price action on the SPY five-minute trade bar. To do so, we must create a five-minute trade bar consolidator and a rolling window to hold 3 trade bars to check if the trade conditions are fulfilled.

PY

```
class ConsolidatorHistoryAlgorithm(QCAlgorithm):
    # To hold 3 consolidated trade bars to identify a breakout pattern.
    windows = RollingWindow(3)

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Request SPY data for signal generation and trading.
        self.spy = self.add_equity("SPY", Resolution.MINUTE).symbol

        # The breakout is based on a 5-minute consolidated trade bar.
        consolidator = TradeBarConsolidator(timedelta(minutes=5))
        # Subscribe for automatically updating the consolidator with SPY data.
        self.subscription_manager.add_consolidator(self.spy, consolidator)
        # Add a consolidator handler to check that the breakout condition is fulfilled and traded.
        consolidator.data_consolidated += self.on_consolidated

        self.set_warm_up(timedelta(15))

    def on_consolidated(self, sender: object, bar: TradeBar) -> None:
        self.windows.add(bar)

        if not self.is_warming_up and self.windows.is_ready:
            # Buy if the breakout price action is fulfilled.
            # 1. Increasing price trend.
            # 2. The last 3 bars are green.
            # 3. The 3rd and 2nd last bars range is decreasing.
            # 4. The last bar exceeds the 2nd last bar by double the 2nd last bar's range.
            second_last_range = self.windows[1].close - self.windows[1].open
            if bar.close > self.windows[1].close and self.windows[1].close > self.windows[2].close and\
            self.windows[2].close > self.windows[2].open and self.windows[1].close > self.windows[1].open and\
            self.windows[0].close > self.windows[0].open and self.windows[2].close - self.windows[2].open > second_last_range and\
            bar.close > self.windows[1].close + 2 * second_last_range:
                self.set_holdings(self.spy, 0.5)

    def on_order_event(self, order_event: OrderEvent) -> None:
        if order_event.status == OrderStatus.FILLED:
            if order_event.ticket.order_type == OrderType.MARKET:
                # Stop loss order at 1%.
                stop_price = order_event.fill_price * 0.99 if order_event.fill_quantity > 0 else order_event.fill_price * 1.01
                self.stop_market_order(self.spy, -self.portfolio[self.spy].quantity, stop_price)
                # Take profit order at 2%.
                take_profit_price = order_event.fill_price * 1.02 if order_event.fill_quantity > 0 else order_event.fill_price * 0.98
                self.limit_order(self.spy, -self.portfolio[self.spy].quantity, take_profit_price)
            elif order_event.ticket.order_type == OrderType.STOP_MARKET or order_event.ticket.order_type == OrderType.LIMIT:
                # Cancel any open order if stop loss or take profit order filled.
                self.transactions.cancel_open_orders()
```

Consolidating Data

Updating Indicators

Introduction

You can use consolidators to automatically update indicators in your algorithms. The consolidators can update your indicators at each time step or with aggregated bars. By default, LEAN updates data point indicators with the close price of the consolidated bars, but you can change it to a custom data field.

Standard Indicator Periods

If your algorithm has a static universe, you can create automatic indicators in just one line of code. When you create an automatic indicator, LEAN creates a consolidator, hooks it up for automatic updates, and then updates the indicator with the consolidated bars.

```
PY
 # Consolidate minute SPY data into 14-bar daily indicators
ema = self.ema("SPY", 14, Resolution.DAILY)
sma = self.sma("SPY", 14, Resolution.DAILY)
```

If your algorithm has a dynamic universe, create a manual indicator and then create a time period consolidator that updates the indicator at each time step. Keep a reference to the consolidator so you can remove it when your algorithm removes the security from the universe.

```
PY
def initialize(self):
    self._ema = ExponentialMovingAverage(14)
    self._consolidator = TradeBarConsolidator(1)
    self._consolidator.data_consolidated += self._on_data_consolidated
    self.subscription_manager.add_consolidator(self._symbol, self._consolidator)

# Define consolidator handler function as a class method
def _on_data_consolidated(self, sender, bar):
    self._ema.update(bar.end_time, bar.close)
```

Custom Indicator Periods

It's common to update indicators with price data that spans a normal time period like one minute or one day. It's less common to update an indicator with exotic time periods (for example, a 7-minute consolidated bar), so these types of indicators may provide more opportunities for alpha. To update indicators with exotic data, create a manual indicator and then call the `register_indicator` method. The `register_indicator` method wires up the indicator for automatic updates at the time interval you provide.

```
PY
# Calculate the SMA with 10 7-minute bars
self._symbol = self.add_equity("SPY", Resolution.MINUTE).symbol
self._indicator = SimpleMovingAverage(10)
self.register_indicator(self._symbol, self._indicator, timedelta(minutes=7))
```

The `register_indicator` method can accept a `timedelta` , `Resolution` , or an unregistered consolidator. If you apply the indicator to a security in a dynamic universe, provide a consolidator so that you can remove it when your algorithm removes the security from the universe.

```
PY
# timedelta
self.register_indicator(self._symbol, self._indicator, timedelta(minutes=7))

# Resolution
self.register_indicator(self._symbol, self._indicator, Resolution.HOUR)

# Consolidator
self._consolidator = TradeBarConsolidator(35)
self.register_indicator(self._symbol, self._indicator, self._consolidator)
```

Custom Indicator Values

Data point indicators use only a single price data in their calculations. By default, those indicators use the closing price. For assets with `TradeBar`

data, that price is the `TradeBar` close price. For assets with `QuoteBar` data, that price is the mid-price of the bid closing price and the ask closing price. To create an indicator with the other fields like the `OPEN`, `HIGH`, `LOW`, or `CLOSE`, provide a `selector` argument to the `register_indicator` method.

```
# Define a 10-period RSI with indicator constructor
self._rsi = RelativeStrengthIndex(10, MovingAverageType.SIMPLE)

# Register the daily High price data to automatically update the indicator
self.register_indicator(self._symbol, self._rsi, Resolution.DAILY, Field.HIGH)
```

The `register_indicator` method can accept a `timedelta`, `Resolution`, or an unregistered consolidator. If you apply the indicator to a security in a dynamic universe, provide a consolidator so that you can remove it when your algorithm removes the security from the universe.

The `Field` class has the following `selector` properties:

Examples

The following examples demonstrate common practices for updating indicators using consolidators.

Example 1: Hammer Pattern With 5-Minute Consolidator

The following algorithm trades Hammer and Inverted Hammer candlestick patterns. The candles are constructed with five-minute SPY trade bars consolidated by a five-minute `TradeBarConsolidator`, while automatically updating with the `register_indicator` method. Both patterns are bullish, so we buy SPY if the pattern is signaled.

```
from QuantConnect.Indicators.CandlestickPatterns import *
class ConsolidatorUpdatingIndicatorsAlgorithm(QCAlgorithm):
    hammer = Hammer()
    inverted_hammer = InvertedHammer()

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Request SPY data for signal generation and trading.
        self.spy = self.add_equity("SPY", Resolution.MINUTE).symbol

        # The candlestick patterns are based on a 5-minute consolidated trade bar.
        consolidator = TradeBarConsolidator(timedelta(minutes=5))
        # Subscribe for automatically updating the indicators with the 5-minute consolidator.
        self.register_indicator(self.spy, self.hammer, consolidator)
        self.register_indicator(self.spy, self.inverted_hammer, consolidator)
        # Add an event handler on candlestick indicators that are updated to trade the pattern.
        self.hammer.updated += self.on_updated
        self.inverted_hammer.updated += self.on_updated

        self.set_warm_up(1)

    def on_updated(self, sender: object, point: IndicatorDataPoint) -> None:
        # Both the hammer and inverted hammer patterns indicate bullish movement, so we buy SPY.
        if point.value == 1 and not self.portfolio[self.spy].is_long:
            self.set_holdings(self.spy, 0.5)

    def on_order_event(self, order_event: OrderEvent) -> None:
        if order_event.status == OrderStatus.FILLED:
            if order_event.ticket.order_type == OrderType.MARKET:
                # Stop loss order at 1%.
                stop_price = order_event.fill_price * (0.99 if order_event.fill_quantity > 0 else 1.01)
                self.stop_market_order(self.spy, -self.portfolio[self.spy].quantity, stop_price)
                # Take profit order at 2%.
                take_profit_price = order_event.fill_price * (1.02 if order_event.fill_quantity > 0 else 0.98)
                self.limit_order(self.spy, -self.portfolio[self.spy].quantity, take_profit_price)
            elif order_event.ticket.order_type == OrderType.STOP_MARKET or order_event.ticket.order_type == OrderType.LIMIT:
                # Cancel any open order if stop loss or take profit order filled.
                self.transactions.cancel_open_orders()
```

Historical Data

Historical Data

Getting Started

Introduction

There are two ways to request historical data in your algorithms: direct historical data requests and indirect algorithm warm up .

History Requests

History requests return all of the data you request as a single object. Follow these steps to get some historical data:

1. Create a new project.

   Projects contain files to run backtests, launch research notebooks, perform parameter optimizations, and deploy live trading strategies. You need to create projects in order to create strategies and share your work with other members.

   The process to create a new project depends on if you use the Cloud Platform , Local Platform , or CLI .

2. In the `initialize` method, add an asset .

   The `initialize` method is the entry point of your algorithm where you define a series of settings, including security subscriptions, starting cash balances, and warm-up periods. LEAN only calls the `initialize` method one time, at the start of your algorithm.

   ```
   spy = self.add_equity('SPY')
   ```
   PY

3. Call the `history` method with the asset's Symbol and a lookback period.

   `Symbol` objects are a way to identify or "finger-print" tradable assets so that no further database look-up is required. All QuantConnect and LEAN Algorithm API methods use `Symbol` objects to identify assets.

   ```
   history = self.history(spy.symbol, 5, Resolution.DAILY)
   ```
   PY

		close	high	low	open	volume
symbol	**time**					
SPY	**2025-02-12 16:00:00**	603.36	604.54	598.520	599.26	38247065.0
	2025-02-13 16:00:00	609.73	609.94	603.215	604.43	36445673.0
	2025-02-14 16:00:00	609.70	610.99	609.080	609.98	23498431.0
	2025-02-18 16:00:00	611.49	611.49	608.390	610.86	24030531.0
	2025-02-19 16:00:00	612.93	613.23	609.560	610.04	26847903.0

Warm Up Periods

Warm-up simulates winding back the clock from the time you deploy the algorithm. In a backest, this is the start date of your algorithm. In live trading, it's the current date. Follow these steps to add a warm-up period to the start of your algorithm:

1. Create a new project.

   The process to create a new project depends on if you use the Cloud Platform , Local Platform , or CLI .

2. In the `initialize` method, set the backtest dates and add an asset .

```
self.set_start_date(2024, 12, 1)
self.set_end_date(2024, 12, 2)
self.add_equity("SPY", Resolution.DAILY)
```

3. In the `initialize` method, call the `set_warm_up` method with the warm-up duration.

```
self.set_warm_up(10, Resolution.DAILY)
```

4. In the `on_data` method, log the time and warm-up state .

```
self.log(f"self.is_warming_up at {self.time}: {self.is_warming_up}")
```

```
Algorithm starting warm up...
self.is_warming_up at 2024-11-22 16:00:00: True
self.is_warming_up at 2024-11-25 16:00:00: True
self.is_warming_up at 2024-11-26 16:00:00: True
self.is_warming_up at 2024-11-27 16:00:00: True
self.is_warming_up at 2024-11-29 13:00:00: True
Algorithm finished warming up.
self.is_warming_up at 2024-12-02 16:00:00: False
```

For more information about warm-up, see Warm Up Periods .

Examples

The following examples demonstrate some common practices for historical data.

Example 1: Simple Moving Average

The following example demonstrates weekly-resampled historical data to calculate the 50-week Simple Moving Average to implement an SMA-cross strategy.

```
class HistoricalDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        # Request SPY data for historical data call and trading.
        self.spy = self.add_equity("SPY").symbol
        # Set a scheduled event to trade SPY with a weekly SMA signal.
        self.schedule.on(self.date_rules.week_start(self.spy), self.time_rules.after_market_open(self.spy, 1), self.trade)

    def trade(self) -> None:
        # Historical data call to calculate signal.
        history = self.history(self.spy, 252, Resolution.DAILY)
        # Obtain the weekly close price to calculate the weekly SMA.
        weekly_close = history.unstack(0).close.resample("W").last()
        # Calculate the current 50-week SMA as a trading signal.
        sma50 = weekly_close.rolling(50).mean().iloc[-1, 0]

        # Trade the SMA cross strategy.
        price = self.securities[self.spy].price
        if price > sma50 and not self.portfolio[self.spy].is_long:
            self.set_holdings(self.spy, 1)
        elif price < sma50 and not self.portfolio[self.spy].is_short:
            self.set_holdings(self.spy, -1)
```

Historical Data

History Requests

Introduction

There are two ways to request historical data in your algorithms: direct historical data requests and indirect algorithm warm up . You can use a direct historical data request at any time throughout your algorithm. It returns all of the data you request as a single object.

Trailing Data Samples

To get historical data for a trailing time period, call `history` method with an an integer and a `Resolution` . For example, if you pass an asset `Symbol` , 5, and `Resolution.MINUTE` as the arguments, it returns the data of the asset during the most recent 5 minutes in the asset's market hours . These trailing minute bars can cross multiple trading days.

PY

```
class TrailingDataSamplesHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of an asset.
        symbol = self.add_equity('SPY').symbol
        # Get the minute-resolution TradeBar data of the asset over the trailing 5 minutes.
        history = self.history(TradeBar, symbol, 5, Resolution.MINUTE)
```

		close	high	low	open	volume
symbol	**time**					
SPY	**2024-12-18 15:56:00**	588.63	590.390	588.57	590.39	1053414.0
	2024-12-18 15:57:00	588.34	588.910	588.24	588.61	930643.0
	2024-12-18 15:58:00	588.11	588.460	588.07	588.34	1138812.0
	2024-12-18 15:59:00	587.92	588.325	587.70	588.10	1576391.0
	2024-12-18 16:00:00	586.28	587.940	585.89	587.92	5865463.0

If you don't pass a `Resolution` , it defaults to the resolution of the security subscription. The following example returns 3 days of data for QQQ and 3 minutes of data for SPY:

PY

```
class TrailingDataSamplesForMulitpleAssetsHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 20)
        self.set_end_date(2024, 12, 31)
        # Add two assets with different resolutions.
        spy = self.add_equity('SPY', Resolution.MINUTE).symbol
        qqq = self.add_equity('QQQ', Resolution.DAILY).symbol
        # Get the trailing 3 bars of data for each asset.
        history = self.history(TradeBar, [spy, qqq], 3)
```

		close	high	low	open	volume
symbol	**time**					
QQQ	**2024-12-17 16:00:00**	535.80	537.49	534.130	536.410	25048673.0
	2024-12-18 16:00:00	516.47	536.87	515.010	535.110	47016560.0
	2024-12-19 16:00:00	514.17	521.75	513.830	521.110	42192908.0
SPY	**2024-12-19 15:58:00**	586.40	586.77	586.365	586.730	872817.0
	2024-12-19 15:59:00	586.50	586.83	586.380	586.420	1524079.0
	2024-12-19 16:00:00	586.10	586.53	585.850	586.495	4342748.0

If there is no data for the time period you request, the result has fewer samples. For instance, say an illiquid asset has no trading activity during the last 15 minutes of the trading day and you request the 10 most recent minute bars at market close, 4 PM Eastern Standard Time (ET). In this case, you won't get any data because LEAN will try to fetch data from 3:50 PM ET to 4 PM ET since the market was open during that time , but there were no trades for the asset. For more information about missing data points, see Missing Data Points .

Trailing Time Periods

To get historical data for a trailing time period, pass a `timedelta` to the `history` method. The days of the `timedelta` represent calendar days.

```
class TrailingTimePeriodHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of an asset.
        symbol = self.add_equity('SPY').symbol
        # Get the minute-resolution TradeBar data of the asset over the trailing 3 days.
        history = self.history(TradeBar, symbol, timedelta(3), Resolution.MINUTE)
```

		close	high	low	open	volume
symbol	**time**					
SPY	**2024-12-16 09:31:00**	606.02	606.400	605.89	606.00	612650.0
	2024-12-16 09:32:00	606.01	606.305	605.94	605.99	132785.0
	...	...	...	...	...	...
	2024-12-18 15:59:00	587.92	588.325	587.70	588.10	1576391.0
	2024-12-18 16:00:00	586.28	587.940	585.89	587.92	5865463.0

If there is no data in the time period, the result is empty. For more information about missing data points, see Missing Data Points .

Date Ranges

To get historical data for a specific date range, call `history` method with start and end `datetime` objects. The `datetime` objects you provide are based in the algorithm time zone .

```
class DateRangeHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 1)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of an asset.
        symbol = self.add_equity('SPY').symbol
        # Get the daily-resolution TradeBar data of the asset during 2020.
        history = self.history(TradeBar, symbol, datetime(2020, 1, 1), datetime(2021, 1, 1), Resolution.DAILY)
```

		close	high	low	open	volume
symbol	**time**					
SPY	**2020-01-02 16:00:00**	301.194352	301.194352	299.029520	299.998363	52757344.0
	2020-01-03 16:00:00	298.913630	300.053991	297.708370	297.782540	65558742.0
	2020-01-06 16:00:00	300.053991	300.137432	297.013028	297.087198	47199709.0
	2020-01-07 16:00:00	299.210309	299.956643	298.756019	299.479175	37979987.0
	2020-01-08 16:00:00	300.804960	302.038033	299.163953	299.451361	62265971.0
	...	...	...	...	...	...
	2020-12-24 13:00:00	348.496921	348.496921	347.033045	347.609151	22897100.0
	2020-12-28 16:00:00	351.490783	351.887446	350.451904	351.150786	34765681.0
	2020-12-29 16:00:00	350.820234	353.219101	350.225239	353.077436	48584327.0
	2020-12-30 16:00:00	351.320785	352.350220	350.933566	351.689115	46030043.0
	2020-12-31 16:00:00	353.105769	353.825429	350.612458	351.188564	58258603.0

If there is no data for the date range you request, the result is empty. For more information about missing data points, see Missing Data Points .

Flat Universe DataFrames

Most history requests return a flat DataFrame by default, where there is one column for each data point attribute. Universe history requests return a Series, where the values in the Series are lists of the universe data objects. For example, the following code snippet returns a Series where each value is a `List[ETFConstituentUniverse]` :

```
class SeriesUniverseHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Add an ETF constituents universe for SPY so you can get its historical data.
        universe = self.add_universe(self.universe.etf('SPY'))
        # Get the trailing 5 days of universe data.
        history = self.history(universe, 5, Resolution.DAILY)
```

```
symbol                                                                  time
qc-universe-etf-constituents-a8cf32b9-ea94-488b-966f-aa2ebea9e40c 2T    2024-12-13    [A RPTMYV3VC57P: ¤0.00, AAPL: ¤0.00, ABBV VCY0...
                                                                        2024-12-14    [A RPTMYV3VC57P: ¤0.00, AAPL: ¤0.00, ABBV VCY0...
                                                                        2024-12-17    [A RPTMYV3VC57P: ¤0.00, AAPL: ¤0.00, ABBV VCY0...
                                                                        2024-12-18    [A RPTMYV3VC57P: ¤0.00, AAPL: ¤0.00, ABBV VCY0...
                                                                        2024-12-19    [A RPTMYV3VC57P: ¤0.00, AAPL: ¤0.00, ABBV VCY0...
Name: data, dtype: object
```

To get the data into a DataFrame instead, set the `flatten` argument to `True` . In this case, the DataFrame has one column for each data point attribute.

PY

```
# Get the trailing 5 days of universe data in DataFrame format
# so you can perform DataFrame wrangling operations.
history = self.history(universe, 5, Resolution.DAILY, flatten=True)
```

	ZBRA R735QTJ8XC9X	2024-12-17	1 days	650402.0	0.000397
	ZTS VDRJHVQ4FNFP	2024-12-17	1 days	5703558.0	0.001505

Default Values

The following table describes the assumptions of the History API:

Argument	Assumption
`resolution`	LEAN guesses the resolution you request by looking at the securities you already have in your algorithm. If you have a security subscription in your algorithm with a matching `Symbol` , the history request uses the same resolution as the subscription. If you don't have a security subscription in your algorithm with a matching `Symbol` , `Resolution.MINUTE` is the default.

Additional Options

The `history` method accepts the following additional arguments:

Argument	Data Type	Description
fill_forward	bool/NoneType	True to fill forward missing data. Otherwise, false.
extended_market_hours	bool/NoneType	True to include extended market hours data. Otherwise, false.
data_mapping_mode	DataMappingMode/NoneType	The contract mapping mode to use for the security history request.
data_normalization_mode	DataNormalizationMode/NoneType	The price scaling mode to use for US Equities or continuous Futures contracts .
contract_depth_offset	int/NoneType	The desired offset from the current front month for continuous Futures contracts .

If you don't provide a value for some of the preceding options, it uses the option value from the security subscription.

```
self.future = self.add_future(Futures.Indices.SP_500_E_MINI)
history = self.history(
    symbols=[self.future.symbol],
    start=self.time - timedelta(days=15),
    end=self.time,
    resolution=Resolution.MINUTE,
    fill_forward=False,
    extended_market_hours=False,
    data_mapping_mode=DataMappingMode.LAST_TRADING_DAY,
    data_normalization_mode=DataNormalizationMode.RAW,
    contract_depth_offset=0
)
```

Examples

The following examples demonstrate some common practices for trading using historical requests.

Example 1: Mean-Variance Portfolio

The following algorithm constructs a monthly rebalance mean-variance portfolio using the top 20 liquid equities. The position sizing can be optimized by 1-year historical daily return of the universe members.

```
from Portfolio.MaximumSharpeRatioPortfolioOptimizer import MaximumSharpeRatioPortfolioOptimizer

class HistoricalRequestAlgorithm(QCAlgorithm):
    # Instantiate the optimizer to perform mean-variance optimization.
    # Mean-variance optimization will not consider a risk-free rate, so we use 0.
    _optimizer = MaximumSharpeRatioPortfolioOptimizer(0.0, 1.0, 0.0)

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Seed the last price to set the initial price of the BTCUSDT holdings.
        self.settings.seed_initial_prices = True

        # Monthly renewal of the top 20 liquid universe to trade popular stocks.
        self.universe_settings.schedule.on(self.date_rules.month_start())
        self._universe = self.add_universe(self.universe.top(20))

        # Set a scheduled event to rebalance the portfolio at the start of every month.
        self.schedule.on(self.date_rules.month_start(), self.time_rules.at(9, 31), self.rebalance)

    def rebalance(self) -> None:
        # Historical data request to get 1-year data for optimization.
        symbols = self._universe.selected
        history = self.history(symbols, 253, Resolution.DAILY).close.unstack(0).dropna()
        # Daily return on the universe members to calculate the optimized weights.
        returns = history.pct_change().dropna()

        # Calculate the optimized weights.
        weights = self._optimizer.optimize(returns)

        # Rebalance the portfolio according to the optimized weights.
        targets = [PortfolioTarget(symbol, size if abs(size) > 0.01 else 0) for symbol, size in zip(symbols, weights)]
        self.set_holdings(targets, liquidate_existing_holdings=True)
```

Historical Data

History Responses

Introduction

When you make a history request, consider what data returns. Depending on how you request the data, history requests return a specific data type. The data that returns is in ascending order from oldest to newest. This order is necessary to use the data to warm up indicators.

DataFrames

The most popular return type is a DataFrame. To request a DataFrame of historical data, call the `history` method with at least one `Symbol` object.

```
class DataFrameHistoryResponseAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2014, 12, 20)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol objects of some assets.
        symbols = [self.add_equity(ticker).symbol for ticker in ['SPY', 'QQQ']]
        # Get 3 days of daily data for the assets.
        history = self.history(symbols, 3, Resolution.DAILY)
```

		close	high	low	open	volume
symbol	**time**					
SPY	**2024-12-17 16:00:00**	604.29	605.16	602.89	604.22	38527534.0
	2024-12-18 16:00:00	586.28	606.40	585.89	604.00	80642184.0
	2024-12-19 16:00:00	586.10	593.00	585.85	591.43	70752398.0
QQQ	**2024-12-17 16:00:00**	535.80	537.49	534.13	536.41	25048673.0
	2024-12-18 16:00:00	516.47	536.87	515.01	535.11	47016560.0
	2024-12-19 16:00:00	514.17	521.75	513.83	521.11	42192908.0

The structure of the DataFrame depends on the dataset . In most cases, there is a mulit-index that contains the `Symbol` and a timestamp. The timestamps in the DataFrame are based on the exchange time zone . Each row of the DataFrame represents the prices at a point in time. Each column of the DataFrame is a property of that data (for example, open, high, low, and close (OHLC)).

If you intend to use the data in the DataFrame to create `TradeBar` or `QuoteBar` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame.

Slices

To request `Slice` objects of historical data, call the `history` method without providing any `Symbol` objects. It returns data for all the data subscriptions in your notebook.

```
# Get the latest 3 data points of all the securities/datasets in the notebook, packaged into Slice objects.
history = self.history(3)
```

When your history request returns `Slice` objects, the `time` properties of these objects are based on the algorithm time zone, but the `end_time`

properties of the individual data objects (for example, `TradeBar` , `QuoteBar` , and `Tick` objects) are based on the exchange time zone . The `end_time` is the end of the sampling period and when the data is actually available. For more information about time periods, see Periods .

Lists

If you intend to use the data in the DataFrame to create objects like a `TradeBar` or `QuoteBar` , request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To request a list of objects containing the historical data, call one of the `history[ Type ]` methods.

```py
class ListHistoryResponseAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 1)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of an asset.
        symbol = self.add_equity('SPY', Resolution.DAILY).symbol
        # Create an indicator that is a function of historical bars.
        indicator = AverageTrueRange(21)
        # Get the latest TradeBar objects of the asset.
        history = self.history[TradeBar](symbol, indicator.warm_up_period)
        # Update the indicator with the historical TradeBar objects.
        for bar in history:
            indicator.update(bar)
```

The methods return different data types, depending on how you call it. The following table shows the return type for each input:

Input Generic `[ Type ]`	**Input** `Symbol` **Type**	**Output Data Type**
`TradeBar`	`Symbol`	`List[TradeBar]`
`TradeBar`	`List[Symbol]`	`List[TradeBars]`
`QuoteBar`	`Symbol`	`List[QuoteBar]`
`QuoteBar`	`List[Symbol]`	`List[QuoteBars]`
`Tick`	`Symbol`	`List[Tick]`
`Tick`	`List[Symbol]`	`List[Ticks]`
`alternativeDataClass` (ex: `CBOE`)	`Symbol`	`List[ alternativeDataClass ]` (ex: `List[CBOE]`)
`alternativeDataClass` (ex: `CBOE`)	`List[Symbol]`	`List[Dict[Symbol, alternativeDataClass ]]` (ex: `List[Dict[Symbol, CBOE]]`)

```py
class ListHistoryResponseAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 1)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of some assets.
        spy = self.add_equity('SPY').symbol
        aapl = self.add_equity('AAPL').symbol

        # Example: List[QuoteBars]
        for quote_bars in self.history[QuoteBar]([spy, aapl], 3):
            t = quote_bars.time
            for symbol, quote_bar in quote_bars.items():
                bid = quote_bar.bid

        # Example: List[Ticks]
        for ticks in self.history[Tick]([spy, aapl], timedelta(3), Resolution.TICK):
            for symbol, tick in ticks.items():
                t = tick.time
                price = tick.price

        # Example: List[Dict[Symbol, QuiverInsiderTrading]]
        spy_insider = self.add_data(QuiverInsiderTrading, spy).symbol
        aapl_insider = self.add_data(QuiverInsiderTrading, aapl).symbol
        for data_by_symbol in self.history[QuiverInsiderTrading]([spy_insider, aapl_insider], 365, Resolution.DAILY):
            for dataset_symbol, insider_trading in data_by_symbol.items():
                asset_symbol = dataset_symbol.underlying
                t = insider_trading.end_time
                shares_traded = insider_trading.shares
```

When your history request returns a list of objects, the `time` properties of these objects are based on the time zone, but the `end_time` properties of the individual objects in the list are based on the exchange time zone . The `end_time` is the end of the sampling period and when the data is actually available. For more information about time periods, see Periods .

Missing Data Points

There are several cases where you may get fewer data points from a history request than you expect.

Illiquid Securities

The default behavior for history requests is to fill-forward the data. However, if an asset had no trading activity during the time period you request historical data for, you won't get any data for that asset.

Requesting Data Before an Asset's IPO

All assets have a day when they first started trading. If your history request includes time before an asset's initial public offering (IPO) date, you won't get any data before the IPO date because the data doesn't exist.

Requesting Data Outside Market Hours

History requests for a trailing number of data samples return data based on the market hours of assets, so they can wrap across multiple trading days to gather the amount of data you request. In contrast, history requests for trailing time periods return data based on a rolling calendar time and history requests for specific date ranges return data for whatever range you request. In these two latter types of history requests, if the period of time is outside of the market hours of an asset, you won't get any data.

Data Issues

Data issues are generally a result of human error or from mistakes in the data collection process. Any QuantConnect member can report a data issue , which our Data Team works to quickly resolve. However, while the data is still missing, your history requests won't be able to return the data. To view the list of current data issues, log in to the Algorithm Lab and then, in the left navigation bar, click Datasets > Data Issues .

Historical Data

Asset Classes

Asset Classes

US Equities

Introduction

This page explains how to get historical data for US Equities. Some of the data you can get include prices, fundamentals, corporate actions, and universe selection data.

Trades

To get historical trade data , call the `history` method with the `TradeBar` type and a security's `Symbol` . This method returns a DataFrame with columns for the open, high, low, close, and volume.

```
PY
class USEquityTradeBarHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        symbol = self.add_equity('SPY').symbol
        # Get the 5 trailing daily TradeBar objects of the security in DataFrame format.
        history = self.history(TradeBar, symbol, 5, Resolution.DAILY)
```

		close	high	low	open	volume
symbol	**time**					
SPY	**2024-12-12 16:00:00**	604.33	607.160	604.33	606.64	24962360.0
	2024-12-13 16:00:00	604.21	607.100	602.82	606.38	29250856.0
	2024-12-16 16:00:00	606.79	607.775	605.22	606.00	33686372.0
	2024-12-17 16:00:00	604.29	605.160	602.89	604.22	38527534.0
	2024-12-18 16:00:00	586.28	606.400	585.89	604.00	80642184.0

```
PY
# Calculate the daily returns.
daily_returns = history.close.pct_change().iloc[1:]
```

```
symbol  time
SPY     2024-12-13 16:00:00   -0.000199
        2024-12-16 16:00:00    0.004270
        2024-12-17 16:00:00   -0.004120
        2024-12-18 16:00:00   -0.029804
Name: close, dtype: float64
```

If you intend to use the data in the DataFrame to create `TradeBar` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `TradeBar` objects instead of a DataFrame, call the `history[TradeBar]` method.

```
# Get the 5 trailing daily TradeBar objects of the security in TradeBar format.
history = self.history[TradeBar](symbol, 5, Resolution.DAILY)
# Iterate through the TradeBar objects and access their volumes.
for trade_bar in history:
    t = trade_bar.end_time
    volume = trade_bar.volume
```

Quotes

To get historical quote data , call the `history` method with the `QuoteBar` type and a security's `Symbol` . This method returns a DataFrame with columns for the open, high, low, close, and size of the bid and ask quotes. The columns that don't start with "bid" or "ask" are the mean of the quote prices on both sides of the market.

```
class USEquityQuoteBarHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        symbol = self.add_equity('SPY').symbol
        # Get the 5 trailing minute QuoteBar objects of the security in DataFrame format.
        history = self.history(QuoteBar, symbol, 5, Resolution.MINUTE)
```

		askclose	askhigh	asklow	askopen	asksize	bidclose	bidhigh	bidlow	bidopen	bidsize	close	high	low	open

	2024-12-18 16:00:00	586.33	587.95	585.89	587.93	200.0	586.30	587.93	585.88	587.92	74700.0	586.315	587.940	585.885	587.925

```
# Calculate the spread at each minute.
spread = history.askclose - history.bidclose
```

```
symbol  time
SPY     2024-12-18 15:56:00    0.04
        2024-12-18 15:57:00    0.03
        2024-12-18 15:58:00    0.02
        2024-12-18 15:59:00    0.01
        2024-12-18 16:00:00    0.03
dtype: float64
```

If you intend to use the data in the DataFrame to create `QuoteBar` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `QuoteBar` objects instead of a DataFrame, call the `history[QuoteBar]` method.

```
PY
# Get the 5 trailing minute QuoteBar objects of the security in QuoteBar format.
history = self.history[QuoteBar](symbol, 5, Resolution.MINUTE)
# Iterate through each QuoteBar and calculate the dollar volume on the bid.
for quote_bar in history:
    t = quote_bar.end_time
    bid_dollar_volume = quote_bar.last_bid_size * quote_bar.bid.close
```

Request second or minute resolution data. Otherwise, the history request won't return any data.

Ticks

To get historical tick data , call the `history` method with a security's `Symbol` and `Resolution.TICK` . This method returns a DataFrame that contains data on bids, asks, and last trade prices.

```
PY
class USEquityTickHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        symbol = self.add_equity('SPY').symbol
        # Get the trailing 2 days of ticks for the security in DataFrame format.
        history = self.history(symbol, timedelta(2), Resolution.TICK)
```

		askprice	asksize	bidprice	bidsize	exchange	lastprice	quantity
symbol	**time**							
SPY	**2024-12-17 09:30:00.000214**	0.00	0.0	604.17	1000.0	NASDAQ	604.17	0.0
	2024-12-17 09:30:00.000214	604.19	1900.0	0.00	0.0	ARCA	604.19	0.0
	2024-12-17 09:30:00.001110	NaN	NaN	NaN	NaN	NYSE	604.19	100.0
	2024-12-17 09:30:00.001480	NaN	NaN	NaN	NaN	ARCA	604.19	69.0
	2024-12-17 09:30:00.001482	0.00	0.0	604.17	1000.0	NASDAQ	604.17	0.0

```
PY
# Select the rows in the DataFrame that represent trades. Drop the bid/ask columns since they are NaN.
trade_ticks = history[history.quantity > 0].dropna(axis=1)
```

		exchange	lastprice	quantity
symbol	**time**			
SPY	**2024-12-17 09:30:00.001110**	NYSE	604.19	100.0
	2024-12-17 09:30:00.001480	ARCA	604.19	69.0
	2024-12-17 09:30:00.001483	ARCA	604.19	100.0
	2024-12-17 09:30:00.001483	ARCA	604.19	231.0
	2024-12-17 09:30:00.001564	NASDAQ	604.19	100.0

If you intend to use the data in the DataFrame to create `Tick` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `Tick` objects instead of a DataFrame, call the `history[Tick]` method.

```
PY
# Get the trailing 2 days of ticks for the security in Tick format.
history = self.history[Tick](symbol, timedelta(2), Resolution.TICK)
# Iterate through each quote tick and calculate the quote size.
for tick in history:
    if tick.tick_type == TickType.Quote:
        t = tick.end_time
        size = max(tick.bid_size, tick.ask_size)
```

Ticks are a sparse dataset, so request ticks over a trailing period of time or between start and end times.

Slices

To get historical Slice data, call the `history` method without passing any `Symbol` objects. This method returns `Slice` objects, which contain data points from all the datasets in your algorithm. If you omit the `resolution` argument, it uses the resolution that you set for each security and dataset when you created the subscriptions.

```
PY
class SliceHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 1)
        self.set_end_date(2024, 12, 31)
        # Add some securities and datasets.
        self.add_equity('SPY')
        # Get the historical Slice objects over the last 5 days for all the subcriptions in your algorithm.
        history = self.history(5, Resolution.DAILY)
        # Iterate through each historical Slice.
        for slice_ in history:
            # Iterate through each TradeBar in this Slice.
            for symbol, trade_bar in slice_.bars.items():
                close = trade_bar.close
```

Fundamentals

To get historical fundamental data , call the `history` method with the `Fundamental` type and an asset's `Symbol` . This method returns a DataFrame with columns for the data point attributes .

```
PY
class USEquityFundamentalHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 27)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of an asset.
        symbol = self.add_equity('AAPL').symbol
        # Get the 3 trailing daily Fundamental objects of the asset in DataFrame format.
        history = self.history(Fundamental, symbol, 3, Resolution.DAILY)
```

		adjusted	ab	ea	as	ay	pr	fil	fo	ga	gr	fin	pr	fis	fu	de	ad	op	pr	ra	sc	se	ty	ti	ev	va	vo

PY

```
# Get the Current Ratio of each row.
current_ratios = history.apply(lambda row: row.operationratios.current_ratio.value, axis=1)
```

```
symbol  time
AAPL    2024-12-24    0.867313
        2024-12-25    0.867313
        2024-12-27    0.867313
dtype: float64
```

To avoid consuming unnecessary computational resources populating the DataFrame, you can instead request `Fundamental` objects. To get a list of `Fundamental` objects, call the `history[Fundamental]` method.

PY

```
# Get the 3 trailing daily Fundamental objects of an asset in Fundamental format.
history = self.history[Fundamental](symbol, 3, Resolution.DAILY)
# Iterate through each Fundamental object and access its properites.
for fundamental in history:
    symbol = fundamental.symbol
    pe_ratio = fundamental.valuation_ratios.pe_ratio
```

Splits

To get historical split data , call the `history` method with the `Split` type and an asset's `Symbol` . This method returns a DataFrame with columns for the reference price, split factor, and split type. Splits are a sparse dataset, so use a time period history request since most days have no data.

PY

```
class USEquitySplitHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 1)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of an asset.
        symbol = self.add_equity('AAPL').symbol
        # Get the splits that occured for the stock over the last 5 years in DataFrame format.
        history = self.history(Split, symbol, timedelta(5*365))
```

		referenceprice	splitfactor	type	value
symbol	**time**				
AAPL	**2020-08-28**	0.00	0.25	0	0.00
	2020-08-31	499.23	0.25	1	499.23

In the preceding DataFrame, the `type` column represents the `SplitType` enumeration, where 0= `SplitType.WARNING` and 1= `SplitType.SPLIT_OCCURRED` .

```
# Select the prices where splits occurred.
split_prices = history[history.type == SplitType.SPLIT_OCCURRED].value
```

```
symbol  time
AAPL    2020-08-31    499.23
Name: value, dtype: float64
```

If you intend to use the data in the DataFrame to create `Split` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `Split` objects instead of a DataFrame, call the `history[Split]` method.

```
# Get the splits that occured for a stock over the last 5 years in Split format.
history = self.history[Split](symbol, timedelta(5*365))
# Iterate through each Split object.
for split in history:
    # Select the time when each split occurred.
    if split.type == SplitType.SPLIT_OCCURRED:
        t = split.end_time
```

Dividends

To get historical dividend data , call the `history` method with the `Dividend` type and an asset's `Symbol` . This method returns a DataFrame with columns for the dividend payment and reference price. Dividends are a sparse dataset, so use a time period history request since most days have no data.

```
class USEquityDividendHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 1)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of an asset.
        symbol = self.add_equity('AAPL').symbol
        # Get the dividends that the stock paid over the last 2 years in DataFrame format.
        history = self.history(Dividend, symbol, timedelta(2*365))
```

		distribution	referenceprice	value
symbol	**time**			
AAPL	**2022-12-23**	0.17	132.23	0.17
	2023-02-10	0.23	150.87	0.23
	2023-05-12	0.24	173.75	0.24
	2023-08-11	0.24	177.97	0.24
	2023-11-10	0.24	182.41	0.24

```
# Calculate the mean dividend payment.
mean_dividend = history.distribution.mean()
```

If you intend to use the data in the DataFrame to create `Dividend` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `Dividend` objects instead of a DataFrame, call the `history[Dividend]` method.

```
# Get the dividends that a stock paid over the last 2 years in Dividend format.
history = self.history[Dividend](symbol, timedelta(2*365))
# Iterate through each Dividend object.
for dividend in history:
    distribution = dividend.distribution
```

Symbol Changes

To get historical symbol change data , call the `history` method with the `SymbolChangedEvent` type and an asset's `Symbol` . This method returns a DataFrame with columns for the old symbol and new symbol during each change.

```
class USEquitySymbolChangedEventHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 1)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of an asset.
        symbol = self.add_equity('META').symbol
        # Get the symbol changes of the stock over the last 10 years in DataFrame format.
        history = self.history(SymbolChangedEvent, symbol, timedelta(10*365))
```

		newsymbol	oldsymbol
symbol	**time**		
META	**2022-06-09**	META	FB

```
# Select the dates of each ticker change.
dates = list(history.index.levels[1])
```

If you intend to use the data in the DataFrame to create `SymbolChangedEvent` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `SymbolChangedEvent` objects instead of a DataFrame, call the `history[SymbolChangedEvent]` method.

```
# Get the symbol changes of a stock over the last 10 years in SymbolChangedEvent format.
history = self.history[SymbolChangedEvent](symbol, timedelta(10*365))
# Iterate through each SymbolChangedEvent object.
for symbol_changed_event in history:
    t = symbol_changed_event.end_time
    old_symbol = symbol_changed_event.old_symbol
    new_symbol = symbol_changed_event.new_symbol
```

Delistings

To get historical delisting data , call the `history` method with the `Delisting` type and an asset's `Symbol` . This method returns a DataFrame with columns for the old symbol and new symbol during each change. Delistings are a sparse dataset, so use a time period history request since most days have no data.

```
class USEquityDelistingHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 1)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of an asset.
        symbol = self.add_equity('BBBY').symbol
        # Get the deslistings of the asset over the last 10 years in DataFrame format.
        history = self.history(Delisting, symbol, timedelta(10*365))
```

		type
symbol	**time**	
BBBY	**2023-05-02**	0
	2023-05-03	1

In the preceding DataFrame, the `type` column represents the `DelistingType` enumeration, where 0= `DelistingType.WARNING` and 1= `DelistingType.DELISTED`.

```
PY
# Select the rows in the DataFrame that represent deslist warnings.
warnings = history[history.type == DelistingType.WARNING].type
```

```
symbol  time
BBBY    2023-05-02    0
Name: type, dtype: int64
```

If you intend to use the data in the DataFrame to create `Delisting` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `Delisting` objects instead of a DataFrame, call the `history[Delisting]` method.

```
PY
# Get the deslistings of an asset over the last 10 years in Delisting format.
history = self.history[Delisting](symbol, timedelta(10*365))
# Iterate through each Deslisting object and access the warning dates.
for deslisting in history:
    if deslisting.type == DelistingType.WARNING:
        warning_date = deslisting.end_time
```

Universes

To get historical universe data , call the `history` method with the `Universe` object. This method returns a DataFrame with columns for the data point attributes.

```
PY
class USEquityUniverseHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 23)
        self.set_end_date(2024, 12, 31)
        # Add a universe of US Equities based on the constituents of an ETF.
        universe = self.add_universe(self.universe.etf('SPY'))
        # Get 5 days of history for the universe.
        history = self.history(universe, timedelta(5), flatten=True)
```

		lastupdate	period	sharesheld	weight

Name: weight, dtype: float64
```

To get the data in the format of the objects that you receive in your universe filter function instead of a DataFrame, use `flatten=False`. This call returns a Series where the values are lists of the universe data objects.

```py
# Get the historical universe data over the last 30 days in a Series where
# the values in the series are lists of the universe selection objects.
history = self.history(universe, timedelta(30), flatten=False)
# Iterate through each day of universe selection.
for (universe_symbol, end_time), constituents in history.items():
    # Select the 10 largest assets in the ETF on this day.
    largest = sorted(constituents, key=lambda c: c.weight)[-10:]
```

Alternative Data

To get historical alternative data, call the `history` method with the dataset `Symbol`. This method returns a DataFrame that contains the data point attributes.

```
class USEquityAlternativeDataHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of an asset.
        symbol = self.add_equity('GME').symbol
        # Add the alternative dataset and save a reference to its Symbol.
        dataset_symbol = self.add_data(QuiverWallStreetBets, symbol).symbol
        # Get the trailing 5 days of QuiverWallStreetBets data for the asset in DataFrame format.
        history = self.history(dataset_symbol, 5, Resolution.DAILY)
```

		date	mentions	rank	sentiment
symbol	**time**				
GME.QuiverWallStreetBets	**2024-12-15**	2024-12-14	2	48	0.74245
	2024-12-16	2024-12-15	1	136	-0.51600
	2024-12-17	2024-12-16	8	53	0.13987
	2024-12-18	2024-12-17	17	32	0.08564
	2024-12-19	2024-12-18	4	117	0.61682

```
# Calculate the changes in sentiment.
sentiment_diff = history.sentiment.diff().iloc[1:]
```

```
symbol                    time
GME.QuiverWallStreetBets  2024-12-16   -1.25845
                          2024-12-17    0.65587
                          2024-12-18   -0.05423
                          2024-12-19    0.53118
Name: sentiment, dtype: float64
```

If you intend to use the data in the DataFrame to create `alternativeDataClass` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of dataset objects instead of a DataFrame, call the `history[ alternativeDataClass ]` method.

```
# Get the trailing 5 days of QuiverWallStreetBets data for an asset in QuiverWallStreetBets format.
history = self.history[QuiverWallStreetBets](dataset_symbol, 5, Resolution.DAILY)
# Iterate through each QuiverWallStreetBets object.
for data_point in history:
    t = data_point.end_time
    sentiment = data_point.sentiment
```

Some alternative datasets provide multiple entries per asset per time step . For example, the True Beats dataset provides EPS and revenue predictions for several upcoming quarters per asset per day. In this case, to organize the data into a DataFrame, set the `flatten` argument to `True` .

```
class USEquityTrueBeatsHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Get the ExtractAlphaTrueBeats data for AAPL on 01/02/2024 organized in a flat DataFrame.
        aapl = self.add_equity("AAPL", Resolution.DAILY)
        aapl.true_beats = self.add_data(ExtractAlphaTrueBeats, aapl.symbol).symbol
        history = self.history(
            aapl.true_beats, datetime(2024, 1, 2), datetime(2024, 1, 3), Resolution.DAILY, flatten=True
        )
```

PY

```
# Calculate the mean TrueBeat estimate for each day.
mean_true_beats_by_day = history.drop('time', axis=1).groupby('time').apply(lambda g: g.truebeat.mean())
```

```
time
2024-01-02 12:30:00   -0.007034
dtype: float64
```

For information on historical data for other alternative datasets, see the documentation in the Dataset Market .

Indicators

To get historical indicator values, call the `indicator_history` method with an indicator and the security's `Symbol` .

```
class USEquityIndicatorHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        symbol = self.add_equity('SPY').symbol
        # Get the 21-day SMA values of the security for the last 5 trading days.
        history = self.indicator_history(SimpleMovingAverage(21), symbol, 5, Resolution.DAILY)
```

To organize the data into a DataFrame, use the `data_frame` property of the result.

```
# Organize the historical indicator data into a DataFrame to enable pandas wrangling.
history_df = history.data_frame
```

	current	rollingsum
2024-12-12 16:00:00	599.186667	12582.92
2024-12-13 16:00:00	599.520952	12589.94
2024-12-16 16:00:00	600.160952	12603.38
2024-12-17 16:00:00	601.043810	12621.92
2024-12-18 16:00:00	600.954762	12620.05

```
# Get the maximum of the SMA values.
sma_max = history_df.current.max()
```

The `indicator_history` method resets your indicator, makes a history request, and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

To make the `indicator_history` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```
# Get the historical values of an indicator over the last 30 days, applying the indicator to the security's volume.
history = self.indicator_history(indicator, symbol, timedelta(30), selector=Field.VOLUME)
```

Some indicators require the prices of two securities to compute their value (for example, Beta). In this case, pass a list of the `Symbol` objects to the method.

```
class USEquityMultiAssetIndicatorHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Add the target and reference securities.
        target_symbol = self.add_equity('AAPL').symbol
        reference_symbol = self.add_equity('SPY').symbol
        # Create a 21-period Beta indicator.
        beta = Beta("", target_symbol, reference_symbol, 21)
        # Get the historical values of the indicator over the last 10 trading days.
        history = self.indicator_history(beta, [target_symbol, reference_symbol], 10, Resolution.DAILY)
        # Get the average Beta value.
        beta_avg = history.data_frame.mean()
```

Short Availability

To get historical values for the borrow fee rate, borrow rebate rate, or shortable quantity of a US Equity, call the `fee_rate` , `rebate_rate` , or `shortable_quantity` methods of its shortable provider .

```
class USEquityShortAvailabilityHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Add an asset and save a reference to its Equity object.
        security = self.add_equity('SPY')
        # Overwrite the default shortable provider to one that provides data.
        security.set_shortable_provider(InteractiveBrokersShortableProvider())
        # Select a time in the past.
        t = self.time - timedelta(30)
        # Pass the time argument to shortable provider to get historical values.
        fee_rate = security.shortable_provider.fee_rate(security.symbol, t)
        rebate_rate = security.shortable_provider.rebate_rate(security.symbol, t)
        shortable_quantity = security.shortable_provider.shortable_quantity(security.symbol, t)
```

For more information about security initializers, see Set Security Initializer .

Examples

The following examples demonstrate some common practices for trading using historical requests.

Example 1: Mean-Variance Portfolio

The following algorithm constructs a monthly rebalance mean-variance portfolio using the top 20 liquid equities. The position sizing can be optimized by 1-year historical daily return of the universe members.

```
from Portfolio.MaximumSharpeRatioPortfolioOptimizer import MaximumSharpeRatioPortfolioOptimizer

class HistoricalRequestAlgorithm(QCAlgorithm):
    # Instantiate the optimizer to perform mean-variance optimization.
    # Mean-variance optimization will not consider a risk-free rate, so we use 0.
    _optimizer = MaximumSharpeRatioPortfolioOptimizer(0.0, 1.0, 0.0)

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Seed the last price to set the initial price of the BTCUSDT holdings.
        self.settings.seed_initial_prices = True

        # Monthly renewal of the top 20 liquid universe to trade popular stocks.
        self.universe_settings.schedule.on(self.date_rules.month_start())

Equity Options

Introduction

This page explains how to get historical data for Equity Options. Some of the data you can get include prices, open interest, Greeks, and universe selection data.

Trades

To get historical trade data , call the `history` method with the `TradeBar` type and a security's `Symbol` . This method returns a DataFrame with columns for the open, high, low, close, and volume.

```
class EquityOptionTradeBarHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        equity = self.add_equity('SPY', data_normalization_mode=DataNormalizationMode.RAW)
        symbol = sorted(self.option_chain(equity.symbol), key=lambda c: c.open_interest)[-1].symbol
        # Get the 5 trailing daily TradeBar objects of the security in DataFrame format.
        history = self.history(TradeBar, symbol, 5, Resolution.DAILY)
```

Name: close, dtype: float64
```

If you intend to use the data in the DataFrame to create `TradeBar` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `TradeBar` objects instead of a DataFrame, call the `history[TradeBar]` method.

```
# Get the 5 trailing daily TradeBar objects of the security in TradeBar format.
history = self.history[TradeBar](symbol, 5, Resolution.DAILY)
# Iterate through the TradeBar objects and access their volumes.
for trade_bar in history:
    t = trade_bar.end_time
    volume = trade_bar.volume
```

Request minute, hour, or daily resolution data. Otherwise, the history request won't return any data.

Quotes

To get historical quote data , call the `history` method with the `QuoteBar` type and a security's `Symbol` . This method returns a DataFrame with columns for the open, high, low, close, and size of the bid and ask quotes. The columns that don't start with "bid" or "ask" are the mean of the quote prices on both sides of the market.

```
class EquityOptionsQuoteBarHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        equity = self.add_equity('SPY', data_normalization_mode=DataNormalizationMode.RAW)
        symbol = sorted(self.option_chain(equity.symbol), key=lambda c: c.open_interest)[-1].symbol
        # Get the 5 trailing minute QuoteBar objects of the security in DataFrame format.
        history = self.history(QuoteBar, symbol, 5, Resolution.MINUTE)
```

2025-01-17  440.0   1     SPY 32OCGBPPW6DTY|SPY R735QTJ8XC9X  2024-12-18 15:56:00    0.02
                                                              2024-12-18 15:57:00    0.02
                                                              2024-12-18 15:58:00    0.02
                                                              2024-12-18 15:59:00    0.02
                                                              2024-12-18 16:00:00    0.04
dtype: float64
```

If you intend to use the data in the DataFrame to create `QuoteBar` objects, request that the history request returns the data type you need. Otherwise,

LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `QuoteBar` objects instead of a DataFrame, call the `history[QuoteBar]` method.

```py
# Get the 5 trailing minute QuoteBar objects of the security in QuoteBar format.
history = self.history[QuoteBar](symbol, 5, Resolution.MINUTE)
# Iterate through each QuoteBar and calculate the dollar volume on the bid.
for quote_bar in history:
    t = quote_bar.end_time
    bid_dollar_volume = quote_bar.last_bid_size * quote_bar.bid.close
```

Request minute, hour, or daily resolution data. Otherwise, the history request won't return any data.

Slices

To get historical Slice data, call the `history` method without passing any `Symbol` objects. This method returns `Slice` objects, which contain data points from all the datasets in your algorithm. If you omit the `resolution` argument, it uses the resolution that you set for each security and dataset when you created the subscriptions.

```py
class SliceHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 1)
        self.set_end_date(2024, 12, 31)
        # Add some securities and datasets.
        equity = self.add_equity('SPY', data_normalization_mode=DataNormalizationMode.RAW)
        contract = sorted(self.option_chain(equity.symbol), key=lambda c: c.open_interest)[-1]
        self.add_option_contract(contract.symbol)
        # Get the historical Slice objects over the last 5 days for all the subcriptions in your algorithm.
        history = self.history(5, Resolution.DAILY)
        # Iterate through each historical Slice.
        for slice_ in history:
            # Iterate through each TradeBar in this Slice.
            for symbol, trade_bar in slice_.bars.items():
                close = trade_bar.close
```

Open Interest

To get historical open interest data , call the `history` method with the `OpenInterest` type and a security's `Symbol` . This method returns a DataFrame with a single column.

```py
class EquityOptionOpenInterestHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        equity = self.add_equity('SPY', data_normalization_mode=DataNormalizationMode.RAW)
        symbol = sorted(self.option_chain(equity.symbol), key=lambda c: c.open_interest)[-1].symbol
        # Get the 5 trailing daily OpenInterest objects of the security in DataFrame format.
        history = self.history(OpenInterest, symbol, 5, Resolution.DAILY)
```

					openinterest

Name: openinterest, dtype: float64
```

If you intend to use the data in the DataFrame to create `OpenInterest` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `OpenInterest` objects instead of a DataFrame, call the `history[OpenInterest]` method.

```
# Get the 5 trailing daily OpenInterest objects of the security in OpenInterest format.
history = self.history[OpenInterest](symbol, 5, Resolution.DAILY)
# Iterate through the TradeBar objects and access their volumes.
for oi in history:
    t = oi.end_time
    open_interest = oi.value
```

Daily Option Chains

To get historical daily Option chain data , call the `history` method with the Option `Symbol` object. The data this method returns contains information on all the currently tradable contracts, not just the contracts that pass your filter. If you pass `flatten=True` , this method returns a DataFrame with columns for the data point attributes.

```
class EquityOptionDailyOptionChainHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 23)
        self.set_end_date(2024, 12, 31)
        # Add an Equity Option universe.
        option = self.add_option('SPY')
        # Get the trailing 5 daily Option chains in DataFrame format.
        history = self.history(option.symbol, 5, flatten=True)
```

Name: volume, dtype: float64
```

To get the data in the format of `OptionUniverse` objects instead of a DataFrame, call the `history[OptionUniverse]` method.

```
# Get the historical OptionUniverse data over the last 30 days.
history = self.history[OptionUniverse](option.symbol, timedelta(30))
# Iterate through each daily Option chain.
for option_universe in history:
    t = option_universe.end_time
    # Select the contract with the most volume.
    most_traded = sorted(option_universe, key=lambda contract: contract.volume)[-1]
```

Indicators

To get historical indicator values, call the `indicator_history` method with an indicator and the security's `Symbol` .

```
class EquityOptionIndicatorHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of the Option contract.
        underlying = self.add_equity('SPY').symbol
        symbol = sorted(self.option_chain(underlying), key=lambda c: c.open_interest)[-1].symbol
        # Get the 21-day SMA values of the contract for the last 5 trading days.
        history = self.indicator_history(SimpleMovingAverage(21), symbol, 5, Resolution.DAILY)
```

To organize the data into a DataFrame, use the `data_frame` property of the result.

```
# Organize the historical indicator data into a DataFrame to enable pandas wrangling.
history_df = history.data_frame
```

	current	rollingsum
2024-12-12 16:00:00	0.377619	7.930

2024-12-18 16:00:00	0.356429	7.485

```
# Get the maximum of the SMA values.
sma_max = history_df.current.max()
```

The `indicator_history` method resets your indicator, makes a history request, and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

To make the `indicator_history` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```
# Get the historical values of an indicator over the last 30 days, applying the indicator to the security's volume.
history = self.indicator_history(indicator, symbol, timedelta(30), selector=Field.VOLUME)
```

Some indicators require the prices of multiple securities to compute their value (for example, the indicators for the Greeks and implied volatility). In this case, pass a list of the `Symbol` objects to the method.

```
class EquityOptionMultiAssetIndicatorHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of the underlying asset.
        underlying = self.add_equity('SPY').symbol
        # Get the Option contract Symbol.
        option = sorted(self.option_chain(underlying), key=lambda c: c.open_interest)[-1].symbol
        # Get the Symbol of the mirror contract.
        mirror = Symbol.create_option(
            underlying, option.id.market, option.id.option_style,
            OptionRight.CALL if option.id.option_right == OptionRight.PUT else OptionRight.PUT,
            option.id.strike_price, option.id.date
        )
        # Create the indicator.
        indicator = ImpliedVolatility(
            option, self.risk_free_interest_rate_model, DividendYieldProvider(underlying),
            mirror, OptionPricingModelType.FORWARD_TREE
        )
        # Get the historical values of the indicator over the last 60 trading minutes.
        history = self.indicator_history(indicator, [underlying, option, mirror], 60, Resolution.MINUTE)
        # Get the average IV value.
        iv_avg = history.data_frame.current.mean()
```

Examples

The following examples demonstrate some common practices for trading using historical requests.

Example 1: Trend Following on 0DTE Option Contract

This algorithm strategically trades 0DTE SPY options by analyzing bid and ask volumes shortly after the market opens. Using scheduled events, it effectively executes trades based on historical quote data, optimizing decision-making. The algorithm aims for timely entries and exits, ensuring efficient capital management and quick adaptability in volatile markets.

```
class ZeroDTEOptionsTradingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 12, 1)
        self.set_end_date(2024, 12, 10)  # Limit to a single day for 0DTE
        self.set_cash(100000)  # Starting cash

        # Request SPY option data for trading and signal generation.
        option = self.add_option("SPY")
        # We are interested in ATM 0DTE options since they are the most popular.
        option.set_filter(lambda u: u.expiration(0, 0).strikes(-3, 3))
        self._option = option.symbol

        # Schedule event to enter and exit option contract position.
        self.schedule.on(self.date_rules.every_day(self._option), self.time_rules.after_market_open(self._option, 16), self.trade_option)
        self.schedule.on(self.date_rules.every_day(self._option), self.time_rules.before_market_close(self._option, 15), self.liquidate)

    def trade_option(self) -> None:
        # Get the option chain for SPY to trade.
        option_chain = self.current_slice.option_chains.get(self._option, None)
        if option_chain:
            for option in option_chain:
                # Request historical quote data for signal generation.
                history = self.history(QuoteBar, option.symbol, 15, Resolution.Minute)
                if not history.empty:
                    # Calculate total bid and ask dollar volume to determine the capital directional force.
                    total_bid_volume = (history['bidclose'] * history['bidsize']).sum()
                    total_ask_volume = (history['askclose'] * history['asksize']).sum()

                    # Follow the capital flow to trade.
                    if total_bid_volume > total_ask_volume:
                        self.market_order(option.symbol, 1)
                    else:
                        self.market_order(option.symbol, -1)
```

Asset Classes

Crypto

Introduction

This page explains how to get historical data for Crypto. Some of the data you can get include prices, indicators, and universe selection data.

Trades

To get historical trade data , call the `history` method with the `TradeBar` type and a security's `Symbol` . This method returns a DataFrame with columns for the open, high, low, close, and volume.

```
PY
class CryptoTradeBarHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        symbol = self.add_crypto('BTCUSD').symbol
        # Get the 5 trailing daily TradeBar objects of the security in DataFrame format.
        history = self.history(TradeBar, symbol, 5, Resolution.DAILY)
```

		close	high	low	open	volume
symbol	**time**					
BTCUSD	**2024-12-15**	101399.99	102650.00	100600.00	101423.26	4054.541500
	2024-12-16	104439.88	105100.00	101221.34	101400.00	7216.743790
	2024-12-17	106099.81	107857.79	103289.21	104445.15	22263.157625
	2024-12-18	106150.00	108388.88	105337.97	106099.98	11729.293641
	2024-12-19	100150.73	106528.13	99939.82	106147.77	21659.470502

```
PY
# Calculate the daily returns.
daily_returns = history.close.pct_change().iloc[1:]
```

```
symbol  time
BTCUSD  2024-12-16    0.029979
        2024-12-17    0.015894
        2024-12-18    0.000473
        2024-12-19   -0.056517
Name: close, dtype: float64
```

If you intend to use the data in the DataFrame to create `TradeBar` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `TradeBar` objects instead of a DataFrame, call the `history[TradeBar]` method.

```
PY
# Get the 5 trailing daily TradeBar objects of the security in TradeBar format.
history = self.history[TradeBar](symbol, 5, Resolution.DAILY)
# Iterate through the TradeBar objects and access their volumes.
for trade_bar in history:
    t = trade_bar.end_time
    volume = trade_bar.volume
```

Quotes

To get historical quote data , call the `history` method with the `QuoteBar` type and a security's `Symbol` . This method returns a DataFrame with columns for the open, high, low, close, and size of the bid and ask quotes. The columns that don't start with "bid" or "ask" are the mean of the quote prices on both sides of the market.

```
PY
class CryptoQuoteBarHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        symbol = self.add_crypto('BTCUSD', market=Market.BITFINEX).symbol
        # Get the 5 trailing minute QuoteBar objects of the security in DataFrame format.
        history = self.history(QuoteBar, symbol, 5, Resolution.MINUTE)
```

```

If you intend to use the data in the DataFrame to create `QuoteBar` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `QuoteBar` objects instead of a DataFrame, call the `history[QuoteBar]` method.

```
PY
# Get the 5 trailing minute QuoteBar objects of the security in QuoteBar format.
history = self.history[QuoteBar](symbol, 5, Resolution.MINUTE)
# Iterate through each QuoteBar and calculate the dollar volume on the bid.
for quote_bar in history:
    t = quote_bar.end_time
    bid_dollar_volume = quote_bar.last_bid_size * quote_bar.bid.close
```

Ticks

To get historical tick data , call the `history` method with a security's `Symbol` and `Resolution.TICK` . This method returns a DataFrame that contains data on bids, asks, and last trade prices.

```
class CryptoTickHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        symbol = self.add_crypto('BTCUSD', market=Market.BITFINEX).symbol
        # Get the trailing 2 days of ticks for the security in DataFrame format.
        history = self.history(symbol, timedelta(2), Resolution.TICK)
```

```
# Select the rows in the DataFrame that represent trades. Drop the bid/ask columns since they are NaN.
trade_ticks = history[history.quantity > 0].dropna(axis=1)
```

		lastprice	quantity
symbol	**time**		
BTCUSD	**2024-12-17 05:00:13.647**	106380.0	0.201870
	2024-12-17 05:01:13.130	106390.0	0.000747
	2024-12-17 05:01:23.446	106380.0	0.197494
	2024-12-17 05:01:31.421	106390.0	0.031909
	2024-12-17 05:01:31.460	106390.0	0.000086

If you intend to use the data in the DataFrame to create `Tick` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `Tick` objects instead of a DataFrame, call the `history[Tick]` method.

```
# Get the trailing 2 days of ticks for the security in Tick format.
history = self.history[Tick](symbol, timedelta(2), Resolution.TICK)
# Iterate through each quote tick and calculate the quote size.
for tick in history:
    if tick.tick_type == TickType.Quote:
        t = tick.end_time
        size = max(tick.bid_size, tick.ask_size)
```

Ticks are a sparse dataset, so request ticks over a trailing period of time or between start and end times.

Slices

To get historical Slice data, call the `history` method without passing any `Symbol` objects. This method returns `Slice` objects, which contain data points from all the datasets in your algorithm. If you omit the `resolution` argument, it uses the resolution that you set for each security and dataset when you created the subscriptions.

```py
class SliceHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 1)
        self.set_end_date(2024, 12, 31)
        # Add some securities and datasets.
        self.add_crypto('BTCUSD')
        # Get the historical Slice objects over the last 5 days for all the subcriptions in your algorithm.
        history = self.history(5, Resolution.DAILY)
        # Iterate through each historical Slice.
        for slice_ in history:
            # Iterate through each TradeBar in this Slice.
            for symbol, trade_bar in slice_.bars.items():
                close = trade_bar.close
```

Universes

To get historical universe data , call the `history` method with the `Universe` object. This method doesn't apply your selection function . It returns all of the universe data in a DataFrame with columns for the data point attributes.

```py
class CryptoUniverseHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 23)
        self.set_end_date(2024, 12, 31)
        # Add a universe of Cryptocurrencies on Coinbase.
        universe = self.add_universe(
            CryptoUniverse.coinbase(
                lambda constitutents: [c.symbol for c in constitutents]
            )
        )
        # Get 5 days of history for the universe.
        history = self.history(universe, timedelta(5), flatten=True)
```

```

To get the data in the format of the objects that you receive in your universe filter function instead of a DataFrame, use `flatten=False`. This call returns a Series where the values are lists of the universe data objects.

PY

```
# Get the historical universe data over the last 30 days in a Series where
# the values in the series are lists of the universe selection objects.
history = self.history(universe, timedelta(30), flatten=False)
# Iterate through each day of universe selection.
for (universe_symbol, end_time), constituents in history.items():
    # Select the 10 assets with the largest dollar volume this day.
    most_liquid = sorted(constituents, key=lambda c: c.volume_in_usd)[-10:]
```

Alternative Data

To get historical alternative data, call the `history` method with the dataset `Symbol`. This method returns a DataFrame that contains the data point attributes.

```
class CryptoAlternativeDataHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of an asset.
        symbol = self.add_crypto('BTCUSD').symbol
        # Add the alternative dataset and save a reference to its Symbol.
        dataset_symbol = self.add_data(BitcoinMetadata, symbol).symbol
        # Get the trailing 5 days of alternative data for the asset in DataFrame format.
        history = self.history(dataset_symbol, 5, Resolution.DAILY)
```

Name: marketcapitalization, dtype: float64
```

For information on historical data for other alternative datasets, see the documentation in the Dataset Market .

Indicators

To get historical indicator values, call the `indicator_history` method with an indicator and the security's `Symbol` .

```
class CryptoIndicatorHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        symbol = self.add_crypto('BTCUSD').symbol
        # Get the 21-day SMA values of the security for the last 5 trading days.
        history = self.indicator_history(SimpleMovingAverage(21), symbol, 5, Resolution.DAILY)
```

To organize the data into a DataFrame, use the `data_frame` property of the result.

```
# Organize the historical indicator data into a DataFrame to enable pandas wrangling.
history_df = history.data_frame
```

	current	rollingsum
2024-12-15	97734.062857	2052415.32
2024-12-16	98039.381905	2058827.02
2024-12-17	98663.181905	2071926.82
2024-12-18	99340.640952	2086153.46
2024-12-19	99540.619048	2090353.00

```
# Get the maximum of the SMA values.
sma_max = history_df.current.max()
```

The `indicator_history` method resets your indicator, makes a history request, and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

To make the `indicator_history` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```
# Get the historical values of an indicator over the last 30 days, applying the indicator to the security's volume.
history = self.indicator_history(indicator, symbol, timedelta(30), selector=Field.VOLUME)
```

Some indicators require the prices of two securities to compute their value (for example, Beta). In this case, pass a list of the `Symbol` objects to the method.

```
class CryptoMultiAssetIndicatorHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Add the target and reference securities.
        target_symbol = self.add_crypto('DOGEUSD').symbol
        reference_symbol = self.add_crypto('BTCUSD').symbol
        # Create a 21-period Beta indicator.
        beta = Beta("", target_symbol, reference_symbol, 21)
        # Get the historical values of the indicator over the last 10 trading days.
        history = self.indicator_history(beta, [target_symbol, reference_symbol], 10, Resolution.DAILY)
        # Get the average Beta value.
        beta_avg = history.data_frame.mean()
```

Examples

The following examples demonstrate some common practices for trading Cryptos using historical requests.

Example 1: Risk-Parity Crypto Pairs Portfolio

The following algorithm constructs a monthly rebalance risk-parity portfolio using the top 10 liquid Crypto pairs in the BitFinex market. A risk Parity portfolio can dissipate the risk of each crypto pair to reduce overall drawdown. The position sizing can be optimized by 1-year historical daily return of the universe members.

PY

```
from Portfolio.RiskParityPortfolioOptimizer import RiskParityPortfolioOptimizer

class CryptoHistoricalDataAlgorithm(QCAlgorithm):

    # Instantiate the optimizer to perform risk-parity optimization.
    # Risk Parity portfolio can dissipate the risk of each crypto pair to reduce overall drawdown.
    _optimizer = RiskParityPortfolioOptimizer(0.0, 1.0)

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Seed the last price to set the initial price of the BTCUSDT holdings.
        self.settings.seed_initial_prices = True

        # Monthly renewal of the top 10 liquid universe to trade popular crypto pairs.
        self.universe_settings.schedule.on(self.date_rules.month_start())
        self._universe = self.add_universe(CryptoCoarseFundamentalUniverse(Market.BITFINEX, self.universe_settings, self.selection))

        # Set a scheduled event to rebalance the portfolio at the start of every month.
        self.schedule.on(
            self.date_rules.month_start(),
            self.time_rules.at(9, 31),
            self.rebalance
        )

    def selection(self, data: List[CryptoUniverse]) -> List[Symbol]:
        # Filter out the crypto pair with a price below $10 to avoid excessive volatility.
        filtered = [datum for datum in data if datum.volume_in_usd]
        # Select the top 10 dollar volume crypto pairs.
        sorted_by_volume_in_usd = sorted(filtered, key=lambda datum: datum.volume_in_usd, reverse=True)[:10]
        return [datum.symbol for datum in sorted_by_volume_in_usd]

    def rebalance(self) -> None:
        # Historical data request to get 1-year data for optimization.
        symbols = self._universe.selected
        history = self.history(symbols, 253, Resolution.DAILY).close.unstack(0).dropna()
        # Daily return on the universe members to calculate the optimized weights.
        returns = history.pct_change().dropna()

        # Calculate the optimized weights.
        weights = self._optimizer.optimize(returns)

        # Rebalance the portfolio according to the optimized weights.
        targets = [PortfolioTarget(symbol, size if abs(size) > 0.01 else 0) for symbol, size in zip(symbols, weights)]
        self.set_holdings(targets, liquidate_existing_holdings=True)
```

Asset Classes

Crypto Futures

Introduction

This page explains how to get historical data for Crypto Futures. Some of the data you can get include prices, margin interest rates, and indicator data.

Trades

To get historical trade data , call the `history` method with the `TradeBar` type and a security's `Symbol` . This method returns a DataFrame with columns for the open, high, low, close, and volume.

```py
class CryptoFutureTradeBarHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        symbol = self.add_crypto_future('BTCUSD').symbol
        # Get the 5 trailing daily TradeBar objects of the security in DataFrame format.
        history = self.history(TradeBar, symbol, 5, Resolution.DAILY)
```

		close	high	low	open	volume
symbol	**time**					
BTCUSD	**2024-12-15**	101383.8	102683.9	100563.7	101403.8	16666498.0
	2024-12-16	104500.0	105323.5	101209.8	101383.9	26232316.0
	2024-12-17	106120.0	107872.1	103320.0	104500.0	44897036.0
	2024-12-18	106171.2	108496.9	105369.3	106120.0	41849071.0
	2024-12-19	100163.2	106550.2	99911.0	106171.2	65325574.0

```py
# Calculate the daily returns.
daily_returns = history.close.pct_change().iloc[1:]
```

```
symbol  time
BTCUSD  2024-12-16    0.030737
        2024-12-17    0.015502
        2024-12-18    0.000482
        2024-12-19   -0.056588
Name: close, dtype: float64
```

If you intend to use the data in the DataFrame to create `TradeBar` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `TradeBar` objects instead of a DataFrame, call the `history[TradeBar]` method.

```py
# Get the 5 trailing daily TradeBar objects of the security in TradeBar format.
history = self.history[TradeBar](symbol, 5, Resolution.DAILY)
# Iterate through the TradeBar objects and access their volumes.
for trade_bar in history:
    t = trade_bar.end_time
    volume = trade_bar.volume
```

Quotes

To get historical quote data , call the `history` method with the `QuoteBar` type and a security's `Symbol` . This method returns a DataFrame with columns for the open, high, low, close, and size of the bid and ask quotes. The columns that don't start with "bid" or "ask" are the mean of the quote prices on both sides of the market.

```
class CryptoFutureQuoteBarHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        symbol = self.add_crypto_future('BTCUSD').symbol
        # Get the 5 trailing minute QuoteBar objects of the security in DataFrame format.
        history = self.history(QuoteBar, symbol, 5, Resolution.MINUTE)
```

dtype: float64
```

If you intend to use the data in the DataFrame to create `QuoteBar` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `QuoteBar` objects instead of a DataFrame, call the `history[QuoteBar]` method.

```
# Get the 5 trailing minute QuoteBar objects of the security in QuoteBar format.
history = self.history[QuoteBar](symbol, 5, Resolution.MINUTE)
# Iterate through each QuoteBar and calculate the dollar volume on the bid.
for quote_bar in history:
    t = quote_bar.end_time
    bid_dollar_volume = quote_bar.last_bid_size * quote_bar.bid.close
```

Ticks

To get historical tick data , call the `history` method with a security's `Symbol` and `Resolution.TICK` . This method returns a DataFrame that contains data on bids, asks, and last trade prices.

```
PY
class CryptoFutureTickHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        symbol = self.add_crypto_future('BTCUSD').symbol
        # Get the trailing 2 days of ticks for the security in DataFrame format.
        history = self.history(symbol, timedelta(2), Resolution.TICK)
```

		askprice	asksize	bidprice	bidsize	lastprice	quantity
symbol	**time**						
BTCUSD	**2024-12-17 05:00:00.132868**	106537.1	12342.0	106537.0	35.0	106537.05	0.0
	2024-12-17 05:00:00.145098	106537.1	12353.0	106537.0	35.0	106537.05	0.0

	2024-12-17 05:00:00.431177	106537.1	12353.0	106537.0	355.0	106537.05	0.0

```
PY
# Select the rows in the DataFrame that represent trades. Drop the bid/ask columns since they are NaN.
trade_ticks = history[history.quantity > 0].dropna(axis=1)
```

		lastprice	quantity
symbol	**time**		
BTCUSD	**2024-12-17 05:00:01.008**	106537.1	2.0
	2024-12-17 05:00:02.729	106537.0	2.0
	2024-12-17 05:00:02.971	106537.0	5.0
	2024-12-17 05:00:05.977	106537.0	4.0
	2024-12-17 05:00:14.072	106537.1	56.0

If you intend to use the data in the DataFrame to create `Tick` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `Tick` objects instead of a DataFrame, call the `history[Tick]` method.

```
PY
# Get the trailing 2 days of ticks for the security in Tick format.
history = self.history[Tick](symbol, timedelta(2), Resolution.TICK)
# Iterate through each quote tick and calculate the quote size.
for tick in history:
    if tick.tick_type == TickType.Quote:
        t = tick.end_time
        size = max(tick.bid_size, tick.ask_size)
```

Ticks are a sparse dataset, so request ticks over a trailing period of time or between start and end times.

Slices

To get historical Slice data, call the `history` method without passing any `Symbol` objects. This method returns `Slice` objects, which contain data points from all the datasets in your algorithm. If you omit the `resolution` argument, it uses the resolution that you set for each security and dataset when you created the subscriptions.

```
PY
class SliceHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 1)
        self.set_end_date(2024, 12, 31)
        # Add some securities and datasets.
        self.add_crypto_future('BTCUSD')
        # Get the historical Slice objects over the last 5 days for all the subcriptions in your algorithm.
        history = self.history(5, Resolution.DAILY)
        # Iterate through each historical Slice.
        for slice_ in history:
            # Iterate through each TradeBar in this Slice.
            for symbol, trade_bar in slice_.bars.items():
                close = trade_bar.close
```

Margin Interest Rates

To get historical margin interest rate data , call the `history` method with the `MarginInterestRate` type and a security's `Symbol` . This method returns a DataFrame with a single column for the interest rate.

```
PY
class CryptoFutureMarginInterestRateHistoryAlgorithmHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        symbol = self.add_crypto_future('BTCUSD').symbol
        # Get the MarginInterestRate data of the security over the last 2 trading days in DataFrame format.
        history = self.history(MarginInterestRate, symbol, 2, Resolution.DAILY)
```

		interestrate
symbol	**time**	
BTCUSD	**2024-12-17 08:00:00**	0.0001

	2024-12-19 00:00:00	0.0001

```
PY
# Calculate the change in interest rates.
delta = history.interestrate.diff()[1:]
```

```
symbol  time
BTCUSD  2024-12-17 16:00:00    0.0
        2024-12-18 00:00:00    0.0
        2024-12-18 08:00:00    0.0
        2024-12-18 16:00:00    0.0
        2024-12-19 00:00:00    0.0
Name: interestrate, dtype: float64
```

If you intend to use the data in the DataFrame to create `MarginInterestRate` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `MarginInterestRate` objects

instead of a DataFrame, call the `history[MarginInterestRate]` method.

```
# Get the MarginInterestRate data of the security over the last 2 trading days in MarginInterestRate format.
history = self.history[MarginInterestRate](symbol, 2, Resolution.DAILY)
# Iterate through the MarginInterestRate objects and access their values
for margin_interest_rate in history:
    t = margin_interest_rate.end_time
    interest_rate = margin_interest_rate.interest_rate
```

Indicators

To get historical indicator values, call the `indicator_history` method with an indicator and the security's `Symbol` .

```
class CryptoFutureIndicatorHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        symbol = self.add_crypto_future('BTCUSD').symbol
        # Get the 21-day SMA values of the security for the last 5 trading days.
        history = self.indicator_history(SimpleMovingAverage(21), symbol, 5, Resolution.DAILY)
```

To organize the data into a DataFrame, use the `data_frame` property of the result.

```
# Organize the historical indicator data into a DataFrame to enable pandas wrangling.
history_df = history.data_frame
```

	current	rollingsum
2024-12-15	97759.090476	2052940.9
2024-12-16	98065.342857	2059372.2
2024-12-17	98689.038095	2072469.8
2024-12-18	99363.738095	2086638.5

```
# Get the maximum of the SMA values.
sma_max = history_df.current.max()
```

The `indicator_history` method resets your indicator, makes a history request, and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

To make the `indicator_history` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```
# Get the historical values of an indicator over the last 30 days, applying the indicator to the security's volume.
history = self.indicator_history(indicator, symbol, timedelta(30), selector=Field.VOLUME)
```

Some indicators require the prices of two securities to compute their value (for example, Beta). In this case, pass a list of the `Symbol` objects to the method.

```
class CryptoFutureMultiAssetIndicatorHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Add the target and reference securities.
        target_symbol = self.add_crypto_future('DOGEUSD').symbol
        reference_symbol = self.add_crypto_future('BTCUSD').symbol
        # Create a 21-period Beta indicator.
        beta = Beta("", target_symbol, reference_symbol, 21)
        # Get the historical values of the indicator over the last 10 trading days.
        history = self.indicator_history(beta, [target_symbol, reference_symbol], 10, Resolution.DAILY)
        # Get the average Beta value.
        beta_avg = history.data_frame.mean()
```

PY

Examples

The following examples demonstrate common practices for trading cryptocurrency futures with historical data.

Example 1: Spot-Future Arbitrage

The example below uses linear regression with historical Spot and Future BTCUSDT data to obtain the cointegrating vector between them. We measure the spread between the two securities and trade mean reversal upon their spread divergence.

PY

```
from sklearn.linear_model import LinearRegression

class CointegrationVectorRegressionAlgorithm(QCAlgorithm):
    # Threshold of spread divergence to enter position.
    entry_threshold = 2

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_account_currency("USDT", 100000)
        self.set_cash("BTC", 2)

        # Request BTCUSDT Crypto and Crypto Future data to form the cointegrating vectors and trade.
        self._future = self.add_crypto_future("BTCUSDT", market=Market.BYBIT).symbol
        self._spot = self.add_crypto("BTCUSDT", market=Market.BYBIT).symbol

        # Initialize cointegration vector.
        self.cointegration_vector = np.array([0.0, 0.0])
        self.residual_mean = 0
        self.residual_std = 1

        # Daily recalibration on the cointegrating vectors.
        self.schedule.on(
            self.date_rules.every_day(self._future),
            self.time_rules.at(0, 1),
            self.recalibrate
        )

    def on_data(self, slice: Slice) -> None:
        y = slice.bars.get(self._future)
        x1 = slice.bars.get(self._spot)
        if y and x1:
            # Calculate the spread based on the cointegration vector.
            spread = self.calculate_spread(y.close, x1.close, self.cointegration_vector)
            normalized_spread = (spread - self.residual_mean) / self.residual_std

            # If the spread is too high, short the dependent and long the independent variables based on the weightings of the
cointegrating vectors.
            # Else, vice versa.
            total_weights = abs(self.cointegration_vector[1]) + 1

```

Asset Classes

Forex

Introduction

This page explains how to get historical data for Forex. Some of the data you can get include quotes, ticks, and indicator data.

Quotes

To get historical quote data , call the `history` method with the `QuoteBar` type and a security's `Symbol` . This method returns a DataFrame with columns for the open, high, low, close, and size of the bid and ask quotes. The columns that don't start with "bid" or "ask" are the mean of the quote prices on both sides of the market.

```py
class ForexQuoteBarHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        symbol = self.add_forex('EURUSD').symbol
        # Get the 5 trailing minute QuoteBar objects of the security in DataFrame format.
        history = self.history(QuoteBar, symbol, 5, Resolution.MINUTE)
```

		askclose	askhigh	asklow	askopen	bidclose	bidhigh	bidlow	bidopen	close	high	low	open
symbol	**time**

        2024-12-19 00:00:00    0.00016
dtype: float64
```

If you intend to use the data in the DataFrame to create `QuoteBar` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `QuoteBar` objects instead of a DataFrame, call the `history[QuoteBar]` method.

```
# Get the 5 trailing minute QuoteBar objects of the security in QuoteBar format.
history = self.history[QuoteBar](symbol, 5, Resolution.MINUTE)
# Iterate through each QuoteBar and calculate the spread.
for quote_bar in history:
    t = quote_bar.end_time
    spread = quote_bar.ask.close - quote_bar.bid.close
```

Ticks

To get historical tick data , call the `history` method with a security's `Symbol` and `Resolution.TICK` . This method returns a DataFrame that contains data on bids, asks, and last trade prices.

```
class ForexTickHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        symbol = self.add_forex('EURUSD').symbol
        # Get the trailing 2 days of ticks for the security in DataFrame format.
        history = self.history(symbol, timedelta(2), Resolution.TICK)
```

		askprice	bidprice	lastprice

	2024-12-17 00:00:08.514324	1.0509	1.05074	1.050820
	2024-12-17 00:00:09.034650	1.0509	1.05075	1.050825
	2024-12-17 00:00:09.222588	1.0509	1.05074	1.050820

```
# Calculate the spread.
spread = history.askprice - history.bidprice
```

```
symbol  time
EURUSD  2024-12-17 00:00:01.113566    0.00016
        2024-12-17 00:00:01.158183    0.00014
        2024-12-17 00:00:08.514324    0.00016
        2024-12-17 00:00:09.034650    0.00015
        2024-12-17 00:00:09.222588    0.00016
dtype: float64
```

If you intend to use the data in the DataFrame to create `Tick` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `Tick` objects instead of a DataFrame, call the `history[Tick]` method.

```
# Get the trailing 2 days of ticks for the security in Tick format.
history = self.history[Tick](symbol, timedelta(2), Resolution.TICK)
# Iterate through each quote tick and calculate the spread.
for tick in history:
    t = tick.end_time
    spread = tick.bid_price - tick.ask_price
```

Ticks are a sparse dataset, so request ticks over a trailing period of time or between start and end times.

Slices

To get historical Slice data, call the `history` method without passing any `Symbol` objects. This method returns `Slice` objects, which contain data points from all the datasets in your algorithm. If you omit the `resolution` argument, it uses the resolution that you set for each security and dataset when you created the subscriptions.

```
PY
class SliceHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 1)
        self.set_end_date(2024, 12, 31)
        # Add some securities and datasets.
        self.add_forex('EURUSD')
        # Get the historical Slice objects over the last 5 minutes for all the subcriptions in your algorithm.
        history = self.history(5, Resolution.MINUTE)
        # Iterate through each historical Slice.
        for slice_ in history:
            # Iterate through each QuoteBar in this Slice.
            for symbol, quote_bar in slice_.bars.items():
                midprice = quote_bar.close
```

Indicators

To get historical indicator values, call the `indicator_history` method with an indicator and the security's `Symbol` .

```
PY
class ForexIndicatorHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        symbol = self.add_forex('EURUSD').symbol
        # Get the 21-day SMA values of the security for the last 5 trading days.
        history = self.indicator_history(SimpleMovingAverage(21), symbol, 5, Resolution.DAILY)
```

To organize the data into a DataFrame, use the `data_frame` property of the result.

```
PY
# Organize the historical indicator data into a DataFrame to enable pandas wrangling.
history_df = history.data_frame
```

	current	rollingsum
2024-12-13 19:00:00	1.051928	22.090485
2024-12-15 19:00:00	1.051755	22.086865

```
PY
# Get the maximum of the SMA values.
sma_max = history_df.current.max()
```

The `indicator_history` method resets your indicator, makes a history request, and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

To make the `indicator_history` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```
# Get the historical values of an indicator over the last 30 days, applying the indicator to the security's ask price.
history = self.indicator_history(indicator, symbol, timedelta(30), selector=Field.ASK_CLOSE)
```

Some indicators require the prices of two securities to compute their value (for example, Beta). In this case, pass a list of the `Symbol` objects to the method.

```
class ForexMultiAssetIndicatorHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Add the target and reference securities.
        target_symbol = self.add_forex('AUDUSD').symbol
        reference_symbol = self.add_forex('EURUSD').symbol
        # Create a 21-period Beta indicator.
        beta = Beta("", target_symbol, reference_symbol, 21)
        # Get the historical values of the indicator over the last 10 trading days.
        history = self.indicator_history(beta, [target_symbol, reference_symbol], 10, Resolution.DAILY)
        # Get the average Beta value.
        beta_avg = history.data_frame.mean()
```

Examples

The following examples demonstrate some common practices for trading Forex with historical data.

Example 1: Arbitration with Cointegration

The below example uses linear regression with historical data of 3 related Forex pairs to obtain the cointegrating vector between them. We measure the spread between the 3 Forex pairs and trade mean reversal upon their spread divergence.

PY

```
from sklearn.linear_model import LinearRegression

class CointegrationVectorRegressionAlgorithm(QCAlgorithm):
    # Threshold of spread divergence to enter position.
    entry_threshold = 0.0001

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000000)

        # Request Forex data to form the cointegrating vectors and trade.
        self.currency_pairs = [self.add_forex(pair).symbol for pair in ["USDJPY", "EURUSD", "EURJPY"]]

        # Initialize cointegration vector
        self.cointegration_vector = np.array([0.0, 0.0, 0.0])

        # Daily recalibration on the cointegrating vectors.
        self.schedule.on(
            self.date_rules.every_day(self.currency_pairs[0]),
            self.time_rules.at(0, 1),
            self.recalibrate
        )

    def on_data(self, slice: Slice) -> None:
        y = slice.quote_bars.get(self.currency_pairs[0])
        x1 = slice.quote_bars.get(self.currency_pairs[1])
        x2 = slice.quote_bars.get(self.currency_pairs[2])
        if y and x1 and x2:
            # Calculate the spread based on the cointegration vector.
            spread = self.calculate_spread(y.close, x1.close, x2.close, self.cointegration_vector)

            # Exit if spread is converged.
            if (self.portfolio[self.currency_pairs[0]].is_short and spread < 0) or (self.portfolio[self.currency_pairs[0]].is_long and
spread > 0):
                self.liquidate()
                return

            # If the spread is too high, short the dependent and long the independent variables based on the weightings of the
cointegrating vectors.
            # Else, vice versa.
            total_weights = 1 / (abs(self.cointegration_vector[1]) + abs(self.cointegration_vector[2]) + 1)
            if spread > self.entry_threshold:
                self.set_holdings(self.currency_pairs[0], -total_weights)
                self.set_holdings(self.currency_pairs[1], self.cointegration_vector[1] * total_weights)
                self.set_holdings(self.currency_pairs[2], self.cointegration_vector[2] * total_weights)
            elif spread < -self.entry_threshold:
                self.set_holdings(self.currency_pairs[0], total_weights)
                self.set_holdings(self.currency_pairs[1], -self.cointegration_vector[1] * total_weights)
                self.set_holdings(self.currency_pairs[2], -self.cointegration_vector[2] * total_weights)

    def recalibrate(self) -> None:
        # Calculate the cointegration vector from historical data.
        log_price = np.log(self.history(self.currency_pairs, 252, Resolution.DAILY).unstack(0).close.dropna())
        self.cointegration_vector = self.calculate_cointegrating_vector(log_price)

    def calculate_cointegrating_vector(self, history: pd.DataFrame) -> np.array:
        try:
            # Perform regression.
            lr = LinearRegression().fit(history[self.currency_pairs[1:]], history[self.currency_pairs[0]])

            # The coefficients array will contain the coefficients for each independent variable.
            return np.array([lr.intercept_, lr.coef_[0], lr.coef_[1]])
        except:
            return self.cointegration_vector

    def calculate_spread(self, y: float, x1: float, x2: float, cointegration_vector: np.array) -> float:
        # Using the cointegration vector to calculate the spread.
        return np.log(y) - (cointegration_vector[0] + np.log(x1) * cointegration_vector[1] + np.log(x2) * cointegration_vector[2])
```

Asset Classes

Futures

Introduction

This page explains how to get historical data for Futures. Some of the data you can get include prices, open interest, indicators, and contract chain data.

Trades

To get historical trade data , call the `history` method with the `TradeBar` type and a security's `Symbol` . This method returns a DataFrame with columns for the open, high, low, close, and volume.

```py
class FutureTradeBarHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        future = self.add_future(Futures.Indices.SP_500_E_MINI)
        symbol = list(self.futures_chain(future.symbol))[0].symbol
        # Get the 5 trailing daily TradeBar objects of the security in DataFrame format.
        history = self.history(TradeBar, symbol, 5, Resolution.DAILY)
```

			close	high	low	open	volume

```

If you intend to use the data in the DataFrame to create `TradeBar` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `TradeBar` objects instead of a DataFrame, call the `history[TradeBar]` method.

```
# Get the 5 trailing daily TradeBar objects of the security in TradeBar format.
history = self.history[TradeBar](symbol, 5, Resolution.DAILY)
# Iterate through the TradeBar objects and access their volumes.
for trade_bar in history:
    t = trade_bar.end_time
    volume = trade_bar.volume
```

Quotes

To get historical quote data , call the `history` method with the `QuoteBar` type and a security's `Symbol` . This method returns a DataFrame with columns for the open, high, low, close, and size of the bid and ask quotes. The columns that don't start with "bid" or "ask" are the mean of the quote prices on both sides of the market.

```
class FutureQuoteBarHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        future = self.add_future(Futures.Indices.SP_500_E_MINI)
        symbol = list(self.futures_chain(future.symbol))[0].symbol
        # Get the 5 trailing minute QuoteBar objects of the security in DataFrame format.
        history = self.history(QuoteBar, symbol, 5, Resolution.MINUTE)
```

```

If you intend to use the data in the DataFrame to create `QuoteBar` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `QuoteBar` objects instead of a DataFrame, call the

`history[QuoteBar]` method.

```
# Get the 5 trailing minute QuoteBar objects of the security in QuoteBar format.
history = self.history[QuoteBar](symbol, 5, Resolution.MINUTE)
# Iterate through each QuoteBar and calculate the dollar volume on the bid.
for quote_bar in history:
    t = quote_bar.end_time
    bid_dollar_volume = quote_bar.last_bid_size * quote_bar.bid.close
```

Ticks

To get historical tick data , call the `history` method with a security's `Symbol` and `Resolution.TICK` . This method returns a DataFrame that contains data on bids, asks, and last trade prices.

```
class FutureTickHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        future = self.add_future(Futures.Indices.SP_500_E_MINI)
        symbol = list(self.futures_chain(future.symbol))[0].symbol
        # Get the trailing 2 days of ticks for the security in DataFrame format.
        history = self.history(symbol, timedelta(2), Resolution.TICK)
```

```

			lastprice	quantity
expiry	**symbol**	**time**		
2024-12-20 13:30:00	**ES YOGVNNAOI1OH**	**2024-12-17 09:30:00.001**	6052.75	1.0
		2024-12-17 09:30:00.002	6053.00	1.0
		2024-12-17 09:30:00.002	6053.00	2.0
		2024-12-17 09:30:00.003	6052.75	1.0
		2024-12-17 09:30:00.003	6052.75	3.0

If you intend to use the data in the DataFrame to create `Tick` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `Tick` objects instead of a DataFrame, call the `history[Tick]` method.

```
# Get the trailing 2 days of ticks for the security in Tick format.
history = self.history[Tick](symbol, timedelta(2), Resolution.TICK)
# Iterate through each quote tick and calculate the quote size.
for tick in history:
    if tick.tick_type == TickType.Quote:
        t = tick.end_time
        size = max(tick.bid_size, tick.ask_size)
```

Ticks are a sparse dataset, so request ticks over a trailing period of time or between start and end times.

Slices

To get historical Slice data, call the `history` method without passing any `Symbol` objects. This method returns `Slice` objects, which contain data points from all the datasets in your algorithm. If you omit the `resolution` argument, it uses the resolution that you set for each security and dataset when you created the subscriptions.

```
class SliceHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 1)
        self.set_end_date(2024, 12, 31)
        # Add some securities and datasets.
        self.add_future(Futures.Indices.SP_500_E_MINI)
        # Get the historical Slice objects over the last 5 days for all the subcriptions in your algorithm.
        history = self.history(5, Resolution.DAILY)
        # Iterate through each historical Slice.
        for slice_ in history:
            # Iterate through each TradeBar in this Slice.
            for symbol, trade_bar in slice_.bars.items():
                close = trade_bar.close
```

Continuous Contract Prices

To get historical trade, quote, or tick data for the continuous contract , use the `symbol` property of the `Future` object when you make the history request.

```
class FutureContinuousContractHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Add the Future and specify the contract rollover settings.
        future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0
        )
        # Get the 5 trailing daily TradeBar objects of the continuous contract.
        history = self.history(TradeBar, future.symbol, 5, Resolution.DAILY)
```

Symbol Changes

To get historical symbol change data , call the `history` method with the `SymbolChangedEvent` type and the continuous contract Symbol. This method returns a DataFrame that contains the old and new Symbol for each rollover.

```
class FutureSymbolChangeEventsHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Add the Future and specify the contract rollover settings.
        future = self.add_future(
            Futures.Indices.SP_500_E_MINI,
            data_mapping_mode=DataMappingMode.OPEN_INTEREST,
            data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
            contract_depth_offset=0
        )
        # Get the contract rollovers for the trailing year.
        history = self.history(SymbolChangedEvent, future.symbol, timedelta(365))
```

			newsymbol	oldsymbol

```
# Select the dates of each rollover.
dates = list(history.index.levels[2])
```

If you intend to use the data in the DataFrame to create `SymbolChangedEvent` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `SymbolChangedEvent` objects instead of a DataFrame, call the `history[SymbolChangedEvent]` method.

```
# Get the rollovers of the continuous contract during the last 10 years in SymbolChangedEvent format.
history = self.history[SymbolChangedEvent](symbol, timedelta(10*365))
# Iterate through each SymbolChangedEvent object.
for symbol_changed_event in history:
    t = symbol_changed_event.end_time
    old_symbol = symbol_changed_event.old_symbol
    new_symbol = symbol_changed_event.new_symbol
```

Open Interest

To get historical open interest data , call the `history` method with the `OpenInterest` type and a security's `Symbol` . This method returns a DataFrame with a single column.

```
class FutureOpenInterestHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        future = self.add_future(Futures.Indices.SP_500_E_MINI)
        symbol = list(self.futures_chain(future.symbol))[0].symbol
        # Get the 5 trailing daily OpenInterest objects of the security in DataFrame format.
        history = self.history(OpenInterest, symbol, 5, Resolution.DAILY)
```

Name: openinterest, dtype: float64
```

If you intend to use the data in the DataFrame to create `OpenInterest` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `OpenInterest` objects instead of a DataFrame, call the `history[OpenInterest]` method.

PY

```
# Get the 5 trailing daily OpenInterest objects of the security in OpenInterest format.
history = self.history[OpenInterest](symbol, 5, Resolution.DAILY)
# Iterate through the TradeBar objects and access their volumes.
for oi in history:
    t = oi.end_time
    open_interest = oi.value
```

Contracts

To get historical Futures contracts, call the `history` method with the `FutureUniverse` type and the continuous contract `Symbol` . The data this method returns contains information on all the currently tradable contracts, not just the contracts that pass your filter. If you pass `flatten=True` , this method returns a DataFrame with columns for the data point attributes.

PY

```
class FutureContractsHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Add a Future.
        future = self.add_future(Futures.Indices.SP_500_E_MINI)
        # Get the daily contract data over the last two trading days.
        history = self.history(FutureUniverse, future.symbol, 2, flatten=True)
```

```py
# Get the 5 trailing daily FutureUniverse objects in FutureUniverse format.
history = self.history[FutureUniverse](future.symbol, 5, Resolution.DAILY)
# Iterate through the FutureUniverse objects and access their volumes.
for future_universe in history:
    t = future_universe.end_time
    most_oi = sorted(future_universe, key=lambda contract: contract.open_interest)[-1]
```

Contango

To get historical contango data for VX Futures , call the `history` method with the dataset `Symbol` . This method returns a DataFrame that contains the data point attributes.

```
class VIXContangoHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Add the dataset and save a reference to its Symbol.
        symbol = self.add_data(VIXCentralContango, "VIX", Resolution.DAILY).symbol
        # Get the trailing 7 days of contango data in DataFrame format.
        history = self.history(symbol, 7, Resolution.DAILY)
```

		contango_f2_minus_f1	contango_f3_minus_f1_div_2	contango_f4_minus_f1_div_3	f1	f2	f3	f4	f5	f6	f7	f8	frontmonthperiod
symbol	**time**												
VIX.VIXCentralContango	**2024-12-13**	0.1314	0.0498	0.0166	14.4062	16.2991	17.1553	17.9005	18.2460	18.5583	18.7923	18.9500	12 1 days
	2024-12-14	0.1212	0.0497	0.0166	14.5190	16.2782	17.1250	17.9474	18.2993	18.5750	18.8390	19.0500	12 1 days
	2024-12-17	0.1299	0.0457	0.0152	14.6997	16.6091	17.4592	18.1963	18.4965	18.7411	19.0282	19.1884	12 1 days
	2024-12-18	0.0765	0.0389	0.0130	15.7483	16.9531	17.6666	18.2998	18.4996	18.7185	19.0108	19.1500	12 1 days

```
# Calculate the changes in contango.
contango_diff = history.f1.diff().iloc[1:]
```

```
symbol                  time
VIX.VIXCentralContango  2024-12-14    0.1128
                        2024-12-17    0.1807
                        2024-12-18    1.0486
Name: f1, dtype: float64
```

If you intend to use the data in the DataFrame to create `VIXCentralContango` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of dataset objects instead of a DataFrame, call the `history[VIXCentralContango]` method.

```
# Get the trailing 7 days of contango data in VIXCentralContango format.
history = self.history[VIXCentralContango](symbol, 7, Resolution.DAILY)
# Iterate through each VIXCentralContango object.
for data_point in history:
    t = data_point.end_time
    value = data_point.contango_f_2_minus_f_1
```

Indicators

To get historical indicator values, call the `indicator_history` method with an indicator and the security's `Symbol` .

```
class FuturesIndicatorHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        symbol = self.add_future(Futures.Indices.SP_500_E_MINI).symbol
        # Get the 21-day SMA values of the security for the last 5 trading days.
        history = self.indicator_history(SimpleMovingAverage(21), symbol, 5, Resolution.DAILY)
```

To organize the data into a DataFrame, use the `data_frame` property of the result.

```
# Organize the historical indicator data into a DataFrame to enable pandas wrangling.
history_df = history.data_frame
```

	current	rollingsum
2024-12-12 17:00:00	6150.577121	129162.119546
2024-12-13 17:00:00	6154.322490	129240.772299
2024-12-16 17:00:00	6162.919815	129421.316116
2024-12-17 17:00:00	6169.413410	129557.681602
2024-12-18 17:00:00	6166.050570	129487.061970

```
# Get the maximum of the SMA values.
sma_max = history_df.current.max()
```

The `indicator_history` method resets your indicator, makes a history request, and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

To make the `indicator_history` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```
# Get the historical values of an indicator over the last 30 days, applying the indicator to the security's volume.
history = self.indicator_history(indicator, symbol, timedelta(30), selector=Field.VOLUME)
```

Some indicators require the prices of two securities to compute their value (for example, Beta). In this case, pass a list of the `Symbol` objects to the method.

```
class FuturesMultiAssetIndicatorHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Add the target and reference securities.
        target_symbol = self.add_future(Futures.Metals.GOLD).symbol
        reference_symbol = self.add_future(Futures.Indices.SP_500_E_MINI).symbol
        # Create a 21-period Beta indicator.
        beta = Beta("", target_symbol, reference_symbol, 21)
        # Get the historical values of the indicator over the last 10 trading days.
        history = self.indicator_history(beta, [target_symbol, reference_symbol], 10, Resolution.DAILY)
        # Get the average Beta value.
        beta_avg = history.data_frame.mean()
```

Examples

The following examples demonstrate some common practices for trading Futures with historical data.

Example 1: Stock-Gold All-Weather Portfolio

The following algorithm constructs a monthly-rebalanced, risk-parity portfolio using S&P 500 E-Mini and Micro Gold Futures contracts. A risk-parity approach balances the contribution to risk from each asset class, helping reduce overall portfolio drawdowns and improve diversification. The position sizing is determined using 1-year of historical daily returns for the selected Futures universe.

PY

```
from Portfolio.RiskParityPortfolioOptimizer import RiskParityPortfolioOptimizer

class FuturesHistoricalDataAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1_000_000)

        # Select the future contracts representing various asset classes to diversify the portfolio.
        self._futures = [self.add_future(
                x,
                fill_forward=True,
                extended_market_hours=True,
                data_normalization_mode=DataNormalizationMode.BACKWARDS_RATIO,
                data_mapping_mode=DataMappingMode.OPEN_INTEREST,
                contract_depth_offset=0
            ) for x in [Futures.Indices.SP_500_E_MINI, Futures.Metals.MICRO_GOLD]]

        # Instantiate the optimizer to perform risk-parity optimization.
        # Risk Parity portfolio can dissipate the risk of each crypto pair to reduce overall drawdown.
        self._optimizer = RiskParityPortfolioOptimizer(0.0, 1.0)

        # Set a scheduled event to rebalance the portfolio at the start of every month.
        self.schedule.on(
            self.date_rules.month_start(),
            self.time_rules.after_market_open(self._futures[0].symbol, 1),
            self.rebalance
        )

    def rebalance(self) -> None:
        # Historical data request to get 1-year data for optimization.
        history = self.history([x.symbol for x in self._futures], 253, Resolution.DAILY, extended_market_hours=True, fill_forward=True)\
            .droplevel([0]).unstack(0).close.dropna()
        # Daily return on the universe members to calculate the optimized weights.
        returns = history.pct_change().dropna()

        # Calculate the optimized weights.
        weights = self._optimizer.optimize(returns)

        # Rebalance the portfolio according to the optimized weights.
        targets = [PortfolioTarget(future.mapped, size/2.0) for future, size in zip(self._futures, weights)]
        self.set_holdings(targets, liquidate_existing_holdings=True)
```

Asset Classes

Future Options

Introduction

This page explains how to get historical data for Future Options. Some of the data you can get include prices and indicator data.

Trades

To get historical trade data , call the `history` method with the `TradeBar` type and a security's `Symbol` . This method returns a DataFrame with columns for the open, high, low, close, and volume.

```
class FutureOptionsTradeBarHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Add a FOP universe.
        future = self.add_future(Futures.Indices.SP_500_E_MINI)
        future.set_filter(lambda universe: universe.front_month())
        self.add_future_option(future.symbol, lambda universe: universe.front_month().strikes(-1, 0).calls_only())

    # Get trailing data whenever a new FOP contract enters the universe.
    def on_securities_changed(self, changes):
        for security in changes.added_securities:
            if security.type == SecurityType.FUTURE_OPTION:
                # Get the 3 trailing daily TradeBar objects of the security in DataFrame format.
                history = self.history(TradeBar, security.symbol, 3, Resolution.DAILY)
```

					close	high	low	open	volume
expiry	**strike**	**type**	**symbol**	**time**					
2024-12-20	**5870.0**	**1**	**ES 32NKVT5YYX1US|ES YOGVNNAOI1OH**	**2024-12-16 17:00:00**	2.15	2.15	1.45	1.80	227.0
				2024-12-17 17:00:00	2.35	3.05	2.30	2.30	14.0
				2024-12-18 17:00:00	38.75	43.75	1.75	1.85	399.0

```
# Calculate the daily returns.
daily_returns = history.close.pct_change().iloc[1:]
```

```
expiry      strike  type  symbol                           time
2024-12-20  5870.0  1     ES 32NKVT5YYX1US|ES YOGVNNAOI1OH  2024-12-17 17:00:00     0.093023
                                                           2024-12-18 17:00:00    15.489362
Name: close, dtype: float64
```

If you intend to use the data in the DataFrame to create `TradeBar` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `TradeBar` objects instead of a DataFrame, call the `history[TradeBar]` method.

```py
# Get the 3 trailing daily TradeBar objects of the security in TradeBar format.
history = self.history[TradeBar](symbol, 3, Resolution.DAILY)
# Iterate through the TradeBar objects and access their volumes.
for trade_bar in history:
    t = trade_bar.end_time
    volume = trade_bar.volume
```

Request minute, hour, or daily resolution data. Otherwise, the history request won't return any data.

Quotes

To get historical quote data , call the `history` method with the `QuoteBar` type and a security's `Symbol` . This method returns a DataFrame with columns for the open, high, low, close, and size of the bid and ask quotes. The columns that don't start with "bid" or "ask" are the mean of the quote prices on both sides of the market.

```py
class FutureOptionsQuoteBarHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Add a FOP universe.
        future = self.add_future(Futures.Indices.SP_500_E_MINI)
        future.set_filter(lambda universe: universe.front_month())
        self.add_future_option(future.symbol, lambda universe: universe.front_month().strikes(-1, 0).calls_only())

    # Get trailing data whenever a new FOP contract enters the universe.
    def on_securities_changed(self, changes):
        for security in changes.added_securities:
            if security.type == SecurityType.FUTURE_OPTION:
                # Get the 3 trailing daily QuoteBar objects of the security in DataFrame format.
                history = self.history(QuoteBar, security.symbol, 3, Resolution.DAILY)
```

					askclose	askhigh	asklow	askopen	asksize	bidclose	bidhigh	bidlow	bidopen	bidsize	close	high	low	open
expiry	strike	type	symbol	time

                                                           2024-12-17 17:00:00    0.25
                                                           2024-12-18 17:00:00    3.50
dtype: float64
```

If you intend to use the data in the DataFrame to create `QuoteBar` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `QuoteBar` objects instead of a DataFrame, call the `history[QuoteBar]` method.

```py
# Get the 3 trailing daily QuoteBar objects of the security in QuoteBar format.
history = self.history[QuoteBar](symbol, 3, Resolution.DAILY)
# Iterate through each QuoteBar and calculate the dollar volume on the bid.
for quote_bar in history:
    t = quote_bar.end_time
    bid_dollar_volume = quote_bar.last_bid_size * quote_bar.bid.close
```

Request minute, hour, or daily resolution data. Otherwise, the history request won't return any data.

Slices

To get historical Slice data, call the `history` method without passing any `Symbol` objects. This method returns `Slice` objects, which contain data points from all the datasets in your algorithm. If you omit the `resolution` argument, it uses the resolution that you set for each security and dataset when you created the subscriptions.

```py
class SliceHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Add some securities and datasets.
        future = self.add_future(Futures.Indices.SP_500_E_MINI)
        future.set_filter(lambda universe: universe.front_month())
        self.add_future_option(future.symbol, lambda universe: universe.front_month().strikes(-1, 0).calls_only())
        # Add a Scheduled Event that runs at the start of each month.
        self.schedule.on(self.date_rules.month_start(future.symbol), self.time_rules.after_market_open(future.symbol, 60), self._trade)

    def _trade(self):
        # Get the historical Slice objects over the last 30 minutes for all the subcriptions in your algorithm.
        for slice_ in self.history(30, Resolution.MINUTE):
            # Iterate through each TradeBar in this Slice.
            for symbol, trade_bar in slice_.bars.items():
                close = trade_bar.close
```

Indicators

To get historical indicator values, call the `indicator_history` method with an indicator and the security's `Symbol` .

```py
class FutureOptionIndicatorHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Add a FOP universe.
        future = self.add_future(Futures.Indices.SP_500_E_MINI)
        future.set_filter(lambda universe: universe.front_month())
        self.add_future_option(future.symbol, lambda universe: universe.front_month().strikes(0, 0).calls_only())

    def on_securities_changed(self, changes):
        for security in changes.added_securities:
            if security.type != SecurityType.FUTURE_OPTION:
                continue
            # Get the 21-day SMA values of the contract for the last 5 trading days.
            history = self.indicator_history(SimpleMovingAverage(21), security.symbol, 5, Resolution.DAILY)
```

To organize the data into a DataFrame, use the `data_frame` property of the result.

```py
# Organize the historical indicator data into a DataFrame to enable pandas wrangling.
history_df = history.data_frame
```

	current	rollingsum
2024-12-12 17:00:00	131.404762	2759.500
2024-12-13 17:00:00	132.101190	2774.125
2024-12-16 17:00:00	135.779762	2851.375
2024-12-17 17:00:00	138.047619	2899.000
2024-12-18 17:00:00	134.095238	2816.000

```
# Get the maximum of the SMA values.
sma_max = history_df.current.max()
```

The `indicator_history` method resets your indicator, makes a history request, and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

To make the `indicator_history` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```
# Get the historical values of an indicator over the last 30 days, applying the indicator to the contract's volume.
history = self.indicator_history(indicator, symbol, timedelta(30), selector=Field.VOLUME)
```

Some indicators require the prices of multiple securities to compute their value (for example, the indicators for the Greeks and implied volatility). In this case, pass a list of the `Symbol` objects to the method.

```
class FutureOptionMultiAssetIndicatorHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Add a FOP universe.
        future = self.add_future(Futures.Indices.SP_500_E_MINI)
        future.set_filter(lambda universe: universe.front_month())
        self.add_future_option(future.symbol, lambda universe: universe.front_month().strikes(0, 0).calls_only())

    def on_securities_changed(self, changes):
        for security in changes.added_securities:
            if security.type != SecurityType.FUTURE_OPTION:
                continue
            option = security.symbol
            # Get the Symbol of the mirror contract.
            mirror = Symbol.create_option(
                option.underlying, option.id.market, option.id.option_style,
                OptionRight.Call if option.id.option_right == OptionRight.PUT else OptionRight.PUT,
                option.id.strike_price, option.id.date
            )
            # Create the indicator.
            indicator = ImpliedVolatility(
                option, self.risk_free_interest_rate_model, ConstantDividendYieldModel(0),
                mirror, OptionPricingModelType.FORWARD_TREE
            )
            # Get the historical values of the indicator over the last 10 minutes.
            history = self.indicator_history(indicator, [option.underlying, option, mirror], 10, Resolution.MINUTE)
            # Get the average IV value.
            iv_avg = history.data_frame.current.mean()
```

Examples

The following examples demonstrate some common practices for trading Future Options with historical data.

Example 1: Trend Following on Front Month ATM Option Contract

This algorithm strategically trades the front month S&P 500 EMini Future Options by analyzing bid and ask volumes shortly after the market opens. Using scheduled events, it effectively executes trades based on historical quote data, optimizing decision-making. The algorithm aims for timely entries and exits, ensuring efficient capital management and quick adaptability in volatile markets.

PY

```
class FutureOptionsTradingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)  # Limit to a single day for 0DTE
        self.set_cash(200000)  # Starting cash

        # Request ES option data for trading and signal generation.

Index

Introduction

This page explains how to get historical price and indicator data for Indices.

Bars

To get historical price data , call the `history` method with an Index `Symbol` . This method returns a DataFrame with columns for the open, high, low, and close.

```py
class IndexPriceHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of an Index.
        symbol = self.add_index('SPX').symbol
        # Get the 5 trailing daily bars of the Index in DataFrame format.
        history = self.history(symbol, 5, Resolution.DAILY)
```

		close	high	low	open
symbol	**time**				
SPX	**2024-12-12 15:15:00**	6051.70	6079.68	6051.70	6074.05
	2024-12-13 15:15:00	6050.83	6078.58	6035.77	6068.48
	2024-12-16 15:15:00	6074.48	6085.19	6059.14	6064.04
	2024-12-17 15:15:00	6050.31	6057.68	6035.19	6046.33
	2024-12-18 15:15:00	5869.22	6070.67	5867.79	6048.69

```py
# Calculate the daily growth.
daily_growth = history.close.pct_change().iloc[1:]
```

```
symbol  time
SPX     2024-12-13 15:15:00   -0.000144
        2024-12-16 15:15:00    0.003909
        2024-12-17 15:15:00   -0.003979
        2024-12-18 15:15:00   -0.029931
Name: close, dtype: float64
```

If you intend to use the data in the DataFrame to create `TradeBar` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `TradeBar` objects instead of a DataFrame, call the `history[TradeBar]` method.

```py
# Get the 5 trailing daily bars of the Index in TradeBar format.
history = self.history[TradeBar](symbol, 5, Resolution.DAILY)
# Iterate through the TradeBar objects and access their prices.
for trade_bar in history:
    price = trade_bar.price
```

Request minute, hour, or daily resolution data. Otherwise, the history request won't return any data.

Slices

To get historical Slice data, call the `history` method without passing any `Symbol` objects. This method returns `Slice` objects, which contain data points from all the datasets in your algorithm. If you omit the `resolution` argument, it uses the resolution that you set for each security and dataset when you created the subscriptions.

```
class SliceHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 1)
        self.set_end_date(2024, 12, 31)
        # Add some securities and datasets.
        self.add_index('SPX')
        # Get the historical Slice objects over the last 5 days for all the subcriptions in your algorithm.
        history = self.history(5, Resolution.DAILY)
        # Iterate through each historical Slice.
        for slice_ in history:
            # Iterate through each TradeBar in this Slice.
            for symbol, trade_bar in slice_.bars.items():
                close = trade_bar.close
```

Indicators

To get historical indicator values, call the `indicator_history` method with an indicator and the security's `Symbol` .

```
class IndexIndicatorHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        symbol = self.add_index('SPX').symbol
        # Get the 21-day SMA values of the security for the last 5 trading days.
        history = self.indicator_history(SimpleMovingAverage(21), symbol, 5, Resolution.DAILY)
```

To organize the data into a DataFrame, use the `data_frame` property of the result.

```
# Organize the historical indicator data into a DataFrame to enable pandas wrangling.
history_df = history.data_frame
```

	current	rollingsum
2024-12-12 15:15:00	6003.055714	126064.17
2024-12-13 15:15:00	6006.096667	126128.03
2024-12-16 15:15:00	6012.036190	126252.76
2024-12-17 15:15:00	6020.634286	126433.32
2024-12-18 15:15:00	6019.442381	126408.29

```
# Get the maximum of the SMA values.
sma_max = history_df.current.max()
```

The `indicator_history` method resets your indicator, makes a history request, and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

To make the `indicator_history` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```
# Get the historical values of an indicator over the last 30 days, applying the indicator to the security's high price.
history = self.indicator_history(indicator, symbol, timedelta(30), selector=Field.HIGH)
```

Some indicators require the prices of two securities to compute their value (for example, Beta). In this case, pass a list of the `Symbol` objects to the method.

```
class IndexMultiAssetIndicatorHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Add the target and reference securities.
        target_symbol = self.add_index('NDX').symbol
        reference_symbol = self.add_index('SPX').symbol
        # Create a 21-period Beta indicator.
        beta = Beta("", target_symbol, reference_symbol, 21)
        # Get the historical values of the indicator over the last 10 trading days.
        history = self.indicator_history(beta, [target_symbol, reference_symbol], 10, Resolution.DAILY)
        # Get the average Beta value.
        beta_avg = history.data_frame.mean()
```

Examples

The following examples demonstrate some common practices for trading with Index historical data.

Example 1: Replicating Portfolio

The example below constructed a replicating SGX portfolio using the top 100 weighted SPY constituents. It provides an alternative way for retail investors to invest in SGX without access to certain financial instruments and a hedging idea on SGX close hours.

PY

```
from sklearn.linear_model import LinearRegression

class SGXMatchingTradingAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.set_warm_up(timedelta(7))

        # Request SGX Index data for matching.
        self._sgx = self.add_index("SGX").symbol
        self._spy = Symbol.create('SPY', SecurityType.EQUITY, Market.USA)
        # We will try to use SPY constituents to reproduce the SGX index.
        self._universe = self.add_universe(
            self.universe.etf(
                self._spy,
                universe_filter_func=lambda x: [
                    y.symbol for y in sorted(
                        [y for y in x if y.weight],
                        key=lambda x: x.weight, reverse=True
                    )[:100]
                ]
            )
        )

        # Schedule an event to rebalance the portfolio.
        self.schedule.on(
            self.date_rules.every_day(self._spy),
            self.time_rules.after_market_open(self._spy, 1),
            self.rebalance
        )

    def rebalance(self) -> None:
        if self.is_warming_up or not self._universe.selected:
            return
        symbols = list(self._universe.selected)
        # Obtain the historical data.
        history = self.history([self._sgx] + symbols, 252, Resolution.DAILY).unstack(0).close
        history = history.groupby(history.index.date).last().dropna()
        # Obtain the weights of SPY constituents that best reproduce SGX.
        weights = self.calculate_weights(history[symbols], history[self._sgx])
        self.set_holdings(
            [PortfolioTarget(symbol, weight) for symbol, weight in zip(symbols, weights)],
            liquidate_existing_holdings=True
        )

    def calculate_weights(self, history: pd.DataFrame, benchmark: pd.Series) -> pd.Series:
        # Use log price to eliminate the compounding effect.
        # Perform regression to obtain the best-replicating portfolio of SGX.
        lr = LinearRegression(fit_intercept=False).fit(np.log(history), np.log(benchmark))
        sum_ = sum(abs(lr.coef_))
        return [c/sum_ for c in lr.coef_]
```

Asset Classes

Index Options

Introduction

This page explains how to get historical data for Index Options. Some of the data you can get include prices, open interest, Greeks, and universe selection data.

Trades

To get historical trade data , call the `history` method with the `TradeBar` type and a security's `Symbol` . This method returns a DataFrame with columns for the open, high, low, close, and volume.

```
class IndexOptionTradeBarHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        index = self.add_index('SPX')
        symbol = sorted(self.option_chain(index.symbol), key=lambda c: c.open_interest)[-1].symbol
        # Get the 5 trailing daily TradeBar objects of the security in DataFrame format.
        history = self.history(TradeBar, symbol, 5, Resolution.DAILY)
```

					close	high	low	open	volume
expiry	**strike**	**type**	**symbol**	**time**					
2024-12-20	**4000.0**	**1**	**SPX 32NKZCP89T8EM|SPX 31**	**2024-12-13 15:15:00**	0.05	0.07	0.05	0.07	5773.0
				2024-12-13 15:15:00	0.05	0.10	0.05	0.05	3052.0
				2024-12-16 15:15:00	0.03	0.10	0.03	0.10	6423.0
				2024-12-17 15:15:00	0.03	0.05	0.03	0.05	6085.0
				2024-12-18 15:15:00	0.85	1.00	0.03	0.03	10551.0

```
# Calculate the daily returns.
daily_returns = history.close.pct_change().iloc[1:]
```

```
expiry      strike  type  symbol                   time
2024-12-20  4000.0  1     SPX 32NKZCP89T8EM|SPX 31  2024-12-13 15:15:00     0.000000
                                                    2024-12-16 15:15:00    -0.400000
                                                    2024-12-17 15:15:00     0.000000
                                                    2024-12-18 15:15:00    27.333333
```

If you intend to use the data in the DataFrame to create `TradeBar` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `TradeBar` objects instead of a DataFrame, call the `history[TradeBar]` method.

```
# Get the 5 trailing daily TradeBar objects of the security in TradeBar format.
history = self.history[TradeBar](symbol, 5, Resolution.DAILY)
# Iterate through the TradeBar objects and access their volumes.
for trade_bar in history:
    t = trade_bar.end_time
    volume = trade_bar.volume
```

Request minute, hour, or daily resolution data. Otherwise, the history request won't return any data.

Quotes

To get historical quote data , call the `history` method with the `QuoteBar` type and a security's `Symbol` . This method returns a DataFrame with columns for the open, high, low, close, and size of the bid and ask quotes. The columns that don't start with "bid" or "ask" are the mean of the quote prices on both sides of the market.

```
class IndexOptionQuoteBarHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        index = self.add_index('SPX')
        symbol = sorted(self.option_chain(index.symbol), key=lambda c: c.open_interest)[-1].symbol
        # Get the 5 trailing minute QuoteBar objects of the security in DataFrame format.
        history = self.history(QuoteBar, symbol, 5, Resolution.MINUTE)
```

                                                    2024-12-18 15:15:00    0.45
dtype: float64
```

If you intend to use the data in the DataFrame to create `QuoteBar` objects, request that the history request returns the data type you need. Otherwise,

LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `QuoteBar` objects instead of a DataFrame, call the `history[QuoteBar]` method.

```
# Get the 5 trailing minute QuoteBar objects of the security in QuoteBar format.
history = self.history[QuoteBar](symbol, 5, Resolution.MINUTE)
# Iterate through each QuoteBar and calculate the dollar volume on the bid.
for quote_bar in history:
    t = quote_bar.end_time
    bid_dollar_volume = quote_bar.last_bid_size * quote_bar.bid.close
```

Request minute, hour, or daily resolution data. Otherwise, the history request won't return any data.

Slices

To get historical Slice data, call the `history` method without passing any `Symbol` objects. This method returns `Slice` objects, which contain data points from all the datasets in your algorithm. If you omit the `resolution` argument, it uses the resolution that you set for each security and dataset when you created the subscriptions.

```
class SliceHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 1)
        self.set_end_date(2024, 12, 31)
        # Add some securities and datasets.
        index = self.add_index('SPX')
        contract = sorted(self.option_chain(index.symbol), key=lambda c: c.open_interest)[-1]
        self.add_option_contract(contract.symbol)
        # Get the historical Slice objects over the last 5 days for all the subcriptions in your algorithm.
        history = self.history(5, Resolution.DAILY)
        # Iterate through each historical Slice.
        for slice_ in history:
            # Iterate through each TradeBar in this Slice.
            for symbol, trade_bar in slice_.bars.items():
                close = trade_bar.close
```

Open Interest

To get historical open interest data , call the `history` method with the `OpenInterest` type and a security's `Symbol` . This method returns a DataFrame with a single column.

```
class IndexOptionOpenInterestHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        index = self.add_index('SPX')
        symbol = sorted(self.option_chain(index.symbol), key=lambda c: c.open_interest)[-1].symbol
        # Get the 5 trailing daily OpenInterest objects of the security in DataFrame format.
        history = self.history(OpenInterest, symbol, 5, Resolution.DAILY)
```

Name: openinterest, dtype: float64
```

If you intend to use the data in the DataFrame to create `OpenInterest` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `OpenInterest` objects instead of a DataFrame, call the `history[OpenInterest]` method.

```
# Get the 5 trailing daily OpenInterest objects of the security in OpenInterest format.
history = self.history[OpenInterest](symbol, 5, Resolution.DAILY)
# Iterate through the TradeBar objects and access their volumes.
for oi in history:
    t = oi.end_time
    open_interest = oi.value
```

Daily Option Chains

To get historical daily Option chain data , call the `history` method with the Option `Symbol` object. The data this method returns contains information on all the currently tradable contracts, not just the contracts that pass your filter. If you pass `flatten=True` , this method returns a DataFrame with columns for the data point attributes.

```
class IndexOptionDailyOptionChainHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 23)
        self.set_end_date(2024, 12, 31)
        # Add an Index Option universe.
        option = self.add_index_option('SPX')
        # Get the trailing 5 daily Option chains in DataFrame format.
        history = self.history(option.symbol, 5, flatten=True)
```

Name: volume, dtype: float64
```

To get the data in the format of `OptionUniverse` objects instead of a DataFrame, call the `history[OptionUniverse]` method.

```
# Get the historical OptionUniverse data over the last 30 days.
history = self.history[OptionUniverse](option.symbol, timedelta(30))
# Iterate through each daily Option chain.
for option_universe in history:
    t = option_universe.end_time
    # Select the contract with the most volume.
    most_traded = sorted(option_universe, key=lambda contract: contract.volume)[-1]
```

Indicators

To get historical indicator values, call the `indicator_history` method with an indicator and the security's `Symbol` .

```
class IndexOptionIndicatorHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of the Option contract.
        underlying = self.add_index('SPX').symbol
        symbol = sorted(self.option_chain(underlying), key=lambda c: c.open_interest)[-1].symbol
        # Get the 21-day SMA values of the contract for the last 5 trading days.
        history = self.indicator_history(SimpleMovingAverage(21), symbol, 5, Resolution.DAILY)
```

To organize the data into a DataFrame, use the `data_frame` property of the result.

```
# Organize the historical indicator data into a DataFrame to enable pandas wrangling.
history_df = history.data_frame
```

	current	rollingsum
2024-12-12 15:15:00	0.617857	12.975

2024-12-16 15:15:00	0.535714	11.250
2024-12-17 15:15:00	0.477381	10.025
2024-12-18 15:15:00	0.472619	9.925

```
# Get the maximum of the SMA values.
sma_max = history_df.current.max()
```

The `indicator_history` method resets your indicator, makes a history request, and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

To make the `indicator_history` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```
# Get the historical values of an indicator over the last 30 days, applying the indicator to the security's volume.
history = self.indicator_history(indicator, symbol, timedelta(30), selector=Field.VOLUME)
```

Some indicators require the prices of multiple securities to compute their value (for example, the indicators for the Greeks and implied volatility). In this case, pass a list of the `Symbol` objects to the method.

```py
class IndexOptionMultiAssetIndicatorHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of the underlying asset.
        underlying = self.add_index('SPX').symbol
        # Get the Option contract Symbol.
        option = sorted(self.option_chain(underlying), key=lambda c: c.open_interest)[-1].symbol
        # Get the Symbol of the mirror contract.
        mirror = Symbol.create_option(
            underlying, option.id.market, option.id.option_style,
            OptionRight.CALL if option.id.option_right == OptionRight.PUT else OptionRight.PUT,
            option.id.strike_price, option.id.date
        )
        # Create the indicator.
        indicator = ImpliedVolatility(
            option, self.risk_free_interest_rate_model, DividendYieldProvider(underlying),
            mirror, OptionPricingModelType.FORWARD_TREE
        )
        # Get the historical values of the indicator over the last 60 trading minutes.
        history = self.indicator_history(indicator, [underlying, option, mirror], 60, Resolution.MINUTE)
        # Get the average IV value.
        iv_avg = history.data_frame.current.mean()
```

Examples

The following examples demonstrate some common practices for trading Index Options with historical data.

Example 1: Standard-Weekly Contracts Cointegration

The following example analyzes the cointegration relationship between the front-month ATM SPX and SPXW calls. By measuring their spread divergence, we trade mean reversal on their spread convergence.

```py
from sklearn.linear_model import LinearRegression

class IndexOptionHistoricalDataAlgorithm(QCAlgorithm):
    _threshold = 2
    _cointegration_vector = [0, 0]
    _spread_mean = 0
    _spread_sd = 1
    _spx_contract = None
    _spxw_contract = None

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(10000000)
        self._index = Symbol.create("SPX", SecurityType.INDEX, Market.USA)
        self._spx = Symbol.create_canonical_option(self._index)
        self._spxw = Symbol.create_canonical_option(self._index, "SPXW", Market.USA, "?SPXW")

        # Select the Index Options to analyze and trade by week.
        self.schedule.on(self.date_rules.week_start(), self.time_rules.at(9, 15), self.select_contract)

    def on_data(self, slice: Slice) -> None:
        if not (self._spx_contract and self._spxw_contract):
            return
        spxw = slice.quote_bars.get(self._spxw_contract)
        spx = slice.quote_bars.get(self._spx_contract)
        if not (spxw and spx):
            return
        # Obtain the current spread to see if there is any price divergence to trade.
        spread = self.calculate_spread(spxw.close, spx.close, self._cointegration_vector)
        z = (spread - self._spread_mean) / self._spread_sd
        # If the spread diverges above or below the threshold, trade to bet on mean reversion.
        if z > self._threshold and not self.portfolio[self._spx_contract].is_long:
            spx_qty = int(10 * self._cointegration_vector[1])
            spxw_qty = -10
            self.market_order(self._spx_contract, spx_qty)
            self.market_order(self._spxw_contract, spxw_qty)

        elif z < -self._threshold and not self.portfolio[self._spxw_contract].is_long:
            spx_qty = int(-10 * self._cointegration_vector[1])
            spxw_qty = 10
            self.market_order(self._spx_contract, spx_qty)
            self.market_order(self._spxw_contract, spxw_qty)

        # If prices converge, exit positions.
        if ((self.portfolio[self._spx_contract].is_long and z < 0) or
            (self.portfolio[self._spxw_contract].is_long and z > 0)):

CFD

Introduction

This page explains how to get historical quotes and indicator data for CFDs.

Quotes

To get historical quote data , call the `history` method with the `QuoteBar` type and a security's `Symbol` . This method returns a DataFrame with columns for the open, high, low, close, and size of the bid and ask quotes. The columns that don't start with "bid" or "ask" are the mean of the quote prices on both sides of the market.

```py
class CFDQuoteBarHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        symbol = self.add_cfd('XAUUSD').symbol
        # Get the 5 trailing minute QuoteBar objects of the security in DataFrame format.
        history = self.history(QuoteBar, symbol, 5, Resolution.MINUTE)
```

		askclose	askhigh	asklow	askopen	bidclose	bidhigh	bidlow	bidopen	close	high	low	open

```py
# Calculate the spread at each minute.
spread = history.askclose - history.bidclose
```

```
symbol  time
XAUUSD  2024-12-18 23:56:00    0.47
        2024-12-18 23:57:00    0.57
        2024-12-18 23:58:00    0.58
        2024-12-18 23:59:00    0.43
        2024-12-19 00:00:00    0.38
dtype: float64
```

If you intend to use the data in the DataFrame to create `QuoteBar` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `QuoteBar` objects instead of a DataFrame, call the `history[QuoteBar]` method.

```
# Get the 5 trailing minute QuoteBar objects of the security in QuoteBar format.
history = self.history[QuoteBar](symbol, 5, Resolution.MINUTE)
# Iterate through each QuoteBar and calculate the spread.
for quote_bar in history:
    t = quote_bar.end_time
    spread = quote_bar.ask.close - quote_bar.bid.close
```

Ticks

To get historical tick data , call the `history` method with a security's `Symbol` and `Resolution.TICK` . This method returns a DataFrame that contains data on bids, asks, and last trade prices.

```
class CFDTickHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        symbol = self.add_cfd('XAUUSD').symbol
        # Get the trailing 2 days of ticks for the security in DataFrame format.
        history = self.history(symbol, timedelta(2), Resolution.TICK)
```

	2024-12-17 00:00:00.770819	2652.02	2651.47	2651.745
	2024-12-17 00:00:00.781622	2652.02	2651.49	2651.755

```
# Calculate the spread.
spread = history.askprice - history.bidprice
```

```
symbol  time
XAUUSD  2024-12-17 00:00:00.047969    0.46
        2024-12-17 00:00:00.716746    0.50
        2024-12-17 00:00:00.742011    0.53
        2024-12-17 00:00:00.770819    0.55
        2024-12-17 00:00:00.781622    0.53
dtype: float64
```

If you intend to use the data in the DataFrame to create `Tick` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of `Tick` objects instead of a DataFrame, call the `history[Tick]` method.

```
# Get the trailing 2 days of ticks for the security in Tick format.
history = self.history[Tick](symbol, timedelta(2), Resolution.TICK)
# Iterate through each quote tick and calculate the spread.
for tick in history:
    t = tick.end_time
    spread = tick.bid_price - tick.ask_price
```

Ticks are a sparse dataset, so request ticks over a trailing period of time or between start and end times.

Slices

To get historical Slice data, call the `history` method without passing any `Symbol` objects. This method returns `Slice` objects, which contain data points from all the datasets in your algorithm. If you omit the `resolution` argument, it uses the resolution that you set for each security and dataset when you created the subscriptions.

```
PY
class SliceHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 1)
        self.set_end_date(2024, 12, 31)
        # Add some securities and datasets.
        self.add_cfd('XAUUSD')
        # Get the historical Slice objects over the last 5 minutes for all the subcriptions in your algorithm.
        history = self.history(5, Resolution.MINUTE)
        # Iterate through each historical Slice.
        for slice_ in history:
            # Iterate through each QuoteBar in this Slice.
            for symbol, quote_bar in slice_.bars.items():
                midprice = quote_bar.close
```

Indicators

To get historical indicator values, call the `indicator_history` method with an indicator and the security's `Symbol` .

```
PY
class CFDIndicatorHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a security.
        symbol = self.add_cfd('SPX500USD').symbol
        # Get the 21-day SMA values of the security for the last 5 trading days.
        history = self.indicator_history(SimpleMovingAverage(21), symbol, 5, Resolution.DAILY)
```

To organize the data into a DataFrame, use the `data_frame` property of the result.

```
PY
# Organize the historical indicator data into a DataFrame to enable pandas wrangling.
history_df = history.data_frame
```

	current	rollingsum
2024-12-13 18:00:00	6033.309524	126699.5
2024-12-15 18:00:00	6039.390476	126827.2
2024-12-16 18:00:00	6045.090476	126946.9
2024-12-17 18:00:00	6049.180952	127032.8
2024-12-18 18:00:00	6044.276190	126929.8

```
PY
# Get the maximum of the SMA values.
sma_max = history_df.current.max()
```

The `indicator_history` method resets your indicator, makes a history request, and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

To make the `indicator_history` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```
# Get the historical values of an indicator over the last 30 days, applying the indicator to the security's ask price.
history = self.indicator_history(indicator, symbol, timedelta(30), selector=Field.ASK_CLOSE)
```

Some indicators require the prices of two securities to compute their value (for example, Beta). In this case, pass a list of the `Symbol` objects to the method.

```
class CFDMultiAssetIndicatorHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 19)
        self.set_end_date(2024, 12, 31)
        # Add the target and reference securities.
        target_symbol = self.add_cfd('XAUUSD').symbol
        reference_symbol = self.add_cfd('SPX500USD').symbol
        # Create a 21-period Beta indicator.
        beta = Beta("", target_symbol, reference_symbol, 21)
        # Get the historical values of the indicator over the last 10 trading days.
        history = self.indicator_history(beta, [target_symbol, reference_symbol], 10, Resolution.DAILY)
        # Get the average Beta value.
        beta_avg = history.data_frame.mean()
```

Examples

The following examples demonstrate some common practices for trading CFD with historical data.

Example 1: Demand Force Following

The following algorithm measures the historical bid-ask spread of XAUUSD CFD contract. If the current spread is higher than the historical spread, meaning the demand force is lower than usual, we sell the contract; else, we buy. To realize the directional speculation, we apply a 2% take profit risk management model and a 1% trailing stop loss risk management model.

```
class CFDHistoricalDataAlgorithm(QCAlgorithm):
    _threshold = 2
    _spread_mean = 0
    _spread_sd = 1

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000000)

        # Request XAUUSD CFD contract to trade.
        self._xauusd = self.add_cfd("XAUUSD").symbol

        # Update the spread mean and SD to calculate the Z-score accurately daily.
        self.schedule.on(
            self.date_rules.every_day(self._xauusd),
            self.time_rules.at(0, 0),
            self.update_spread
        )

        # Take profit at 2%.
        self.add_risk_management(MaximumUnrealizedProfitPercentPerSecurity(0.02))
        # Trailing stop loss at 1%.
        self.add_risk_management(TrailingStopRiskManagementModel(0.01))

    def update_spread(self) -> None:
        # Obtain historical quote data to obtain the mean and SD of the bid-ask spread.
        history = self.history(QuoteBar, self._xauusd, 390, Resolution.MINUTE).unstack(0)        # minute bar of 1 day
        if "askclose" in history and "bidclose" in history:
            spread = history.askclose - history.bidclose
            self._spread_mean = np.mean(spread.values)
            self._spread_sd = np.std(spread.values, ddof=1)

    def on_data(self, slice: Slice) -> None:
        quote = slice.quote_bars.get(self._xauusd)
        # Obtain the current bid-ask spread as a trade signal.
        if quote and quote.ask and quote.bid:
            spread = quote.ask.close - quote.bid.close
            z = (spread - self._spread_mean) / self._spread_sd

            # If the spread is lower than expected, expect demand to be higher than usual, and buy XAUUSD.
            if z <= -self._threshold:
                self.set_holdings(self._xauusd, 1)
            # If the spread is higher than expected, expect demand to be lower than usual and sell XAUUSD.
            elif z >= self._threshold:
                self.set_holdings(self._xauusd, -1)
```

Historical Data

Alternative Data

Introduction

Alternative datasets provide signals to inform trading decisions. To view all the alternative datasets available on QuantConnect, see the Dataset Market . This page explains how to get historical data for alternative datasets.

Data Points

To get historical alternative data points, call the `history` method with the dataset `Symbol` . This method returns a DataFrame that contains the data point attributes.

```py
class AlternativeDataHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 20)
        self.set_end_date(2024, 12, 31)
        # Get the Symbol of a dataset.
        dataset_symbol = self.add_data(Fred, 'RVXCLS').symbol
        # Get the trailing 5 days of Fred data in DataFrame format.
        history = self.history(dataset_symbol, 5, Resolution.DAILY)
```

		value
symbol	**time**	
RVXCLS.Fred	**2024-12-17**	23.02
	2024-12-18	24.01
	2024-12-19	32.76
	2024-12-20	29.90

```py
# Calculate the dataset's rate of change.
roc = history.pct_change().iloc[1:]
```

		value
symbol	**time**	
RVXCLS.Fred	**2024-12-18**	0.043006
	2024-12-19	0.364431
	2024-12-20	-0.087302

If you intend to use the data in the DataFrame to create `alternativeDataClass` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of dataset objects instead of a DataFrame, call the `history[ alternativeDataClass ]` method.

```py
# Get the trailing 5 days of Fred data for an asset in Fred format.
history = self.history[Fred](dataset_symbol, 5, Resolution.DAILY)
# Iterate through the historical data points.
for data_point in history:
    t = data_point.end_time
    value = data_point.value
```

Some alternative datasets provide multiple entries per asset per time step . For example, the US Regulatory Alerts dataset can provide multiple alerts per day. In this case, to organize the data into a DataFrame, set the `flatten` argument to `True` .

```
class RegalyticsHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 20)
        self.set_end_date(2024, 12, 31)
        # Get the all the Regalytics articles that were published over the last day, organized in a DataFrame.
        dataset_symbol = self.add_data(RegalyticsRegulatoryArticles, "REG").symbol
        history = self.history(dataset_symbol, 1, Resolution.DAILY, flatten=True)
```

       'Statement|Release',
       'AWCs (Letters of Acceptance, Waiver, and Consent)'], dtype=object)
```

Universes

To get historical data for an alternative data universe , call the `history` method with the `Universe` object. Set the `flatten` argument to `True` to get a DataFrame that has columns for the data point attributes.

PY

```
class AltDataUniverseHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 23)
        self.set_end_date(2024, 12, 31)
        # Add a universe of US Equities based on an alternative dataset.
        universe = self.add_universe(BrainStockRankingUniverse)
        # Get 5 days of history for the universe.
        history = self.history(universe, timedelta(5), flatten=True)
```

2024-12-19  FIC R735QTJ8XC9X    0.073250
2024-12-20  FIC R735QTJ8XC9X    0.065142
2024-12-21  FIC R735QTJ8XC9X    0.065142
2024-12-22  FIC R735QTJ8XC9X    0.065142
2024-12-23  FIC R735QTJ8XC9X    0.065142
Name: value, dtype: float64
```

To get the data in the format of the objects that you receive in your universe filter function instead of a DataFrame, use `flatten=False` .

PY

```
# Get the historical universe data over the last 5 days in a Series where
# the values in the series are lists of the universe selection objects.
history = self.history(universe, timedelta(5), flatten=False)
# Select the asset with the greatest value each day.
for (universe_symbol, time), data in history.items():
    leader = sorted(data, key=lambda x: x.value)[-1]
```

Slices

To request `Slice` objects of historical data, call the `history` method without providing any `Symbol` objects. It returns data for all the data subscriptions in your algorithm, so the result may include more than just alternative data.

PY

```
class SliceHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 23)
        self.set_end_date(2024, 12, 31)
        # Add an asset and an alternative dataset.
        symbol = self.add_crypto('BTCUSD', Resolution.DAILY, Market.BITFINEX).symbol
        dataset_symbol = self.add_data(BitcoinMetadata, symbol).symbol
        # Get the latest 3 data points of all the securities/datasets in the algorithm, packaged into Slice objects.
        history = self.history(3)
        # Iterate through each Slice and get the synchronized data points at each moment in time.
        for slice_ in history:
            t = slice_.time
            if symbol in slice_:
                price = slice_[symbol].price
            if dataset_symbol in slice_:
                hash_rate = slice_[dataset_symbol].hash_rate
```

When your history request returns `Slice` objects, the `time` properties of these objects are based on the algorithm time zone, but the `end_time` properties of the individual data objects are based on the exchange time zone . The `end_time` is the end of the sampling period and when the data is actually available.

Sparse Datasets

A sparse dataset is a dataset that doesn't have data for every time step of its resolution. For example, the US Energy Information Administration (EIA) datasets have a daily resolution but the data for the "U.S. Ending Stocks of Finished Motor Gasoline in Thousand Barrels (Mbbl)" series only updates once a week. So when you request the trailing 30 days of historical data for it, you only get a few data points.

PY

```
class SparseDatasetHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 23)
        self.set_end_date(2024, 12, 31)
        # Add a sparse dataset. In this case, the default resolution is daily.
        symbol = self.add_data(USEnergy, 'PET.WGFSTUS1.W').symbol
        # Get 30 days of history for the dataset.
        history = self.history(symbol, 30)
```

		value
symbol	**time**	
PET.WGFSTUS1.W.USEnergy	**2024-11-29**	14445.0
	2024-12-06	16528.0
	2024-12-13	16452.0
	2024-12-20	16833.0

Most alternative datasets have only one resolution, which is usually daily. To check if a dataset is sparse and to view its resolution(s), see the documentation in the Dataset Market .

Examples

The following examples demonstrate some common practices for trade with historical Alternative Data.

Example 1: Inverted Yield Curve

The following algorithm trades the smoothened yield curve difference, calculated from the difference between 10-year yield and 2-year yield historical data and smoothened by the exponential moving average. If the yield curve is inverted, short SPY from this market downturn indicator.

```py
class AlternativeHistoricalDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000000)

        # Requesting yield curve data for trade signal generation (inversion)
        self._yield_curve_symbol = self.add_data(USTreasuryYieldCurveRate, "USTYCR").symbol
        # Request XAUUSD CFD contract to trade.
        self._spy = self.add_equity("SPY").symbol

        # Ignore orders with very small sizes.
        self.settings.minimum_order_margin_portfolio_percentage = 0.01

        # Trade every day after the market opens with an updated smoothened yield curve difference.
        self.schedule.on(
            self.date_rules.every_day(self._spy),
            self.time_rules.after_market_open(self._spy, 1),
            self.trade
        )

    def trade(self) -> None:
        # Obtain historical yield curve data to calculate the smoothened yield curve difference.
        history = self.history(self._yield_curve_symbol, 250, Resolution.DAILY).unstack(0)
        if "tenyear" in history and "twoyear" in history:
            diffs = history.tenyear - history.twoyear
            smoothened_diff = diffs.ewm(250).mean().values[-1]
            # If the smoothened yield curve difference is inverted, short SPY with the downside signal.
            self.set_holdings(self._spy, -1 if smoothened_diff < 0 else 1)
```

Historical Data

Custom Data

Introduction

You can import external datasets into your algorithm to use alongside other datasets from the Dataset Market. This page explains how to get historical data for custom datasets. Before you can get historical data for the dataset, define the `get_source` and `reader` methods of the custom data class. For examples of custom dataset implementations, see Key Concepts .

Slices

To request `Slice` objects of historical data, call the `history` method without providing any `Symbol` objects. It returns data for all the data subscriptions in your notebook, so the result may include more than just custom data.

```
# Get the latest 3 data points of all the securities/datasets in the notebook, packaged into Slice objects.
history = self.history(3)
```

When your history request returns `Slice` objects, the `time` properties of these objects are based on the algorithm time zone, but the `end_time` properties of the individual data objects are based on the exchange time zone . The `end_time` is the end of the sampling period and when the data is actually available.

Data Points

To get historical data points for a custom dataset, call the `history` method with the dataset `Symbol` . This method returns a DataFrame that contains the data point attributes of the dataset class. For an example definition of a custom data class, see the CSV Format Example .

```
class CustomSecurityHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add a custom dataset and save a reference to it's Symbol.
        dataset_symbol = self.add_data(MyCustomDataType, "MyCustomDataType", Resolution.DAILY).symbol
        # Get the trailing 5 days of MyCustomDataType data in DataFrame format.
        history = self.history(dataset_symbol, 5, Resolution.DAILY)
```

		close	high	low	open	value
symbol	**time**					
MYCUSTOMDATATYPE1M07S8	**2014-07-08**	7787.15	7792.00	7755.10	7780.40	7787.15
	2014-07-09	7623.20	7808.85	7595.90	7804.05	7623.20
	2014-07-10	7585.00	7650.10	7551.65	7637.95	7585.00

If you intend to use the data in the DataFrame to create `customDatasetClass` objects, request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To get a list of dataset objects instead of a DataFrame, call the `history[ customDatasetClass ]` method.

```
# Get the trailing 5 days of MyCustomDataType data for an asset in MyCustomDataType format.
history = self.history[MyCustomDataType](dataset_symbol, 5, Resolution.DAILY)
```

If the dataset provides multiple entries per time step , in the `get_source` method of your custom data class, return a `SubscriptionDataSource` that uses `FileFormat.UNFOLDING_COLLECTION` . To get the historical data of this custom data type in a DataFrame, set the `flatten` argument to `True` .

```
history = self.history(dataset_symbol, 1, Resolution.DAILY, flatten=True)
```

Universes

To get historical data for a custom data universe , call the `history` method with the `Universe` object. For an example definition of a custom data universe class, see the CSV Format Example .

```
class CustomDataUniverseHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add a universe from a custom data source and save a reference to it.
        universe = self.add_universe(
            StockDataSource, "my-stock-data-source", Resolution.DAILY, lambda data: [x.symbol for x in data]
        )
        # Get the historical universe data over the last 5 days in DataFrame format.
        history = self.history(universe, timedelta(5))
```

Missing Data Points

History requests for a trailing number of data samples return data based on the market hours of assets. The default market hours for custom securities is to be always open. Therefore, history requests for a trailing number of data samples may return fewer samples than you expect. To set the market hours of the dataset, see Market Hours .

Examples

The following examples demonstrate some common practices for trading with historical custom data.

Example 1: Custom Universe Data

The following algorithm trades based on a custom universe dataset. It obtains historical data on the universe's weights and uses the exponential moving average as the investment weight.

```py
class CustomUniverseExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add a universe that reads from the Object Store.
        self._universe = self.add_universe(
            CustomUniverseData, "CustomUniverse", Resolution.DAILY, lambda x: [y.symbol for y in x]
        )
        # Add a Scheduled Event to rebalance the portfolio.
        spy = Symbol.create('SPY', SecurityType.EQUITY, Market.USA)
        self.schedule.on(
            self.date_rules.every_day(spy),
            self.time_rules.after_market_open(spy, 1),
            self.rebalance
        )

    def rebalance(self) -> None:
        # We invest by the EMA of the given weight.
        history = self.history(self._universe, 5, Resolution.DAILY)
        if history.empty:
            return
        history = history.set_index('symbol', append=True).unstack('symbol').fillna(0)
        weights = history.ewm(5).mean().iloc[-1].droplevel(0)
        # Normalized weights.
        weights = weights / weights.sum()
        self.set_holdings([PortfolioTarget(symbol, weight) for symbol, weight in weights.items()], liquidate_existing_holdings=True)

class CustomUniverseData(PythonData):
    def get_source(self, config: SubscriptionDataConfig, date: datetime, is_live_mode: bool) -> SubscriptionDataSource:
        # Define the location and format of the data file.
        return SubscriptionDataSource(
            "portfolio-targets.csv", SubscriptionTransportMedium.OBJECT_STORE, FileFormat.CSV
        )

    def reader(self, config: SubscriptionDataConfig, line: str, date: datetime, is_live_mode: bool) -> BaseData:
        # Skip the header row.
        if not line[0].isnumeric():
            return None
        # Split the line by each comma.
        items = line.split(",")
        # Parse the data from the CSV file.
        data = CustomUniverseData()
        data.end_time = datetime.strptime(items[0], "%Y-%m-%d")
        data.time = data.end_time - timedelta(1)
        data['symbol'] = Symbol.create(items[1], SecurityType.EQUITY, Market.USA)
        data["weight"] = float(items[2])
        return data
```

Historical Data

Universe Data

Introduction

Universe selection is the process of selecting a basket of assets you may trade. Dynamic universe selection increase diversification and decrease selection bias in your algorithm. To get the history of a universe, call the `history` method with the universe object. Set the `flatten` argument to `True` to organize the data in a DataFrame for easy pandas wrangling. Note that the `history` method doesn't filter the universe with your filter function. It simply returns all of the assets and data points in the universe dataset.

US Equity Fundamentals

The following example gets the history of a US Equity fundamental universe :

```
class USEquityFundamentalUniverseHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 23)
        self.set_end_date(2024, 12, 31)
        # Add a universe of US Equities based on the Fundamentals dataset.
        universe = self.add_universe(lambda fundamentals: [f.symbol for f in fundamentals])
        # Get 5 days of history for the universe.
        history = self.history(universe, timedelta(5), flatten=True)
```

Crypto

The following example gets the history of a Crypto universe :

```py
class CryptoUniverseHistoryAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 12, 23)
        self.set_end_date(2024, 12, 31)
        # Add a universe of Cryptocurrencies.
        universe = self.add_universe(CryptoUniverse.coinbase(lambda data: [x.symbol for x in data]))
        # Get 5 days of history for the universe.
        history = self.history(universe, timedelta(5), flatten=True)
```

Examples

The following examples demonstrate some common practices for trading with historical universe data.

Example 1: Historical Ranking Prediction

The following example forms an equal-weighted portfolio at the start of each month with the 5 assets that have the greatest 21-day ranking in the Brain ML Stock Ranking dataset.

```
class UniverseHistoricalDataAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000000)
        self.settings.seed_initial_prices = True

        # Add a monthly update to the universe of BrainStockRanking data.
        self.universe_settings.schedule.on(self.date_rules.month_start("SPY"))
        self._universe = self.add_universe(BrainStockRankingUniverse)

        # Trade on every month's start, based on the predicted rank in the next month.
        self.schedule.on(
            self.date_rules.month_start("SPY"),
            self.time_rules.at(9, 31),
            self.trade
        )

        self.set_warm_up(1)

    def trade(self) -> None:
        # Get the last 5 bars of history for the universe.
        history = self.history(self._universe, 5, fill_forward=False, flatten=True).rank21days.unstack(0)
        # Obtain the 5 highest average rank stocks to invest in equally.
        top_ranked = history.mean(axis=1).nlargest(n=5)
        self.set_holdings([PortfolioTarget(symbol, 0.2) for symbol in top_ranked.index], liquidate_existing_holdings=True)
```

Historical Data

Warm Up Periods

Introduction

LEAN supports an automated fast-forward system called "Warm Up". It simulates winding back the date you deployed your algorithm by a specific time period. In backtests, it changes the start date of your algorithm to an earlier time. In live trading, it fetches data from before your deployment and fast forwards through your strategy up to the present day. Warm Up is a great way to prepare your algorithm and its indicators for trading. You can't place trades during the warm-up period because the data feed is replaying historical data for setting algorithm state.

Set Warm Up Periods

You can set a warm-up period based on a number of bars or a period of time.

Trailing Data Samples

To set a warm-up based on a trailing number of data samples, in your algorithm's `initialize` method, call the `set_warm_up` method with an integer argument.

```py
# Feed in 100 bars before start date
self.set_warm_up(100)
```

LEAN calculates the start of the warm-up period for each of your security subscriptions by using the number of bars you specify, the resolution of each security, and the trading calendar of each security. After it calculates the start time of the warm-up period for each security, it sets the earliest start time as the start of the algorithm warm-up period. For instance, in the following example, the warm-up period consists of 100 minute resolution bars for SPY and as many second resolution bars for BTCUSD that occur from the start of the SPY warm-up period to the algorithm `start_date` .

```py
class WarmUpWithTrailingDataSamplesAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.add_equity("SPY", Resolution.MINUTE, fill_forward=False)
        self.add_crypto("BTCUSD", Resolution.SECOND, fill_forward=False)
        self.set_warm_up(100)
```

To use a specific resolution of data for the warm-up period, pass a `resolution` argument to the `set_warm_up` method.

```py
# Feed in data for 100 trading days before the start date
self.set_warm_up(100, Resolution.DAILY)
```

If you pass an integer and a resolution, the warm-up period consists of the number of bars and resolution you set, regardless of the resolution of your data subscriptions. In this case, LEAN calculates the start of the warm-up period for each of your security subscriptions just like it does when you only pass an integer argument. After it calculates the start time of the warm-up period for each security, it sets the earliest start time as the start of the algorithm warm-up period.

If you pass a resolution argument and you registered indicators or consolidators for automatic updates, the warm-up period resolution must be less than or equal to the lowest resolution of your automatic indicators and consolidators. For instance, in the following example, the indicators use minute resolution data, so you can set the warm-up period to use tick, second, or minute resolution data.

```
class WarmUpWithTrailingDataSamplesAndResolutionAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self._spy = self.add_equity("SPY", Resolution.MINUTE, fill_forward=False).symbol
        self._btc = self.add_crypto("BTCUSD", Resolution.SECOND, fill_forward=False).symbol

        self._spy_sma = self.sma(self._spy, 10)
        self._btc_sma = self.sma(self._btc, 10, Resolution.MINUTE)

        self.set_warm_up(100, Resolution.MINUTE)
```

Trailing Time Periods

To set a warm-up based on a trailing time period, in your algorithm's `initialize` method, call the `set_warm_up` method with a `timedelta` . The warm-up period consists of that `timedelta` before the start date and pipes in data that matches the resolution of your data subscriptions.

```
# Wind time back 7 days from start
self.set_warm_up(timedelta(7))
```

To use a specific resolution of data for the warm-up period, pass a `resolution` argument to the `set_warm_up` method.

```
# Feed in 100 days of daily data before the start date
self.set_warm_up(timedelta(days=100), Resolution.DAILY)
```

If you pass a `timedelta` and a resolution, the warm-up period consists of the time period and resolution you set, regardless of the resolution of your data subscriptions.

Warm Up Status

You can't place trades during the warm-up period because the data feed is replaying historical data for setting algorithm state. To check if the algorithm is currently in a warm up period, use the `is_warming_up` property.

```
class WarmUpStatusAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        symbol = self.add_equity('IBM', Resolution.DAILY).symbol
        self._ema = self.ema(symbol, 100)
        self.set_warmup(100)

    def on_data(self, data) -> None:
        if self.is_warming_up:
            return
        self.plot('EMA', 'Is ready', int(self._ema.is_ready))
```

Event Handler

The `on_warmup_finished` event handler executes when the warm up period ends, even if you don't set a warm up period.

```
def on_warmup_finished(self) -> None:
    pass # Done warming up
```

Missing Data Points

There are several cases where you may get fewer data points from during warm-up than you expect.

Illiquid Securities

The default behavior for LEAN is to fill-forward the data. However, if an asset had no trading activity during the time period you request historical data for, you won't get any data for that asset.

Requesting Data Before an Asset's IPO

All assets have a day when they first started trading. If your warm-up period includes time before an asset's initial public offering (IPO) date, you won't get any data before the IPO date because the data doesn't exist.

Requesting Data Outside Market Hours

Warming up with a trailing number of data samples means the data is based on the market hours of assets, so they can wrap across multiple trading days to gather the amount of data you request. In contrast, warming up with a trailing time period provides means the data is based on a rolling calendar time. In this latter types of warm-up, if the period of time is outside of the market hours of an asset, you won't get any data.

Data Issues

Data issues are generally a result of human error or from mistakes in the data collection process. Any QuantConnect member can report a data issue , which our Data Team works to quickly resolve. However, while the data is still missing, your warm-up won't be able to provide the data. To view the list of current data issues, log in to the Algorithm Lab and then, in the left navigation bar, click Datasets > Data Issues .

Data Provider Limitations

When you run warm-up, consider the functionality of the data provider you use. For example, the QuantConnect data provider has quotas on the amount of data you can request and the Interactive Brokers data provider can be slow, so it can timeout if you run warm-up with too many assets. For more information about all the data providers, see their respective documentation in Cloud Platform , Local Platform , or the CLI .

Warm Up vs History Requests

Warm-up and history requests both provide historical data. The approach you take depends on your specific use case. A benefit to using warm-up is that it only takes one line of code to pump historical data into your algorithm, which processes universe selection and updates all the indicators. A consequence to using warm-up is that it may provide more historica data than you actually need since it provides data on all the subscriptions in your algorithm. If you have derivative assets in your algorithm, warm-up can be very slow to process.

Examples

The following examples demonstrate some common practices for warm up.

Example 1: Warm Up Indicator

The following algorithm trades mean-reversion according to signals from a Bollinger Bands indicator. It uses warm up so the indicator is ready by the start date of the algorithm.

```py
class WarmUpPeriodsAlgorithm(QCAlgorithm):
    bbands = BollingerBands(20, 2)

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Request SPY data for signal generation and trading.
        self.spy = self.add_equity("SPY", Resolution.MINUTE).symbol

        # The candlestick patterns are based on a daily consolidated trade bar.
        consolidator = TradeBarConsolidator(timedelta(1))
        # Subscribe to update the indicators with the 1-day consolidator automatically.
        self.register_indicator(self.spy, self.bbands, consolidator)
        # Add an event handler on candlestick indicators that are updated to trade the indicator.
        self.bbands.updated += self.on_updated

        # Warm up the indicator and the SPY price data.
        self.set_warm_up(20, Resolution.DAILY)

    def on_updated(self, sender: object, point: IndicatorDataPoint) -> None:
        if not sender.is_ready:
            return

        # Trade according to the updated indicator values.
        upper_band = sender.upper_band.current.value
        lower_band = sender.lower_band.current.value
        holdings = self.portfolio[self.spy]

        # Trade mean-reversal of the Bollinger Band.
        if holdings.price > upper_band and not holdings.is_short:
            self.set_holdings(self.spy, -0.5)
        if holdings.price < lower_band and not holdings.is_long:
            self.set_holdings(self.spy, 0.5)
```

Example 2: Warm Up Universe Selection

The following algorithm forms an equal-weighted portfolio with the 100 most liquid US Equities that are above their 60-day Exponential Moving Average (EMA). It uses the warm-up feature to prime the indicators in advance so it can start trading by the start date of the algorithm.

PY

```
class WarmUpPeriodsAlgorithm(QCAlgorithm):
    ema_by_symbol = {}

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.settings.seed_initial_prices = True

        # The universe is filtered by only the ones with prices above EMA, suggesting an uptrend.
        self._universe = self.add_universe(self.selection_by_ema)

        # Rebalance weekly.
        self.schedule.on(
            self.date_rules.week_start(),
            self.time_rules.at(9, 31),
            self.rebalance
        )

        self.set_warm_up(60, Resolution.DAILY)

    def selection_by_ema(self, fundamentals: List[Fundamental]) -> List[Symbol]:
        for f in fundamentals:
            # Create an EMA indicator for the symbol if it is not available.
            self.ema_by_symbol[f.symbol] = self.ema_by_symbol.get(f.symbol, ExponentialMovingAverage(60))
            # Update the indicator using the updated price data to select the updated data.
            self.ema_by_symbol[f.symbol].update(f.end_time, f.adjusted_price)

        # We don't add new securities during the warm-up process
        if self.is_warming_up:
            return Universe.UNCHANGED

        # Select the ones with the current price above EMA to filter for the uptrend stocks.
        def is_uptrend(f):
            ema = self.ema_by_symbol[f.symbol]
            return ema.is_ready and ema.current.value > f.adjusted_price

        # Only trades the top 100 liquid stocks since their trend capitalizes quicker.
        fundamentals = sorted([f for f in fundamentals if is_uptrend(f)],
            key=lambda x: x.dollar_volume, reverse=True)

        return [f.symbol for f in fundamentals[:100]]

    def rebalance(self) -> None:
        #  Equally invest in uptrend stocks to dissipate capital risk evenly.
        weight = 1 / len(self._universe.selected) if self._universe.selected else 0
        if weight == 0:
            return
        targets = [PortfolioTarget(symbol, weight) for symbol in self._universe.selected]
        self.set_holdings(targets)

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        # Exit position if the equity is below EMA since it becomes a downgoing trend.
        [self.liquidate(r.symbol) for r in changes.removed_securities]
```

Historical Data

Rolling Window

Introduction

A `RollingWindow` is an array of a fixed-size that holds trailing data. It's more efficient to use `RollingWindow` objects to hold periods of data than to make multiple historical data requests . With a `RollingWindow` , you just update the latest data point while a `history` call fetches all of the data over the period you request. `RollingWindow` objects operate on a first-in, first-out process to allow for reverse list access semantics with positive and negative indexing. Index 0 refers to the most recent item in the window and the largest index refers to the last item in the window. Index -1 refers to the latest item as well.

Create Rolling Windows

To create rolling windows, instantiate the `RollingWindow` object with a maximum size.

```
PY
self._close_price_window = RollingWindow(4)
self._trade_bar_window = RollingWindow(2)
self._quote_bar_window = RollingWindow(2)
self._tuple_window = RollingWindow(2)
```

You can define the rolling window type with `RollingWindow[T]` , where `T` is the native or C# type of elements in the window.

```
PY
self._close_price_window = RollingWindow[float](4)
self._trade_bar_window = RollingWindow[TradeBar](2)
self._quote_bar_window = RollingWindow[QuoteBar](2)
```

The typeless version, `RollingWindow(int)` , allows for Python types. For example, `tuple` .

Add Data

To add data to a `RollingWindow` , call the `add` method.

```
PY
self._close_price_window.add(data["SPY"].close)
self._trade_bar_window.add(data["SPY"])
self._quote_bar_window.add(data["EURUSD"])
self._tuple_window.add((1, 2))
```

To update the data at a specific index, set the value for that index. If the index doesn't currently exist, it increases the size and fills the empty indices with a default value (zero or `None`).

```
PY
self._close_price_window[0] = data["SPY"].close
self._trade_bar_window[0] = data["SPY"]
self._quote_bar_window[0] = data["EURUSD"]
self._tuple_window[0] = (1, 2)
```

Warm Up

To warm up a `RollingWindow` , make a history request and then iterate through the result to add the data to the `RollingWindow` .

```
class WarmUpRollingWindowAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        spy = self.add_equity("SPY", Resolution.DAILY).symbol
        history_trade_bar = self.history[TradeBar](spy, 10, Resolution.DAILY)
        history_quote_bar = self.history[QuoteBar](spy, 10, Resolution.MINUTE)

        # Warm up the close price and trade bar rolling windows with the previous 10-day trade bar data
        close_price_window = RollingWindow(10)
        trade_bar_window = RollingWindow(10)
        for trade_bar in history_trade_bar:
            close_price_window.add(trade_bar.close)
            trade_bar_window.add(trade_bar)

        # Warm up the quote bar rolling window with the previous 10-minute quote bar data
        quote_bar_window = RollingWindow(10)
        for quote_bar in history_quote_bar:
            quote_bar_window.add(quote_bar)
```

Check Readiness

To check if a `RollingWindow` is full, use its `is_ready` flag.

```
if not self._close_price_window.is_ready:
    return
```

Adjust Size

To adjust the `RollingWindow` size, set the `size` property.

```
self._close_price_window.size = 3
self._trade_bar_window.size = 3
self._quote_bar_window.size = 3
self._tuple_window.size = 3
```

When you decrease the size, it removes the oldest values that no longer fit in the `RollingWindow` . When you explicitly increase the `size` member, it doesn't automatically add any new elements to the `RollingWindow` . However, if you set the value of an index in the `RollingWindow` and the index doesn't currently exist, it fills the empty indices with a default value (zero or `None`). For example, the following code increases the `size` to 10, sets the 10th element to 3, and sets the 4th-9th elements to the default value:

```
self._close_price_window[9] = 3
```

Access Data

`RollingWindow` objects operate on a first-in, first-out process to allow for reverse list access semantics with positive and negative indexing. Index 0 refers to the most recent item in the window and the largest index refers to the last item in the window. Index -1 refers to the latest item as well.

```
current_close = self._close_price_window[0]
previous_close = self._close_price_window[1]
oldest_close = self._close_price_window[self._close_price_window.count-1]
oldest_close = self._close_price_window[-1]   # Negative indexing
```

To get the item that was most recently removed from the `RollingWindow` , use the `most_recently_removed` property.

```
removed_close = self._close_price_window.most_recently_removed
```

Combine with Indicators

The `window` property of the indicators is a built-in `RollingWindow` that stores historical values. It holds a collection of `IndicatorDataPoint` objects, enabling quick access to the most recent historical indicator values for analysis, calculations, or comparisons in trading and financial strategies. Its

default size 2, but you can adjust its size. To warm up the indicator and its `RollingWindow`, call the `indicator_history` method with the window size as an argument.

```
class IndicatorRollingWindowAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        spy = self.add_equity("SPY").symbol
        qqq = self.add_equity("QQQ").symbol

        # Manual SMA indicator example.
        self._sma = SimpleMovingAverage(20)
        # Automatic Beta indicator example.
        self._beta = self.b(spy, qqq, 20)

        # Adjust the window size to 5 to access the previous 5 indicator data points.
        self._sma.window.size = 5
        self._beta.window.size = 5

        # Warm up the indicator and window for immediate usage.
        self.indicator_history(self._sma, spy, self._sma.window.size, Resolution.DAILY)
        # For indicators using 2+ symbols, use an iterable symbol list.
        self.indicator_history(self._beta, [spy, qqq], self._beta.window.size, Resolution.DAILY)
```

Combine with Consolidators

To store a history of consolidated bars, in the consolidation handler, add the consolidated bar to the `RollingWindow`.

```
self._consolidator.data_consolidated += self._on_data_consolidated

# Define consolidator handler function as a class method
def _on_data_consolidated(self, sender, consolidated_bar):
    self._trade_bar_window.add(consolidated_bar)
```

Market Session

The `Session` property of a `Security` object contains the open, high, low, close, volume, and open interest of trading sessions. The `Session` object is a `RollingWindow` object with size of zero by default. To enable market session tracking, set the size of the `Session` object to 2, so the previous session data is at index 1.

```
session = self.securities[self._symbol].session
session.size = 2
today_open = session.open
today_high = session.high
today_low = session.low
today_cumulative_volume = session.volume
if session.is_ready:
    yesterday_close = session[1].close
```

Increase the size of the `Session` object to store more session data. You can use cached data in the `Session` property instead of requesting historical daily data.

```
equity = self.add_equity("SPY")
# Increase the session lookback to 252 from default (0)
equity.session.size = 252
# Get all closing prices in the session history
closes = [x.close for x in session][::-1]
```

Cast to Other Types

You can cast a `RollingWindow` to a list or a DataFrame. If you cast it to a list, reverse the list so the most recent element is at the last index of the list. This is the order the elements would be in if you added the elements to the list with the `Add` method. To cast a `RollingWindow` to a DataFrame, the `RollingWindow` must contain `Slice`, `Tick`, `QuoteBar`, or `TradeBar` objects. If the `RollingWindow` contains ticks, the ticks must have unique timestamps.

```
closes = list(self._close_price_window)[::-1]  # Make sure to reverse the list.

tick_df = self.pandas_converter.get_data_frame[Tick](list(self._tick_window)[::-1])
trade_bar_df = self.pandas_converter.get_data_frame[TradeBar](list(self._trade_bar_window)[::-1])
quote_bar_df = self.pandas_converter.get_data_frame[QuoteBar](list(self._quote_bar_window)[::-1])
```

PY

Delete Data

To remove all of the elements from a `RollingWindow` , call the `reset` method.

```
self._close_price_window.reset()
```

PY

Examples

The following examples demonstrate some common practices for rolling windows.

Example 1: Price Actions

The following algorithm saves the trailing 3 `TradeBar` objects into a `RollingWindow` . When it identifies a volume contraction breakout price action pattern on the SPY, it buys to ride on the capital inflow. To exit positions, it places a 2% take profit and 1% stop loss order in the `on_order_event` method.

```py
class RollingWindowAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Add SPY data for signal generation and trading.
        self.spy = self.add_equity("SPY", Resolution.MINUTE).symbol

        # Set up a rolling window to hold the last 3 trade bars for price action detection as the trade signal.
        self.windows = RollingWindow(3)
        # Warm up the rolling window.
        history = self.history[TradeBar](self.spy, 3, Resolution.MINUTE)
        for bar in history:
            self.windows.add(bar)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self.spy)
        if bar:
            # Trade the price action if the previous bars fulfill a contraction breakout.
            if self.contraction_action and self.breakout(bar.close):
                self.set_holdings(self.spy, 0.5)

            # Add the current bar to the window.
            self.windows.add(bar)

    def contraction_action(self) -> None:
        # We trade contraction type price action, where the buying preesure is increasing.
        # 1. The last 3 bars are green.
        # 2. The price is increasing in trend.
        # 3. The trading volume is increasing as well.
        # 4. The range of the bars are decreasing.
        return (
            self.windows[2].close > self.windows[2].open and
            self.windows[1].close > self.windows[1].open and
            self.windows[0].close > self.windows[0].open and
            self.windows[0].close > self.windows[1].close > self.windows[2].close and
            self.windows[0].volume > self.windows[1].volume > self.windows[2].volume and
            self.windows[2].close - self.windows[2].open > self.windows[1].close - self.windows[1].open > self.windows[0].close -
self.windows[0].open
        )

    def breakout(self, current_close: float) -> None:
        # Trade breakout from contraction: the breakout should be much greater than the contracted range of the last bar.
        return current_close - self.windows[0].close > (self.windows[0].close - self.windows[0].open) * 2

    def on_order_event(self, order_event: OrderEvent) -> None:
        if order_event.status == OrderStatus.FILLED:
            if order_event.ticket.order_type == OrderType.MARKET:
                # Stop loss order at 1%.
                stop_price = order_event.fill_price * (0.99 if order_event.fill_quantity > 0 else 1.01)
                self.stop_market_order(self.spy, -self.portfolio[self.spy].quantity, stop_price)
                # Take profit order at 2%.
                take_profit_price = order_event.fill_price * (1.02 if order_event.fill_quantity > 0 else 0.98)
                self.limit_order(self.spy, -self.portfolio[self.spy].quantity, take_profit_price)
            elif order_event.ticket.order_type == OrderType.STOP_MARKET or order_event.ticket.order_type == OrderType.LIMIT:
                # Cancel open orders if stop loss or take profit order fills.
                self.transactions.cancel_open_orders()
```

Example 2: Bid-Ask Spread

The following algorithm trades the microeconomy of SPY's supply-demand relationship. It buys when the current bid-ask spread is less than average spread over the last 20 QuoteBar objects, indicating demand is approaching supply. When the spread is greater than the average, it shorts SPY. To save the last spread values, it uses a `RollingWindow` .

```py
class RollingWindowAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1);
        self.set_end_date(2024, 12, 31)

        # Add SPY data for signal generation and trading.
        self.spy = self.add_equity("SPY", Resolution.MINUTE).symbol

        # Set up a rolling window to hold the last 20 bar's bid-ask spread for trade signal generation.
        self.windows = RollingWindow(20)
        # Warm up for the rolling window with quote data.
        history = self.history[QuoteBar](self.spy, 20, Resolution.MINUTE)
        for bar in history:
            self.windows.add(bar.ask.close - bar.bid.close)

    def on_data(self, slice: Slice) -> None:
        bar = slice.quote_bars.get(self.spy)
        if bar:
            # Update the window with the current bid-ask spread.
            spread = bar.ask.close - bar.bid.close
            self.windows.add(spread)

            # Buy if the current spread is smaller than average, indicating demand is approaching supply. Buy force will drive up price.
            if spread < np.mean(list(self.windows)):
                self.set_holdings(self.spy, -0.5)
            # Short if the current spread is larger than average, indicating supply is gradually overwhelming demand.
            elif spread > np.mean(list(self.windows)):
                self.set_holdings(self.spy, 0.5)
```

Example 3: EMA Acceleration

The following algorithm trades SPY based on the direction and acceleration of its exponential moving average (EMA). It buys when the EMA is increasing and accelerating upward, indicating a strong uptrend. It short sells when the EMA is decreasing and accelerating downward, indicating a strong downtrend. To compare the current EMA value to its previous values, the algorithm utilizes the EMA's internal `RollingWindow` .

```py
class RollingWindowAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Add SPY data for trading.
        self.spy = self.add_equity("SPY", Resolution.MINUTE).symbol

        # Set up an automatic EMA indicator for trade signal generation.
        self._ema = self.ema(self.spy, 20, Resolution.DAILY)
        # Extend the size of the EMA's internal rolling window so we can access its historical values.
        self._ema.window.size = 3
        # Warm-up the indicator and its internal rolling window
        self.indicator_history(self._ema, self.spy, self._ema.window.size)

        # Schedule an event to rebalance SPY position at daily market open.
        self.schedule.on(self.date_rules.every_day(self.spy), self.time_rules.after_market_open(self.spy, 0), self.rebalance)

    def rebalance(self) -> None:
        # Buy if the current EMA is increasing with acceleration, indicating strong uptrend.
        if (self._ema.window[1].value < self._ema.current.value and
            self._ema.window[0].value - self._ema.window[1].value > self._ema.window[1].value - self._ema.window[2].value):
            self.set_holdings(self.spy, 0.5)
        # Short if the current EMA is decreasing with acceleration, indicating strong downtrend.
        elif (self._ema.window[1].value > self._ema.current.value and
            self._ema.window[0].value - self._ema.window[1].value < self._ema.window[1].value - self._ema.window[2].value):
            self.set_holdings(self.spy, -0.5)
        # Liquidate if no strong trend indicated.
        elif self.portfolio.invested:
            self.liquidate(self.spy)
```

Example 4: Market Session as History

Using `Session` instead of history requests or rolling window to cache the last 252 OHLCV bars, the following algorithm buys SPY accordingly when the market opens above the 252-day max of closing prices.

PY

```
class MarketSessionAsDailyHistory(QCAlgorithm):
    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        equity = self.add_equity("SPY")

        # Increase the session lookback to 252 from default (0)
        # since our strategy break out the 252-day max of closing prices
        equity.session.size = 252
        # Warm up with daily data for speed
        self.set_warm_up(equity.session.size, Resolution.DAILY)

        self.schedule.on(self.date_rules.every_day("SPY"), self.time_rules.after_market_open("SPY", 1), self.trade_break_out)

    def trade_break_out(self):
        '''Break-out strategy. If the market opens above the 252-day max of closing prices,
        allocate all in SPY. Liquidate if it opens below the mean.
        '''
        session = self.securities["SPY"].session
        # The session is ready when the number of samples is greater than the size (252)
        if self.is_warming_up or not session.is_ready:
            return

        # Create a pandas Series of the closing prices of session
        # to use the max and mean methods
        closes = pd.Series([x.close for x in session][::-1])
        _open, _max, _mean = session.open, closes.max(), closes.mean()

        # Invest all in SPY if the open break out the 252-day max and liquidate below the mean
        if _open > _max:
            self.set_holdings("SPY", 1, tag=f'{_open=:.2f}, {_max=:.2f}')
        if _open < _mean:
            self.liquidate("SPY", tag=f'{_open=:.2f}, {_mean=:.2f}')
```

Historical Data

Common Errors

Introduction

Errors can occur when you request historical data. This page explains some of the most common ones you may encounter.

Indicator Readiness

Indicators can't produce a valid value until they have enough historical data to be ready . If your indicators require more data than what is currently available (for example, data before an asset's IPO), the `indicator_history` method will return fewer data points than you request and the warm-up techniques for manual and automatic indicators won't be able to make your indicators ready.

Trading During Warm Up

You can't place trades during the warm-up period because the data feed is replaying historical data for setting algorithm state. If you try to place a trade during warm-up, LEAN throws the following error:

Backtest Handled Error: This operation is not allowed in or during warm up: OrderRequest.Submit. Please move this code to the method.

Numerical Precision

Some factor files have INF split values, which indicate that the stock has so many splits that prices can't be calculated with correct numerical precision. To allow history requests with these symbols, we need to move the starting date forward when reading the data or use raw data normalization . If there are numerical precision errors in the factor files for a security in your history request, LEAN throws the following error:

"Warning: when performing history requests, the start date will be adjusted if there are numerical precision errors in the factor files."

Live Intraday Data Source

In live trading, if you make a history request for minute data at noon and the history period covers the start of the previous day to the present moment, the data from the previous day will be backtest data. The data of the current day will be live data that we collected throughout the morning. If you make this history request in a backtest, you might get slightly different data for the current day because of post-processing from the data vendor.

In cloud deployments, QuantConnect is the default data provider. If you remove it and use a different data provider, you won't get any price data from QuantConnect. However, we provide the following datasets:

- US Equity Security Master
- US Futures Security Master
- US Equity Option Universe
- US Index Option Universe
- Universe selection datasets
- Non-streaming alternative datasets

QC Data Provider Limitations

When you request historical data or run warm-up , the amount of historical data you can access depends on the resolution of your data subscriptions. The following table shows the amount of trailing historical data you can access for each data resolution:

Resolution	Available History
Daily	All historical data
Hour	All historical data
Minute	1 year
Second	2 months
Tick	1 month

In live trading, history requests for Index or Options with the QuantConnect data provider only returns data up to the end of the previous day. For example, if you make a history request for these asset classes at 1 PM Eastern Time (ET), you won't get any data for the current day.

For more information about the QuantConnect data provider, see QuantConnect .

Other Data Provider Limitations

LEAN supports other data providers, including IQFeed and Polygon. For more information about the limitations of these other data providers, see their respective documentation in Cloud Platform , Local Platform , or the CLI .

Brokerage Limitations

LEAN supports several brokerages that can provide historical data. However, some of them have limitations on historical data. For example, Interactive Brokers can be slow, so it can timeout if you request historical data for too many assets at once. For more information about these brokerages and the data they provide, see Datasets .

Historical Data

Live Trading

Introduction

When you make history requests in live trading, be aware of the associated data delays and the data provider's functionality.

Data Delays

Backtests have access to data up to t-1 to t-4 days, where t is the current day. The availability depends on the data type.

In live trading, history requests take 5-10 seconds to return the data. While LEAN processes the request, the algorithm doesn't receive any new data points.

Multiple Data Providers

When you deploy a live algorithm, you can add multiple data provider. If you use multiple data providers, the order you select them in defines their order of precedence in Lean. For example, if you set QuantConnect as the first provider and Interactive Brokers (IB) as the second provider, Lean only uses the IB data provider for securities that aren't available from the QuantConnect data provider. This configuration makes it possible to use the QuantConnect data provider for Equity universe selection and then place Options trades on the securities in the universe.

Data Provider Limitations

History requests from third-party data providers are much slower than from the QuantConnect data provider. If you need data from a third-party data provider, request small amounts or your algorithm may take longer than 10 minutes to process and cause a timeout. For more information about the data providers, see their respective documentation in Cloud Platform , Local Platform , or the CLI .

Trading and Orders

Trading and Orders

Key Concepts

Introduction

LEAN has dozens of methods to create, update, and cancel orders. You can place orders automatically with helper methods or manually through methods on the algorithm API. You can fetch, update, and cancel manual orders with order tickets . As the state of your orders change, LEAN creates events that notify your algorithm.

In backtesting, LEAN simulates order fills with historical data, but you can create your own fill, fee, slippage, and margin models via plugin points. You control how optimistic or pessimistic order fills are with transaction model classes. For more information about these types of models, see Reality Modeling .

Orders and Tickets

When you call one of the order methods to place an order, LEAN performs pre-order checks to ensure that the order meets some requirements and uses the last known price to check you have enough capital . To see the requirements of each order, see the Requirements section of the documentation for the order types and the Orders section of your brokerage model . If you can place the order, LEAN creates `Order` and OrderTicket objects. The order ticket is sent to your brokerage. As the brokerage processes your order, it returns another order ticket and it's compared against the order to see if the order is satisfied. Orders fill asynchronously in live trading, so if you want to change an order, you must request it with the order ticket. Order changes are not guaranteed since your order may fill by the time brokerage receives the request.

Order Types

LEAN supports the following order types:

- Market
- Limit
- Limit if touched
- Stop market
- Stop limit
- Trailing stop
- Market on open
- Market on close
- Combo market
- Combo limit
- Combo leg limit
- Option exercise

Symbol Properties

The `symbol_properties` are a property of the `Security` object. LEAN uses some of the `symbol_properties` to prevent invalid orders, and to calculate order quantities for a given target.

`SymbolProperties` objects have the following properties:

To get the `symbol_properties` , use the property on the `Security` object.

```py
symbol_properties = self.securities["BTCUSD"].symbol_properties
lot_size = symbol_properties.lot_size
minimum_order_size = symbol_properties.minimum_order_size
minimum_price_variation = symbol_properties.minimum_price_variation
```

LEAN uses the `minimum_price_variation` to round the `limit_price` , `stop_price` , and the `trigger_price` .

Quote Currency

The quote currency is the currency you must give the seller to buy an asset. For currency trades, the quote currency is the currency ticker on the right side of the currency pair. For other types of assets, the quote currency is usually USD, but the quote currency for India Equities is INR. To get the quote currency of a `Security` , use the `quote_currency` property.

```py
aapl_quote_currency = self.securities["AAPL"].quote_currency # USD
btcusdt_quote_currency = self.securities["BTCUSDT"].quote_currency # USDT
```

The `quote_currency` is a `Cash` object, which have the following properties:

You can use the `conversion_rate` property to calculate the value of the minimum price movement in the account currency

```py
cfd = self.securities["SG30SGD"]
quote_currency = cfd.quote_currency # SGD
contract_mutiplier = cfd.symbol_properties.contract_multiplier
minimum_price_variation = cfd.symbol_properties.minimum_price_variation

# Value of a pip in account currency
pip = minimum_price_variation * contract_mutiplier * quote_currency.conversion_rate
```

Trade Models

Reality models make backtests as realistic as possible to how the strategy would perform in live trading.

Split Adjustment

If a split event occurs before your order is filled, the unfilled portion of the order is adjusted automatically, where its quantity is multiplied by the split factor and the limit/stop/trigger price (if any) is divided by the split factor.

Open Order Margin Requirements

When an order fills, LEAN uses the portfolio information to check if you have enough capital to maintain the remaining open orders. If you don't, they are canceled.

The following table shows the order events of three orders of SPY 240109C00470000:

Time	Id	Type	Price	Quantity	Status
2024-01-08 09:31	1	Buy Market	0.91	20	`FILLED`
	2	Sell Stop Market	0.81	-20	`SUBMITTED`
2024-01-08 10:31	3	Sell Market	1.50	-10	`FILLED`
	2	Sell Stop Market	0.81	-20	`INVALID`

When the sell market order fills at 10:31, LEAN checks the sell stop order and sets its status to `OrderStatus.INVALID` due to insufficient buying power to complete it.

Asynchronous Execution

In live trading, we send your orders to the API of your brokerage and wait for their response to update the status of the order ticket from `NEW` to `SUBMITTED` , `CANCELED` , or `INVALID` . When you place multiple orders, waiting for responses from the brokerage delays the last orders of the batch. To avoid this delay, you can place orders asynchronously. When you place an order asynchronously, LEAN sends the order to your brokerage and

immediately continues executing your algorithm without waiting for a response. When the response from the brokerage arrives, LEAN updates the status of the order ticket accordingly, and your algorithm receives an order event .

Live Trading Considerations

In live trading, orders fill asynchronously. We send your order to the API of your brokerage and wait for their response to update the state of your algorithm and portfolio. The timing of live order fills doesn't depend on the resolution of your security subscriptions. When your order fills, the fill price and fee is set by your brokerage. You can add event handlers to your algorithm to monitor the brokerage connection and brokerage messages .

In backtesting, the trade fill timing depends on the resolution of your security subscription. For example, if you subscribe to a security with minute resolution data, the algorithm only receives data in one-minute time slices . As a result, the fill model can only evaluate if the order should fill on a minute-by-minute frequency.

Trading and Orders

Order Management

Order Management

Order Tickets

Introduction

When you create an order, you get an `OrderTicket` object to manage your order.

Properties

`OrderTicket` objects have the following attributes:

Track Orders

As the state of your order updates over time, your order ticket automatically updates. To track an order, you can check any of the preceding order ticket properties.

To get an order field, call the `get` method with an `OrderField` .

```py
def initialize(self) -> None:
    self._symbol = self.add_equity("SPY").symbol
    self._ticket = None

def on_data(self, slice: Slice) -> None:
    # Place order if not invested and save the order ticket for later retrival.
    if not self.portfolio.invested and self._symbol in slice.bars:
        self._ticket = self.limit_order(self._symbol, 10, slice.bars[self._symbol].close)
    # Get the limit price if the order is filled.
    elif self.portfolio.invested:
        limit_price = self._ticket.get(OrderField.LIMIT_PRICE)
```

The `OrderField` enumeration has the following members:

In addition to using order tickets to track orders, you can receive order events through the `on_order_event` event handler.

Update Orders

To update an order, use its `OrderTicket` . You can update other orders until they are filled or the brokerage prevents modifications. You just can't update orders during warm up and initialization .

Updatable Properties

The specific properties you can update depends on the order type. The following table shows the properties you can update for each order type.

Order Type	Updatable Properties				
	Tag	Quantity	LimitPrice	TriggerPrice	StopPrice
Market Order					
Limit Order	✓	✓	✓		
Limit If Touched Order	✓	✓	✓	✓	
Stop Market Order	✓	✓			✓
Stop Limit Order	✓	✓	✓		✓
Market On Open Order	✓	✓			
Market On Close Order	✓	✓			

Update Methods

To update an order, pass an `UpdateOrderFields` object to the `update` method. The method returns an `OrderResponse` to signal the success or failure of the update request.

```py
def initialize(self) -> None:
    self._symbol = self.add_equity("SPY").symbol
    self._ticket = None

def on_data(self, slice: Slice) -> None:
    # Place order if not invested and save the order ticket for later retrival.
    if not self._ticket and self._symbol in slice.bars:
        self._ticket = self.limit_order("SPY", 100, slice.bars[self._symbol].close * 0.98)
    # If order is placed, update the limit price to be 90% of the orginal.
    elif self._ticket != None and self._ticket.status == OrderStatus.SUBMITTED:
        # Update the order tag and limit price
        update_settings = UpdateOrderFields()
        update_settings.limit_price = self._ticket.get(OrderField.LIMIT_PRICE) * 0.9
        update_settings.tag = "Limit Price Updated for SPY Trade"
        response = self._ticket.update(update_settings)

        # Check if the update request is successfully submitted to the broker.
        # Note that it may not represent the order is updated successfully: during the order updating process, it may be filled or
canceled.
        if response.is_success:
            self.debug("Order update request is submitted successfully")
```

To update individual fields of an order, call any of the following methods:

- `update_limit_price`
- `update_quantity`
- `update_stop_price`
- `update_tag`

```py
response = ticket.update_limit_price(limit_price, tag)

response = ticket.update_quantity(quantity, tag)

response = ticket.update_stop_price(stop_price, tag)

response = ticket.update_tag(tag)
```

Update Order Requests

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `update_requests` method.

```
update_requests = ticket.update_requests()
```

Workaround for Brokerages That Don't Support Updates

Not all brokerages fully support order updates. To check what functionality your brokerage supports for order updates, see the Orders section of the documentation for your brokerage model . If your brokerage doesn't support order updates and you want to update an order, cancel the order . When you get an order event that confirms the order is no longer active, place a new order.

```
def initialize(self) -> None:
    self._symbol = self.add_equity("SPY").symbol
    self._ticket = None

def on_data(self, slice: Slice) -> None:
    # Place order if not invested and save the order ticket for later retrival.
    if not self._ticket and self._symbol in slice.bars:
        self._ticket = self.limit_order("SPY", 100, slice.bars[self._symbol].close)
    # If order is placed, cancel the order and place a new one as substituent.
    elif self._ticket != None and self._ticket.status == OrderStatus.SUBMITTED:
        self._ticket.cancel()

def on_order_event(self, order_event: OrderEvent) -> None:
    if (self._ticket and order_event.order_id == self._ticket.order_id and
        order_event.status == OrderStatus.CANCELED):
        # Place a new order
        quantity = self._ticket.quantity - self._ticket.quantity_filled
        limit_price = self.securities[self._ticket.symbol].price + 1
        self._ticket = self.limit_order(self._ticket.symbol, quantity, limit_price)
```

Cancel Orders

To cancel an order, call the `cancel` method on the `OrderTicket` . The method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
def initialize(self) -> None:
    self._symbol = self.add_equity("SPY").symbol
    self._ticket = None

def on_data(self, slice: Slice) -> None:
    # Place order if not invested and save the order ticket for later retrival.
    if not self._ticket and self._symbol in slice.bars:
        self._ticket = self.limit_order("SPY", 100, slice.bars[self._symbol].close)
    # If order is placed, cancel the order if it is not filled within 2 minutes.
    elif self._ticket != None and self._ticket.time < slice.time - timedelta(minutes=2) and self._ticket.status == OrderStatus.SUBMITTED:
        response = self._ticket.cancel("Canceled SPY trade")

        # Check if the cancel request is successfully submitted to the broker.
        # Note that it may not represent the order is canceled successfully: during the order updating process, it may be filled.
        if response.is_success:
            self.debug("Order cancel request successfully submitted")
```

You can't cancel market orders because they are immediately transmitted to the brokerage. You also can't cancel any orders during warm up and initialization .

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `cancel_order_request` method. The method returns `None` if the order hasn't been cancelled.

```
request = ticket.cancel_order_request()
```

Order Response

When you update or cancel an order, LEAN returns an `OrderReponse` object, which have the following attributes:

If your order changes fail, check the `ErrorCode` or `ErrorMessage` . For more information about specific order errors, see the Order Response Error Reference .

To get most recent order response, call the `get_most_recent_order_response` method.

```
response = ticket.get_most_recent_order_response()
```

Examples

The following examples demonstrate some common practices for order ticket management.

Example 1: Timed Exit

The following algorithm is an EMA-crossover strategy. Using the filled time of the order ticket, we can control to exit the position after 45 minutes.

```
class OrderTicketExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self._symbol = self.add_equity("SPY").symbol
        self._ticket = None
        # Set up EMA indicator for trade signal generation.
        self._ema = self.ema("SPY", 20, Resolution.DAILY)
        # Warm up the indicator for its readiness to use immediately.
        self.warm_up_indicator(self._symbol, self._ema)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        # Place order if not order yet and save the order ticket for later retrival.
        if not self._ticket and bar:
            # EMA crossover: buy if price is above EMA, which indicate uptrend.
            if self._ema.current.value < bar.close:
                self._ticket = self.limit_order("SPY", 100, slice.bars[self._symbol].close * 0.995)
            # EMA crossover: sell if price is below EMA, which indicate down trend.
            else:
                self._ticket = self.limit_order("SPY", -100, slice.bars[self._symbol].close * 1.005)
        # Exit position if it is in the portfolio for more than 45 minutes.
        elif self._ticket and self._ticket.time + timedelta(minutes=45) < self.utc_time:
            self.liquidate()
            self._ticket = None
```

Example 2: Intraday Stop Loss

The following algorithm demonstrates an intraday long position with a 10% stop loss order. Before the market closes, cancel the stop loss order if it is not filled and exit the position at market close with a market on close order.

```
class OrderTicketExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self._symbol = self.add_equity("QQQ").symbol
        self._ticket = None
        self._day = -1

        # Schedule an event to handle exiting position before market close if stop loss is not hit.
        # Market on close order requires ordering 15 minutes before market close.
        self.schedule.on(
            self.date_rules.every_day(self._symbol),
            self.time_rules.before_market_close(self._symbol, 16),
            self.exit_position
        )

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        # Place order if not invested. Make sure only trade once a day to avoid chasing the loss.
        if not self.portfolio.Invested and self._day != slice.time.day and bar:
            self.market_order(self._symbol, 10)
            # Update the day variable to avoid repeat ordering.
            self._day = slice.time.day

    def on_order_event(self, order_event: OrderEvent) -> None:
        # Make sure to order the stop loss order on the filled market order only.
        if order_event.status == OrderStatus.FILLED and order_event.fill_quantity > 0:
            # Place a 10% stop loss order to avoid large loss. Save the order ticket for tracking its status later.
            self._ticket = self.stop_market_order(order_event.symbol, -order_event.fill_quantity, order_event.fill_price*0.9)

    def exit_position(self) -> None:
        # Only need to cancel the order and handle exit position if the stop loss order is not fully filled.
        if self._ticket and self._ticket.status != OrderStatus.FILLED:
            self._ticket.cancel()
            # Market on close order to exit position at market close with the remaining quantity.
            self.market_on_close_order(self._symbol, -10 - self._ticket.quantity_filled)
```

Example 3: Crypto Trailing Stop Order

This example trades BTCUSD with a similar logic of Example 2, but apply a trailing stop loss of 10% instead. Crypto exchanges does not support trailing stop loss order. Yet, we can cancel and reorder a stop loss order with the updated stop loss price. If the market price of the crypto pair is above the previous level, update the stop loss order by the above.

```py
class OrderTicketExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Set the market argument to trade in specific exchange.
        self._symbol = self.add_crypto("BTCUSD", market=Market.COINBASE).symbol
        # A variable to hold the stop loss order to track if it should be updated.
        self._ticket = None
        # A day variable to avoid over-ordering (trade once per day)
        self._day = -1
        # A variable to hold the price of the high price in the lifetime of the open position for updating the stop loss price.
        self.high_price = 0
        # Update the stop loss when new high is 1% higher
        self.update_step = 1.01

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if not bar: return
        # Place order if not invested. Make sure only trade once a day to avoid chasing the loss.
        if not self.portfolio.invested and self._day != self.time.day:
            self.market_order(self._symbol, 1)
            # Place a 10% stop loss order to avoid large loss. Save the order ticket for tracking its status later.
            self._ticket = self.stop_market_order(self._symbol, -1, bar.close*0.9)
            self.high_price = bar.high * self.update_step
            # Update the day variable to avoid repeat ordering.
            self._day = self.time.day

        # Update the trailing stop order. Since order updating is not supported in crypto exchanges, we cancel and reorder.
        # Trailing stop price will only need to be updated when the market price is higher than the current price.
        if self._ticket and self._ticket.status in [OrderStatus.SUBMITTED, OrderStatus.PARTIALLY_FILLED] and bar.high > self.high_price:
            self._ticket.cancel()
            self._ticket = self.stop_market_order(self._symbol, -self.portfolio[self._symbol].quantity, bar.high*0.9)
            self.high_price = bar.high * self.update_step
```

Demonstration Algorithms
OrderTicketDemoAlgorithm.py Python

Order Management

Transaction Manager

Introduction

The algorithm transactions manager (`SecurityTransactionManager`) contains a collection of helper methods to quickly access all your orders. To access the transaction manager, use the `transactions` property of your algorithm. If you save a reference to your order tickets , you shouldn't need to use the transaction manager. LEAN updates the order tickets as the brokerage processes your orders.

Get a Single Order Ticket

If you didn't save a reference to the order ticket when you created an order, you can call the `get_order_ticket` method to get it. You need to pass the order ID to the method. If you don't have the order ID, you can use the `last_order_id` property to get the order ID of the most recent order.

```
PY
order_id = self.transactions.last_order_id
ticket = self.transactions.get_order_ticket(order_id)
```

Get Order Tickets

To get order tickets, call the `get_order_tickets` or `get_open_order_tickets` method. You can pass in a filter function to filter all of the order tickets or pass a `Symbol` to get the order tickets for a specific asset.

```
PY
# Get all order tickets
order_tickets = self.transactions.get_order_tickets()

# Get order tickets that pass a filter
filtered_order_tickets = self.transactions.get_order_tickets(lambda order_ticket: order_ticket.symbol == symbol)

# Get all open order tickets
open_order_tickets = self.transactions.get_open_order_tickets()

# Get all open order tickets for a symbol
symbol_open_order_tickets = self.transactions.get_open_order_tickets(symbol)

# Get open order tickets that pass a filter
filtered_open_order_tickets = self.transactions.get_open_order_tickets(lambda order_ticket: order_ticket.quantity > 10)
```

Get a Single Order

To get a clone of a specific order, call the `get_order_by_id` method with the order Id. To get the order Id, use the `order_id` property of the order ticket or use the `LastOrderID` property if you want the most recent order.

```
PY
order_id = self.transactions.last_order_id
order = self.transactions.get_order_by_id(order_id)
```

Order objects are immutable and changes to the order object will not impact the trade. To make an update to an order you must use Order Tickets . `Order` objects have the following attributes:

Get Orders

To get a list of orders, call the `get_orders` , `get_open_orders` , or `get_orders_by_brokerage_id` method. These method returns a list of `Order` objects.

```py
# Get all completed orders
completed_Orders = self.transactions.get_orders()

# Get all completed orders that pass a filter
filtered_completed_orders = self.transactions.get_orders(lambda x: x.quantity > 10)

# Retrieve a list of all completed orders for a symbol
symbol_completed_orders = self.transactions.get_orders(lambda x: x.symbol == symbol)

# Get all open orders
open_orders = self.transactions.get_open_orders()

# Get all open orders that pass a filter
filtered_open_orders = self.transactions.get_open_orders(lambda x: x.quantity > 10)

# Retrieve a list of all open orders for a symbol
symbol_open_orders = self.transactions.get_open_orders(symbol)

# Get all open and completed orders that correspond to an Id that the brokerage assigned in live trading
orders_by_brokerage_id = self.transactions.get_orders_by_brokerage_id(brokerageId)
```

`Order` objects have the following attributes:

The `orders_count` property gets the current number of orders that have been processed.

Get Remaining Order Quantity

To get the unfilled quantity of open orders, call the `get_open_orders_remaining_quantity` method.

```py
# Get the quantity of all open orders
all_open_quantity = self.transactions.get_open_orders_remaining_quantity()

# Get the quantity of open orders that pass a filter
filtered_open_quantity = self.transactions.get_open_orders_remaining_quantity(
    lambda order_ticket: order_ticket.quantity > 10
)

# Get the quantity of open orders for a symbol
symbol_open_quantity = self.transactions.get_open_orders_remaining_quantity(symbol)
```

Cancel Orders

To cancel open orders, call the `cancel_open_orders` method. This method returns a list of `OrderTicket` objects that correspond to the canceled orders.

```py
 # Cancel all open orders
all_cancelled_orders = self.transactions.cancel_open_orders()

# Cancel orders related to IBM and apply a tag
ibm_cancelled_orders = self.transactions.cancel_open_orders("IBM", "Hit stop price")
```

Live Trading Considerations

LEAN doesn't save orders and order tickets across live deployments.

When you deploy your algorithm, LEAN fetches the open orders from your brokerage and populate the algorithm transactions manager (`SecurityTransactionManager`).

Examples

The following examples demonstrate some common practices for using the transaction manager.

Example 1: 2-Level Take Profit And Stop Loss

The following algorithm trades volatility using the CBOE VIX dataset . It makes use of the transaction manager to handle a 2-layer take profit and stop loss risk management.

PY

```
class TransactionManagerAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

Market Orders

Introduction

Market orders are instructions to trade a specific number of units, regardless of the fill price. If your highest priority is to fill an order as fast as possible, use market orders. If the order book of the security you're trading has sufficient liquidity when the brokerage receives your order, it immediately fills. However, if there is not enough liquidity by the brokerage, you may need to wait a few minutes to fill the order, you may get partial fills, and you may incur additional costs from market impact.

Place Orders

To send a market order, call the `market_order` , `buy` , `sell` , or `order` method and provide a `Symbol` and quantity. If you don't have sufficient capital for the order, it's rejected. By default, market orders are synchronous and fill immediately.

```py
# Buy orders
self.market_order("IBM", 100)
self.buy("AAPL", 10)
self.order("SPY", 20)

# Sell orders
self.market_order("AMZN", -15)
self.sell("TSLA", 25)
self.order("SPY", -20)
```

You can also provide a tag and order properties to the `order` and `market_order` methods.

```py
self.market_order(symbol, quantity, tag=tag, order_properties=order_properties)
```

If you place a market order during pre-market or post-market hours, LEAN converts your order to market on open order. To override this behavior, create a custom fill model . To be notified when the default fill model allows you to submit market orders outside of regular trading hours, subscribe to GitHub Issue #3947 .

Monitor Order Fills

If the brokerage has sufficient liquidity in their order book, market orders fill immediately. Otherwise, you get partial fills. To monitor the fills of your order, save a reference to the order ticket .

```py
ticket = self.market_order("XLK", 10)
self.debug(f"Quantity filled: {ticket.quantity_filled}; Fill price: {ticket.average_fill_price}")
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Cancel Orders

To cancel a market order, call the `cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```py
response = ticket.cancel("Cancelled Trade")
if response.is_success:
    self.debug("Order successfully cancelled")
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `cancel_order_request` method on the order ticket. The method returns `None` if the order hasn't been cancelled.

```
request = ticket.cancel_order_request()
```

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `True` .

```
self.market_order("IBM", 100, asynchronous=True);
```

Synchronous Timeouts

Market orders are synchronous by default, so your algorithm waits for the order to fill before moving to the next line of code. If your order takes longer than five seconds to fill, your algorithm continues executing even if the trade isn't filled. To adjust the timeout period, set the `transactions.market_order_fill_timeout` property.

```
 # Adjust the market fill-timeout to 30 seconds.
self.transactions.market_order_fill_timeout = timedelta(seconds=30)
```

Market orders may take a few minutes to fill for illiquid assets such as out-of-the-money Options or penny stocks.

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with market orders, set the brokerage model to a brokerage that supports them.

```
self.set_brokerage_model(BrokerageName.QUANTCONNECT_BROKERAGE)
```

To check if your brokerage has any special requirements for market orders, see the Orders section of the brokerage model documentation .

Requirements

You can submit market orders during regular trading hours for all asset classes. For Futures and Future Options, you can place market orders during regular and extended market hours. For all other asset classes, if you place market orders at/after the last minute of regular market hours, LEAN converts the market orders into market-on-open orders as long as the asset class supports them . To view the trading hours of each asset class, follow these steps:

1. Open the Asset Classes documentation.
2. Click an asset class.
3. Click Market Hours .

Examples

The following backtest verifies the `market_order` behavior. The algorithm buys SPY on the first day and liquidates the position on the second day. The following table shows the first two trades in the backtest:

Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2021-07-01T09:31:00Z	SPY	429.11	10	Market	Filled	4291.10	
2021-07-02T09:31:00Z	SPY	431.54	-10	Market	Filled	-4315.40	

On July 1, 2021, the algorithm buys SPY at $429.11. The fill model fills this order at the ask close price.

On July 2, 2021, the algorithm sells the SPY holdings at $431.54. The fill model fills this order at the bid close price.

To reproduce these results, backtest the following algorithm:

PY

```
class MarketOrderAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 4)
        self.set_cash(100000)
        self.universe_settings.data_normalization_mode = DataNormalizationMode.RAW
        self.add_equity("SPY")

    def on_data(self, data):
        if not self.portfolio.invested and self.time.day == 1:
            self.market_order("SPY", 10)

        elif self.portfolio.invested and self.time.day != 1:
            self.market_order("SPY", -10)
```

Order Types

Limit Orders

Introduction

Limit orders are instructions to trade a quantity of an asset at a specific price or a better price. A marketable limit order has a limit price that crosses the spread. An unmarketable limit order has a limit price that doesn't cross the spread. For example, if an asset has an ask price of 100 and you place a limit order to buy at 100 or higher, that's a marketable limit order that should immediately fill. If you place a limit order to buy at $99.99 or lower, that's an unmarketable limit order that should go on the order book. Unmarketable limit orders save you from paying spread costs. Some brokerages even charge you a lower transaction fee if you use unmarketable limit orders rather than marketable limit orders.

Limit orders are helpful in illiquid markets. You can use them to get a good entry price or to set a take-profit level on an existing holding. However, if the market trades away from your limit price, you may have to adjust your limit price or wait for the market to trade back to your limit price to fill the order.

Place Orders

To send a limit order, call the `limit_order` method with a `Symbol` , quantity, and limit price. You can also provide a tag and order properties to the `limit_order` method. If you do not have sufficient capital for the order, it's rejected.

```py
self.limit_order(symbol, quantity, limit_price, tag, order_properties)
```

To buy an asset with a marketable limit order, set the limit price to the current ask price or higher.

To sell an asset with a marketable limit order, set the limit price to the current bid price or lower.

To buy an asset with an unmarketable limit order, set the limit price below the current ask price.

```py
# Buy 1 Bitcoin when the price drops to $34,000
self.limit_order("BTCUSD", 1, 34000)
```

To sell an asset with an unmarketable limit order, set the limit price above the current bid price.

```
# Sell 1 Bitcoin when the price moves up to $60,000
self.limit_order("BTCUSD", -1, 60000)
```

Monitor Order Fills

Limit orders fill when the security price passes the limit price. To monitor the fills of your order, save a reference to the order ticket .

```
# Buy 10 shares of XLK at $140
ticket = self.limit_order("XLK", 10, 140)
self.debug(f"Quantity filled: {ticket.quantity_filled}; Fill price: {ticket.average_fill_price}")
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity, limit price, and tag of limit orders until the order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `update` method returns an OrderResponse to signal the success or failure of the update request.

```
# Create a new order and save the order ticket
ticket = self.limit_order("SPY", 100, 221.05, tag="original tag")

# Update the order
update_settings = UpdateOrderFields()
update_settings.quantity = 80
update_settings.limit_price = 222.00
update_settings.tag = "new tag"
response = ticket.update(update_settings)

# Check if the update was successful
if response.is_success:
    self.debug("Order updated successfully")
```

To update individual fields of an order, call any of the following methods:

- `update_limit_price`
- `update_quantity`
- `update_tag`

```
response = ticket.update_limit_price(limit_price, tag)

response = ticket.update_quantity(quantity, tag)

response = ticket.update_tag(tag)
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `update_requests` method.

```
update_requests = ticket.update_requests()
```

Cancel Orders

To cancel a limit order, call the `cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
response = ticket.cancel("Cancelled Trade")
if response.is_success:
    self.debug("Order successfully cancelled")
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `cancel_order_request` method on the order ticket. The method returns `None` if the order hasn't been cancelled.

```
request = ticket.cancel_order_request()
```

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `True` .

```
self.limit_order("SPY", 10, 429.0, asynchronous=True);
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with limit orders, set the brokerage model to a brokerage that supports them.

```
self.set_brokerage_model(BrokerageName.QUANTCONNECT_BROKERAGE)
```

To check if your brokerage has any special requirements for limit orders, see the Orders section of the brokerage model documentation .

Requirements

Limit orders can be submitted at any time for all security types.

If your algorithm subscribes to extended market hours, they can be filled outside regular trading hours.

Examples

The following backtest verifies the `limit_order` method behavior. On the first day, the algorithm buys SPY with an unmarketable limit order. On the second day, the algorithm sells SPY with an unmarketable limit order and places another unmarketable limit order to buy SPY, which doesn't fill. The following table shows the first three trades in the backtest:

Submitted Time	Filled Time	Symbol	Limit Price	Filled Price	Quantity	Type	Status	Value	Tag
2021-07-01T09:31:00Z	2021-07-01T09:32:00Z	SPY	429.00	429.00	10	Limit	Filled	4290.00	Limit Price: ¤429.00
2021-07-02T09:31:00Z	2021-07-02T09:35:00Z	SPY	431.70	431.70	-10	Limit	Filled	-4317.00	Limit Price: ¤431.70
2021-07-02T09:31:00Z	/	SPY	400.00	/	10	Limit	Submitted	/	Limit Price: ¤400.00

On July 1, 2021 at 9:31 AM Eastern Time (ET), the algorithm places a buy limit order with a limit price of 429 when the ask low price is 428.81 and the ask high price is 429.15. The order fills at 9:32 AM ET at a price of 429. The fill model fills buy limit orders when the ask low price is less than the limit price. It sets the fill price of the order to the minimum of ask high price and the limit price.

On July 2, 2021 at 9:31 AM ET, the algorithm places a sell limit order at 431.70 and a buy limit order at 400. At the time of the order, the bid high price is 431.65, the bid low price is 431.49, and the ask low price is 431.50. The sell limit order fills at 9:35 AM ET at a price of 431.70 and the buy limit order doesn't fill. The fill model fills sell limit order when the bid high price is greater than the limit price. It sets the fill price of the order to the maximum of the bid low price and the limit price. The buy limit order doesn't fill because the ask low price is above the limit price for the remainder of the backtest period.

To reproduce these results, backtest the following algorithm:

PY

```
class LimitOrderAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.universe_settings.data_normalization_mode = DataNormalizationMode.RAW
        self.add_equity("SPY")

    def on_data(self, data):
        if self.time.day == 1 and self.time.hour == 9 and self.time.minute == 31:
            self.limit_order("SPY", 10, 429.0)

        elif self.time.day == 2 and self.time.hour == 9 and self.time.minute == 31:
            self.limit_order("SPY", -10, 431.7)
            self.limit_order("SPY", 10, 400)
```

Order Types

Limit if Touched Orders

Introduction

Limit if touched (LIT) orders are instructions to place a limit order once an asset touches a specific price level. A buy LIT order has a trigger price below the current market price and a sell LIT order has a trigger price above the current market price. In effect, LIT orders are the opposite of stop limit orders .

Place Orders

To send a LIT order, call the `limit_if_touched_order` method and provide a `Symbol` , quantity, trigger price, and limit price. You can also provide a tag and order properties to the `limit_if_touched_order` method. If you do not have sufficient capital for the order, it's rejected.

```
self.limit_if_touched_order(symbol, quantity, trigger_price, limit_price, tag, order_properties)
```

To buy an asset with a LIT order that has a marketable limit price, set the trigger price below the current market price and set the limit price above the trigger price.

```
# Once Bitcoin trades down to $36,000, place a limit order to buy 1 Bitcoin at $38,000
self.limit_if_touched_order("BTCUSD", 1, 33000, 36000)
```

To sell an asset with a LIT order that has a marketable limit price, set the trigger price above the current market price and set the limit price below the trigger price.

```
# Once Bitcoin trades up to $62,000, place a limit order to sell 1 Bitcoin at $59,000
self.limit_if_touched_order("BTCUSD", -1, 62000, 59000)
```

To buy an asset with a LIT order that has an unmarketable limit price, set the trigger price below the current market price and set the limit price below the trigger price.

```py
# Once Bitcoin trades down to $46,000, place a limit order to buy 1 Bitcoin at $36,000
self.limit_if_touched_order("BTCUSD", 1, 46000, 36000)
```

To sell an asset with a LIT order that has an unmarketable limit price, set the trigger price above the current market price and set the limit price above the trigger price.

```py
# Once Bitcoin trades up to $54,000, place a limit order to sell 1 Bitcoin at $62,000
self.limit_if_touched_order("BTCUSD", -1, 54000, 62000)
```

Monitor Order Fills

LIT orders fill when the security price touches the trigger price and is at least as favorable as the limit price. To monitor the fills of your order, save a reference to the order ticket .

```
# Once SPY trades down to $425, place a limit order to buy 10 shares at $415
ticket = self.limit_if_touched_order("SPY", 10, 425, 415)
self.debug(f"Quantity filled: {ticket.quantity_filled}; Fill price: {ticket.average_fill_price}")
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity, trigger price, limit price, and tag of LIT orders until the order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `update` method returns an OrderResponse to signal the success or failure of the update request.

```
# Create a new order and save the order ticket
ticket = self.limit_if_touched_order("SPY", 100, 350, 340, tag="Original tag")

# Update the order
update_order_fields = UpdateOrderFields()
update_order_fields.quantity = 80
update_order_fields.trigger_price = 380
update_order_fields.limit_price = 370
update_order_fields.tag = "New tag"
response = ticket.update(update_settings)

# Check the OrderResponse
if response.is_success:
    self.debug("Order updated successfully")
```

To update individual fields of an order, call any of the following methods:

- `update_limit_price`
- `update_quantity`
- `update_trigger_price`
- `update_tag`

```
response = ticket.update_limit_price(limit_price, tag)

response = ticket.update_quantity(quantity, tag)

response = ticket.update_trigger_price(trigger_price, tag)

response = ticket.update_tag(tag)
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `update_requests` method.

```
update_requests = ticket.update_requests()
```

Cancel Orders

To cancel a LIT order, call the `cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
response = ticket.cancel("Cancelled Trade")
if response.is_success:
    self.debug("Order successfully cancelled")
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `cancel_order_request` method on the order ticket. The method returns `None` if the order hasn't been cancelled.

```
request = ticket.cancel_order_request()
```

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `True` .

```
self.limit_if_touched_order("SPY", 10, 429.0, 428.95, asynchronous=True);
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with LIT orders, set the brokerage model to a brokerage that supports them.

```
self.set_brokerage_model(BrokerageName.QUANTCONNECT_BROKERAGE)
```

To check if your brokerage has any special requirements for LIT orders, see the Orders section of the brokerage model documentation .

Requirements

LIT orders can be submitted at any time for all security types.

If your algorithm subscribes to extended market hours, they can be filled outside regular trading hours.

Examples

The following backtest verifies the `limit_if_touched_order` behavior. The following table shows the trades in the backtest:

Submitted Time	Filled Time	Symbol	Trigger Price	Limit Price	Filled Price	Quantity	Type	Status	Value	Tag
2021-07-01T09:31:00Z	2021-07-01T09:38:00Z	SPY	429.00	428.95	428.95	10	Limit if touched	Filled	4285.00	Trigger Price: ¤429.00 Limit Price: ¤428.95
2021-07-02T09:31:00Z	2021-07-02T09:49:00Z	SPY	431.70	431.75	431.84	-10	Limit if touched	Filled	-4318.40	Trigger Price: ¤431.70 Limit Price: ¤431.75
2021-07-02T09:31:00Z	/	SPY	431.70	400.00	/	10	Limit if touched	Submitted	/	Trigger Price: ¤431.70 Limit Price: ¤400.00
/	/	SPY	400.00	400.00	/	10	Limit if touched	Submitted	/	Trigger Price: ¤400.00 Limit Price: ¤400.00

On July 1, 2021 at 9:31 AM Eastern Time (ET), the algorithm places a LIT order to buy SPY with a trigger price of 429 and a limit price of 428.95. At the time of the order submission, the low price was 428.80 and the bid close price was 429.10. The order fills at 9:38 AM ET at a price of $428.95. The fill model sets the limit price for buy orders when the low price is less than or equal to the trigger price, fills the order when the bid close price is less than or equal to the limit price, and sets the fill price to the minimum of the ask price and the limit price.

On July 2, 2021 at 9:31 AM ET, the algorithm places a LIT order to sell SPY with a trigger price of 431.70 and a limit price of 431.75. At the time of the order submission, the high price was 431.78 and the ask close price was 431.55. The order fills at 9:49 AM ET at a price of $431.84. The fill model sets the limit price for sell orders when the high price is greater than or equal to the trigger price, fills the order when the ask close price is greater than or equal to the limit price, and sets the fill price to the maximum of the bid price and the limit price.

On July 2, 2021, the algorithm places a third LIT order to buy SPY with a trigger price of 431.70 and a limit price of 400. The fill model sets the fill price, but it doesn't fill the order because the limit price is too low. On the same day, the algorithm places a fourth LIT order to buy SPY with a trigger price of 400 and a limit price of 400. The fill model doesn't set the limit price for this order because SPY doesn't touch the trigger price before the backtest ends.

To reproduce these results, backtest the following algorithm:

```
class LimitIfTouchedOrderAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 4)
        self.set_cash(100000)
        self.universe_settings.data_normalization_mode = DataNormalizationMode.RAW
        self.add_equity("SPY")

    def on_data(self, data):
        if self.time.day == 1 and self.time.hour == 9 and self.time.minute == 31:
            self.limit_if_touched_order("SPY", 10, 429.0, 428.95)

        elif self.time.day == 2 and self.time.hour == 9 and self.time.minute == 31:
            self.limit_if_touched_order("SPY", -10, 431.7, 431.75)
            self.limit_if_touched_order("SPY", 10, 431.7, 400)
            self.limit_if_touched_order("SPY", 10, 400, 400)
```

Order Types

Stop Market Orders

Introduction

Stop market orders fill as a market order when the asset reaches a specific price. A buy stop market order triggers when the asset price is greater than or equal to the stop price. A sell stop market order triggers when the asset price is less than or equal to the stop price. You can use stop market orders to buy breakouts or to mitigate the risk of large losses. However, if the market gaps past your stop price, the order may fill at a worse price than the stop price you set. There is no guarantee that a stop market order fills at the stop price.

Place Orders

To send a stop market order, call the `stop_market_order` method and provide a `Symbol` , quantity, and stop price. You can also provide a tag and order properties to the `stop_market_order` method. If you do not have sufficient capital for the order, it is rejected.

```py
self.stop_market_order(symbol, quantity, stop_price, tag, order_properties)
```

To buy an asset with a stop market order, set the stop price above the current ask price.

```py
# When Bitcoin trades up to $60,000, buy 1 Bitcoin
self.stop_market_order("BTCUSD", 1, 60000)
```

To sell an asset with a stop market order, set the stop price below the current bid price.

```py
# When Bitcoin trades down to $43,000, sell 1 Bitcoin
self.stop_market_order("BTCUSD", -1, 43000)
```

Monitor Order Fills

Stop market orders fill as a market order when the security price passes the stop price. To monitor the fills of your order, save a reference to the order ticket .

```py
# When XLK trades down to $130, sell 10 shares
ticket = self.stop_market_order("XLK", -10, 130)
self.debug(f"Quantity filled: {ticket.quantity_filled}; Fill price: {ticket.average_fill_price}")
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity, stop price, and tag of stop market orders until the order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `update` method returns an OrderResponse to signal the success or failure of the update request.

```py
# Create a new order and save the order ticket
ticket = self.stop_market_order("SPY", -100, 415, tag="original tag")

# Update the order
update_settings = UpdateOrderFields()
update_settings.quantity = -80
update_settings.stop_price = 400
update_settings.tag = "new tag"
response = ticket.update(update_settings)

# Check if the update was successful
if response.is_success:
    self.debug("Order updated successfully")
```

To update individual fields of an order, call any of the following methods:

- `update_quantity`
- `update_stop_price`
- `update_tag`

```py
response = ticket.update_quantity(quantity, tag)

response = ticket.update_stop_price(stop_price, tag)

response = ticket.update_tag(tag)
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `update_requests` method.

```
update_requests = ticket.update_requests()
```

Cancel Orders

To cancel a stop market order, call the `cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
response = ticket.cancel("Cancelled Trade")
if response.is_success:
    self.debug("Order successfully cancelled")
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `cancel_order_request` method on the order ticket. The method returns `None` if the order hasn't been cancelled.

```
request = ticket.cancel_order_request()
```

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `True` .

```
self.stop_market_order("SPY", 10, 429.0, asynchronous=True);
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with stop market orders, set the brokerage model to a brokerage that supports them.

```
self.set_brokerage_model(BrokerageName.QUANTCONNECT_BROKERAGE)
```

To check if your brokerage has any special requirements for stop market orders, see the Orders section of the brokerage model documentation .

Requirements

Stop market orders can be submitted at any time for all security types.

Examples

The following backtest verifies the `stop_market_order` behavior. On even days, the algorithm buys SPY at the current market price and sells when the price drops 1%. On odd days, the algorithm shorts SPY and buys when the price rises 1%. The following table shows the first four trades in the backtest:

Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2021-07-01T13:31:00Z	SPY	429.10	-1	Market	Filled	-429.10	
2021-07-01T13:31:00Z	SPY	433.44	1	Stop Market	Filled	433.44	Stop Price: 433.43
2021-07-02T17:04:00Z	SPY	433.44	1	Market	Filled	433.44	
2021-07-02T17:04:00Z	SPY	429.00	-1	Stop Market	Filled	-429.00	Stop Price: 429.10

On July 1, 2021, the algorithm shorts SPY at 429.10 and then buys it back at 433.44 when the stop price is 433.43. The stop price is 1% above the market price. Note that 429.10 is not the market price when the algorithm places the first two orders.429.10 is the fill price at the bid, but it's not far from the market price because 429.1 * 1.01 = 433.39. The fill price of the stop market order is 433.44, which, as expected, is higher than $433.43. The fill model assumes the worst-case scenario between the market price and the stop price. In this case, the worst-case scenario is the maximum of the market price and stop price.

On July 2, 2021, the algorithm buys SPY at 433.44 and sells it at 429 when the stop price is 429.10. The stop price is 1% below the market price. Note that 433.44 is not the market price when the algorithm places the second two orders.433.44 is the fill price at the ask, but it's not far off from the market price because 433.44 * 0.99 = 429.11. The fill price of the stop market order is 429, which, as expected, is lower than $429.10. The fill model assumes the worst-case scenario between the market price and the stop price. In this case, the worst-case scenario is the minimum of the market price and stop price.

To reproduce these results, backtest the following algorithm:

PY

```
class StopMarketOrderAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 7)
        self.set_cash(100000)
        self.universe_settings.data_normalization_mode = DataNormalizationMode.RAW
        self.add_equity("SPY")

    def on_data(self, data):
        if not self.portfolio.invested:
            quantity = 1
            factor = 0.99
            if self.time.day % 2 != 0:
                quantity = -1
                factor = 1.01

            self.market_order("SPY", quantity)
            self.stop_market_order("SPY", -quantity, data["SPY"].close * factor)
```

Order Types

Stop Limit Orders

Introduction

Stop limit orders are instructions to place a limit order once an asset passes a specific price level. They are similar to stop market orders , but use limit orders instead of market orders to give you more control over the fill price. A buy stop limit order has a stop price above the current market price and a sell stop limit order has a stop price below the current market price. In effect, they are the opposite of limit if touched orders .

Place Orders

To send a stop limit order, call the `stop_limit_order` method and provide a `Symbol` , quantity, stop price, and limit price. You can also provide a tag and order properties to the `stop_limit_order` method. If you do not have sufficient capital for the order, it is rejected.

```py
self.stop_limit_order(symbol, quantity, stop_rice, limit_price, tag, order_properties)
```

To buy an asset with a stop limit order that has a marketable limit price, set the stop price above the current market price and set the limit price above the stop price.

```py
# When Bitcoin trades up to $59,000, buy 1 Bitcoin with a limit order at $62,000
self.stop_limit_order("BTCUSD", 1, 59000, 62000)
```

To buy an asset with a stop limit order that has an unmarketable limit price, set the stop price above the current market price and set the limit price below the stop price.

```py
# When Bitcoin trades up to $52,000, buy 1 Bitcoin with a limit order at $41,000
self.stop_limit_order("BTCUSD", 1, 52000, 41000)
```

To sell an asset with a stop limit order that has an unmarketable limit price, set the stop price below the current market price and set the limit price above the stop price.

```py
# When Bitcoin trades down to $49,000, sell 1 Bitcoin with a limit order at $58,000
self.stop_limit_order("BTCUSD", -1, 49000, 58000)
```

To sell an asset with a stop limit order that has a marketable limit price, set the stop price below the current market price and set the limit price below the stop price.

```py
# When Bitcoin trades down to $37,000, sell 1 Bitcoin with a limit order at $34,000
self.stop_limit_order("BTCUSD", -1, 37000, 34000)
```

Monitor Order Fills

Stop limit orders fill as limit orders when the security price passes the stop price. To monitor the fills of your order, save a reference to the order ticket .

```
# When GLD trades up to $200, buy 10 shares with a limit order at $205
ticket = self.stop_limit_order("GLD", 10, 200, 205)
self.debug(f"Quantity filled: {ticket.quantity_filled}; Fill price: {ticket.average_fill_price}")
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity, stop price, limit price, and tag of stop limit orders until the order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `update` method returns an OrderResponse to signal the success or failure of the update request.

```
# Create a new order and save the order ticket
ticket = self.stop_limit_order("SPY", -10, 400, 390, tag="original tag")

# Update the order
update_settings = UpdateOrderFields()
update_settings.quantity = -15
update_settings.stop_price = 415
update_settings.limit_price = 395
update_settings.tag = "new tag"
response = ticket.update(update_settings)

# Check if the update was successful
if response.is_success:
    self.debug("Order updated successfully")
```

To update individual fields of an order, call any of the following methods:

- `update_limit_price`
- `update_quantity`
- `update_stop_price`
- `update_tag`

```
response = ticket.update_limit_price(limit_price, tag)

response = ticket.update_quantity(quantity, tag)

response = ticket.update_stop_price(stop_price, tag)

response = ticket.update_tag(tag)
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `update_requests` method.

```
update_requests = ticket.update_requests()
```

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `True` .

```
self.stop_limit_order("SPY", -10, 428.95, 429.00, asynchronous=True);
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with stop limit orders, set the brokerage model to a brokerage that supports them.

```
self.set_brokerage_model(BrokerageName.QUANTCONNECT_BROKERAGE)
```

To check if your brokerage has any special requirements for stop limit orders, see the Orders section of the brokerage model documentation .

Requirements

Stop limit orders can be submitted at any time for all security types.

If your algorithm subscribes to extended market hours, they can be filled outside regular trading hours.

Examples

The following backtest verifies the `stop_limit_order` behavior. The following table shows the trades in the backtest:

Submitted Time	Filled Time	Symbol	Stop Price	Limit Price	Filled Price	Quantity	Type	Status	Value	Tag
2021-07-01T09:31:00Z	2021-07-01T09:37:00Z	SPY	428.95	429.00	429.00	-10	Stop Limit	Filled	-4290.00	Stop Price: ¤428.95 Limit Price: ¤429.00
2021-07-02T09:31:00Z	2021-07-02T10:12:00Z	SPY	431.80	431.75	431.75	10	Stop Limit	Filled	4317.50	Stop Price: ¤431.80 Limit Price: ¤431.75

On July 1, 2021 at 9:31 AM Eastern Time (ET), the algorithm places a stop limit order to sell SPY with a stop price of 428.95 and a limit price of 429. At the time of the order submission, the ask high price is 429.16 and the ask close price is 429.11. The order fills at 9:37 AM ET at a price of $429. The fill model triggers the stop for buy orders when the ask high price is greater than the stop price, fills the order when the ask close price is less than the limit price, and sets the fill price to the maximum of the ask high price and the limit price.

On July 2, 2021 at 9:31 AM ET, the algorithm places a stop limit order to buy SPY with a stop price of 431.80 and a limit price of 431.75. At the time of the order submissions, the bid low price is 431.49 and the bid close price is 431.54. The order fills at 10:12 AM ET at a price of $431.75. The fill model triggers the stop for sell orders when bid low price is less than the stop price, fills the order when the ask close price is less than the limit price, and sets the fill price to the minimum of the ask high price and the limit price.

PY

```
class StopLimitOrderAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 4)
        self.set_cash(100000)
        self.universe_settings.data_normalization_mode = DataNormalizationMode.RAW
        self.add_equity("SPY")

    def on_data(self, data):
        if self.time.day == 1 and self.time.hour == 9 and self.time.minute == 31:
            self.stop_limit_order("SPY", -10, 428.95, 429.00)

        elif self.time.day == 2 and self.time.hour == 9 and self.time.minute == 31:
            self.stop_limit_order("SPY", 10, 431.80, 431.75)
```

Order Types

Trailing Stop Orders

Introduction

Trailing stop orders are stop market orders with a dynamic stop price. A sell trailing stop starts with the stop price at a fixed amount below the market price. As the market price rises, the stop price rises by the trail amount, but if the stock price falls, the stop loss price doesn't change. A buy trailing stop order starts with the stop price at a fixed amount above the market price. As the market price falls, the stop price falls by the trail amount, but if the stock price rises, the stop loss price doesn't change.

Trailing stop orders fill as a market order when the asset reaches the stop price. You can use trailing stop orders to buy breakouts or to mitigate the risk of large losses while protecting your gains. However, if the market gaps past your stop price, the order may fill at a worse price than the stop price you set. There's no guarantee that a trailing stop order fills at the stop price.

Place Orders

To send a trailing stop order, call the `trailing_stop_order` method and provide a `Symbol` , quantity, trailing amount, and the trailing type. You can also provide a tag and order properties to the `trailing_stop_order` method. If you do not have sufficient capital for the order, it is rejected.

```
self.trailing_stop_order(symbol, quantity, trailing_amount, trailing_as_percentage, tag, order_properties)
```

If you set the `trailing_as_percentage` parameter to `False` , the `trailing_amount` is denominated in the asset's quote currency .

Buy With a Currency-Based Trailing Stop

To buy an asset with a currency-based trailing stop order, pass the trailing amount and disable the `trailing_as_percentage` parameter.

```
# Buy 1 share of SPY through a trailing stop order that starts $30 above the current price
self.trailing_stop_order("SPY", 1, 30, False)
```

Buy With a Percent-Based Trailing Stop

To buy an asset with a percent-based trailing stop order, pass the trailing percent and enable the `trailing_as_percentage` parameter.

```py
# Buy 1 share of SPY through a trailing stop order that starts 7% above the current price
self.trailing_stop_order("SPY", 1, 0.07, True)
```

Sell With a Currency-Based Trailing Stop

To sell an asset with a currency-based trailing stop order, pass the trailing amount and disable the `trailing_as_percentage` parameter.

```py
# Sell 1 share of SPY through a trailing stop order that starts $20 below the current price
self.trailing_stop_order("SPY", -1, 20, False)
```

Sell With a Percent-Based Trailing Stop

To sell an asset with a percent-based trailing stop order, pass the trailing percent and enable the `trailing_as_percentage` parameter.

```
# Sell 1 share of SPY through a trailing stop order that starts 5% above the current price
self.trailing_stop_order("SPY", -1, 0.05, True)
```

Custom Starting Prices

In the preceding examples, LEAN calculates the stop price based on the current security price. If you want the order to start with a stop price closer to the security price than the `trailing_amount` , pass a `stop_price` parameter to the `trailing_stop_order` method.

```
self.trailing_stop_order(symbol, quantity, stop_price, trailing_amount, trailing_as_percentage, tag, order_properties)
```

Monitor Order Fills

Trailing stop orders fill as a market order when the security price passes the stop price. To monitor the fills of your order, save a reference to the order ticket .

```
# When XLK trades down to less than 5% of the current price
ticket = self.trailing_stop_order("XLK", -10, 0.05, trailing_as_percentage=True)
self.debug(f"Quantity filled: {ticket.quantity_filled}; Fill price: {ticket.average_fill_price}")
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

The security's fill model automatically updates the stop price of trailing stop orders as the security's price moves away from the stop price. You can update the quantity, stop price, and tag of trailing stop orders until the order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `update` method returns an OrderResponse to signal the success or failure of the update request.

```
# Create a new order and save the order ticket
ticket = self.trailing_stop_order("SPY", -100, 415, 10, trailing_as_percentage=False, tag="original tag")

# Update the order
update_settings = UpdateOrderFields()
update_settings.quantity = -80
update_settings.stop_price = 400
update_settings.tag = "new tag"
response = ticket.update(update_settings)

# Check if the update was successful
if response.is_success:
     self.debug("Order updated successfully")
```

To update individual fields of an order, call any of the following methods:

- `update_quantity`
- `update_stop_price`
- `update_tag`

```
response = ticket.update_quantity(quantity, tag)

response = ticket.update_stop_price(stop_price, tag)

response = ticket.update_tag(tag)
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `update_requests` method.

```
update_requests = ticket.update_requests()
```

Cancel Orders

To cancel a trailing stop order, call the `cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
response = ticket.cancel("Cancelled Trade")
if response.is_success:
    self.debug("Order successfully cancelled")
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `cancel_order_request` method on the order ticket. The method returns `None` if the order hasn't been cancelled.

```
request = ticket.cancel_order_request()
```

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `True` .

```
self.trailing_stop_order("SPY", -100, 0.01, trailing_as_percentage=True, asynchronous=True);
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with trailing stop orders, set the brokerage model to a brokerage that supports them.

```
self.set_brokerage_model(BrokerageName.QUANTCONNECT_BROKERAGE)
```

To check if your brokerage has any special requirements for trailing stop orders, see the Orders section of the brokerage model documentation .

If your brokerage doesn't support them, you can implement a workaround with stop market orders . For an example, see the Buy and Hold with a Trailing Stop Bootcamp lesson.

Requirements

Trailing stop orders can be submitted at any time for all security types.

Examples

The following backtest verifies the `trailing_stop_order` behavior. On even days, the algorithm buys SPY at the current market price and sells when the price drops 1%. On odd days, the algorithm shorts SPY and buys when the price rises 1%. The following table shows the first four trades in the backtest:

Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2021-07-01T13:31:00Z	SPY	429.10	-1	Market	Filled	-429.10	
2021-07-01T13:31:00Z	SPY	433.16	1	Trailing Stop	Filled	433.16	Stop Price: 433.431400 Trailing Amount: 1.00%
2021-07-02T16:53:00Z	SPY	433.16	1	Market	Filled	433.16	
2021-07-02T16:53:00Z	SPY	429.00	-1	Trailing Stop	Filled	-429.00	Stop Price: 428.823450 Trailing Amount: 1.00%

On July 1, 2021, the algorithm shorts SPY at 429.10 and then buys it back at 433.16 when the stop price is 433.16. The stop price is 0.95% above the market price. Note that 429.10 is not the market price when the algorithm places the first two orders. The market price is429.14, and the initial stop price is 429.14 * 1.01 = 433.4314. The market price drops to 428.86 at 9:40, and the stop price is set to 428.86 * 1.01 = 433.1486. The fill price of the stop market order is 433.16, which, as expected, is higher than 433.15. The fill model assumes the worst-case scenario between the market price and the stop price. In this case, the worst-case scenario is the maximum of the market price and stop price.

On July 2, 2021, the algorithm buys SPY at 433.16 and then sells it at 429 when the stop price is 429.00. The stop price is 0.96% below the market price. Note that 433.16 is not the market price when the algorithm places the second two orders. The market price is433.155, and the initial stop price is 433.155 * 0.99 = 428.82345. The market prices increased to 434.76 on July 7 at 3:35 PM, and the stop price is set to 434.76 * 0.99 = 430.4124. The fill price of the stop market order is 429, which, as expected, is lower than 430.41. The fill model assumes the worst-case scenario between the market price and the stop price. In this case, the worst-case scenario is the minimum of the market price and stop price in a gap down opening.

To reproduce these results, backtest the following algorithm:

PY

```
class TrailingStopOrderAlgorithm(QCAlgorithm):
    trailing_amount = 0.01

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 9)
        self.set_cash(100000)

        self.symbol = self.add_equity("SPY", data_normalization_mode = DataNormalizationMode.RAW).symbol

    def on_data(self, data):
        if not self.portfolio.invested:
            quantity = 1 if self.time.day % 2 == 0 else -1

            self.market_order(self.symbol, quantity)
            self.trailing_stop_order(self.symbol, -quantity, self.trailing_amount, True)
```

Order Types

Market On Open Orders

Introduction

Market on open (MOO) orders fill at the official opening auction price for a security. Market that operate 24/7 don't support MOO orders.

Place Orders

To send a MOO order, call the `market_on_open_order` method and provide a `Symbol` and quantity. Submit the order at least two minutes before the market opens to be included in the opening auction. If you do not have sufficient capital for the order, it's rejected.

```py
# Buy 100 shares of IBM at the market open
self.market_on_open_order("IBM", 100)

# Sell 100 shares of IBM at the market open
self.market_on_open_order("IBM", -100)
```

You can provide a tag and order properties to the `market_on_open_order` method.

```py
self.market_on_open_order(symbol, quantity, tag=tag, order_properties=order_properties)
```

Monitor Order Fills

MOO orders fill at the opening auction. If the auction is heavily skewed to one side of the market, your MOO order may not fill. To monitor the fills of your order, save a reference to the order ticket .

```py
# Buy 10 shares of SPY at the market open
ticket = self.market_on_open_order("SPY", 10)
self.debug(f"Quantity filled: {ticket.quantity_filled}; Fill price: {ticket.average_fill_price}")
```

You won't know the fill price of the order until after the market opens. If the asset price moves before the market open to where you can't afford the quantity of the order, the brokerage rejects your order. To increase the probability of a successful trade, leave a sufficient buying power buffer to handle daily price gaps.

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity and tag of MOO orders until the order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `update` method returns an OrderResponse to signal the success or failure of the update request.

```py
# Create a new order and save the order ticket
ticket = self.market_on_open_order("AAPL", 100, tag="original tag")

# Update the order
update_settings = UpdateOrderFields()
update_settings.quantity = 75
update_settings.tag = "new tag"
response = ticket.update(update_settings)

# Check if the update was successful
if response.is_success:
    self.debug("Order updated successfully")
```

To update individual fields of an order, call any of the following methods:

- `update_quantity`
- `update_tag`

```
response = ticket.update_quantity(quantity, tag)

response = ticket.update_tag(tag)
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `update_requests` method.

```
update_requests = ticket.update_requests()
```

Cancel Orders

To cancel a MOO order, call the `cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
response = ticket.cancel("Cancelled Trade")
if response.is_success:
    self.debug("Order successfully cancelled")
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `cancel_order_request` method on the order ticket. The method returns `None` if the order hasn't been cancelled.

```
request = ticket.cancel_order_request()
```

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `True` .

```
self.market_on_open_order("SPY", 10, asynchronous=True);
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with MOO orders, set the brokerage model to a brokerage that supports them.

```
self.set_brokerage_model(BrokerageName.QUANTCONNECT_BROKERAGE)
```

To check if your brokerage has any special requirements for MOO orders, see the Orders section of the brokerage model documentation .

Requirements

You can submit MOO orders at any time for Equity, Equity Options, and Index Options.

Markets that operate 24/7 don't support MOO orders. The Forex market doesn't operate during the weekend. However, MOO orders are invalid if you place them after this market closes for the weekend.

MOO orders don't support the `GoodTilDate` time in force . If you submit a MOO order with the `GoodTilDate` time in force, LEAN automatically adjusts the time in force to be `GoodTilCanceled` .

Examples

The following backtest verifies the `market_on_open_order` behavior. The following table shows the first trade in the backtest:

Submitted Time	Filled Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2021-07-01T10:31:00Z	2021-07-02T09:31:00Z	SPY	431.67	10	Market On Open	Filled	4316.70	

On July 1, 2021 at 10:31 AM Eastern Time (ET), the algorithm places a market on open order to buy SPY. The fill model fills the order on July 2, 2021 at 9:31 AM at a price of $431.67, which is the official opening auction price for July 2, 2021.

To reproduce these results, backtest the following algorithm:

```py
class MarketOnOpenOrderAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 4)
        self.set_cash(100000)
        self.universe_settings.data_normalization_mode = DataNormalizationMode.RAW
        self.add_equity("SPY")

    def on_data(self, data):
        if self.time.day == 1 and self.time.hour == 10 and self.time.minute == 31:
            self.market_on_open_order("SPY", 10)
```

Order Types

Market On Close Orders

Introduction

Market on close (MOC) orders fill at the official closing auction price for a security. Markets that operate 24/7 don't support MOC orders.

Place Orders

To send a MOC order, call the `market_on_close_order` method with a `Symbol` and quantity. If you don't have sufficient capital for the order, it is rejected.

```
PY
# Buy 100 shares of AAPL at the market open
self.market_on_close_order("AAPL", 100)

# Sell 100 shares of AAPL at the market open
self.market_on_close_order("AAPL", -100)
```

You can provide a tag and order properties to the `market_on_close_order` method.

```
PY
self.market_on_close_order(symbol, quantity, tag=tag, order_properties=order_properties)
```

By default, you must place MOC orders at least 15.5 minutes before the close, but some exchanges let you submit them closer to the market closing time. To adjust the buffer period that's required, set the `MarketOnCloseOrder.submission_time_buffer` property.

```
PY
MarketOnCloseOrder.submission_time_buffer = timedelta(minutes=10)
```

You can also place MOC orders after the market close.

Monitor Order Fills

MOC orders fill at the closing auction. If the auction is heavily skewed to one side of the market, your MOC order may not fill. To monitor the fills of your order, save a reference to the order ticket .

```
PY
# Buy 10 shares of SPY at the market close
ticket = self.market_on_close_order("SPY", 10)
self.debug(f"Quantity filled: {ticket.quantity_filled}; Fill price: {ticket.average_fill_price}")
```

You won't know the fill price of the order until after the market closes. If the asset price moves before the market close to where you can't afford the quantity of the order, the brokerage rejects your order. To increase the probability of a successful trade, leave a sufficient buying power buffer to handle the price movements before the close.

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity and tag of MOC orders until the order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `update` method returns an OrderResponse to signal the success or failure of the update request.

```
# Create a new order and save the order ticket
ticket = self.market_on_open_order("SLV", 25, tag="original tag")

# Update the order
update_settings = UpdateOrderFields()
update_settings.quantity = 50
update_settings.tag = "new tag"
response = ticket.update(update_settings)

# Check if the update was successful
if response.is_success:
    self.debug("Order updated successfully")
```

To update individual fields of an order, call any of the following methods:

- `update_quantity`
- `update_tag`

```
response = ticket.update_quantity(quantity, tag)

response = ticket.update_tag(tag)
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `update_requests` method.

```
update_requests = ticket.update_requests()
```

Cancel Orders

To cancel a MOC order, call the `cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
response = ticket.cancel("Cancelled Trade")
if response.is_success:
    self.debug("Order successfully cancelled")
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `cancel_order_request` method on the order ticket. The method returns `None` if the order hasn't been cancelled.

```
request = ticket.cancel_order_request()
```

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `True` .

```
self.market_on_close_order("SPY", 10, asynchronous=True);
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with MOC orders, set the brokerage model to a brokerage that supports them.

```
self.set_brokerage_model(BrokerageName.QUANTCONNECT_BROKERAGE)
```

To check if your brokerage has any special requirements for MOC orders, see the Orders section of the brokerage model documentation .

Requirements

By default, you must place MOC orders at least 15.5 minutes before the close, but some exchanges let you submit them closer to the market closing time. To adjust the buffer period that's required, set the `MarketOnCloseOrder.submission_time_buffer` property.

```
MarketOnCloseOrder.submission_time_buffer = timedelta(minutes=10)
```

Markets that operate 24/7 don't support MOC orders. The Forex market doesn't operate during the weekend.

MOC orders don't support the `GoodTilDate` time in force . If you submit a MOC order with the `GoodTilDate` time in force, LEAN automatically adjusts the time in force to be `GoodTilCanceled` .

Examples

The following backtest verifies the `market_on_close_order` behavior. The following table shows the first trade in the backtest:

Submitted Time	Filled Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2021-07-01T10:31:00Z	2021-07-01T16:00:00Z	SPY	430.43	10	Market On Close	Filled	4304.30	

On July 1, 2021 at 10:31 AM Eastern Time (ET), the algorithm places a market on open order to buy SPY. The fill model fills the order on July 1, 2021 at 4:00 PM ET at a price of $430.43, which is the official closing auction price for July 1, 2021.

To reproduce these results, backtest the following algorithm:

```
class MarketOnCloseOrderAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 4)
        self.set_cash(100000)
        self.universe_settings.data_normalization_mode = DataNormalizationMode.RAW
        self.add_equity("SPY")

    def on_data(self, data):
        if self.time.day == 1 and self.time.hour == 10 and self.time.minute == 31:
            self.market_on_close_order("SPY", 10)
```

Order Types

Combo Market Orders

Introduction

Combo market orders are individual orders that contain market orders for multiple securities. Combo market orders currently only work for trading Option contracts.

Place Orders

To send a combo market order, create multiple `Leg` objects to represent the legs of the combo order, then call the `combo_market_order` method. At least one leg must have a positive quantity and at least one leg must have a negative quantity. The legs must each target a unique contract. If you don't have sufficient capital for the order, it's rejected. By default, combo market orders are synchronous and fill immediately.

```
PY
for canonical_symbol, chain in slice.option_chains.items():
    # Select contracts
    contracts = [c for c in chain][:2]
    if len(contracts) < 2:
        return

    # Create order legs
    legs = []
    quantities = [1, -1]
    for i, contract in enumerate(contracts):
        legs.append(Leg.create(contract.symbol, quantities[i]))

    # Place order
    self.combo_market_order(legs, 1)
```

The quantity of the legs sets the ratio of the leg orders while the quantity argument of the `combo_market_order` method sets the combo order size and acts as a global multiplier. In the preceding example, if we set the global multiplier to two, then the algorithm buys two units of the first contract and sells two units of the second contract. The quantity argument of the `combo_market_order` method also sets the order direction of the combo order, which affects how the fill model fills the order.

You can also provide a tag and order properties to the `combo_market_order` method.

```
PY
self.combo_market_order(legs, quantity, tag=tag, order_properties=order_properties)
```

Monitor Order Fills

If the brokerage has sufficient liquidity in their order book, combo market orders fill immediately. Otherwise, you get partial fills. To monitor the fills of your order, save a reference to the order tickets .

```
PY
ticket = self.combo_market_order(legs, 1)
for ticket in tickets:
    self.debug(f"Symbol: {ticket.symbol}; Quantity filled: {ticket.quantity_filled}; Fill price: {ticket.average_fill_price}")
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Cancel Orders

To cancel a combo market order, call the `cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
PY
response = ticket.cancel("Cancelled Trade")
if response.is_success:
    self.debug("Order successfully cancelled")
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `cancel_order_request` method on the order ticket. The method returns `None` if the order hasn't been cancelled.

```
request = ticket.cancel_order_request()
```

PY

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `True` .

```
self.combo_market_order(legs, quantity, asynchronous=True);
```

PY

Synchronous Timeouts

Combo market orders are synchronous by default, so your algorithm waits for the order to fill before moving to the next line of code. If your order takes longer than five seconds to fill, your algorithm continues executing even if the trade isn't filled. To adjust the timeout period, set the `transactions.market_order_fill_timeout` property.

```
 # Adjust the market fill-timeout to 30 seconds.
self.transactions.market_order_fill_timeout = timedelta(seconds=30)
```

PY

Combo market orders may take a few minutes to fill for illiquid assets such as out-of-the-money Options.

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with combo market orders, set the brokerage model to a brokerage that supports them.

```
self.set_brokerage_model(BrokerageName.QUANTCONNECT_BROKERAGE)
```

PY

To check if your brokerage has any special requirements for combo market orders, see the Orders section of the brokerage model documentation .

Requirements

You can submit combo market orders during regular trading hours for all asset classes. For Futures and Future Options, you can place combo market orders during regular and extended market hours. For all other asset classes, if you place combo market orders at/after the last minute of regular market hours, LEAN converts the combo market orders into market-on-open orders as long as the asset class supports them . To view the trading hours of each asset class, follow these steps:

1. Open the Asset Classes documentation.
2. Click an asset class.
3. Click Market Hours .

Examples

The following backtest verifies the `combo_market_order` behavior. The algorithm buys one contract and sells one contract at the same time. The following table shows the two trades in the backtest:

Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2015-12-24T09:31:00Z	GOOG 160115C00745000	16.90	1	Buy	Filled	16.90	
2015-12-24T09:31:00Z	GOOG 160115C00747500	14.20	-1	Sell	Filled	-14.20	

On December 24, 2015, the algorithm buys GOOG 16011SC00745000 at 16.90 and sells GOOG 160115C00747500 at 14.20. The fill model fills the buy order at the ask close price and fills the sell order at the bid close price.

To reproduce these results, backtest the following algorithm:

```py
class ComboMarketOrderAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 12, 24)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        option = self.add_option("GOOG")
        option.set_filter(min_strike=-2, max_strike=2, min_expiry=timedelta(days=0), max_expiry=timedelta(days=180))

    def on_data(self, data: Slice):
        if self.portfolio.invested:
            return

        for canonical_symbol, chain in data.option_chains.items():
            contracts = [c for c in chain][:2]
            if len(contracts) < 2:
                return

            quantities = [1, -1]
            legs = []
            for i, contract in enumerate(contracts):
                legs.append(Leg.create(contract.symbol, quantities[i]))

            tickets = self.combo_market_order(legs, 1)
```

Order Types

Combo Limit Orders

Introduction

Combo limit orders are individual orders that contain limit orders for muliple securities. Combo limit orders are different from combo leg limit orders because you must set the limit price of all the leg orders to be the same with combo limit orders. With combo leg limit orders, you can create the order without forcing each leg to have the same limit price. Combo limit orders currently only work for trading Option contracts and their underlying Equities.

Place Orders

To send a combo limit order, create multiple `Leg` objects to represent the legs of the combo order, then call the `combo_limit_order` method. At least one leg must have a positive quantity and a tleast one leg must have a negative quantity. The legs must each target a unique contract, but don't set the `OrderPrice` property for any of the legs. If you don't have sufficient capital for the order, it's rejected.

```
PY
for canonical_symbol, chain in slice.option_chains.items():
    # Select contracts
    contracts = [c for c in chain][:2]
    if len(contracts) < 2:
        return

    # Create order legs
    legs = []
    quantities = [1, -1]
    for i, contract in enumerate(contracts):
        legs.append(Leg.create(contract.symbol, quantities[i]))

    # Calculate limit price
    limit_price = round(sum([self.securities[leg.symbol].close for leg in legs]) * 0.95, 2)

    # Place order
    self.combo_limit_order(legs, 1, limit_price)
```

The quantity of the legs sets the ratio of the leg orders while the quantity argument of the `combo_limit_order` method sets the combo order size and acts as a global multiplier. In the preceding example, if we set the global multiplier to two, then the algorithm buys two units of the first contract and sells two units of the second contract. The quantity also sets the order direction of the combo limit order, which affects how the fill model fills the order.

You can also provide a tag and order properties to the `combo_limit_order` method.

```
PY
self.combo_limit_order(legs, quantity, limit_price, tag=tag, order_properties=order_properties)
```

Monitor Order Fills

Combo limit orders fill all the legs at the same time. Each leg can fill when the sum of the security prices of the legs pass the limit price of the combo order. To monitor the fills of your order, save a reference to the order tickets .

```
PY
tickets = self.combo_limit_order(legs, 1, limit_price)
for ticket in tickets:
    self.debug(f"Symbol: {ticket.symbol}; Quantity filled: {ticket.quantity_filled}; Fill price: {ticket.average_fill_price}")
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity, limit price, and tag of the limit orders in each leg until the combo order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . To update the limit price of the combo order, you only need to update the limit price of one of the leg orders. The `update`

method returns an OrderResponse to signal the success or failure of the update request.

```
# Create a new order and save the order tickets
tickets = self.combo_limit_order(legs, 1, limit_price)

# Update the leg orders
for ticket in tickets:
    update_settings = UpdateOrderFields()
    update_settings.quantity = 2 * np.sign(ticket.quantity)
    update_settings.limit_price = ticket.get(OrderField.LIMIT_PRICE) + 0.01
    update_settings.tag = f"Update #{len(ticket.update_requests) + 1}"
    response = ticket.update(update_settings)

    # Check if the update was successful
    if response.is_success:
        self.debug(f"Order updated successfully for {ticket.symbol}")
```

To update individual fields of an order, call any of the following methods:

- `update_limit_price`
- `update_quantity`
- `update_tag`

```
response = ticket.update_limit_price(limit_price, tag)

response = ticket.update_quantity(quantity, tag)

response = ticket.update_tag(tag)
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `update_requests` method.

```
update_requests = ticket.update_requests()
```

Cancel Orders

To cancel a combo limit order, call the `cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
response = ticket.cancel("Cancelled Trade")
if response.is_success:
    self.debug("Order successfully cancelled")
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `cancel_order_request` method on the order ticket. The method returns `None` if the order hasn't been cancelled.

```
request = ticket.cancel_order_request()
```

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `True` .

```
self.combo_limit_order(legs, 1, limit_price, asynchronous=True);
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with combo limit orders, set the brokerage model to a brokerage that supports them.

```py
self.set_brokerage_model(BrokerageName.QUANTCONNECT_BROKERAGE)
```

To check if your brokerage has any special requirements for combo limit orders, see the Orders section of the brokerage model documentation .

Requirements

Combo limit orders can be submitted at any time for all security types.

If your algorithm subscribes to extended market hours, they can be filled outside regular trading hours.

Examples

The following backtest verifies the `combo_limit_order` behavior. The algorithm buys one contract and sells one contract at the same time. The following table shows the two trades in the backtest:

Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2015-12-24T09:31:00Z	GOOG 16011SC00745000	16.50	1	Buy	Filled	16.50	
2015-12-24T09:31:00Z	GOOG 160115C00747500	14.60	-1	Sell	Filled	-14.60	

On December 24, 2015 at 9:31 AM Eastern Time (ET), the algorithm places a combo limit order to buy one GOOG 16011SC00745000 contract and sell one GOOG 160115C00747500 contracts. The limit price is 75% of the contract spread, which equals 2.02. The combo order doesn't fill immediately because the contract spread 2.40 > 2.02. By 9:36 AM, the spread drops to1.90, which is below the limit price, so the fill model fills the combo limit order.

To reproduce these results, backtest the following algorithm:

PY

```
import itertools

class ComboMarketOrderAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 12, 24)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        option = self.add_option("GOOG")
        option.set_filter(min_strike=-2, max_strike=2, min_expiry=timedelta(days=0), max_expiry=timedelta(days=180))

        self.tickets = []

    def on_data(self, slice: Slice):
        if len(self.tickets) == 0:
            for canonical_symbol, chain in slice.option_chains.items():
                # Select contracts
                contracts = [contract for contract in chain if contract.right == OptionRight.CALL]
                contracts = [(key, list(group)) for key, group in itertools.groupby(contracts, key=lambda x: x.expiry)]
                contracts.sort(key=lambda x: x[0])
                contracts = contracts[0][1]
                contracts.sort(key=lambda x: x.strike)

                if len(contracts) < 2:
                    return

                # Create order legs
                quantities = [1, -1]
                legs = []
                for i, contract in enumerate(contracts[:2]):
                    legs.append(Leg.create(contract.symbol, quantities[i]))

                # Calculate limit price
                self.limit_price = round((slice.quote_bars[contracts[0].symbol].ask.low - slice.quote_bars[contracts[1].symbol].bid.low)
* 0.75, 2)

                # Place order
                self.tickets = self.combo_limit_order(legs, 1, self.limit_price)
        else:
            if self.time.hour == 9 and self.time.minute == 37:
                self.quit()
                return

            price = 0
            for ticket in self.tickets:
                quote_bar = slice.quote_bars[ticket.symbol]
                price += ((quote_bar.ask if ticket.quantity > 0 else quote_bar.bid).low * np.sign(ticket.quantity))
            self.log(f"{self.time}. Limit price: {self.limit_price}; Aggregate price: {round(price, 2)}; Ready to fill: {price <
self.limit_price}")

    def on_order_event(self, orderEvent: OrderEvent) -> None:
        if orderEvent.status == OrderStatus.FILLED:
            self.log(f"{self.time} -- Order {orderEvent.order_id} filled at {orderEvent.fill_price}")
```

Order Types

Combo Leg Limit Orders

Introduction

Combo leg limit orders are individual orders that contain limit orders for muliple securities. Combo leg limit orders are different from combo limit orders because you can create combo leg limit orders without forcing each leg to have the same limit price. Combo leg limit orders currently only work for trading Option contracts.

Place Orders

To send a combo leg limit order, create multiple `Leg` objects to represent the legs of the combo order, then call the `combo_leg_limit_order` method. The legs must each target a unique contract. At least one leg must have a positive quantity and at least one leg must have a negative quantity. If you don't have sufficient capital for the order, it's rejected.

```py
for canonical_symbol, chain in slice.option_chains.items():
    # Select contracts
    contracts = [c for c in chain][:2]
    if len(contracts) < 2:
        return

    # Create order legs
    legs = []
    quantities = [1, -1]
    factors = [0.98, 1.02]
    for i, contract in enumerate(contracts):
        legs.append(Leg.create(contract.symbol, quantities[i], contract.last_price * factors[i]))

    # Place order
    self.combo_leg_limit_order(legs, 1)
```

The quantity of the legs sets the ratio of the leg orders while the quantity argument of the `combo_leg_limit_order` method sets the combo order size and acts as a global multiplier. In the preceding example, if we set the global multiplier to two, then the algorithm buys two units of the first contract and sells two units of the second contract. The quantity also sets the order direction of the combo limit order, which affects how the fill model fills the order.

You can also provide a tag and order properties to the `combo_leg_limit_order` method.

```py
self.combo_leg_limit_order(legs, quantity, tag=tag, order_properties=order_properties)
```

Monitor Order Fills

Combo leg limit orders fill all the legs at the same time. Each leg can fill when the security price passes the limit price of the leg. To monitor the fills of your order, save a reference to the order tickets .

```py
tickets = self.combo_leg_limit_order(legs, 1)
for ticket in tickets:
    self.debug(f"Symbol: {ticket.symbol}; Quantity filled: {ticket.quantity_filled}; Fill price: {ticket.average_fill_price}")
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity, limit price, and tag of the leg limit orders until the combo order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `update` method returns an OrderResponse to signal the success or failure of the update request.

```
# Create a new order and save the order tickets
tickets = self.combo_leg_limit_order(legs, 1)

# Update the leg orders
for ticket in tickets:
    direction = np.sign(ticket.quantity)
    update_settings = UpdateOrderFields()
    update_settings.quantity = 2 * direction
    update_settings.limit_price = ticket.get(OrderField.LIMIT_PRICE) + 0.01 * direction
    update_settings.tag = f"Update #{len(ticket.update_requests) + 1}"
    response = ticket.update(update_settings)

    # Check if the update was successful
    if response.is_success:
        self.debug(f"Order updated successfully for {ticket.symbol}")
```

To update individual fields of an order, call any of the following methods:

- `update_limit_price`
- `update_quantity`
- `update_tag`

```
response = ticket.update_limit_price(limit_price, tag)

response = ticket.update_quantity(quantity, tag)

response = ticket.update_tag(tag)
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `update_requests` method.

```
update_requests = ticket.update_requests()
```

Cancel Orders

To cancel a combo leg limit order, call the `cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
response = ticket.cancel("Cancelled Trade")
if response.is_success:
    self.debug("Order successfully cancelled")
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `cancel_order_request` method on the order ticket. The method returns `None` if the order hasn't been cancelled.

```
request = ticket.cancel_order_request()
```

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `True` .

```
self.combo_leg_limit_order(legs, 1, asynchronous=True);
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with combo leg limit orders, set the brokerage model to a

brokerage that supports them.

```
self.set_brokerage_model(BrokerageName.QUANTCONNECT_BROKERAGE)
```

To check if your brokerage has any special requirements for combo leg limit orders, see the Orders section of the brokerage model documentation .

Requirements

Combo leg limit orders can be submitted at any time for all security types.

If your algorithm subscribes to extended market hours, they can be filled outside regular trading hours.

Examples

The following backtest verifies the `combo_leg_limit_order` behavior. The algorithm buys one contract and sells one contract at the same time. The following table shows the two trades in the backtest:

Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2015-12-24T09:31:00Z	GOOG 16011SC00745000	16.10	2	Buy	Filled	32.20	Update #72
2015-12-24T09:31:00Z	GOOG 160115C00747500	14.11515	-2	Sell	Filled	-28.2303	Update #72

On December 24, 2015 at 9:31 AM Eastern Time (ET), the algorithm places a combo leg limit order to buy one GOOG 16011SC00745000 contract and sell two GOOG 160115C00747500 contracts. The limit price of both orders is 99.9% of the respective contract price, which is 16.2837 for GOOG 16011SC00745000 and 14.83515 for GOOG 160115C00747500. The combo order doesn't fill immediately, so the algorithm updates the leg orders at each time step. During the first update, the algorithm sets the quantity of the GOOG 160115C00747500 leg to -2. During each update, the limit price moves 0.01 closer to the market. That is, the limit price of GOOG 16011SC00745000 increases by0.01 and the limit price of GOOG 160115C00747500 decreases by $0.01. After the 72nd update, the ask low price is below the limit price of the leg to buy GOOG 16011SC00745000 and the bid high price is above the limit price of the leg to sell GOOG 160115C00747500, so the fill model fills the combo leg limit order at 10:44 AM ET.

To reproduce these results, backtest the following algorithm:

PY

```
import itertools

class ComboLegLimitOrderAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 12, 24)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        option = self.add_option("GOOG")
        option.set_filter(min_strike=-2, max_strike=2, min_expiry=timedelta(days=0), max_expiry=timedelta(days=180))

        self.tickets = []

    def on_data(self, slice: Slice):
        if len(self.tickets) == 0:
            for canonical_symbol, chain in slice.option_chains.items():
                # Select contracts
                contracts = [contract for contract in chain if contract.right == OptionRight.CALL]
                contracts = [(key, list(group)) for key, group in itertools.groupby(contracts, key=lambda x: x.expiry)]
                contracts.sort(key=lambda x: x[0])
                contracts = contracts[0][1]
                contracts.sort(key=lambda x: x.strike)

                if len(contracts) < 2:
                    return

                # Create order legs
                quantities = [1, -2]
                legs = []
                for i, contract in enumerate(contracts[:2]):
                    legs.append(Leg.create(contract.symbol, quantities[i], slice[contract.symbol].close * .999))

                # Place order
                self.tickets = self.combo_leg_limit_order(legs, 1)
        else:
            if self.time.hour == 10 and self.time.minute == 45:
                self.quit()
                return

            for ticket in self.tickets:
                order_direction = np.sign(ticket.quantity)
                limit_price = ticket.get(OrderField.LIMIT_PRICE)

                # Log the limit prices and contract prices
                quote_bar = slice.quote_bars[ticket.symbol]
                current_price = quote_bar.ask.low if order_direction == 1 else quote_bar.bid.high
                ready_to_fill = current_price < limit_price if order_direction == 1 else current_price > limit_price
                self.log(f"{self.time} - {ticket.symbol}. Current price: {current_price}; Limit price: {round(limit_price, 2)};
Direction: {order_direction}; Ready to fill: {ready_to_fill}")

                # Update the leg orders
                update_settings = UpdateOrderFields()
                update_settings.quantity = 2 * order_direction
                update_settings.limit_price = limit_price + 0.01 * order_direction
                update_settings.tag = f"Update #{len(ticket.update_requests) + 1}"
                response = ticket.update(update_settings)

    def on_order_event(self, orderEvent: OrderEvent) -> None:
        if orderEvent.status == OrderStatus.FILLED:
            self.log(f"{self.time} -- Order {orderEvent.order_id} filled at {orderEvent.fill_price}")
```

Order Types

Option Exercise Orders

Introduction

If you buy an Option contract, you can exercise your right to buy or sell the underlying asset at the strike price. However, you don't need to exercise it. You can sell the Option or let it expire worthless if it's out of the money. If you hold a long position in an Option that expires in the money, LEAN automatically exercises it at the expiration date. If you sell an Option contract and the buyer exercises their right to buy or sell the underlying asset, you are assigned the Option and must trade with the buyer at the strike price.

Place Orders

You can exercise American-style Option contracts anytime before they expire. Depending on your brokerage and the delivery method, you may be able to exercise European-style Option contracts on their expiration date. To exercise an Option, call the `exercise_option` method with the Option contract `Symbol` and a quantity. If you do not have sufficient capital for the order, it's rejected. By default, Option exercise orders are synchronous and fill immediately.

```
PY
ticket = self.exercise_option(contract_symbol, quantity)
```

You can provide a tag and order properties to the `exercise_option` method.

```
PY
self.exercise_option(symbol, quantity, tag=tag, order_properties=order_properties)
```

Monitor Order Fills

To monitor the fills of your order, save a reference to the order ticket .

```
PY
ticket = self.exercise_option(contract_symbol, quantity)
self.debug(f"Quantity filled: {ticket.quantity_filled}; Fill price: {ticket.average_fill_price}")
```

For more information about how LEAN models Option exercise orders in backtests, see the Exercise Option model .

Option Assignments

If you sell an Option in a backtest, LEAN can simulate an Option exercise order on behalf of the buyer. By default, LEAN scans your portfolio every hour. It considers exercising American-style Options if they are within 4 days of their expiration and it considers exercising European-style Options on their day of expiration. If you have sold an Option that's 5% in-the-money and the Option exercise order is profitable after the cost of fees, LEAN exercises the Option. For more information about how we simulate Option assignments, see the Assignment reality model.

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `True` .

```
PY
ticket = self.exercise_option(contract_symbol, quantity, asynchronous=True);
```

Synchronous Timeouts

Option exercise orders are synchronous by default, so your algorithm waits for the order to fill before moving to the next line of code. If your order takes longer than five seconds to fill, your algorithm continues executing even if the trade isn't filled. To adjust the timeout period, set the `transactions.market_order_fill_timeout` property.

```
 # Adjust the market fill-timeout to 30 seconds.
self.transactions.market_order_fill_timeout = timedelta(seconds=30)
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with Option exercise orders, set the brokerage model to a brokerage that supports them.

```
self.set_brokerage_model(BrokerageName.QUANTCONNECT_BROKERAGE)
```

To check if your brokerage has any special requirements for Option exercise orders, see the Orders section of the brokerage model documentation .

Requirements

Option exercise orders can only be submitted for option contracts with a long position. European-style options cannot be exercised before their expiration date.

Examples

The following backtest verifies the `exercise_option` behavior. The following table shows the first three trades in the backtest:

Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2021-07-01T09:31:00Z	SPY 221216C00085000	345.30	1	Buy Market	Filled	34530.00	
2021-07-01T09:31:00Z	SPY 221216C00085000	0.00	-1	Sell Option Exercise	Filled	0.00	Automatic Exercise
2021-07-01T09:31:00Z	SPY	85.00	100	Sell Option Exercise	Filled	8500.00	Option Exercise

The algorithm first brought a deep ITM option based on the set option selection conditions by 345.30, then exercise it actively, so 100 shares of SPY (in which 1 contract represents) was brought at its strike price at 85.00, with the option discarded from the portfolio.

To reproduce these results, backtest the following algorithm:

PY

```
class OptionExerciseOrderAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        self.settings.seed_initial_prices = True
        self.add_security_initializer(self.custom_security_initializer)

        spy = self.add_equity("SPY", Resolution.MINUTE)
        self.spy = spy.symbol

    def custom_security_initializer(self, security):
        security.set_data_normalization_mode(DataNormalizationMode.RAW)

    def on_data(self, data):
        if not self.portfolio.invested:
            contracts = self.option_chain_provider.get_option_contract_list(self.spy, self.time)
            contracts = sorted([x for x in contracts if x.id.option_right == OptionRight.CALL], key=lambda x: x.id.strike_price)
            if not contracts: return

            self.strike = contracts[0].id.strike_price

            contracts = sorted([x for x in contracts if x.id.strike_price == self.strike], key=lambda x: x.id.date)

            self.contract = contracts[0]
            self.add_option_contract(self.contract, Resolution.MINUTE)

            self.buy(self.contract, 1)

        if self.portfolio[self.contract].invested and self.strike < self.securities[self.spy].price:
            self.exercise_option(self.contract, 1)
            self.quit()
```

Order Types

Other Order Types

Introduction

We are often asked to support other order types like one cancels the other, trailing stop, and multi-leg orders. Currently, LEAN doesn't support these order types, but we will add them over time. Part of the difficulty of implementing them is the incomplete brokerage support.

One Cancels the Other Orders

One cancels the other (OCO) orders are a set of orders that when one fills, it cancels the rest of the orders in the set. An example is to set a take-profit and a stop-loss order right after you enter a position. In this example, when either the take-profit or stop-loss order fills, you cancel the other order. OCO orders usually create an upper and lower bound on the exit price of a trade.

When you place OCO orders, their price levels are usually relative to the fill price of an entry trade. If your entry trade is a synchronous market order, you can immediately get the fill price from the order ticket. If your entry trade doesn't execute immediately, you can get the fill price in the on_order_events event handler. Once you have the entry fill price, you can calculate the price levels for the OCO orders.

```py
# Get the fill price from the order ticket of a sync market order
self._market = self.market_order("SPY", 1)
fill_price = self._market.average_fill_price

# Get the fill price from the OnOrderEvent event handler
def on_order_event(self, order_event: OrderEvent) -> None:
    if order_event.status == OrderStatus.FILLED and order_event.ticket.order_type == OrderType.MARKET:
        fill_price = order_event.fill_price
```

After you have the target price levels, to implement the OCO orders, you can place active orders or track the security price to simulate the orders.

Place Active Orders

To place active orders for the OCO orders, use a combination of limit orders and stop limit orders . Place these orders so that their price levels that are far enough apart from each other. If their price levels are too close, several of the orders can fill in a single time step. When one of the orders fills, in the `on_order_event` event handler, cancel the other orders in the OCO order set.

```py
_stop_loss = None
_take_profit = None

def on_order_event(self, order_event: OrderEvent) -> None:
    if order_event.status != OrderStatus.FILLED:
        return

    match order_event.ticket.order_type:
        case OrderType.MARKET:
            self._stop_loss = self.stop_market_order(order_event.symbol, -order_event.fill_quantity, order_event.fill_price*0.95)
            self._take_profit = self.limit_order(order_event.symbol, -order_event.fill_quantity, order_event.fill_price*1.10)
        case OrderType.STOP_MARKET:
            self._take_profit.cancel()
        case OrderType.LIMIT:
            self._stop_loss.cancel()
```

Simulate Orders

To simulate OCO orders, track the asset price in the `on_data` method and place market or limit orders when asset price reaches the take-profit or stop-loss level. The benefit of manually simulating the OCO orders is that both of the orders can't fill in the same time step.

```
def on_data(self, slice: Slice) -> None:
    if not self.portfolio.invested:
        ticket = self.market_order("SPY", 1)
        self.entry_price = ticket.average_fill_price

    bar = slice.get("SPY")
    if bar:
        if bar.price >= self.entry_price * 1.10:
            self.liquidate(symbol="SPY", -1, tag="take profit")

        elif bar.price <= self.entry_price * 0.95:
            self.liquidate(symbol="SPY", -1, tag="stop loss")
```

Multi-Leg Orders

Multi-leg orders are orders that contain multiple sub-orders. Examples of multi-leg orders include Option strategies like spreads , straddles , and strangles . You can manually implement other types of multi-leg orders with the built-in order types.

Examples

The following example demonstrates a helper class for OCO orders. This is not an officially supported OCO order type as it's possible for both the take profit and stop loss orders to fill in the same bar. Before you use this approach, verify that your brokerage model supports stop market orders and limit orders.

```
class OCOTrade:

    def __init__(self, algorithm, symbol, quantity, entry_stop_price, take_profit_price, stop_loss_price):
        self._algorithm = algorithm
        self._symbol = symbol
        self._take_profit_price = take_profit_price
        self._stop_loss_price = stop_loss_price
        self._entry = algorithm.stop_market_order(symbol, quantity, entry_stop_price)
        self._take_profit = None
        self._stop_loss = None

    def on_order_event(self, order_event):
        if order_event.status != OrderStatus.FILLED:
            return
        _id = order_event.order_id
        if self._entry and self._entry.order_id == _id:
            quantity = order_event.fill_quantity
            self._take_profit = self._algorithm.limit_order(self._symbol, -quantity, self._take_profit_price)
            self._stop_loss = self._algorithm.stop_market_order(self._symbol, -quantity, self._stop_loss_price)
            self._entry = None

Trading and Orders

Pre-trade Risk Control

Introduction

LEAN performs pre-order checks to ensure that the order meets some requirements to ensure that the order is valid and can be executed. These checks are include risk controls such as validation of order size and price limits, and whether the order can be executed by a given brokerage at a given time.

Basic Validation

Orders undergo basic validation checks to ensure they meet certain criteria before being submitted. The following list outlines some of the key checks performed:

1. **Tradable:** Ensures that the security is tradable or in the market.

   Your algorithm cannot place orders for indices , delisted securities, expired contracts, or any assets removed from your universe. For example, the option filter or universe selection removed a contract because it doesn't meet the criteria set by the filter.

2. **Market Hours:** Checks that the order can be placed at the current time.

   For example, market orders cannot be placed outside of regular trading hours. LEAN converts market orders to market-on-open orders if possible.

3. **Price:** Checks that the last known price is not zero.

   LEAN requires the last known price for buying power calculations .

4. **Order Size:** Ensures that the order quantity is not zero or less than the lot size.

LEAN ensures that your algorithm has a valid data subscription for the security and receives its market data before placing an order. For example, you can place a market order to trade SPY, LEAN calls the `self.add_equity("SPY")` for you and seeds initial prices.

Order Type

QuantConnect supports several order types . To see the requirements of each order, see the Requirements section of the documentation for the order types . LEAN doesn't allow placing orders that don't meet these requirements. For example, your algorithm cannot place a market-on-close order from cryto-currencies because they operate 24/7.

Buying Power

When you place an order, LEAN uses the buying power model to determine whether the order should be submitted so you avoid placing orders that would be rejected by the brokerage. Buying power calculations can be very complex and depend on many factors, including the brokerage or even the time of day. The main factors include your current portfolio holdings, available cash, and margin requirements.

The buying power calculations are restricted to portfolio your algorithm is connected to. QuantConnect doesn't support multi-account risk controls.

Brokerage

QuantConnect supports several brokerages . Each brokerage trades different asset classes and support different order types. LEAN doesn't allow placing orders that don't meet these requirements. For example, your algorithm cannot place a trailing stop order for most brokerages.

By default, LEAN uses the default brokerage model that suports all order types and all asset classes. To avoid issues with unsupported order types and asset classes when live trading, set the brokerage model to a brokerage that supports them.

```
self.set_brokerage_model(BrokerageName.TRADE_STATION)
```
PY

QuantConnect ensures your algorithm is always online, checking its status every few seconds. While a strategy is live it is also always connected to your brokerage, ensuring there is a route to quickly place trades when needed.

Trading and Orders

Position Sizing

Introduction

LEAN provides several methods to help you set specific portfolio weights for assets. These methods account for lot size and pre-calculated order fees.

Single Asset Targets

The `set_holdings` method calculates the number of asset units to purchase based on the portfolio weight you provide and then submits market orders . This method provides a quick way to set up a portfolio with a set of weights for assets. If you already have holdings, you may want to liquidate the existing holdings first to free up buying power.

```
 # Allocate 50% of buying power to IBM
self.set_holdings("IBM", 0.5)

# Allocate 50% of portfolio value to IBM, but liquidate other holdings first
self.set_holdings("IBM", 0.5, liquidate_existing_holdings=True)

# Provide a tag and order properties to the SetHoldings method
self.set_holdings(symbol, weight, liquidate_existing_holdings, tag, order_properties)
```

If the percentage you provide translates to an order quantity of 0 or to a small quantity that doesn't exceed the `minimum_order_margin_portfolio_percentage` algorithm setting , then the `set_holdings` method doesn't place an order and doesn't log anything.

Multiple Asset Targets

When you trade a weighted basket of assets, sometimes you must intelligently scale down existing positions before increasing allocations to other assets. If you call the `set_holdings` method with a list of `PortfolioTarget` objects, LEAN sorts the orders based on your position delta and then places the orders that reduce your position size in an asset before it places orders that increase your position size in an asset. When you call the `set_holdings` method with a list of `PortfolioTarget` objects, the decimal you pass to the `PortfolioTarget` constructor represents the portfolio weight. In this situation, don't use the `PortfolioTarget.percent` method.

```
# Purchase a portfolio of targets, processing orders intelligently.
# PortfolioTarget accepts a Symbol and decimal percent of buying power.
targets = [PortfolioTarget("SPY", 0.8), PortfolioTarget("IBM", 0.2)]
self.set_holdings(targets)
```

If you want the targets you pass to define the target portfolio state, enable the `liquidate_existing_holdings` argument.

```
self.set_holdings([PortfolioTarget("SPY", 0.8), PortfolioTarget("IBM", 0.2)], liquidate_existing_holdings=True)
```

The method also accepts tag and order properties arguments.

```
self.set_holdings(targets, liquidate_existing_holdings, tag, order_properties)
```

If the percentage you provide translates to an order quantity of 0 or to a small quantity that doesn't exceed the `minimum_order_margin_portfolio_percentage` algorithm setting , then the `set_holdings` method doesn't place an order and doesn't log anything.

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `True` .

```
self.set_holdings("IBM", 0.5, asynchronous=True);
```

When you set multiple asset targets, you likely want to send asynchronous orders.

```
targets = [PortfolioTarget("SPY", 0.8), PortfolioTarget("IBM", 0.2)]
self.set_holdings(targets, asynchronous=True)
```

Calculate Order Quantities

The `set_holdings` method uses market order to reach the target portfolio weight you provide. If you want to use a different order type, you need to specify the quantity to trade. To calculate the number of units to trade based on a portfolio weight, call the `calculate_order_quantity` method. The method calculates the quantity based on the current price of the asset and adjusts it for the fee model of the security. The target weight you provide is an unleveraged value. For instance, if you have 2x leverage and request a 100% weight, the method calculates the quantity that uses half of your available margin.

```
 # Calculate the fee-adjusted quantity of shares with given buying power
quantity = self.calculate_order_quantity("IBM", 0.4)
```

Buying Power Buffer

If you place a market on open order near the market close, the market can gap overnight to a worse open price. If the gap is large enough against your trade direction, you may not have sufficient buying power at the open to fill your trade. To ensure a high probability of order fills through market gaps and discontinuities, the `set_holdings` method assumes a 0.25% cash buffer. If LEAN rejects your orders due to buying power, widen the cash buffer through the algorithm `settings` property.

```
# Set the cash buffer to 5%
self.settings.free_portfolio_value_percentage = 0.05

# Set the cash buffer to $10,000
self.settings.free_portfolio_value = 10000
```

If you use `free_portfolio_value_percentage` , you must set it in the `initialize` or `post_initialize` event handler. If you use `free_portfolio_value` , you must set it after the `post_initialize` event handler.

Examples

The following examples demonstrate some common practices for position sizing.

Example 1: Covered Call

PY

```
class PositionSizingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(10_000_000)

        # Seed the price to ensure securities have information for margin calculations.
        self.settings.seed_initial_prices = True

        # Request SPY data for trading. We use raw price data to compare the strike price fairly for ATM contract selection.
        self.spy = self.add_equity("SPY", data_normalization_mode=DataNormalizationMode.RAW).symbol

        # Set a scheduled event to rebalance the covered call positions.
        self.schedule.on(
            self.date_rules.week_start(self.spy),
            self.time_rules.after_market_open(self.spy, 1),
            self.rebalance
        )

    def rebalance(self) -> None:
        option_chain = self.option_chain(self.spy)
        # Filter for the calls within 1-week expiry.
        expiry = max(x.expiry for x in option_chain if x.expiry <= self.time + timedelta(6))
        filtered = [x for x in option_chain if x.right == OptionRight.CALL and x.expiry == expiry]
        # Select the ATM call.
        atm_call = sorted(filtered, key=lambda x: abs(x.strike - self.securities[self.spy].price))[0]
        atm_call = self.add_option_contract(atm_call).symbol

        # Calculate the order size for the covered call.
        quantity = int(self.calculate_order_quantity(self.spy, 0.5) // 100)
        # Covered call involves 100 shares of SPY and -1 ATM call contract.
        if quantity > 0:
            self.combo_market_order(
                [Leg.create(self.spy, 100), Leg.create(atm_call, -1)],
                quantity,
                asynchronous=True
            )
```

Trading and Orders

Liquidating Positions

Introduction

The `liquidate` method lets you liquidate individual assets or your entire portfolio. The method creates market orders to close positions and returns the tickets of the liquidation orders. If you have pending open orders for the security when you call `liquidate` , LEAN tries to cancel them. The `liquidate` method works for all asset classes, except Crypto. To liquidate Crypto positions, see Crypto Trades .

Liquidate Individual Positions

To liquidate your holdings in an individual security, call the `liquidate` method and provide a ticker or `Symbol` .

```
# Liquidate all IBM in your portfolio
order_tickets = self.liquidate("IBM")
```

You can pass an order tag and properties to the `liquidate` method.

```
order_properties = OrderProperties()
order_properties.time_in_force = TimeInForce.DAY
order_tickets = self.liquidate("AAPL", tag="Liquidated", order_properties=order_properties)
```

Liquidate All Positions

To liquidate all of the positions in your portfolio, call the `liquidate` method without any ticker of `Symbol` arguments.

```
// Liquidate your entire portfolio
order_tickets = self.liquidate()
```

You can pass an order tag and properties to the `liquidate` method.

```
order_properties = OrderProperties()
order_properties.time_in_force = TimeInForce.DAY
order_tickets = self.liquidate(tag="Liquidated", order_properties=order_properties)
```

Asynchronous Liquidations

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `True` .

```
order_tickets = self.liquidate(asynchronous=True, order_properties=order_properties);
```

Enable and Disable Liquidations

By default, the `liquidate` method is functional. To enable and disable it, set the `liquidate_enabled` algorithm setting .

```
# Disable liquidations
self.settings.liquidate_enabled = False

# Enable liquidations
self.settings.liquidate_enabled = True
```

Market Closed Considerations

If you liquidate your positions when the market is closed, LEAN converts the orders into market on open orders. If your brokerage doesn't support market on open orders , the order is invalid.

Examples

The following examples demonstrate some common practices for liquidating positions.

Example 1: Liquidate Universe Removal

The following algorithm holds equal positions for the top 10 liquid universe to follow their hype while updating weekly. When a stock is removed from the universe, we liquidate the position in the `on_securities_changed` method.

```py
class LiquidatingPositionsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Update the universe weekly to allow time to capitalize on the hype.
        self.universe_settings.schedule.on(self.date_rules.week_start())
        # Filter for the 10 most popular stocks to invest the hype.
        self._universe = self.add_universe(self.universe.top(10))

        # Set a schedule event to rebalance weekly.
        self.schedule.on(
            self.date_rules.week_start("SPY"),
            self.time_rules.at(9, 31),
            self.rebalance
        )

    def rebalance(self) -> None:
        # Evenly invest in the universe members to dissipate the capital risk equally.
        count = len(self._universe.members)
        targets = [PortfolioTarget(x.key, 1 / count) for x in self._universe.members]
        self.set_holdings(targets)

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        # Liquidate the ones leaving the universe since they are not the most popular.
        # Note that the liquidation will be market-on-open orders due to the time of securities removal.
        for removed in changes.removed_securities:
            self.liquidate(removed.symbol)
```

Example 2: Liquidate Existing Positions

The example below trades the same strategy as the previous one. Still, instead of liquidating the positions when the stocks leave the universe, we liquidate the position using the `liquidate_existing_holdings` argument in the `set_holdings` . Note that the time of the liquidation will be slightly delayed due to the time of the scheduled event.

```py
class LiquidatingPositionsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Update the universe weekly to allow time to capitalize on the hype.
        self.universe_settings.schedule.on(self.date_rules.week_start())
        # Filter for the 10 most popular stocks to invest the hype.
        self._universe = self.add_universe(self.universe.top(10))

        # Set a scheduled event to rebalance weekly.
        self.schedule.on(
            self.date_rules.week_start("SPY"),
            self.time_rules.at(9, 31),
            self.rebalance
        )

    def rebalance(self) -> None:
        # Evenly invest in the universe members to dissipate the capital risk equally.
        count = len(self._universe.members)
        targets = [PortfolioTarget(x.key, 1 / count) for x in self._universe.members]
        # We can use `liquidate_existing_holdings` arguments to liquidate the ones not in the universe anymore.
        self.set_holdings(targets, liquidate_existing_holdings=True)
```

Example 3: Liquidate Upon Assignment

The following algorithm sells SPY ATM puts weekly to earn the premium when SPY price is rising. In the case where the price of SPY drops and the put is being assigned, we liquidate the SPY position in the `on_assignment_order_event` .

PY

```
class LiquidatingPositionsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Seed the price with the last known price to ensure the underlying price data is available on initial option contract filtering.
        self.settings.seed_initial_prices = True

        # Request SPY data for option selection using its price.
        # Use raw data normalization mode since we need to compare the SPY price with the strike price.
        self.spy = self.add_equity("SPY", data_normalization_mode=DataNormalizationMode.RAW).symbol

        # Set a scheduled event to rebalance weekly.
        self.schedule.on(
            self.date_rules.week_start(),
            self.time_rules.at(9, 31),
            self.rebalance
        )

    def rebalance(self) -> None:
        # Select the 1-week ATM put SPY option to short.
        option_chain = self.option_chain(self.spy)
        expiry = max(x.expiry for x in option_chain if x.expiry < self.time + timedelta(6))
        atm_put = sorted([x for x in option_chain if x.expiry == expiry and x.right == OptionRight.PUT],
                         key=lambda x: abs(x.strike - self.securities[self.spy].price))[0]
        atm_put_symbol = self.add_option_contract(atm_put).symbol

        # Sell the ATM put option to earn the premium.
        self.sell(atm_put_symbol, 2)

    def on_assignment_order_event(self, assignment_event: OrderEvent) -> None:
        # Liquidate any assigned positions of SPY since we only earn the premium.
        self.liquidate(self.spy)
```

Trading and Orders

Crypto Trades

Introduction

All fiat and Crypto currencies are individual assets. When you buy a pair like BTCUSDT, you trade USDT for BTC. In this case, LEAN removes some USDT from your portfolio cash book and adds some BTC. The virtual pair BTCUSDT represents your position in the trade, but the virtual pair doesn't actually exist. It simply represents an open trade.

Place Trades

When you place Crypto trades, don't use the `calculate_order_quantity` or `set_holdings` methods. Instead, calculate the order quantity based on the currency amounts in your cash book and place manual orders.

The following code snippet demonstrates how to allocate 90% of your portfolio to BTC.

```
PY
def on_data(self, data: Slice):
    self.set_crypto_holdings(self._symbol, .9)

def set_crypto_holdings(self, symbol, percentage):
    crypto = self.securities[symbol]
    base_currency = crypto.base_currency

    # Calculate the target quantity in the base currency
    target_quantity = percentage * (self.portfolio.total_portfolio_value - self.settings.free_portfolio_value) /
base_currency.conversion_rate
    quantity = target_quantity - base_currency.amount

    # Round down to observe the lot size
    lot_size = crypto.symbol_properties.lot_size
    quantity = round(quantity / lot_size) * lot_size

    if self.is_valid_order_size(crypto, quantity):
        self.market_order(symbol, quantity)

# Brokerages have different order size rules
# Binance considers the minimum volume (price x quantity):
def is_valid_order_size(self, crypto, quantity):
    return abs(crypto.price * quantity) > crypto.symbol_properties.minimum_order_size
```

The preceding example doesn't take into account order fees. You can add a 0.1% buffer to accommodate it.

The following example demonstrates how to form an equal-weighted Crypto portfolio and stay within the cash buffer .

```
PY
def on_data(self, data: Slice):
    percentage = (1 - self.settings.free_portfolio_value_percentage) / len(self.symbols);
    for symbol in self.symbols:
        self.set_crypto_holdings(symbol, percentage)
```

You can replace the `settings.free_portfolio_value_percentage` for a class variable (e.g. `self.cash_buffer`).

When you place Crypto trades, ensure you have a sufficient balance of the base or quote currency before each trade. If you hold multiple assets and you want to put all of your capital into BTCUSDT, you need to first convert all your non-BTC assets into USDT and then purchase BTCUSDT.

By default, the account currency is USD and your starting cash is 100,000. Some Crypto exchanges don't support fiat currencies, which means you can't convert the 100,000 USD to the pair's quote currency . In this case, set your account currency to the quote currency with a positive quantity.

```
PY
self.set_account_currency("USDT", 1000)   # Set the account currency to Tether and its quantity to 1,000 USDT
```

For a full example of placing crypto trades, see the BasicTemplateCryptoAlgorithm .

Liquidate Positions

If you use the `liquidate` method to liquidate a Crypto position, it only liquidates the quantity of the virtual pair. Since the virtual pair BTCUSDT may not represent all of your BTC holdings, don't use the `liquidate` method to liquidate Crypto positions. Instead, calculate the order quantity based on the currency amounts in your cash book and place manual orders. The following code snippet demonstrates how to liquidate a BTCUSDT position.

```
PY
def on_data(self, data: Slice):
    self.liquidate_crypto(self._symbol)

def liquidate_crypto(self, symbol):
    crypto = self.securities[symbol]
    base_currency = crypto.base_currency

    # Avoid negative amount after liquidate
    quantity = min(crypto.holdings.quantity, base_currency.amount)

    # Round down to observe the lot size
    lot_size = crypto.symbol_properties.lot_size
    quantity = (round(quantity / lot_size) - 1) * lot_size

    if self.is_valid_order_size(crypto, quantity):
        self.market_order(symbol, -quantity)
```

The order fees don't respect the lot size. When you try to liquidate a position, the absolute value of the base currency quantity can be less than the lot size and greater than zero. In this case, your algorithm holds a position that you can't liquidate, yet `self.portfolio[symbol].invested` is `False` . For more information about `self.portfolio[symbol].invested` , see Holdings Status . The following code snippet demonstrates how to determine if you can liquidate a position:

```
PY
def on_data(self, data: Slice):
    crypto = self.securities[self._symbol]
    if abs(crypto.holdings.quantity) > crypto.symbol_properties.lot_size:
        self.liquidate_crypto(self._symbol)
```

Examples

The following examples demonstrate some common practices for crypto holdings.

Example 1: ETH-BTC Proxy Trading

The following algorithm trades trend-following of the ETHBTC crypto pair using a 20-day EMA indicator. To reduce friction (e.g. slippage), we trade the more liquid and popular BTCUSDT and ETHUSDT pair instead. For example, if ETHBTC is above EMA (uptrend), we sell all BTCUSDT holdings and buy ETHUSDT with the same USDT value, going flat on BTC while holding ETH.

PY

```
class CryptoHoldingsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_account_currency("USDT", 1000000)

        # We would like to trade the EMA cross between 2 popular cryptos: BTC & ETH,
        # so we request ETHBTC data to find trading opportunities.
        self.ethbtc = self.add_crypto("ETHBTC", Resolution.DAILY, market=Market.COINBASE).symbol
        # Trade through BTCUSDT & ETHUSDT, though, since stable coin trades have lower friction costs and higher liquidity.
        btcusdt = self.add_crypto("BTCUSDT", Resolution.DAILY, market=Market.COINBASE)
        ethusdt = self.add_crypto("ETHUSDT", Resolution.DAILY, market=Market.COINBASE)
        self.btcusdt = btcusdt.symbol
        self.ethusdt = ethusdt.symbol

        # Simulate an account with various crypto cash through holdings.
        # Set the cash book directly with the crypto amounts
        btcusdt.holdings.set_holdings(btcusdt.price, 5)
        btcusdt.base_currency.add_amount(5)
        ethusdt.holdings.set_holdings(ethusdt.price, 22.5)
        ethusdt.base_currency.add_amount(22.5)

        # Add automatic updating of the EMA indicator for trend trade signal emission.
        self._ema = self.ema(self.ethbtc, 20, Resolution.DAILY)
        # Warm up the indicator for its readiness usage immediately.
        self.warm_up_indicator(self.ethbtc, self._ema, Resolution.DAILY)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self.ethbtc)
        btc = slice.bars.get(self.btcusdt)
        eth = slice.bars.get(self.ethusdt)

        if bar and self._ema.is_ready and btc and eth:
            ema = self._ema.current.value
            btc_holdings = self.portfolio.cash_book["BTC"].amount
            eth_holdings = self.portfolio.cash_book["ETH"].amount

            # ETHBTC's current price is higher than EMA, suggesting an uptrend.
            if bar.close > ema and not self.portfolio[self.btcusdt].is_short:
                # To follow the up trend of ETHBTC, sell ALL BTCUSDT and buy ETHUSDT with the same value.
                if btc_holdings > 0:
                    btc_value = btc_holdings * btc.close
                    # Sell all BTC
                    self.market_order(self.btcusdt, -btc_holdings)
                    # Buy ETH with the same USDT value
                    eth_size = btc_value / eth.close
                    self.market_order(self.ethusdt, eth_size)
            # ETHBTC's current price is below the EMA, suggesting a downtrend.
            elif bar.close < ema and not self.portfolio[self.btcusdt].is_long:
                # To follow the downtrend of ETHBTC, sell ALL ETHUSDT and buy BTCUSDT with the same value.
                if eth_holdings > 0:
                    eth_value = eth_holdings * eth.close
                    # Sell all ETH
                    self.market_order(self.ethusdt, -eth_holdings)
                    # Buy BTC with the same USDT value
                    btc_size = eth_value / btc.close
                    self.market_order(self.btcusdt, btc_size)
```

Bear Call Spread

Introduction

Bear call spread , also known as short call spread , consists of selling an ITM call and buying an OTM call. Both calls have the same underlying Equity and the same expiration date. The ITM call serves as a hedge for the OTM call. The bear call spread profits from a drop in underlying asset price.

Implementation

Follow these steps to implement the bear call spread strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```
PY
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(500000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.call_spread(30, 5))
```

   The `call_spread` filter narrows the universe down to just the two contracts you need to form a bear call spread.

2. In the `on_data` method, select the expiration and strikes of the contracts in the strategy legs.

```
PY
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Select the call Option contracts with the furthest expiry
    expiry = max([x.expiry for x in chain])
    calls = [i for i in chain if i.expiry == expiry and i.right == OptionRight.CALL]
    if not calls == 0:
        return

    # Select the ITM and OTM contract strike prices from the remaining contracts
    strikes = [x.strike for x in calls]
    otm_strike = max(strikes)
    itm_strike = min(strikes)
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.bear_call_spread` method with the details of each leg and then pass the result to the `buy` method.

```
PY
option_strategy = OptionStrategies.bear_call_spread(self._symbol, itm_strike, otm_strike, expiry)
self.buy(option_strategy, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
itm_call = [x for x in calls if x.strike == itm_strike][0]
otm_call = [x for x in calls if x.strike == otm_strike][0]

legs = [
    Leg.create(itm_call.symbol, -1),
    Leg.create(otm_call.symbol, 1)
]
self.combo_market_order(legs, 1)
```

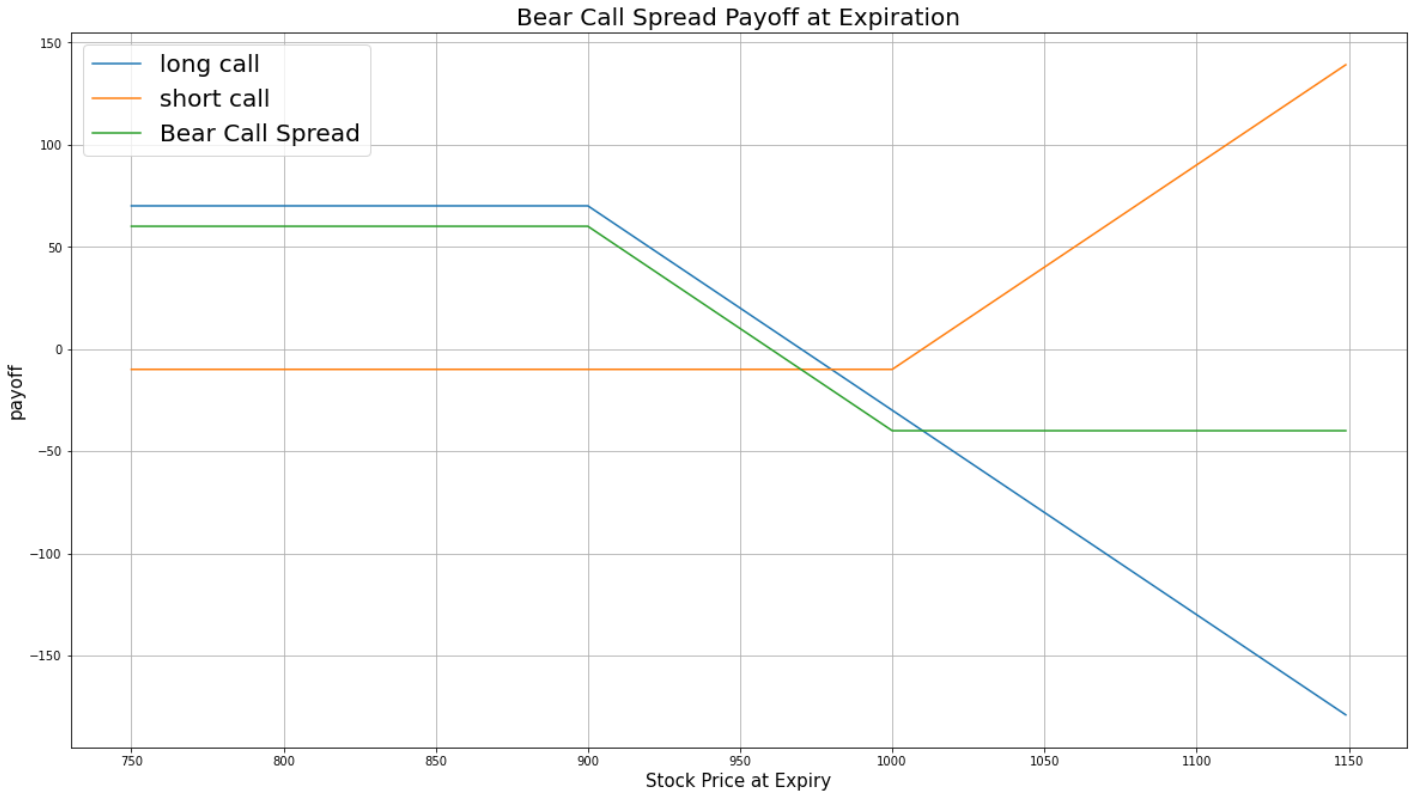
Strategy Payoff

The bear call spread is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^{OTM})^{+}\\ C^{ITM}_T & = & (S_T - K^{ITM})^{+}\\ P_T & = & (C^{OTM}_T - C^{ITM}_T + C^{ITM}_0 - C^{OTM}_0)\times m - fee\\ \end{array} \begin{array}{rcll} \textrm{where} & C^{OTM}_T & = & \textrm{OTM call value at time T}\\ & C^{ITM}_T & = & \textrm{ITM call value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{OTM} & = & \textrm{OTM call strike price}\\ & K^{ITM} & = & \textrm{ITM call strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{ITM}_0 & = & \textrm{ITM call value at position opening (debit paid)}\\ & C^{OTM}_0 & = & \textrm{OTM call value at position opening (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock price is $1,078.92 at expiration. You sold an ITM call at a strike of $1,125.00 for $57.80 and bought an OTM call at a strike of $1,197.50 for $26.90 .

The following chart shows the payoff at expiration:



The maximum profit is the net credit you receive from opening the trade, $C^{ITM}_0 - C^{OTM}_0$. If the price declines, both calls expire worthless.

The maximum loss is $K^{OTM} - K^{ITM} + C^{ITM}_0 - C^{OTM}_0$, which occurs when the underlying price is above the strike prices of both call Option contracts.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
OTM call	26.90	1197.50
ITM call	57.80	1125.00
Underlying Equity at expiration	1078.92	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^{OTM})^{+}\\ & = & (1078.92-1197.50)^{+}\\ & = & 0\\ C^{ITM}_T & = & (S_T - K^{ITM})^{+}\\ & = & (1078.92-1125.00)^{+}\\ & = & 0\\ P_T & = & (C^{OTM}_T - C^{ITM}_T + C^{ITM}_0 - C^{OTM}_0)\times m - fee\\ & = & (0-0+57.80-26.90)\times100-1.00\times2\\ & = & 3088\\ \end{array}$$

So, the strategy profits $3,088.

The following algorithm implements a bear call spread Option strategy:

```py
class BearCallSpreadStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(500000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self._symbol = option.symbol
        option.set_filter(
            lambda universe: universe.call_spread(30, 5)
        )

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested:
            return

        # Get the OptionChain
        chain = slice.option_chains.get(self._symbol, None)
        if not chain:
            return

        # Get the furthest expiry date of the contracts
        expiry = sorted(chain, key=lambda x: x.expiry, reverse=True)[0].expiry

        # Select the call Option contracts with the furthest expiry
        calls = [i for i in chain if i.expiry == expiry and i.right == OptionRight.CALL]
        if len(calls) == 0:
            return

        # Select the ITM and OTM contracts
        ordered_calls = sorted(calls, key=lambda x: x.strike)
        itm_call = ordered_calls[0]
        otm_call = ordered_calls[-1]

        # Place the order
        option_strategy = OptionStrategies.bear_call_spread(
            self._symbol, itm_call.strike, otm_call.strike, expiry
        )
        self.buy(option_strategy, 1)
```

Option Strategies

Bear Put Spread

Introduction

Bear put spread , also known as short put spread , consists of buying an ITM put and selling an OTM put. Both puts have the same underlying Equity and the same expiration date. The OTM put serves as a hedge for the ITM put. The bear put spread profits from a decline in underlying asset price.

Implementation

Follow these steps to implement the bear put spread strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(500000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.put_spread(30, 5))
```

   The `put_spread` filter narrows the universe down to just the two contracts you need to form a bear put spread.

2. In the `on_data` method, select the expiration and strikes of the contracts in the strategy legs.

```
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Select the put Option contracts with the furthest expiry
    expiry = max([x.expiry for x in chain])
    puts = [i for i in chain if i.expiry == expiry and i.right == OptionRight.PUT]
    if not puts == 0:
        return

    # Select the ITM and OTM contract strike prices from the remaining contracts
    strikes = [x.strike for x in puts]
    otm_strike = min(strikes)
    itm_strike = max(strikes)
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.bear_put_spread` method with the details of each leg and then pass the result to the `buy` method.

```
option_strategy = OptionStrategies.bear_put_spread(self._symbol, itm_strike, otm_strike, expiry)
self.buy(option_strategy, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
itm_put = [x for x in puts if x.strike == itm_strike][0]
otm_put = [x for x in puts if x.strike == otm_strike][0]

legs = [
    Leg.create(itm_put.symbol, 1),
    Leg.create(otm_put.symbol, -1)
]
self.combo_market_order(legs, 1)
```

Strategy Payoff

The bear put spread is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} P^{OTM}_T & = & (K^{OTM} - S_T)^{+}\\ P^{ITM}_T & = & (K^{ITM} - S_T)^{+}\\ P_T & = & (P^{ITM}_T - P^{OTM}_T + P^{OTM}_0 - P^{ITM}_0)\times m - fee\\ \end{array} \begin{array}{rcl} \textrm{where} & P^{OTM}_T & = & \textrm{OTM put value at time T}\\ & P^{ITM}_T & = & \textrm{ITM put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{OTM} & = & \textrm{OTM put strike price}\\ & K^{ITM} & = & \textrm{ITM put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & P^{ITM}_0 & = & \textrm{ITM put value at position opening (debit paid)}\\ & P^{OTM}_0 & = & \textrm{OTM put value at position opening (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock price is $829.08 at expiration. You sold an OTM put at a strike of $767.50 for $4.60 and bought an ITM put at a strike of $835.00 for $40.00 .

The following chart shows the payoff at expiration:

The maximum profit is $K^{ITM} - K^{OTM} + P^{OTM}_0 - P^{ITM}_0$. If the underlying price is below than the strike prices of both put Option contracts, they are worth $(K - S_T)$ at expiration.

The maximum loss is the net debit you paid to open the position, $P^{OTM}_0 - P^{ITM}_0$.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
OTM put	4.60	767.50
ITM put	40.00	835.00
Underlying Equity at expiration	829.08	-

Therefore, the payoff is

$$\begin{array}{rcll} P^{OTM}_T & = & (K^{OTM} - S_T)^{+}\\ & = & (767.50-829.08)^{+}\\ & = & 0\\ P^{ITM}_T & = & (K^{ITM} - S_T)^{+}\\ & = & (835.00-829.08)^{+}\\ & = & 5.92\\ P_T & = & (P^{ITM}_T - P^{OTM}_T + P^{OTM}_0 - P^{ITM}_0)\times m - fee\\ & = & (5.92-0+4.60-40.00)\times100-1.00\times2\\ & = & -2950\\ \end{array}$$

So, the strategy loses $2,950.

The following algorithm implements a bear put spread strategy:

```py
class BearPutSpreadStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(500000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self.symbol = option.symbol
        option.set_filter(self.universe_func)

    def universe_func(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
        return universe.put_spread(30, 5)

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested: return

        # Get the OptionChain
        chain = slice.option_chains.get(self.symbol, None)
        if not chain: return

        # Get the furthest expiry date of the contracts
        expiry = sorted(chain, key = lambda x: x.expiry, reverse=True)[0].expiry

        # Select the put Option contracts with the furthest expiry
        puts = [i for i in chain if i.expiry == expiry and i.right == OptionRight.PUT]
        if len(puts) == 0: return

        # Select the ITM and OTM contract strike prices from the remaining contracts
        put_strikes = sorted([x.strike for x in puts])
        otm_strike = put_strikes[0]
        itm_strike = put_strikes[-1]

        option_strategy = OptionStrategies.bear_put_spread(self.symbol, itm_strike, otm_strike, expiry)
        self.buy(option_strategy, 1)
```

Option Strategies

Bull Call Spread

Introduction

Bull call spread , also known as long call spread , consists of buying an ITM call and selling an OTM call. Both calls have the same underlying Equity and the same expiration date. The OTM call serves as a hedge for the ITM call. The bull call spread profits from a rise in underlying asset price.

Implementation

Follow these steps to implement the bull call spread strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```py
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(500000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.call_spread(30, 5))
```

   The `call_spread` filter narrows the universe down to just the two contracts you need to form a bull call spread.

2. In the `on_data` method, select the expiration and strikes of the contracts in the strategy legs.

```py
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Select the call Option contracts with the furthest expiry
    expiry = max([x.expiry for x in chain])
    calls = [i for i in chain if i.expiry == expiry and i.right == OptionRight.CALL]
    if not calls == 0:
        return

    # Select the ITM and OTM contract strike prices from the remaining contracts
    strikes = [x.strike for x in calls]
    otm_strike = max(strikes)
    itm_strike = min(strikes)
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.bull_call_spread` method with the details of each leg and then pass the result to the `buy` method.

```py
option_strategy = OptionStrategies.bull_call_spread(self._symbol, itm_strike, otm_strike, expiry)
self.buy(option_strategy, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
itm_call = [x for x in calls if x.strike == itm_strike][0]
otm_call = [x for x in calls if x.strike == otm_strike][0]

legs = [
    Leg.create(itm_call.symbol, 1),
    Leg.create(otm_call.symbol, -1)
]
self.combo_market_order(legs, 1)
```

Strategy Payoff

The bull call spread is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^{OTM})^{+}\\ C^{ITM}_T & = & (S_T - K^{ITM})^{+}\\ P_T & = & (C^{ITM}_T - C^{OTM}_T + C^{OTM}_0 - C^{ITM}_0)\times m - fee\\ \end{array} \begin{array}{rcll} \textrm{where} & C^{OTM}_T & = & \textrm{OTM call value at time T}\\ & C^{ITM}_T & = & \textrm{ITM call value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{OTM} & = & \textrm{OTM call strike price}\\ & K^{ITM} & = & \textrm{ITM call strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{ITM}_0 & = & \textrm{ITM call value at position opening (debit paid)}\\ & C^{OTM}_0 & = & \textrm{OTM call value at position opening (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock price is $829.08 at expiration. You sold an OTM call at a strike of $835.00 for $3.00 and bought an ITM call at a strike of $767.50 for $41.00 .

The following chart shows the payoff at expiration:

The maximum profit is $K^{OTM} - K^{ITM} + C^{OTM}_0 - C^{ITM}_0$. If the underlying price increases to exceed both strikes at expiration, both calls are worth $(S_T - K)$ at expiration.

The maximum loss is the net debit you paid to open the position, $C^{OTM}_0 - C^{ITM}_0$.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
OTM call	3.00	835.00
ITM call	41.00	767.50
Underlying Equity at expiration	829.08	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^{OTM})^{+}\\ & = & (829.08-835.00)^{+}\\ & = & 0\\ C^{ITM}_T & = & (S_T - K^{ITM})^{+}\\ & = & (829.08-767.50)^{+}\\ & = & 61.58\\ P_T & = & (C^{ITM}_T - C^{OTM}_T + C^{OTM}_0 - C^{ITM}_0)\times m - fee\\ & = & (61.58-0+3.00-41.00)\times100-1.00\times2\\ & = & 2356\\ \end{array}$$

So, the strategy profits $2,356.

The following algorithm implements a bull call spread strategy:

```py
class BullCallSpreadStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(500000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self.symbol = option.symbol
        option.set_filter(self.universe_func)

    def universe_func(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
        return universe.call_spread(30, 5)

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested: return

        # Get the OptionChain
        chain = slice.option_chains.get(self.symbol, None)
        if not chain: return

        # Get the furthest expiration date of the contracts
        expiry = sorted(chain, key = lambda x: x.expiry, reverse=True)[0].expiry

        # Select the call Option contracts with the furthest expiry
        calls = [i for i in chain if i.expiry == expiry and i.right == OptionRight.CALL]
        if len(calls) == 0: return

        # Select the ITM and OTM contract strike prices from the remaining contracts
        call_strikes = sorted([x.strike for x in calls])
        itm_strike = call_strikes[0]
        otm_strike = call_strikes[-1]

        option_strategy = OptionStrategies.bull_call_spread(self.symbol, itm_strike, otm_strike, expiry)
        self.buy(option_strategy, 1)
```

Option Strategies

Bull Put Spread

Introduction

Bull put spread , also known as long put spread , consists of buying an OTM put and selling an ITM put. Both puts have the same underlying Equity and the same expiration date. The OTM put serves as a hedge for the ITM put. The bull put spread profits from a rise in underlying asset price.

Implementation

Follow these steps to implement the bull put spread strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```py
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(500000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.put_spread(30, 5))
```

   The `put_spread` filter narrows the universe down to just the two contracts you need to form a bull put spread.

2. In the `on_data` method, select the expiration and strikes of the contracts in the strategy legs.

```py
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Select the put Option contracts with the furthest expiry
    expiry = max([x.expiry for x in chain])
    puts = [i for i in chain if i.expiry == expiry and i.right == OptionRight.PUT]
    if not puts == 0:
        return

    # Select the ITM and OTM contract strike prices from the remaining contracts
    strikes = [x.strike for x in puts]
    otm_strike = min(strikes)
    itm_strike = max(strikes)
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.bull_put_spread` method with the details of each leg and then pass the result to the `buy` method.

```py
option_strategy = OptionStrategies.bull_put_spread(self._symbol, itm_strike, otm_strike, expiry)
self.buy(option_strategy, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
itm_put = [x for x in puts if x.strike == itm_strike][0]
otm_put = [x for x in puts if x.strike == otm_strike][0]

legs = [
    Leg.create(itm_put.symbol, -1),
    Leg.create(otm_put.symbol, 1)
]
self.combo_market_order(legs, 1)
```

Strategy Payoff

This is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} P^{OTM}_T & = & (K^{OTM} - S_T)^{+}\\ P^{ITM}_T & = & (K^{ITM} - S_T)^{+}\\ P_T & = & (P^{OTM}_T - P^{ITM}_T + P^{ITM}_0 - P^{OTM}_0)\times m - fee\\ \end{array} \begin{array}{rcl} \textrm{where} & P^{OTM}_T & = & \textrm{OTM put value at time T}\\ & P^{ITM}_T & = & \textrm{ITM put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{OTM} & = & \textrm{OTM put strike price}\\ & K^{ITM} & = & \textrm{ITM put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & P^{ITM}_0 & = & \textrm{ITM put value at position opening (credit received)}\\ & P^{OTM}_0 & = & \textrm{OTM put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock price is $829.08 at expiration. You sold an ITM put at a strike of $835.00 for $35.50 and bought an OTM put at a strike of $767.50 for $5.70 .

The following chart shows the payoff at expiration:

The maximum profit is the net credit you received when opening the position, $P^{ITM}_0 - P^{OTM}_0$. If the underlying price is higher than the strike prices of both put contracts at expiration, both puts expire worthless.

The maximum loss is $K^{OTM} - K^{ITM} + P^{ITM}_0 - P^{OTM}_0$.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
OTM put	5.70	767.50
ITM put	35.50	835.00
Underlying Equity at expiration	829.08	-

Therefore, the payoff is

$$\begin{array}{rcll} P^{OTM}_T & = & (K^{OTM} - S_T)^{+}\\ & = & (767.50-829.08)^{+}\\ & = & 0\\ P^{ITM}_T & = & (K^{ITM} - S_T)^{+}\\ & = & (835.00-829.08)^{+}\\ & = & 5.92\\ P_T & = & (P^{OTM}_T - P^{ITM}_T + P^{ITM}_0 - P^{OTM}_0)\times m - fee\\ & = & (0-5.92+35.50-5.70)\times100-1.00\times2\\ & = & 2386\\ \end{array}$$

So, the strategy profits $2,386.

The following algorithm implements a bull put spread strategy:

```py
class BullPutSpreadStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(500000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self.symbol = option.symbol
        option.set_filter(self.universe_func)

    def universe_func(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
        return universe.put_spread(30, 5)

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested: return

        # Get the OptionChain
        chain = slice.option_chains.get(self.symbol, None)
        if not chain: return

        # Get the furthest expiration date of the contracts
        expiry = sorted(chain, key = lambda x: x.expiry, reverse=True)[0].expiry

        # Select the put Option contracts with the furthest expiry
        puts = [i for i in chain if i.expiry == expiry and i.right == OptionRight.PUT]
        if len(puts) == 0: return

        # Select the ITM and OTM contract strikes from the remaining contracts
        put_strikes = sorted([x.strike for x in puts])
        otm_strike = put_strikes[0]
        itm_strike = put_strikes[-1]

        option_strategy = OptionStrategies.bull_put_spread(self.symbol, itm_strike, otm_strike, expiry)
        self.buy(option_strategy, 1)
```

Option Strategies

Long Call Butterfly

Introduction

The long call butterfly strategy is the combination of a bull call spread and a bear call spread . In the call butterfly, all of the calls should have the same underlying Equity, the same expiration date, and the same strike price distance between the ITM-ATM and OTM-ATM call pairs. The long call butterfly consists of a long ITM call, a long OTM call, and 2 short ATM calls. This strategy profits from low volatility in the underlying Equity price.

Implementation

Follow these steps to implement the long call butterfly strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(500000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.call_butterfly(30, 5))
```

   The `call_spread` filter narrows the universe down to just the three contracts you need to form a long call butterfly.

2. In the `on_data` method, select the contracts of the strategy legs.

```
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain.
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Get the furthest expiry date of the contracts.
    expiry = max([x.expiry for x in chain])

    # Select the call Option contracts with the furthest expiry.
    calls = [i for i in chain if i.expiry == expiry and i.right == OptionRight.CALL]
    if len(calls) == 0:
        return

    # Select the target contracts.
    atm_call = sorted(calls, key=lambda x: abs(x.strike - chain.underlying.price))[0]
    itm_call = sorted(calls, key=lambda x: x.strike)[-2]
    otm_call = [x for x in calls if x.strike == atm_call.strike * 2 - itm_call.strike][0]
```

3. In the `on_data` method, place the orders.

   Approach A: Call the `OptionStrategies.butterfly_call` method with the details of each leg and then pass the result to the `buy` method.

```
option_strategy = OptionStrategies.butterfly_call(self._symbol, itm_call.strike, atm_call.strike, otm_call.strike, expiry)
self.buy(option_strategy, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
legs = [
    Leg.create(atm_call.symbol, -2),
    Leg.create(itm_call.symbol, 1),
    Leg.create(otm_call.symbol, 1)
]
self.combo_market_order(legs, 1)
```

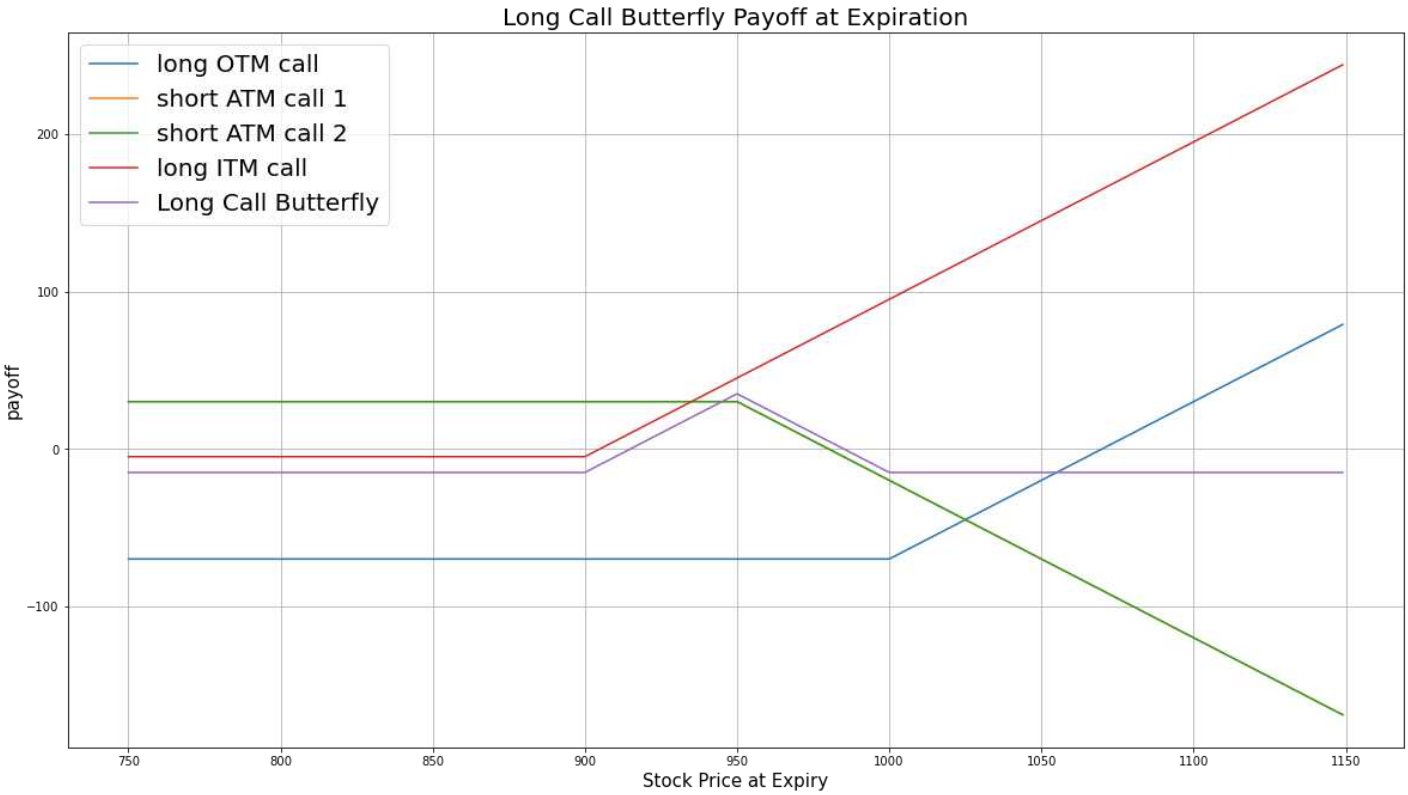
Strategy Payoff

The long call butterfly is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{OTM}_T &=& (S_T - K^{OTM})^{+}\\ C^{ITM}_T &=& (S_T - K^{ITM})^{+}\\ C^{ATM}_T &=& (S_T - K^{ATM})^{+}\\ P_T &=& (C^{OTM}_T + C^{ITM}_T - 2\times C^{ATM}_T + 2\times C^{ATM}_0 - C^{ITM}_0 - C^{OTM}_0)\times m - fee\\ \end{array} \begin{array}{rcl} \textrm{where} & C^{OTM}_T &= \textrm{OTM call value at time T}\\ & C^{ITM}_T &= \textrm{ITM call value at time T}\\ & C^{ATM}_T &= \textrm{ATM call value at time T}\\ & S_T &= \textrm{Underlying asset price at time T}\\ & K^{OTM} &= \textrm{OTM call strike price}\\ & K^{ITM} &= \textrm{ITM call strike price}\\ & K^{ATM} &= \textrm{ATM call strike price}\\ & P_T &= \textrm{Payout total at time T}\\ & C^{ITM}_0 &= \textrm{ITM call value at position opening (debit paid)}\\ & C^{OTM}_0 &= \textrm{OTM call value at position opening (debit paid)}\\ & C^{ATM}_0 &= \textrm{OTM call value at position opening (credit received)}\\ & m &= \textrm{Contract multiplier}\\ & T &= \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock price at expiration is $829.08 . You bought an OTM call at a strike of $767.50 for $4.90 , sold 2 ATM calls at a strike of $800.00 for $15.00 each, and bought an ITM call at a strike of $832.50 for $41.00 .

The following chart shows the payoff at expiration:



The maximum profit is $K^{ATM} - K^{ITM} + 2\times C^{ATM}_0 - C^{ITM}_0 - C^{OTM}_0$. It occurs when the underlying price is the same price at expiration as it was when opening the position and the payouts of the bull and bear call spreads are at their maximum.

The maximum loss is the net debit paid: $2\times C^{ATM}_0 - C^{ITM}_0 - C^{OTM}_0$. It occurs when the underlying price is less than ITM strike or greater than OTM strike at expiration.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the long call butterfly:

Asset	Price ($)	Strike ($)
OTM call	4.90	767.50
ATM call	15.00	800.00
ITM call	41.00	832.50
Underlying Equity at expiration	829.08	-

Therefore, the payoff is

\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^{OTM})^{+}\\ & = & (767.50-829.08)^{+}\\ & = & 0\\ C^{ITM}_T & = & (S_T - K^{ITM})^{+}\\ & = & (832.50-829.08)^{+}\\ & = & 3.42\\ C^{ATM}_T & = & (S_T - K^{ATM})^{+}\\ & = & (800.00-829.08)^{+}\\ & = & 0\\ P_T & = & (C^{OTM}_T + C^{ITM}_T - 2\times C^{ATM}_T + 2\times C^{ATM}_0 - C^{ITM}_0 - C^{OTM}_0)\times m - fee\\ & = & (0+3.42-0\times2-4.90-41.00+15.00\times2)\times100-1.00\times4\\ & = & -1252 \end{array}

So, the strategy loses $1,252.

The following algorithm implements a long call butterfly Option strategy:

```py
class LongCallButterflyStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(500000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self.symbol = option.symbol
        option.set_filter(self.universe_func)

    def universe_func(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
        return universe.strikes(-15, 15).expiration(timedelta(0), timedelta(31))

    def on_data(self, data: Slice) -> None:
        # avoid extra orders
        if self.portfolio.invested: return

        # Get the OptionChain of the self.symbol
        chain = data.option_chains.get(self.symbol, None)
        if not chain: return

        # sorted the optionchain by expiration date and choose the furthest date
        expiry = sorted(chain, key = lambda x: x.expiry, reverse=True)[0].expiry

        # filter the call options from the contracts which expire on the furthest expiration date in the option chain.
        calls = [i for i in chain if i.expiry == expiry and i.right == OptionRight.CALL]
        if len(calls) == 0: return

        # sort the call options with the same expiration date according to their strike price.
        call_strikes = sorted([x.strike for x in calls])

        # get at-the-money strike
        atm_strike = sorted(calls, key=lambda x: abs(x.strike - chain.underlying.price))[0].strike

        # Get the distance between lowest strike price and ATM strike, and highest strike price and ATM strike.
        # Get the lower value as the spread distance as equidistance is needed for both side.
        spread = min(abs(call_strikes[0] - atm_strike), abs(call_strikes[-1] - atm_strike))

        # select the strike prices for forming the option legs
        itm_strike = atm_strike - spread
        otm_strike = atm_strike + spread

        option_strategy = OptionStrategies.call_butterfly(self.symbol, otm_strike, atm_strike, itm_strike, expiry)
        # We open a position with 1 unit of the option strategy
        self.buy(option_strategy, 1)
        # self.sell(option_strategy, 1) if short call butterfly
```

Option Strategies

Short Call Butterfly

Introduction

The short call butterfly strategy is the combination of a bull call spread and a bear call spread . In the call butterfly, all of the calls should have the same underlying Equity, the same expiration date, and the same strike price distance between the ITM-ATM and OTM-ATM call pairs. The short call butterfly consists of a short ITM call, a short OTM call, and 2 long ATM calls. This strategy profits from high volatility in the underlying Equity price.

Implementation

Follow these steps to implement the short call butterfly strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```py
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(500000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.call_butterfly(30, 5))
```

   The `call_butterfly` filter narrows the universe down to just the three contracts you need to form a short call butterfly.

2. In the `on_data` method, select the contracts of the strategy legs.

```py
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Get the furthest expiry date of the contracts
    expiry = max([x.expiry for x in chain])

    # Select the call Option contracts with the furthest expiry
    calls = [i for i in chain if i.expiry == expiry and i.right == OptionRight.CALL]
    if len(calls) == 0:
        return

    # Select the ATM, ITM and OTM contracts from the remaining contracts
    atm_call = sorted(calls, key=lambda x: abs(x.strike - chain.underlying.price))[0]
    itm_call = sorted(calls, key=lambda x: x.strike)[1]
    otm_call = [x for x in calls if x.strike == atm_call.strike * 2 - itm_call.strike][0]
```

3. In the `on_data` method, place the orders.

   Approach A: Call the `OptionStrategies.short_butterfly_call` method with the details of each leg and then pass the result to the `buy` method.

```py
option_strategy = OptionStrategies.short_butterfly_call(self._symbol, otm_call.strike, atm_call.strike, itm_call.strike, expiry)
self.buy(option_strategy, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
legs = [
    Leg.create(atm_call.symbol, 2),
    Leg.create(itm_call.symbol, -1),
    Leg.create(otm_call.symbol, -1)
]
self.combo_market_order(legs, 1)
```

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

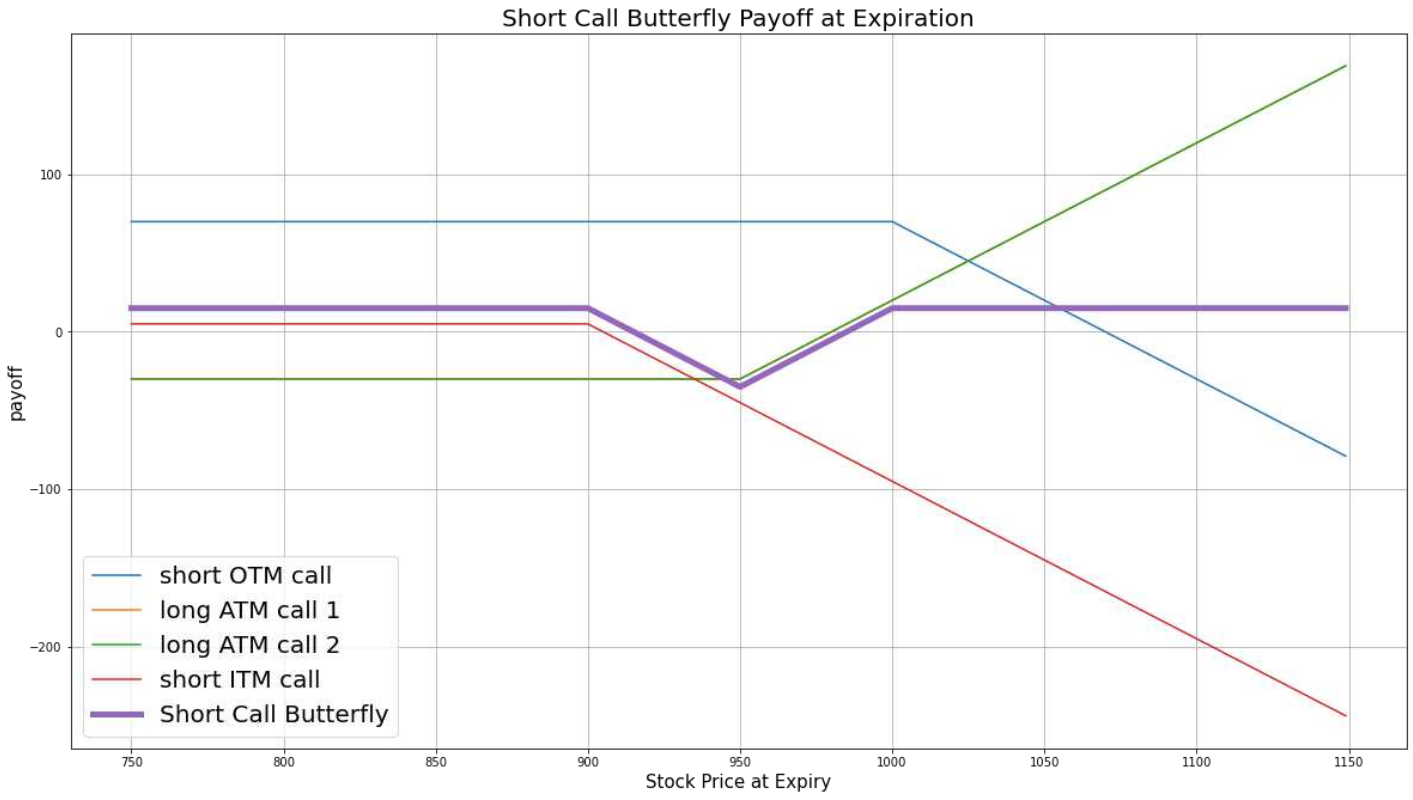
Strategy Payoff

The short call butterfly is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^{OTM})^{+}\\ C^{ITM}_T & = & (S_T - K^{ITM})^{+}\\ C^{ATM}_T & = & (S_T - K^{ATM})^{+}\\ P_T & = & (2\times C^{ATM}_T - C^{OTM}_T - C^{ITM}_T - 2\times C^{ATM}_0 + C^{ITM}_0 + C^{OTM}_0)\times m - fee \end{array} \begin{array}{rcll} \textrm{where} & C^{OTM}_T & = & \textrm{OTM call value at time T}\\ & C^{ITM}_T & = & \textrm{ITM call value at time T}\\ & C^{ATM}_T & = & \textrm{ATM call value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{OTM} & = & \textrm{OTM call strike price}\\ & K^{ITM} & = & \textrm{ITM call strike price}\\ & K^{ATM} & = & \textrm{ATM call strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{ITM}_0 & = & \textrm{ITM call value at position opening (credit received)}\\ & C^{OTM}_0 & = & \textrm{OTM call value at position opening (credit received)}\\ & C^{ATM}_0 & = & \textrm{ATM call value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock price at expiration is $829.08 . You bought an OTM call at a strike of $767.50 for $4.90 , sold 2 ATM calls at a strike of $800.00 for $15.00 each, and bought an ITM call at a strike of $832.50 for $41.00 .

The following chart shows the payoff at expiration:



The maximum profit is the net credit received: $C^{ITM}_0 + C^{OTM}_0 - 2\times C^{ATM}_0$. It occurs when the underlying price is less than ITM strike or greater than OTM strike at expiration.

The maximum loss is $K^{ATM} - K^{ITM} + C^{ITM}_0 + C^{OTM}_0 - 2\times C^{ATM}_0$. It occurs when the underlying price is at the same level as when you opened the trade.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the short call butterfly:

Asset	Price ($)	Strike ($)
OTM call	4.90	767.50
ATM call	15.00	800.00
ITM call	41.00	832.50
Underlying Equity at expiration	829.08	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^{OTM})^{+}\\ & = & (767.50-829.08)^{+}\\ & = & 0\\ C^{ITM}_T & = & (S_T - K^{ITM})^{+}\\ & = & (832.50-829.08)^{+}\\ & = & 3.42\\ C^{ATM}_T & = & (S_T - K^{ATM})^{+}\\ & = & (800.00-829.08)^{+}\\ & = & 0\\ P_T & = & (-C^{OTM}_T - C^{ITM}_T + 2\times C^{ATM}_T - 2\times C^{ATM}_0 + C^{ITM}_0 + C^{OTM}_0)\times m - fee\\ & = & (-0-3.42+0\times2+4.90+41.00-15.00\times2)\times100-1.00\times4\\ & = & 1244 \end{array}$$

So, the strategy gains $1,244.

The following algorithm implements a short call butterfly Option strategy:

```py
class LongCallButterflyStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(500000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self.symbol = option.symbol
        option.set_filter(self.universe_func)

    def universe_func(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
        return universe.call_butterfly(30, 5)

    def on_data(self, data: Slice) -> None:
        # avoid extra orders
        if self.portfolio.invested: return

        # Get the OptionChain of the self.symbol
        chain = data.option_chains.get(self.symbol, None)
        if not chain: return

        # sorted the optionchain by expiration date and choose the furthest date
        expiry = sorted(chain, key = lambda x: x.expiry, reverse=True)[0].expiry

        # filter the call options from the contracts which expire on the furthest expiration date in the option chain.
        calls = [i for i in chain if i.expiry == expiry and i.right == OptionRight.CALL]
        if len(calls) == 0: return

        # sort the call options with the same expiration date according to their strike price.
        call_strikes = sorted([x.strike for x in calls])

        # get at-the-money strike
        atm_strike = sorted(calls, key=lambda x: abs(x.strike - chain.underlying.price))[0].strike

        # Get the distance between lowest strike price and ATM strike, and highest strike price and ATM strike.
        # Get the lower value as the spread distance as equidistance is needed for both side.
        spread = min(abs(call_strikes[0] - atm_strike), abs(call_strikes[-1] - atm_strike))

        # select the strike prices for forming the option legs
        itm_strike = atm_strike - spread
        otm_strike = atm_strike + spread

        option_strategy = OptionStrategies.short_butterfly_call(self.symbol, otm_strike, atm_strike, itm_strike, expiry)
        # We open a position with 1 unit of the option strategy
        self.buy(option_strategy, 1)
```

LongAndShortButterflyCallStrategiesAlgorithm.py Python

Option Strategies

Long Put Butterfly

Introduction

Long Put butterfly is the combination of a bull put spread and a bear put spread . In this strategy, all the puts have the same underlying stock, the same expiration date, and the strike price distance of ITM-ATM and OTM-ATM put pairs are the same. The long put butterfly strategy consists of buying an ITM put, buying an OTM put, and selling 2 ATM puts. This strategy profits from low volatility.

Implementation

Follow these steps to implement the long put butterfly strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(500000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.put_butterfly(30, 5))
```

   The `put_butterfly` filter narrows the universe down to just the three contracts you need to form a long put butterfly.

2. In the `on_data` method, select the contracts of the strategy legs.

```
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Get the furthest expiry date of the contracts
    expiry = max([x.expiry for x in chain])

    # Select the call Option contracts with the furthest expiry
    puts = [i for i in chain if i.expiry == expiry and i.right == OptionRight.PUT]
    if len(puts) == 0:
        return

    # Select the ATM, ITM and OTM contracts from the remaining contracts
    atm_put = sorted(puts, key=lambda x: abs(x.strike - chain.underlying.price))[0]
    itm_put = sorted(puts, key=lambda x: x.strike)[-2]
    otm_put = [x for x in puts if x.strike == atm_put.strike * 2 - itm_put.strike][0]
```

3. In the `on_data` method, place the orders.

   Approach A: Call the `OptionStrategies.butterfly_put` method with the details of each leg and then pass the result to the `buy` method.

```
option_strategy = OptionStrategies.butterfly_put(self._symbol, itm_put.strike, atm_put.strike, otm_put.strike, expiry)
self.buy(option_strategy, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```py
legs = [
    Leg.create(atm_put.symbol, -2),
    Leg.create(itm_put.symbol, 1),
    Leg.create(otm_put.symbol, 1)
]
self.combo_market_order(legs, 1)
```

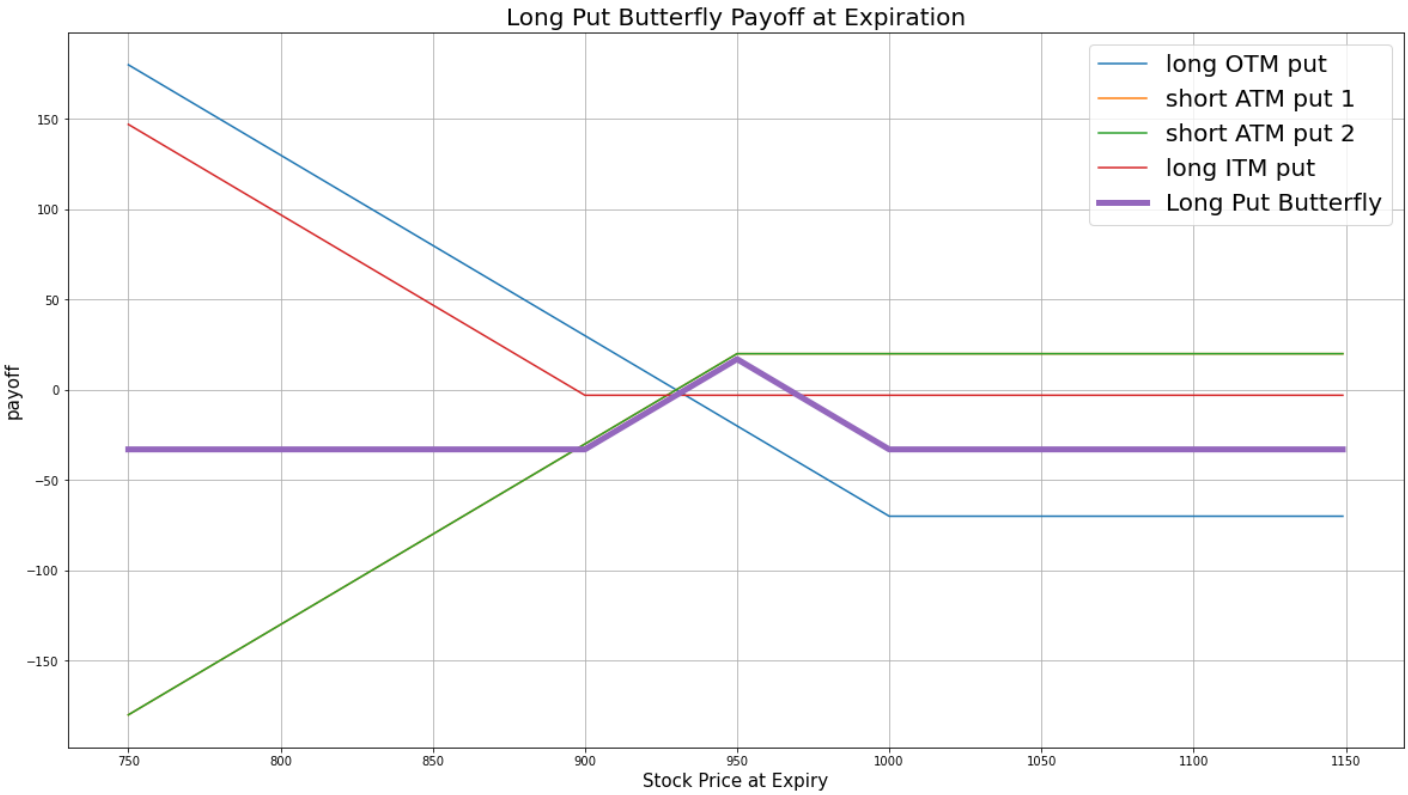
Strategy Payoff

The long put butterfly is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} P^{OTM}_T & = & (K^{OTM} - S_T)^{+}\\ P^{ITM}_T & = & (K^{ITM} - S_T)^{+}\\ P^{ATM}_T & = & (K^{ATM} - S_T)^{+}\\ P_T & = & (P^{OTM}_T + P^{ITM}_T - 2\times P^{ATM}_T + 2\times P^{ATM}_0 - P^{ITM}_0 - P^{OTM}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & P^{OTM}_T & = & \textrm{OTM put value at time T}\\ & P^{ITM}_T & = & \textrm{ITM put value at time T}\\ & P^{ATM}_T & = & \textrm{ATM put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{OTM} & = & \textrm{OTM put strike price}\\ & K^{ITM} & = & \textrm{ITM put strike price}\\ & K^{ATM} & = & \textrm{ATM put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & P^{ITM}_0 & = & \textrm{ITM put value at position opening (debit paid)}\\ & P^{OTM}_0 & = & \textrm{OTM put value at position opening (debit paid)}\\ & P^{ATM}_0 & = & \textrm{ATM put value at position opening (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock price at expiration is $829.08 . You bought an ITM put at a strike of $832.50 for $37.80 , sold 2 ATM puts at a strike of $800.00 for $14.70 each, and bought an OTM put at a strike of $767.50 for $5.70 .

The following chart shows the payoff at expiration:



The maximum profit is $K^{ATM} - K^{OTM} + 2\times P^{ATM}_0 - P^{ITM}_0 - P^{OTM}_0$. It occurs when the underlying price is the same at expiration as it was when you open the trade. In this case, the payout of the combined bull put and bear put spreads are at their maximum.

The maximum loss is the net debit paid, $2\times P^{ATM}_0 - P^{ITM}_0 - P^{OTM}_0$. It occurs when the underlying price is below the ITM strike price or above the OTM strike price at expiration.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the long put butterfly algorithm:

Asset	Price ($)	Strike ($)
ITM put	37.80	832.50
ATM put	14.70	800.00
OTM put	5.70	767.50
Underlying Equity at expiration	829.08	-

Therefore, the payoff is

$$\begin{array}{rcl} P^{OTM}_T & = & (K^{OTM} - S_T)^{+}\\ & = & (829.08-832.50)^{+}\\ & = & 0\\ P^{ITM}_T & = & (K^{ITM} - S_T)^{+}\\ & = & (829.08-767.50)^{+}\\ & = & 61.58\\ P^{ATM}_T & = & (K^{ATM} - S_T)^{+}\\ & = & (829.08-800.00)^{+}\\ & = & 29.08\\ P_T & = & (P^{OTM}_T + P^{ITM}_T - 2\times P^{ATM}_T + 2\times P^{ATM}_0 - P^{ITM}_0 - P^{OTM}_0)\times m - fee\\ & = & (61.58+0-29.08\times2-5.70-37.80+14.70\times2)\times100-1.00\times4\\ & = & -1072 \end{array}$$

So, the strategy loses $1,072.

The following algorithm implements a long put butterfly Option strategy:

```py
class PutButterflyStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(500000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self.symbol = option.symbol
        option.set_filter(self.universe_func)

    def universe_func(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
        return universe.put_butterfly(30, 5)

    def on_data(self, data: Slice) -> None:
        # avoid extra orders
        if self.portfolio.invested: return

        # Get the OptionChain of the self.symbol
        chain = data.option_chains.get(self.symbol, None)
        if not chain: return

        # sorted the optionchain by expiration date and choose the furthest date
        expiry = sorted(chain, key = lambda x: x.expiry, reverse=True)[0].expiry

        # filter the put options from the contracts which expire on the furthest expiration date in the option chain.
        puts = [i for i in chain if i.expiry == expiry and i.right == OptionRight.PUT]
        if len(puts) == 0: return

        # sort the put options with the same expiration date according to their strike price.
        put_strikes = sorted([x.strike for x in puts])

        # get at-the-money strike
        atm_strike = sorted(puts, key=lambda x: abs(x.strike - chain.underlying.price))[0].strike

        # Get the distance between lowest strike price and ATM strike, and highest strike price and ATM strike.
        # Get the lower value as the spread distance as equidistance is needed for both side.
        spread = min(abs(put_strikes[0] - atm_strike), abs(put_strikes[-1] - atm_strike))

        # select the strike prices for forming the option legs
        itm_strike = atm_strike + spread
        otm_strike = atm_strike - spread

        option_strategy = OptionStrategies.put_butterfly(self.symbol, itm_strike, atm_strike, otm_strike, expiry)
        # We open a position with 1 unit of the option strategy
        self.buy(option_strategy, 1)
        # self.sell(option_strategy, 1) if short put butterfly
```

Option Strategies

Short Put Butterfly

Introduction

Short Put butterfly is the combination of a bull put spread and a bear put spread . In this strategy, all the puts have the same underlying stock, the same expiration date, and the strike price distance of ITM-ATM and OTM-ATM put pairs are the same. The short put butterfly strategy consists of selling an ITM put, selling an OTM put, and buying 2 ATM puts. This strategy profits from a drastic change in underlying price.

Implementation

Follow these steps to implement the short put butterfly strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```py
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(500000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.put_butterfly(30, 5))
```

   The `put_butterfly` filter narrows the universe down to just the three contracts you need to form a short put butterfly.

2. In the `on_data` method, select the contracts of the strategy legs.

```py
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Get the furthest expiry date of the contracts
    expiry = max([x.expiry for x in chain])

    # Select the call Option contracts with the furthest expiry
    puts = [i for i in chain if i.expiry == expiry and i.right == OptionRight.PUT]
    if len(puts) == 0:
        return

    # Select the ATM, ITM and OTM contracts from the remaining contracts
    atm_put = sorted(puts, key=lambda x: abs(x.strike - chain.underlying.price))[0]
    itm_put = sorted(puts, key=lambda x: x.strike)[-2]
    otm_put = [x for x in puts if x.strike == atm_put.strike * 2 - itm_put.strike][0]
```

3. In the `on_data` method, place the orders.

   Approach A: Call the `OptionStrategies.short_butterfly_put` method with the details of each leg and then pass the result to the `buy` method.

```py
option_strategy = OptionStrategies.short_butterfly_put(self._symbol, itm_put.strike, atm_put.strike, otm_put.strike, expiry)
self.buy(option_strategy, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
legs = [
    Leg.create(atm_put.symbol, 2),
    Leg.create(itm_put.symbol, -1),
    Leg.create(otm_put.symbol, -1)
]
self.combo_market_order(legs, 1)
```

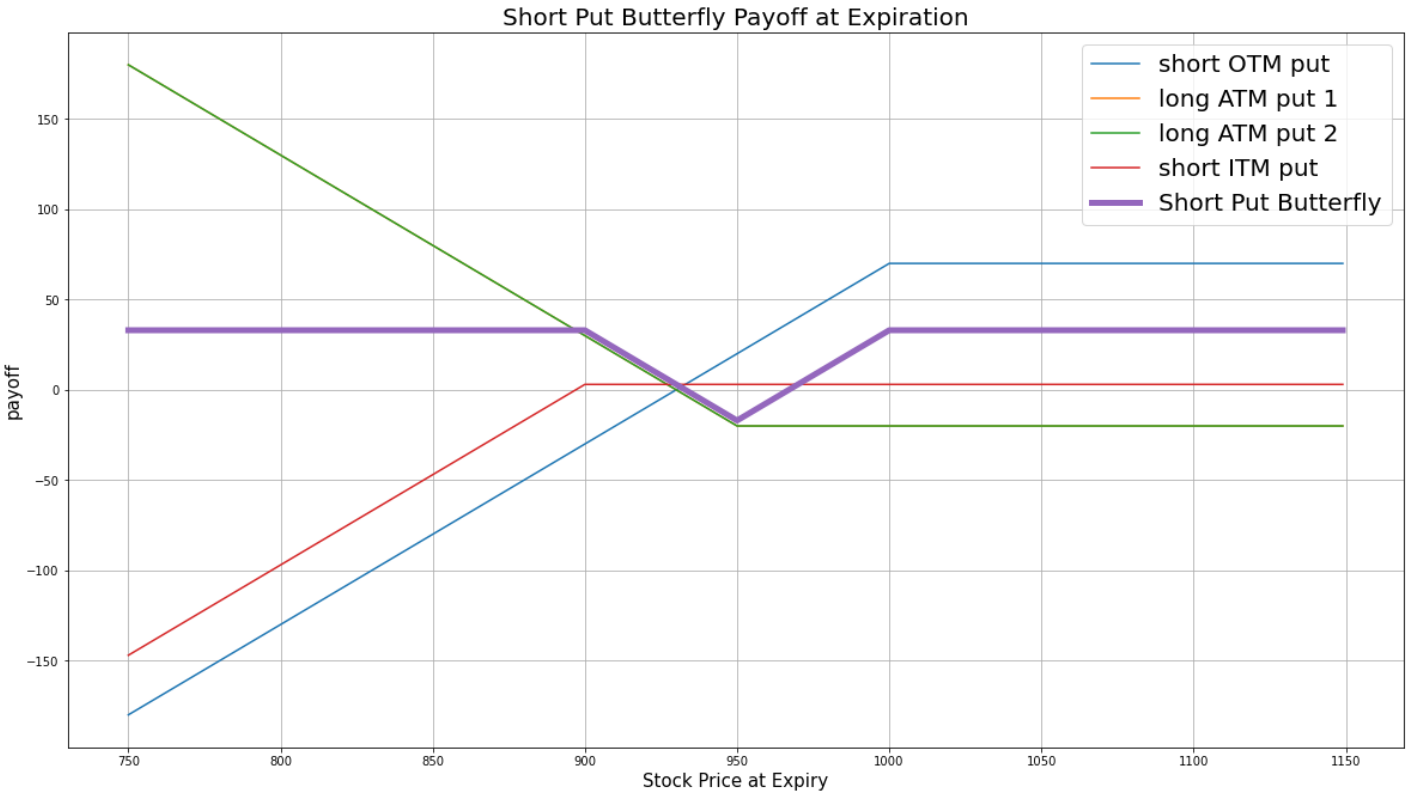
Strategy Payoff

The short put butterfly is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} P^{OTM}_T &=& (K^{OTM} - S_T)^{+}\\ P^{ITM}_T &=& (K^{ITM} - S_T)^{+}\\ P^{ATM}_T &=& (K^{ATM} - S_T)^{+}\\ P_T &=& (2\times P^{ATM}_T - P^{OTM}_T - P^{ITM}_T - 2\times P^{ATM}_0 + P^{ITM}_0 + P^{OTM}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & P^{OTM}_T &= \textrm{OTM put value at time T}\\ & P^{ITM}_T &= \textrm{ITM put value at time T}\\ & P^{ATM}_T &= \textrm{ATM put value at time T}\\ & S_T &= \textrm{Underlying asset price at time T}\\ & K^{OTM} &= \textrm{OTM put strike price}\\ & K^{ITM} &= \textrm{ITM put strike price}\\ & K^{ATM} &= \textrm{ATM put strike price}\\ & P_T &= \textrm{Payout total at time T}\\ & P^{ITM}_0 &= \textrm{ITM put value at position opening (credit received)}\\ & P^{OTM}_0 &= \textrm{OTM put value at position opening (credit received)}\\ & P^{ATM}_0 &= \textrm{ATM put value at position opening (debit paid)}\\ & m &= \textrm{Contract multiplier}\\ & T &= \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock price at expiration is $829.08 . You bought an ITM put at a strike of $832.50 for $37.80 , sold 2 ATM puts at a strike of $800.00 for $14.70 each, and bought an OTM put at a strike of $767.50 for $5.70 .

The following chart shows the payoff at expiration:



The maximum profit is the net credit received, $P^{ITM}_0 + P^{OTM}_0 - 2\times P^{ATM}_0$. It occurs when the underlying price is below the ITM strike or above the OTM strike at expiration.

The maximum loss is $K^{ATM} - K^{OTM} - 2\times P^{ATM}_0 + P^{ITM}_0 + P^{OTM}_0$. It occurs when the underlying price at expiration is at the same price as when you opened the trade.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the short put butterfly algorithm:

Asset	Price ($)	Strike ($)
ITM put	37.80	832.50
ATM put	14.70	800.00
OTM put	5.70	767.50
Underlying Equity at expiration	829.08	-

Therefore, the payoff is

$$\begin{array}{rcl} P^{OTM}_T & = & (K^{OTM} - S_T)^{+}\\ & = & (829.08-832.50)^{+}\\ & = & 0\\ P^{ITM}_T & = & (K^{ITM} - S_T)^{+}\\ & = & (829.08-767.50)^{+}\\ & = & 61.58\\ P^{ATM}_T & = & (K^{ATM} - S_T)^{+}\\ & = & (829.08-800.00)^{+}\\ & = & 29.08\\ P_T & = & (-P^{OTM}_T - P^{ITM}_T + 2\times P^{ATM}_T - 2\times P^{ATM}_0 + P^{ITM}_0 + P^{OTM}_0)\times m - fee\\ & = & (-61.58-0+29.08\times2+5.70+37.80-14.70\times2)\times100-1.00\times4\\ & = & 1064 \end{array}$$

So, the strategy gains $1,064.

The following algorithm implements a short put butterfly Option strategy:

```py
class PutButterflyStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(500000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self.symbol = option.symbol
        option.set_filter(self.universe_func)

    def universe_func(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
        return universe.put_butterfly(30, 5)

    def on_data(self, data: Slice) -> None:
        # avoid extra orders
        if self.portfolio.invested: return

        # Get the OptionChain of the self.symbol
        chain = data.option_chains.get(self.symbol, None)
        if not chain: return

        # sorted the optionchain by expiration date and choose the furthest date
        expiry = sorted(chain, key = lambda x: x.expiry, reverse=True)[0].expiry

        # filter the put options from the contracts which expire on the furthest expiration date in the option chain.
        puts = [i for i in chain if i.expiry == expiry and i.right == OptionRight.PUT]
        if len(puts) == 0: return

        # sort the put options with the same expiration date according to their strike price.
        put_strikes = sorted([x.strike for x in puts])

        # get at-the-money strike
        atm_strike = sorted(puts, key=lambda x: abs(x.strike - chain.underlying.price))[0].strike

        # Get the distance between lowest strike price and ATM strike, and highest strike price and ATM strike.
        # Get the lower value as the spread distance as equidistance is needed for both side.
        spread = min(abs(put_strikes[0] - atm_strike), abs(put_strikes[-1] - atm_strike))

        # select the strike prices for forming the option legs
        itm_strike = atm_strike + spread
        otm_strike = atm_strike - spread

        option_strategy = OptionStrategies.short_butterfly_put(self.symbol, itm_strike, atm_strike, otm_strike, expiry)
        # We open a position with 1 unit of the option strategy
        self.buy(option_strategy, 1)
        # self.sell(option_strategy, 1) if short put butterfly
```

LongAndShortButterflyPutStrategiesAlgorithm.py Python

Option Strategies

Long Call Calendar Spread

Introduction

Long call calendar spread , also known as call horizontal spread , is a combination of a longer-term (far-leg/front-month) call and a shorter-term (near-leg/back-month) call, where all calls have the same underlying stock and the same strike price. The long call calendar spread consists of buying a longer-term call and selling a shorter-term call. This strategy profits from a decrease in the underlying price. It also profits from the time decay value because the theta \theta (the Option price decay by 1 day closer to maturity) of the shorter-term call is larger than longer-term call.

Implementation

Follow these steps to implement the long call calendar spread strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(500000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.call_calendar_spread(0, 30, 60))
```

   The `call_calendar_spread` filter narrows the universe down to just the two contracts you need to form a long call calendar spread.

2. In the `on_data` method, select the strike price and expiration dates of the contracts in the strategy legs.

```
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Get the ATM strike
    atm_strike = sorted(chain, key=lambda x: abs(x.strike - chain.underlying.price))[0].strike

    # Select the ATM call Option contracts
    calls = [i for i in chain if i.strike == atm_strike and i.right == OptionRight.CALL]
    if len(calls) == 0:
        return

    # Select the near and far expiry dates
    expiries = sorted([x.expiry for x in calls])
    near_expiry = expiries[0]
    far_expiry = expiries[-1]
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.call_calendar_spread` method with the details of each leg and then pass the result to the `buy` method.

```
option_strategy = OptionStrategies.call_calendar_spread(self._symbol, atm_strike, near_expiry, far_expiry)
self.buy(option_strategy, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
near_expiry_call = [x for x in calls if x.expiry == near_expiry][0]
far_expiry_call = [x for x in calls if x.expiry == far_expiry][0]

legs = [
    Leg.create(near_expiry_call.symbol, -1),
    Leg.create(far_expiry_call.symbol, 1)
]
self.combo_market_order(legs, 1)
```

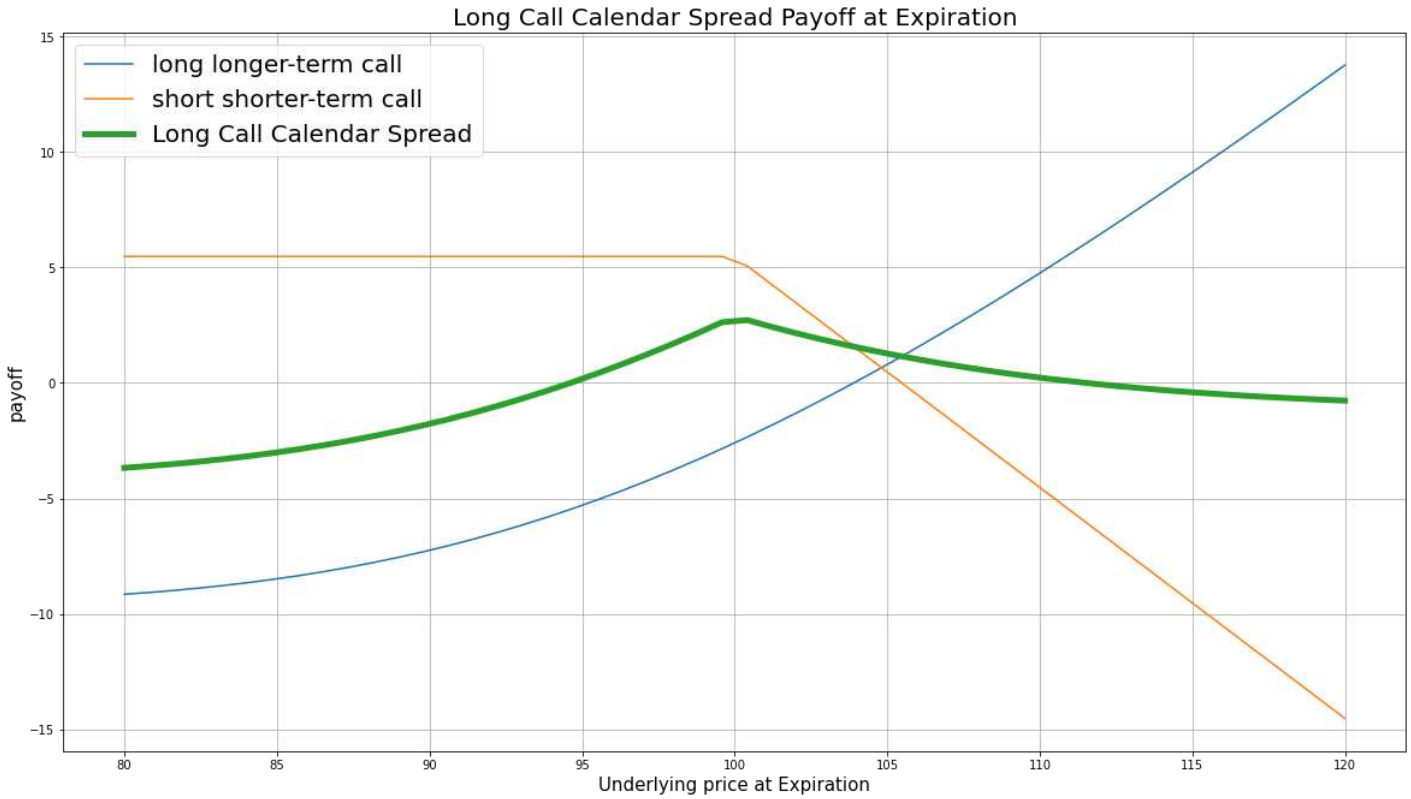
Strategy Payoff

The long call calendar spread is a limited-reward-limited-risk strategy. The payoff at the shorter-term expiration is

$$\begin{array}{rcll} C^{\textrm{short-term}}_T & = & (S_T - K)^{+}\\ P_T & = & (C^{\textrm{long-term}}_T - C^{\textrm{short-term}}_T + C^{\textrm{short-term}}_0 - C^{\textrm{long-term}}_0)\times m - fee\\ \end{array} \begin{array}{rcll} \textrm{where} & C^{\textrm{short-term}}_T & = & \textrm{Shorter term call value at time T}\\ & C^{\textrm{long-term}}_T & = & \textrm{Longer term call value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{\textrm{short-term}}_0 & = & \textrm{Shorter term call value at position opening (credit received)}\\ & C^{\textrm{long-term}}_0 & = & \textrm{Longer term call value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of shorter term call expiration} \end{array}$$

In this example, you bought a longer-term call at a strike of $800.00 for $20.00 and sold a shorter-term call at the same strike for $11.30 .

The following chart shows the payoff at expiration:



The maximum profit is undetermined because it depends on the underlying volatility. It occurs when $S_T = S_0$ and the spread of the calls are at their maximum.

The maximum loss is the net debit paid, $C^{\textrm{short-term}}_0 - C^{\textrm{long-term}}_0$. It occurs when the underlying price moves very deep ITM or OTM so the values of both calls are close to zero.

If the Option is American Option, there is a risk of early assignment on the contract you sell. If the buyer exercises the call you sell, you could lose all the debit you received if you don't close the long call and the underlying price drops below the long call strike price.

Example

The following table shows the price details of the assets in the long call calendar spread:

Asset	Price ($)	Strike ($)
Longer-term call at the start of the trade	4.40	835.00
Shorter-term call at the start of the trade	36.80	767.50
Longer-term call at time T	31.35	835.00
Underlying Equity at time T	829.08	-

Therefore, the payoff at time T (the expiration of the short-term call) is

$$\begin{array}{rcll} C^{\textrm{short-term}}_T & = & (S_T - K)^{+}\\ & = & (828.07-800.00)^{+}\\ & = & 28.07\\ P_T & = & (C^{\textrm{long-term}}_T - C^{\textrm{short-term}}_T + C^{\textrm{short-term}}_0 - C^{\textrm{long-term}}_0)\times m - fee\\ & = & (31.35-28.07+11.30-20.00)\times100-1.00\times2\\ & = & -544 \end{array}$$

So, the strategy loses $544.

The following algorithm implements a long call calendar spread Option strategy:

```py
class LongCallCalendarSpreadStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(500000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self.symbol = option.symbol
        option.set_filter(self.universe_func)

    def universe_func(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
        return universe.call_calendar_spread(0, 30, 60)

    def on_data(self, data: Slice) -> None:
        # avoid extra orders
        if self.portfolio.invested: return

        # Get the OptionChain of the self.symbol
        chain = data.option_chains.get(self.symbol, None)
        if not chain: return

        # get at-the-money strike
        atm_strike = sorted(chain, key=lambda x: abs(x.strike - chain.underlying.price))[0].strike

        # filter the call options from the contracts which is ATM in the option chain.
        calls = [i for i in chain if i.strike == atm_strike and i.right == OptionRight.CALL]
        if len(calls) == 0: return

        # sorted the optionchain by expiration date
        expiries = sorted([x.expiry for x in calls], key = lambda x: x)

        # select the farest expiry as far-leg expiry, and the nearest expiry as near-leg expiry
        near_expiry = expiries[0]
        far_expiry = expiries[-1]

        option_strategy = OptionStrategies.call_calendar_spread(self.symbol, atm_strike, near_expiry, far_expiry)
        # We open a position with 1 unit of the option strategy
        self.buy(option_strategy, 1)
        # self.sell(option_strategy, 1) if short call calendar spread
```

Option Strategies

Short Call Calendar Spread

Introduction

Call calendar spread , also known as call horizontal spread , is a combination of a longer-term (far-leg/front-month) call and a shorter-term (near-leg/back-month) call, where all calls have the same underlying stock and the same strike price. The short call calendar spread consists of selling a longer-term call and buying a shorter-term call. The strategy profits from from an increase in the underlying price.

Implementation

Follow these steps to implement the short call calendar spread strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(500000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.call_calendar_spread(0, 30, 60))
```

   The `call_calendar_spread` filter narrows the universe down to just the two contracts you need to form a short call calendar spread.

2. In the `on_data` method, select the strike price and expiration dates of the contracts in the strategy legs.

```
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Get the ATM strike
    atm_strike = sorted(chain, key=lambda x: abs(x.strike - chain.underlying.price))[0].strike

    # Select the ATM call Option contracts
    calls = [i for i in chain if i.strike == atm_strike and i.right == OptionRight.CALL]
    if len(calls) == 0:
        return

    # Select the near and far expiry dates
    expiries = sorted([x.expiry for x in calls])
    near_expiry = expiries[0]
    far_expiry = expiries[-1]
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.short_call_calendar_spread` method with the details of each leg and then pass the result to the `buy` method.

```
option_strategy = OptionStrategies.short_call_calendar_spread(self._symbol, atm_strike, near_expiry, far_expiry)
self.buy(option_strategy, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
near_expiry_call = [x for x in calls if x.expiry == near_expiry][0]
far_expiry_call = [x for x in calls if x.expiry == far_expiry][0]

legs = [
    Leg.create(near_expiry_call.symbol, 1),
    Leg.create(far_expiry_call.symbol, -1)
]
self.combo_market_order(legs, 1)
```

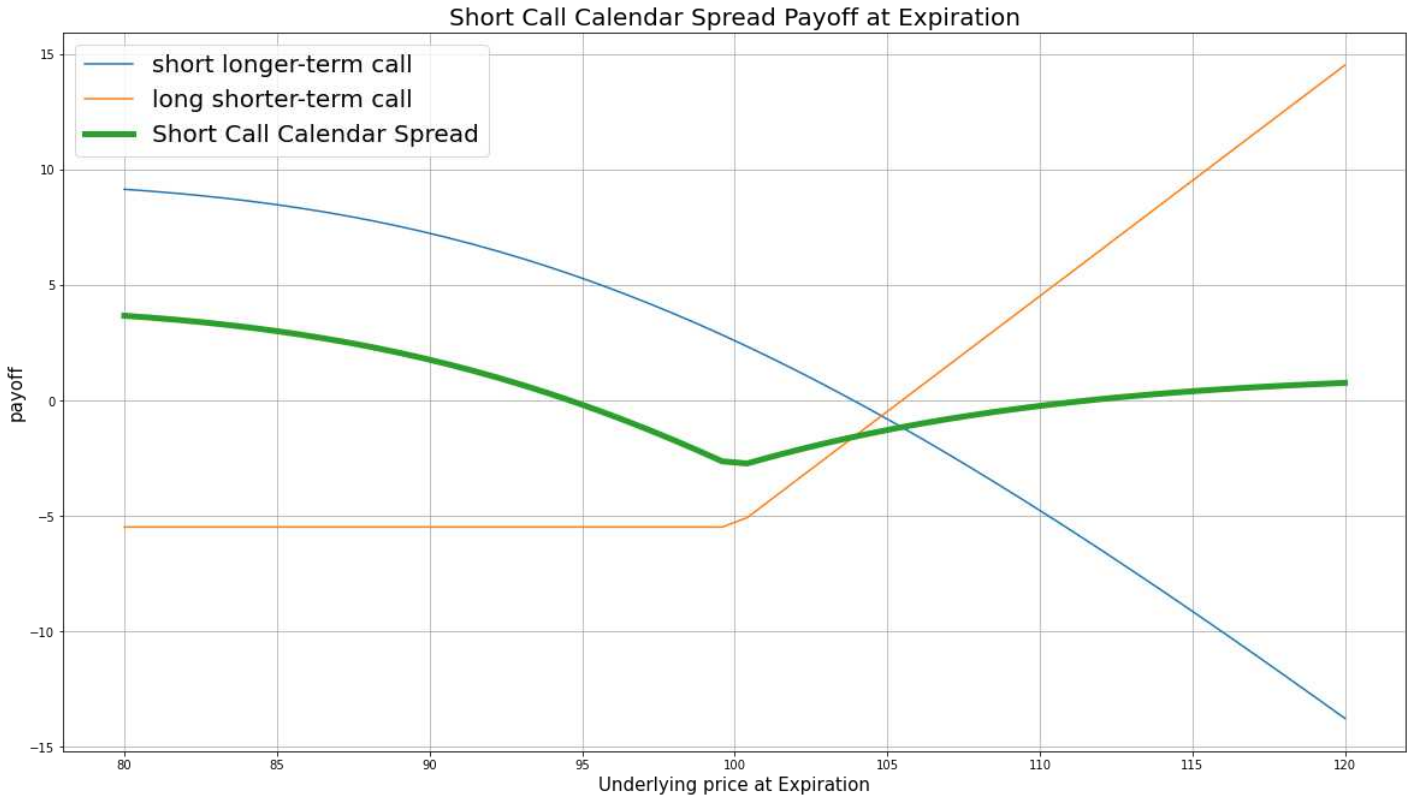
Strategy Payoff

The short call calendar spread is a limited-reward-limited-risk strategy. The payoff at the shorter-term expiration is

$$\begin{array}{rcll} C^{\textrm{short-term}}_T & = & (S_T - K)^{+}\\ P_T & = & (C^{\textrm{short-term}}_T - C^{\textrm{long-term}}_T + C^{\textrm{long-term}}_0 - C^{\textrm{short-term}}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & C^{\textrm{short-term}}_T & = & \textrm{Shorter term call value at time T}\\ & C^{\textrm{long-term}}_T & = & \textrm{Longer term call value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{\textrm{short-term}}_0 & = & \textrm{Shorter term call value at position opening (debit paid)}\\ & C^{\textrm{long-term}}_0 & = & \textrm{Longer term call value at position opening (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of shorter term call expiration} \end{array}$$

In this example, you bought a longer-term call at a strike of $800.00 for $20.00 and sold a shorter-term call at the same strike for $11.30 .

The following chart shows the payoff at expiration:



The maximum profit is the net credit received, $C^{\textrm{long-term}}_0 - C^{\textrm{short-term}}_0$. It occurs when the underlying price moves very deep ITM or OTM so the values of both calls are close to zero.

The maximum loss is undetermined because it depends on the underlying volatility. It occurs when $S_T = S_0$ and the spread of the 2 calls are at their maximum.

If the Option is American Option, there is a risk of early assignment on the contract you sell. If you don't close the call positions together, the naked short call will have unlimited drawdown risk after the long call expires.

Example

The following table shows the price details of the assets in the short call calendar spread:

Asset	Price ($)	Strike ($)
Longer-term call at the start of the trade	4.40	835.00
Shorter-term call at the start of the trade	36.80	767.50
Longer-term call at time T	31.35	835.00
Underlying Equity at time T	829.08	-

Therefore, the payoff at time T (the expiration of the short-term call) is

$$\begin{array}{rcll} C^{\textrm{short-term}}_T & = & (S_T - K)^{+}\\ & = & (828.07-800.00)^{+}\\ & = & 28.07\\ P_T & = & (-C^{\textrm{long-term}}_T + C^{\textrm{short-term}}_T - C^{\textrm{short-term}}_0 + C^{\textrm{long-term}}_0)\times m - fee\\ & = & (-31.35+28.07-11.30+20.00)\times100-1.00\times2\\ & = & 540 \end{array}$$

So, the strategy gains $540.

The following algorithm implements a short call calendar spread Option strategy:

```
class LongCallCalendarSpreadStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(500000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self.symbol = option.symbol
        option.set_filter(self.universe_func)

    def universe_func(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
        return universe.call_calendar_spread(0, 30, 60)

    def on_data(self, data: Slice) -> None:
        # avoid extra orders
        if self.portfolio.invested: return

        # Get the OptionChain of the self.symbol
        chain = data.option_chains.get(self.symbol, None)
        if not chain: return

        # get at-the-money strike
        atm_strike = sorted(chain, key=lambda x: abs(x.strike - chain.underlying.price))[0].strike

        # filter the call options from the contracts which is ATM in the option chain.
        calls = [i for i in chain if i.strike == atm_strike and i.right == OptionRight.CALL]
        if len(calls) == 0: return

        # sorted the optionchain by expiration date
        expiries = sorted([x.expiry for x in calls], key = lambda x: x)

        # select the farest expiry as far-leg expiry, and the nearest expiry as near-leg expiry
        near_expiry = expiries[0]
        far_expiry = expiries[-1]

        option_strategy = OptionStrategies.short_call_calendar_spread(self.symbol, atm_strike, near_expiry, far_expiry)
        # We open a position with 1 unit of the option strategy
        self.buy(option_strategy, 1)
```

LongAndShortCallCalendarSpreadStrategiesAlgorithm.py Python

Option Strategies

Long Put Calendar Spread

Introduction

Put calendar spread , also known as put horizontal spread , is a combination of a longer-term (far-leg/front-month) put and a shorter-term (near-leg/back-month) put, where both puts have the same underlying stock and the same strike price. The long put calendar spread consists of buying a longer-term put and selling a shorter-term put. This strategy profits from a decrease in price movement. The strategy also profits from the time decay value because the theta \theta (the Option price decay by 1 day closer to maturity) of the shorter-term put is larger than the longer-term put.

Implementation

Follow these steps to implement the long put calendar spread strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(500000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.put_calendar_spread(0, 30, 60))
```

   The `put_calendar_spread` filter narrows the universe down to just the two contracts you need to form a long put calendar spread.

2. In the `on_data` method, select the strike price and expiration dates of the contracts in the strategy legs.

```
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Get the ATM strike
    atm_strike = sorted(chain, key=lambda x: abs(x.strike - chain.underlying.price))[0].strike

    # Select the ATM put Option contracts
    puts = [i for i in chain if i.strike == atm_strike and i.right == OptionRight.PUT]
    if len(puts) == 0:
        return

    # Select the near and far expiry dates
    expiries = sorted([x.expiry for x in puts])
    near_expiry = expiries[0]
    far_expiry = expiries[-1]
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.put_calendar_spread` method with the details of each leg and then pass the result to the `buy` method.

```
option_strategy = OptionStrategies.put_calendar_spread(self._symbol, atm_strike, near_expiry, far_expiry)
self.buy(option_strategy, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
near_expiry_put = [x for x in puts if x.expiry == near_expiry][0]
far_expiry_put = [x for x in puts if x.expiry == far_expiry][0]

legs = [
    Leg.create(near_expiry_put.symbol, -1),
    Leg.create(far_expiry_put.symbol, 1)
]
self.combo_market_order(legs, 1)
```

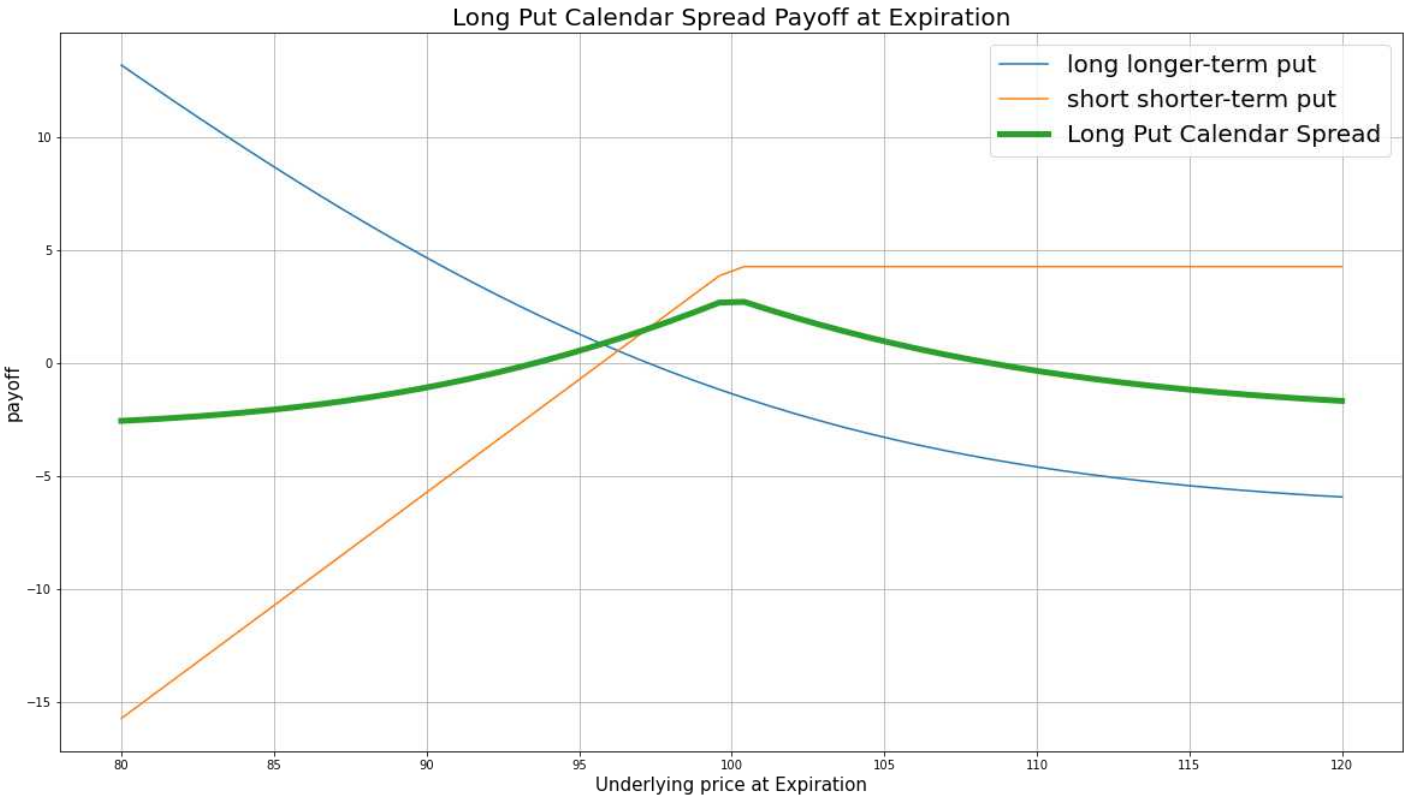
Strategy Payoff

The long put calendar spread is a limited-reward-limited-risk strategy. The payoff is taken at the shorter-term expiration. The payoff is

$$\begin{array}{rcll} P^{\textrm{short-term}}_T & = & (K - S_T)^{+}\\ P_T & = & (P^{\textrm{long-term}}_T - P^{\textrm{short-term}}_T + P^{\textrm{short-term}}_0 - P^{\textrm{long-term}}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & & \\ P^{\textrm{short-term}}_T & = & \textrm{Shorter term put value at time T}\\ P^{\textrm{long-term}}_T & = & \textrm{Longer term put value at time T}\\ S_T & = & \textrm{Underlying asset price at time T}\\ K & = & \textrm{Strike price}\\ P_T & = & \textrm{Payout total at time T}\\ P^{\textrm{short-term}}_0 & = & \textrm{Shorter term put value at position opening (credit received)}\\ P^{\textrm{long-term}}_0 & = & \textrm{Longer term put value at position opening (debit paid)}\\ m & = & \textrm{Contract multiplier}\\ T & = & \textrm{Time of shorter term put expiration} \end{array}$$

In this example, you bought a longer-term put at a strike of $800.00 for $19.30 and sold a shorter-term put at the same strike for $11.30 .

The following chart shows the payoff at expiration:



The maximum profit is undetermined because it depends on the underlying volatility. It occurs when $S_T = S_0$ and the spread of the puts are at their maximum.

The maximum loss is the net debit paid, $P^{\textrm{short-term}}_0 - P^{\textrm{long-term}}_0$. It occurs when the underlying price moves very deep ITM or OTM so the values of both puts are close to zero.

If the Option is American Option, there is a risk of early assignment on the contract you sell. Naked long puts pose risk of losing all the debit paid if you don't close the position with short put together and the price drops below its strike.

Example

The following table shows the price details of the assets in the long put calendar spread algorithm:

Asset	Price ($)	Strike ($)
Shorter-term put at position opening	11.30	800.00
Longer-term put at position opening	19.30	800.00
Longer-term put at shorter-term expiration	3.50	800.00
Underlying Equity at shorter-term expiration	828.07	-

Therefore, the payoff is

$$\begin{array}{rcll} P^{\textrm{short-term}}_T & = & (K - S_T)^{+}\\ & = & (800.00-828.07)^{+}\\ & = & 0\\ P_T & = & (P^{\textrm{long-term}}_T - P^{\textrm{short-term}}_T + P^{\textrm{short-term}}_0 - P^{\textrm{long-term}}_0)\times m - fee\\ & = & (3.50-0+11.30-19.30)\times100-1.00\times2\\ & = & -452\\ \end{array}$$

So, the strategy loses $452.

The following algorithm implements a long put calendar spread Option strategy:

```py
class PutCalendarSpreadStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(500000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self.symbol = option.symbol
        option.set_filter(self.universe_func)

    def universe_func(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
        return universe.put_calendar_spread(0, 30, 60)

    def on_data(self, data: Slice) -> None:
        # avoid extra orders
        if self.portfolio.invested: return

        # Get the OptionChain of the self.symbol
        chain = data.option_chains.get(self.symbol, None)
        if not chain: return

        # get at-the-money strike
        atm_strike = sorted(chain, key=lambda x: abs(x.strike - chain.underlying.price))[0].strike

        # filter the put options from the contracts which is ATM in the option chain.
        puts = [i for i in chain if i.strike == atm_strike and i.right == OptionRight.PUT]
        if len(puts) == 0: return

        # sorted the optionchain by expiration date
        expiries = sorted([x.expiry for x in puts], key = lambda x: x)

        # select the farest expiry as far-leg expiry, and the nearest expiry as near-leg expiry
        near_expiry = expiries[0]
        far_expiry = expiries[-1]

        option_strategy = OptionStrategies.put_calendar_spread(self.symbol, atm_strike, near_expiry, far_expiry)
        # We open a position with 1 unit of the option strategy
        self.buy(option_strategy, 1)
        # self.sell(option_strategy, 1) if short put calendar spread

    def on_end_of_algorithm(self):
        for symbol, sec in self.securities.items():
            self.log(f"{symbol} :: {sec.price}")
```

Option Strategies

Short Put Calendar Spread

Introduction

Put calendar spread , also known as put horizontal spread , is a combination of a longer-term (far-leg/front-month) put and a shorter-term (near-leg/back-month) put, where both puts have the same underlying stock and the same strike price. The short put calendar spread consists of selling a longer-term put and buying a shorter-term put. This strategy profits from an increase in price movement.

Implementation

Follow these steps to implement the short put calendar spread strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(500000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.put_calendar_spread(0, 30, 60))
```

   The `put_calendar_spread` filter narrows the universe down to just the two contracts you need to form a short put calendar spread.

2. In the `on_data` method, select the strike price and expiration dates of the contracts in the strategy legs.

```
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Get the ATM strike
    atm_strike = sorted(chain, key=lambda x: abs(x.strike - chain.underlying.price))[0].strike

    # Select the ATM put Option contracts
    puts = [i for i in chain if i.strike == atm_strike and i.right == OptionRight.PUT]
    if len(puts) == 0:
        return

    # Select the near and far expiry dates
    expiries = sorted([x.expiry for x in puts])
    near_expiry = expiries[0]
    far_expiry = expiries[-1]
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.short_put_calendar_spread` method with the details of each leg and then pass the result to the `buy` method.

```
option_strategy = OptionStrategies.short_put_calendar_spread(self._symbol, atm_strike, near_expiry, far_expiry)
self.buy(option_strategy, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```py
near_expiry_put = [x for x in puts if x.expiry == near_expiry][0]
far_expiry_put = [x for x in puts if x.expiry == far_expiry][0]

legs = [
    Leg.create(near_expiry_put.symbol, 1),
    Leg.create(far_expiry_put.symbol, -1)
]
self.combo_market_order(legs, 1)
```

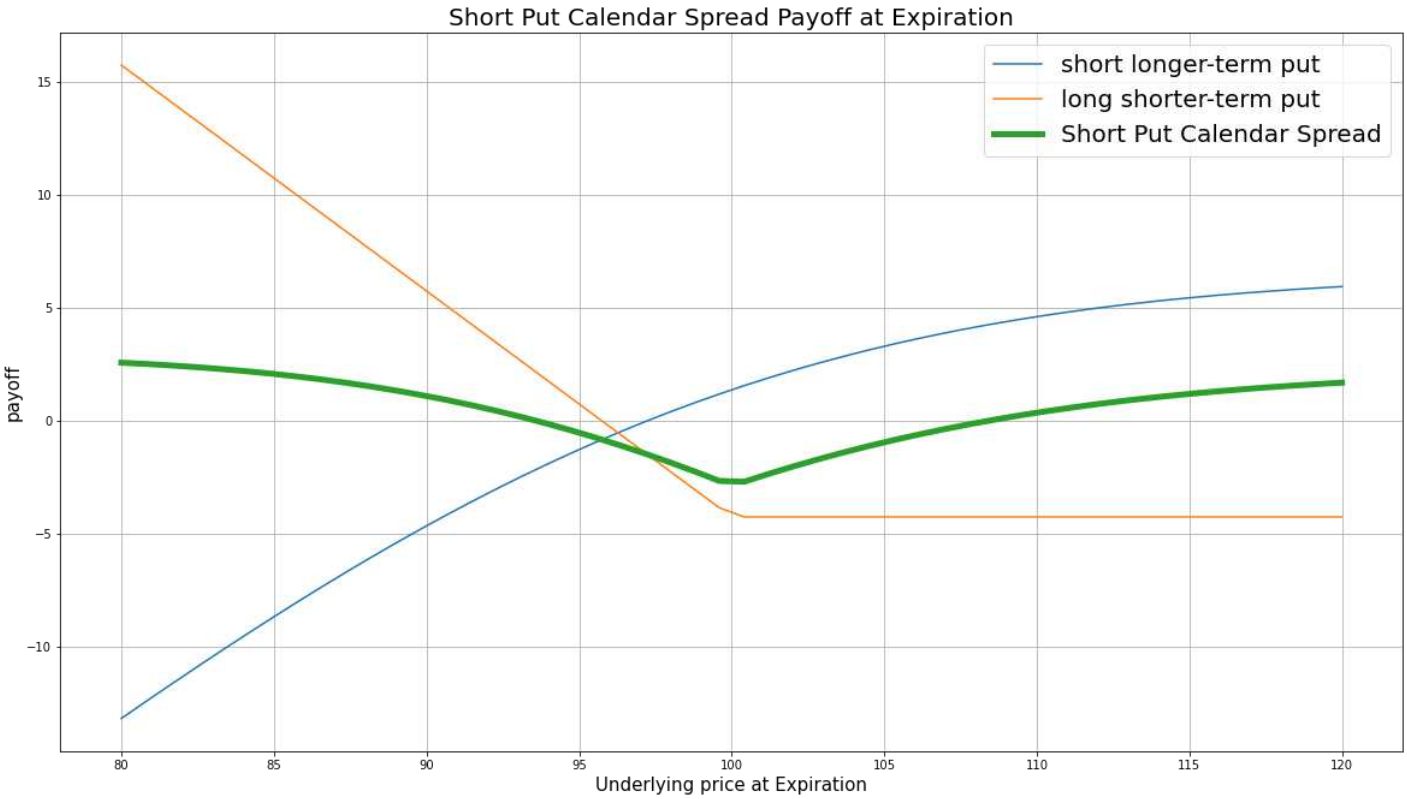
Strategy Payoff

The short put calendar spread is a limited-reward-limited-risk strategy. The payoff is taken at the shorter-term expiration. The payoff is

$$\begin{array}{rcll} P^{\textrm{short-term}}_T & = & (K - S_T)^{+}\\ P_T & = & (P^{\textrm{short-term}}_T - P^{\textrm{long-term}}_T + P^{\textrm{long-term}}_0 - P^{\textrm{short-term}}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & & \\ P^{\textrm{short-term}}_T & = & \textrm{Shorter term put value at time T}\\ P^{\textrm{long-term}}_T & = & \textrm{Longer term put value at time T}\\ S_T & = & \textrm{Underlying asset price at time T}\\ K & = & \textrm{Strike price}\\ P_T & = & \textrm{Payout total at time T}\\ P^{\textrm{short-term}}_0 & = & \textrm{Shorter term put value at position opening (debit paid)}\\ P^{\textrm{long-term}}_0 & = & \textrm{Longer term put value at position opening (credit received)}\\ m & = & \textrm{Contract multiplier}\\ T & = & \textrm{Time of shorter term put expiration} \end{array}$$

In this example, you bought a longer-term put at a strike of $800.00 for $19.30 and sold a shorter-term put at the same strike for $11.30 .

The following chart shows the payoff at expiration:



The maximum profit is the net credit received, $P^{\textrm{long-term}}_0 - P^{\textrm{short-term}}_0$. It occurs when the underlying price moves very deep ITM or OTM so the values of both puts are close to zero.

The maximum loss is undetermined because it depends on the underlying volatility. It occurs when $S_T = S_0$ and the spread of the 2 puts are at their maximum.

If the Option is American Option, there is a risk of early assignment on the contract you sell. Additionally, if you don't close the put positions together, the naked short put will have unlimited drawdown risk after the long put expires.

Example

The following table shows the price details of the assets in the short put calendar spread algorithm:

Asset	Price ($)	Strike ($)
Shorter-term put at position opening	11.30	800.00
Longer-term put at position opening	19.30	800.00
Longer-term put at shorter-term expiration	3.50	800.00
Underlying Equity at shorter-term expiration	828.07	-

Therefore, the payoff is

$$\begin{array}{rcl} P^{\textrm{short-term}}_T & = & (K - S_T)^{+}\\ & = & (800.00-828.07)^{+}\\ & = & 0\\ P_T & = & (-P^{\textrm{long-term}}_T + P^{\textrm{short-term}}_T - P^{\textrm{short-term}}_0 + P^{\textrm{long-term}}_0)\times m - fee\\ & = & (-3.50+0-11.30+19.30)\times100-1.00\times2\\ & = & 448\\ \end{array}$$

So, the strategy gains $448.

The following algorithm implements a short put calendar spread Option strategy:

```py
class PutCalendarSpreadStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(500000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self.symbol = option.symbol
        option.set_filter(self.universe_func)

    def universe_func(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
        return universe.put_calendar_spread(0, 30, 60)

    def on_data(self, data) -> None:
        # avoid extra orders
        if self.portfolio.invested: return

        # Get the OptionChain of the self.symbol
        chain = data.option_chains.get(self.symbol, None)
        if not chain: return

        # get at-the-money strike
        atm_strike = sorted(chain, key=lambda x: abs(x.strike - chain.underlying.price))[0].strike

        # filter the put options from the contracts which is ATM in the option chain.
        puts = [i for i in chain if i.strike == atm_strike and i.right == OptionRight.PUT]
        if len(puts) == 0: return

        # sorted the optionchain by expiration date
        expiries = sorted([x.expiry for x in puts], key = lambda x: x)

        # select the farest expiry as far-leg expiry, and the nearest expiry as near-leg expiry
        near_expiry = expiries[0]
        far_expiry = expiries[-1]

        option_strategy = OptionStrategies.short_put_calendar_spread(self.symbol, atm_strike, near_expiry, far_expiry)
        # We open a position with 1 unit of the option strategy
        self.buy(option_strategy, 1)

    def on_end_of_algorithm(self) -> None:
        for symbol, sec in self.securities.items():
            self.log(f"{symbol} :: {sec.price}")
```

Option Strategies

Covered Call

Introduction

A Covered Call consists of a long position in a stock and a short position in call Options for the same amount of stock. Covered calls aim to profit from the Option premium by selling calls written on the stock you already own. At any time for American Options or at expiration for European Options, if the stock moves below the strike price, you keep the premium and still maintain the underlying Equity position. If the underlying price moves above the strike, the Option buyer can exercise the Options contract , which means you sell your stock at the strike price and keep the premium. Another risk of a covered call comes from the long stock position, which can drop in value.

Implementation

Follow these steps to implement the covered call strategy:

1. In the `initialize` method, set the start date, end date, starting cash, and Options universe .

```
PY
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(100000)

    self.universe_settings.asynchronous = True
    option = self.add_option("IBM")
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.naked_call(30, 0))
```

   The `naked_call` filter narrows the universe down to just the one contract you need to form a covered call.

2. In the `on_data` method, select the Option contract.

```
PY
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    chain = slice.option_chains.get(self._symbol)
    if not chain:
        return

    # Find ATM call with the farthest expiry
    expiry = max([x.expiry for x in chain])
    call_contracts = sorted([x for x in chain
        if x.right == OptionRight.CALL and x.expiry == expiry],
        key=lambda x: abs(chain.underlying.price - x.strike))

    if not call_contracts:
        return

    atm_call = call_contracts[0]
```

3. In the `on_data` method, place the orders.

   Approach A: Call the `OptionStrategies.covered_call` method with the details of each leg and then pass the result to the `buy` method.

```
PY
covered_call = OptionStrategies.covered_call(self._symbol, atm_call.strike, expiry)
self.buy(covered_call, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
legs = [
    Leg.create(atm_call.symbol, -1),
    Leg.create(chain.underlying.symbol, chain.underlying.symbol_properties.contract_multiplier)
]
self.combo_market_order(legs, 1)
```

Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcl} C^{K}_T & = & (S_T - K)^{+}\\ P_T & = & (S_T - S_0 + C^{K}_0 - C^{K}_T)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & C^{K}_T & = \textrm{Call value at time T}\\ & S_T & = \textrm{Underlying asset price at time T}\\ & K & = \textrm{Call strike price}\\ & P_T & = \textrm{Payout total at time T}\\ & S_0 & = \textrm{Underlying asset price when the trade opened}\\ & C^{K}_0 & = \textrm{Call price when the trade opened (credit received)}\\ & m & = \textrm{Contract multiplier}\\ & T & = \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock traded at $187.07 at expiration. You held the underlying and sold a call at a strike of $185.00 for $3.35 .

The following chart shows the payoff at expiration:

The maximum profit is $K - S_T + C^{K}_0$, which occurs when the underlying price is at or above the strike price of the call at expiration.

The maximum loss is $S_0 - C^{K}_0$, which ocurrs when the underlying price drops.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Call	3.35	185.00
Underlying Equity at start of the trade	187.07	-
Underlying Equity at expiration	190.01	-

Therefore, the payoff is

$$\begin{array}{rcl} C^{K}_T & = & (S_T - K)^{+}\\ & = & (190.01 - 185)^{+}\\ & = & 5.01\\ P_T & = & (S_T - S_0 + C^{K}_0 - C^{K}_T)\times m - fee\\ & = & (190.01 - 187.07 + 3.35 - 5.01)\times m - fee\\ & = & 1.28 \times 100 - 2\\ & = & 126 \end{array}$$

So, the strategy gains $126.

The following algorithm implements a covered call strategy:

```py
class CoveredCallAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        option = self.add_option("IBM")
        self.symbol = option.symbol

        option.set_filter(lambda universe: universe.naked_call(30, 0))

        self.call = None

        # use the underlying equity as the benchmark
        self.set_benchmark(self.symbol.underlying)

    def on_data(self, slice: Slice) -> None:
        if self.call and self.portfolio[self.call].invested:
            return

        chain = slice.option_chains.get(self.symbol)
        if not chain:
            return

        # Find ATM call with the farthest expiry
        expiry = max([x.expiry for x in chain])
        call_contracts = sorted([x for x in chain
            if x.right == OptionRight.CALL and x.expiry == expiry],
            key=lambda x: abs(chain.underlying.price - x.strike))

        if not call_contracts:
            return

        atm_call = call_contracts[0]

        covered_call = OptionStrategies.covered_call(self.symbol, atm_call.strike, expiry)
        self.buy(covered_call, 1)

        self.call = atm_call.symbol
```

Option Strategies

Covered Put

Introduction

A Covered Put consists of a short position in a stock and a short position in put Options for the same amount of stock. Covered puts aim to profit from the Option premium by selling puts written on the stock you already shorted. At any time for American Options or at expiration for European Options, if the stock moves below the strike price, you keep the premium and still maintain the underlying Equity position. If the underlying price moves above the strike, the Option buyer can exercise the Options contract , which mean you buy the stock at the strike price but you will still keep the premium. Another risk of a covered put comes from the short stock position, which can drop in value.

Implementation

Follow these steps to implement the covered put strategy:

1. In the `initialize` method, set the start date, end date, starting cash, and Options universe .

```
PY
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(100000)

    self.universe_settings.asynchronous = True
    option = self.add_option("IBM")
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.naked_put(30, 0))
```

   The `naked_put` filter narrows the universe down to just the one contract you need to form a covered put.

2. In the `on_data` method, select the Option contract.

```
PY
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    chain = slice.option_chains.get(self._symbol)
    if not chain:
        return

    # Find ATM put with the farthest expiry
    expiry = max([x.expiry for x in chain])
    put_contracts = sorted([x for x in chain
        if x.right == OptionRight.PUT and x.expiry == expiry],
        key=lambda x: abs(chain.underlying.price - x.strike))

    if not put_contracts:
        return

    atm_put = put_contracts[0]
```

3. In the `on_data` method, place the orders.

   Approach A: Call the `OptionStrategies.covered_put` method with the details of each leg and then pass the result to the `buy` method.

```
PY
covered_put = OptionStrategies.covered_put(self._symbol, atm_put.strike, expiry)
self.buy(covered_put, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```py
legs = [
    Leg.create(atm_put.symbol, -1),
    Leg.create(chain.underlying.symbol, -chain.underlying.symbol_properties.contract_multiplier)
]
self.combo_market_order(legs, 1)
```

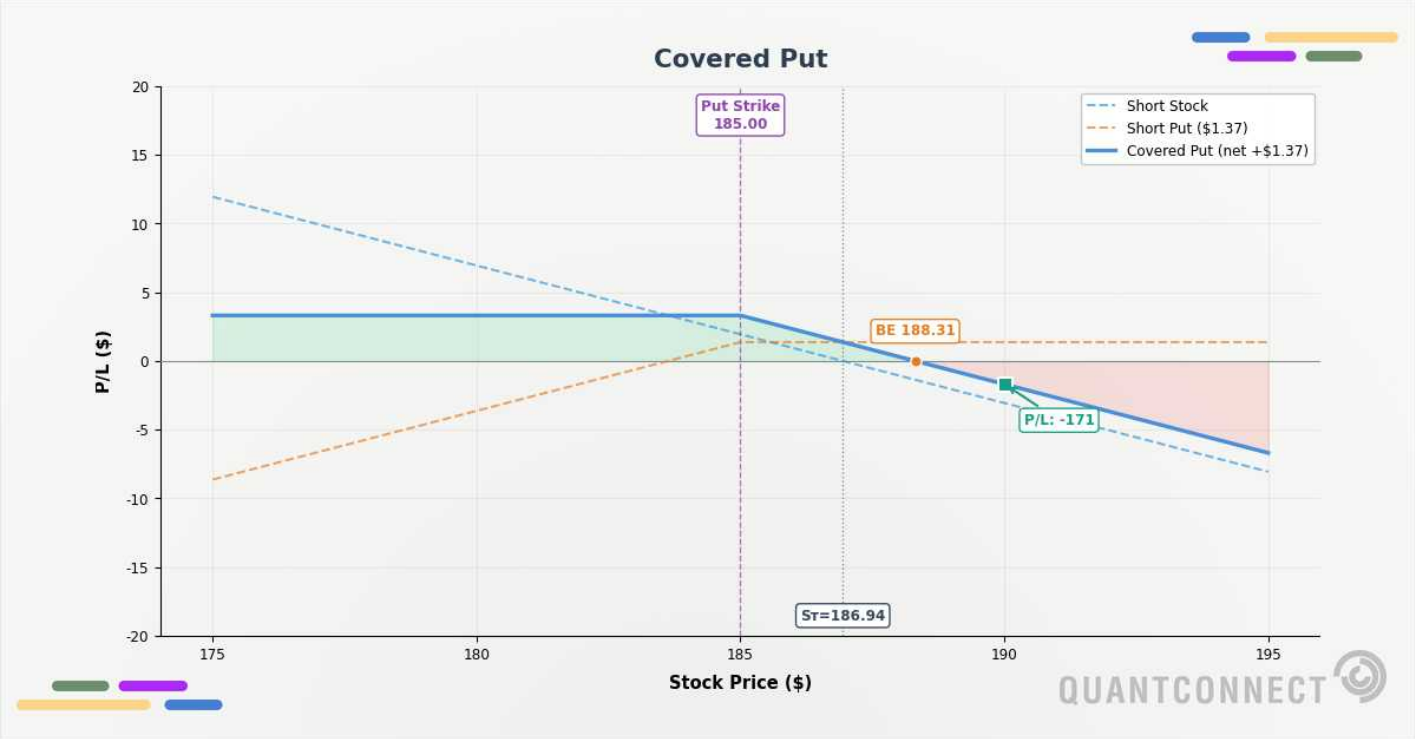
Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcl} P^{K}_T & = & (K - S_T)^{+}\\ P_T & = & (S_0 - S_T + P^{K}_0 - P^{K}_T)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & P^{K}_T & = & \textrm{Put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & S_0 & = & \textrm{Underlying asset price when the trade opened}\\ & P^{K}_0 & = & \textrm{Put price when the trade opened (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock traded at $186.94 at expiration. You held the underlying and sold a put at a strike of $185.00 for $1.37 .

The following chart shows the payoff at expiration:



The maximum profit is $S_T - K + P^{K}_0$. It occurs when the underlying price is at or below the strike price of the put at expiration.

If the underlying price increase, the maximum loss is unlimited.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Put	1.37	185.00
Underlying Equity at start of the trade	186.94	-
Underlying Equity at expiration	190.01	-

Therefore, the payoff is

$$\begin{array}{rcl} P^{K}_T & = & (K - S_T)^{+}\\ & = & (185 - 190.01)^{+}\\ & = & 0\\ P_T & = & (S_0 - S_T + P^{K}_0 - P^{K}_T)\times m - fee\\ & = & (186.94 - 190.01 + 1.37 - 0)\times m - fee\\ & = & -1.70 \times 100 - 2\\ & = & -172 \end{array}$$

So, the strategy loses $172.

The following algorithm implements a covered put strategy:

```py
class CoveredputAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        option = self.add_option("IBM")
        self.symbol = option.symbol
        option.set_filter(lambda universe: universe.naked_put(30, 0))

        self.put = None

        # use the underlying equity as the benchmark
        self.set_benchmark(self.symbol.underlying)

    def on_data(self, slice: Slice) -> None:
        if self.put and self.portfolio[self.put].invested:
            return

        chain = slice.option_chains.get(self.symbol)
        if not chain:
            return

        # Find ATM put with the farthest expiry
        expiry = max([x.expiry for x in chain])
        put_contracts = sorted([x for x in chain
            if x.right == OptionRight.PUT and x.expiry == expiry],
            key=lambda x: abs(chain.underlying.price - x.strike))

        if not put_contracts:
            return

        atm_put = put_contracts[0]

        covered_put = OptionStrategies.covered_put(self.symbol, atm_put.strike, expiry)
        self.buy(covered_put, 1)

        self.put = atm_put.symbol
```

Option Strategies

Long Iron Butterfly

Introduction

The Long Iron Butterfly is an option strategy which involves four Option contracts. All the contracts have the same underlying stock and expiration, but the order of strike prices for the four contracts is A>B>C. The following table describes the strike price of each contract:

Position	Strike
1 OTM call	A
-1 ATM call	B
-1 ATM put	B
1 OTM put	C=B-(A-B)

The long iron butterfly consists of selling an OTM call, selling an OTM put, buying an ATM call, and buying an ATM put. This strategy profits from a decrease in price movement (implied volatility).

Implementation

Follow these steps to implement the long iron butterfly strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(100000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.iron_butterfly(30, 5));
```

   The `iron_butterfly` filter narrows the universe down to just the four contracts you need to form a long iron butterfly.

2. In the `on_data` method, select the contracts in the strategy legs.

```
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Select expiry
    expiry = max([x.expiry for x in chain])

    # Separate the call and put contracts
    calls = [i for i in chain if i.right == OptionRight.CALL and i.expiry == expiry]
    puts = [i for i in chain if i.right == OptionRight.PUT and i.expiry == expiry]
    if not calls or not puts:
        return

    # Get the ATM and OTM strike prices
    atm_strike = sorted(calls, key = lambda x: abs(chain.underlying.price - x.strike))[0].strike
    otm_put_strike = min([x.strike for x in puts])
    otm_call_strike = 2 * atm_strike - otm_put_strike
```

3. In the `on_data` method, select the contracts and place the orders.

Approach A: Call the `OptionStrategies.iron_butterfly` method with the details of each leg and then pass the result to the `buy` method.

```
iron_butterfly = OptionStrategies.iron_butterfly(self._symbol, otm_put_strike, atm_strike, otm_call_strike, expiry)
self.buy(iron_butterfly, 2)
```

Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
# Select the contracts
atm_call = [x for x in calls if x.strike == atm_strike][0]
atm_put = [x for x in puts if x.strike == atm_strike][0]
otm_call = [x for x in calls if x.strike == otm_call_strike][0]
otm_put = [x for x in puts if x.strike == otm_put_strike][0]

legs = [
    Leg.create(atm_call.symbol, -1),
    Leg.create(atm_put.symbol, -1),
    Leg.create(otm_call.symbol, 1),
    Leg.create(otm_put.symbol, 1)
]
self.combo_market_order(legs, 1)
```

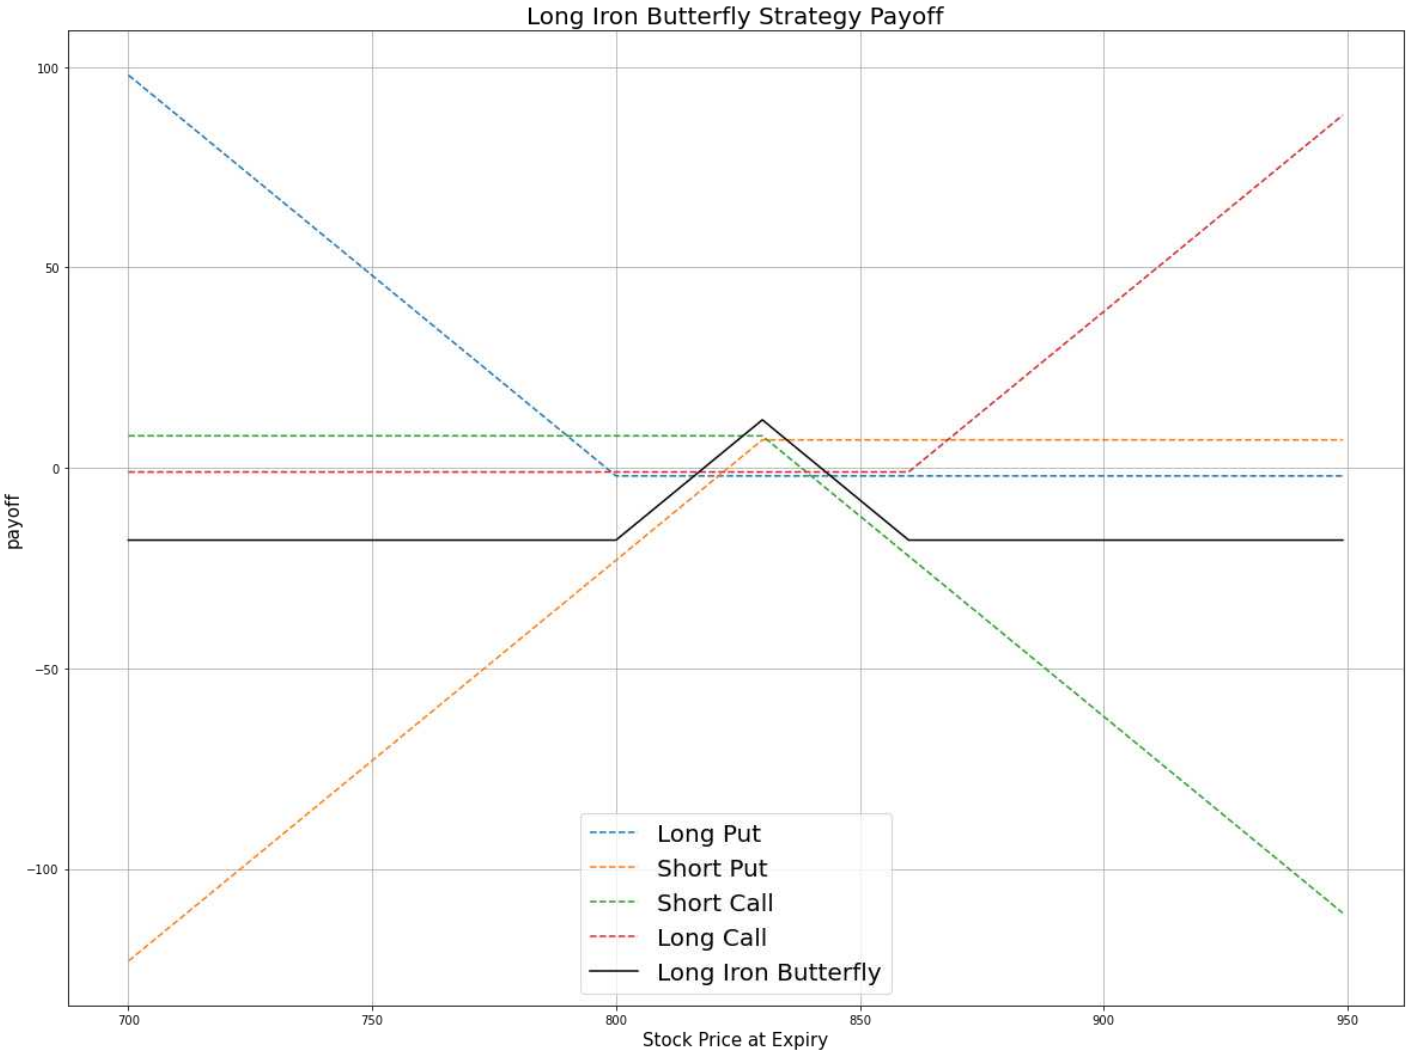
Strategy Payoff

The long call butterfly is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^C_{OTM})^{+}\\ C^{ATM}_T & = & (S_T - K^C_{ATM})^{+}\\ P^{OTM}_T & = & (K^P_{OTM} - S_T)^{+}\\ P^{ATM}_T & = & (K^P_{ATM} - S_T)^{+}\\ P_T & = & (C^{OTM}_T + P^{OTM}_T - C^{ATM}_T - P^{ATM}_T - C^{OTM}_0 - P^{OTM}_0 + C^{ATM}_0 + P^{ATM}_0)\times m - fee \end{array} \begin{array}{rcll} \textrm{where} & C^{OTM}_T & = & \textrm{OTM call value at time T}\\ & C^{ATM}_T & = & \textrm{ATM call value at time T}\\ & P^{OTM}_T & = & \textrm{OTM put value at time T}\\ & P^{ATM}_T & = & \textrm{ATM put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^C_{OTM} & = & \textrm{OTM call strike price}\\ & K^C_{ATM} & = & \textrm{ATM call strike price}\\ & K^P_{OTM} & = & \textrm{OTM put strike price}\\ & K^P_{ATM} & = & \textrm{ATM put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{OTM}_0 & = & \textrm{OTM call value at position opening (debit paid)}\\ & C^{ATM}_0 & = & \textrm{ATM call value at position opening (credit received)}\\ & P^{OTM}_0 & = & \textrm{OTM put value at position opening (debit paid)}\\ & P^{ATM}_0 & = & \textrm{ATM put value at position opening (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock price at expiration is $843.25 . You traded an OTM call at $855.00 for $1.35 , an OTM put at $810.00 for $1.50 , an ATM call at $832.50 for $10.30 , and an ATM put at $832.50 for $9.50 .

The following chart shows the payoff at expiration:



The maximum profit is the net credit received, C^{ATM}_0 + P^{ATM}_0 - C^{OTM}_0 - P^{OTM}_0. It occurs when the underlying price stays the same as when you opened the trade.

The maximum loss is K^C_{OTM} - K^C_{ATM} - C^{ATM}_0 - P^{ATM}_0 + C^{OTM}_0 + P^{OTM}_0. It occurs when the underlying price is below the OTM put strike price or above the OTM call strike price at expiration.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
OTM call	1.35	855.00
OTM put	1.50	810.00
ATM call	10.30	832.50
ATM put	9.50	832.50
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^C_{OTM})^{+}\\ & = & (843.25-855.00)^{+}\\ & = & 0\\ C^{ATM}_T & = & (S_T - K^C_{ATM})^{+}\\ & = & (843.25-832.50)^{+}\\ & = & 10.75\\ P^{OTM}_T & = & (K^P_{OTM} - S_T)^{+}\\ & = & (810.00-843.25)^{+}\\ & = & 0\\ P^{ATM}_T & = & (K^P_{ATM} - S_T)^{+}\\ & = & (832.50.00-843.25)^{+}\\ & = & 0\\ P_T & = & (C^{ATM}_T + P^{ATM}_T - C^{OTM}_T - P^{OTM}_T - C^{ATM}_0 - P^{ATM}_0 + C^{OTM}_0 + P^{OTM}_0)\times m - fee\\ & = & (10.75+0-0-0-10.30-9.50+1.35+1.50)\times100-1\times4\\ & = & -624 \end{array}

So, the strategy losses $624.

The following algorithm implements a long iron butterfly Option strategy:

```py
class LongButterflyOptionStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self._symbol = option.symbol

        # set our strike/expiry filter for this option chain
        option.set_filter(lambda x: x.iron_butterfly(30, 5))

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested:
            return

        # Get the OptionChain
        chain = slice.option_chains.get(self._symbol, None)
        if not chain:
            return

        # Select expiry
        expiry = max([x.expiry for x in chain])

        # Separate the call and put contracts
        calls = [i for i in chain if i.right == OptionRight.CALL and i.expiry == expiry]
        puts = [i for i in chain if i.right == OptionRight.PUT and i.expiry == expiry]
        if not calls or not puts:
            return

        # Get the ATM and OTM strike prices
        atm_strike = sorted(calls, key = lambda x: abs(x.strike - chain.underlying.price))[0].strike
        otm_put_strike = min([x.strike for x in puts])
        otm_call_strike = 2 * atm_strike - otm_put_strike

        iron_butterfly = OptionStrategies.iron_butterfly(self._symbol, otm_put_strike, atm_strike, otm_call_strike, expiry)
        self.buy(iron_butterfly, 1)
```

Option Strategies

Short Iron Butterfly

Introduction

The Short Iron Butterfly is an option strategy which involves four Option contracts. All the contracts have the same underlying stock and expiration, but the order of strike prices for the four contracts is A>B>C. The following table describes the strike price of each contract:

Position	Strike
1 OTM call	A
-1 ATM call	B
-1 ATM put	B
1 OTM put	C=B-(A-B)

The short call butterfly consists of buying an OTM call, buying an OTM put, selling an ATM call, and selling an ATM put. This strategy profits from an increase in price movement (implied volatility) and from time decay value since ATM options decay sharper.

Implementation

Follow these steps to implement the short iron butterfly strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(100000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.iron_butterfly(30, 5));
```

   The `iron_butterfly` filter narrows the universe down to just the four contracts you need to form a short iron butterly.

2. In the `on_data` method, select the contracts in the strategy legs.

```
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Select expiry
    expiry = max([x.expiry for x in chain])

    # Separate the call and put contracts
    calls = [i for i in chain if i.right == OptionRight.CALL and i.expiry == expiry]
    puts = [i for i in chain if i.right == OptionRight.PUT and i.expiry == expiry]
    if not calls or not puts:
        return

    # Get the ATM and OTM strike prices
    atm_strike = sorted(calls, key = lambda x: abs(chain.underlying.price - x.strike))[0].strike
    otm_put_strike = min([x.strike for x in puts])
    otm_call_strike = 2 * atm_strike - otm_put_strike
```

3. In the `on_data` method, select the contracts and place the orders.

Approach A: Call the `OptionStrategies.short_iron_butterfly` method with the details of each leg and then pass the result to the `buy` method.

```
PY
short_iron_butterfly = OptionStrategies.short_iron_butterfly(self._symbol, otm_put_strike, atm_strike, otm_call_strike, expiry)
self.buy(short_iron_butterfly, 2)
```

Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
PY
# Select the contracts
atm_call = [x for x in calls if x.strike == atm_strike][0]
atm_put = [x for x in puts if x.strike == atm_strike][0]
otm_call = [x for x in calls if x.strike == otm_call_strike][0]
otm_put = [x for x in puts if x.strike == otm_put_strike][0]

legs = [
    Leg.create(atm_call.symbol, 1),
    Leg.create(atm_put.symbol, 1),
    Leg.create(otm_call.symbol, -1),
    Leg.create(otm_put.symbol, -1)
]
self.combo_market_order(legs, 1)
```

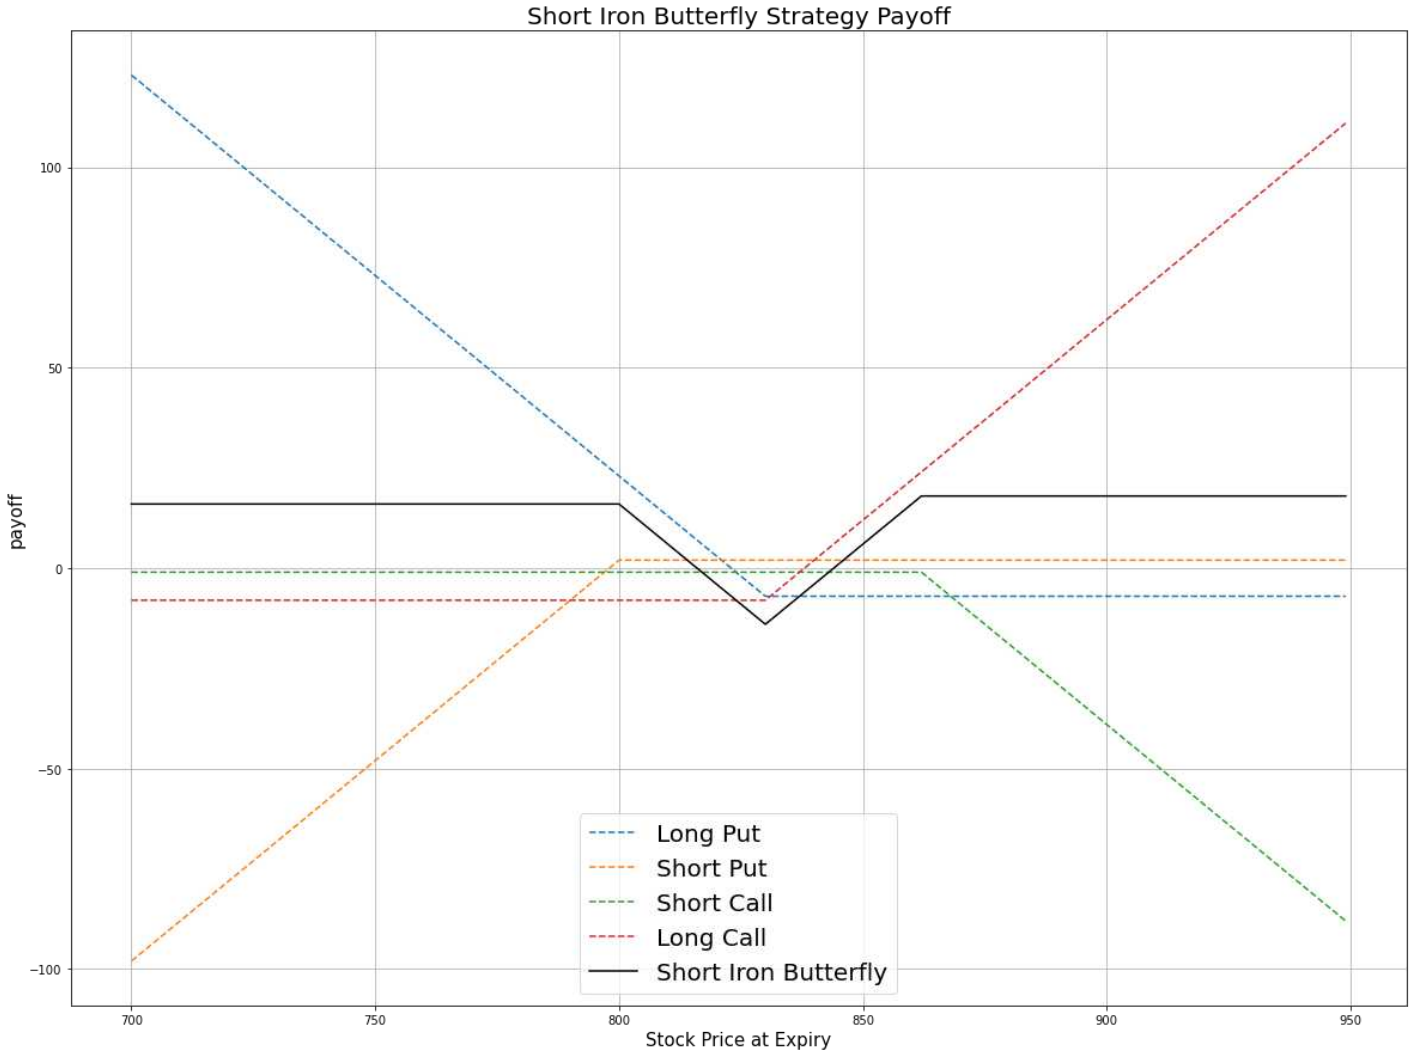
Strategy Payoff

The short iron butterfly is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{OTM}_T &=& (S_T - K^C_{OTM})^{+}\\ C^{ATM}_T &=& (S_T - K^C_{ATM})^{+}\\ P^{OTM}_T &=& (K^P_{OTM} - S_T)^{+}\\ P^{ATM}_T &=& (K^P_{ATM} - S_T)^{+}\\ P_T &=& (C^{ATM}_T + P^{ATM}_T - C^{OTM}_T - P^{OTM}_T - C^{ATM}_0 - P^{ATM}_0 + C^{OTM}_0 + P^{OTM}_0)\times m - fee \end{array} \begin{array}{rcll} \textrm{where} & C^{OTM}_T &=& \textrm{OTM call value at time T}\\ & C^{ATM}_T &=& \textrm{ATM call value at time T}\\ & P^{OTM}_T &=& \textrm{OTM put value at time T}\\ & P^{ATM}_T &=& \textrm{ATM put value at time T}\\ & S_T &=& \textrm{Underlying asset price at time T}\\ & K^C_{OTM} &=& \textrm{OTM call strike price}\\ & K^C_{ATM} &=& \textrm{ATM call strike price}\\ & K^P_{OTM} &=& \textrm{OTM put strike price}\\ & K^P_{ATM} &=& \textrm{ATM put strike price}\\ & P_T &=& \textrm{Payout total at time T}\\ & C^{OTM}_0 &=& \textrm{OTM call value at position opening (credit received)}\\ & C^{ATM}_0 &=& \textrm{ATM call value at position opening (debit paid)}\\ & P^{OTM}_0 &=& \textrm{OTM put value at position opening (credit received)}\\ & P^{ATM}_0 &=& \textrm{ATM put value at position opening (debit paid)}\\ & m &=& \textrm{Contract multiplier}\\ & T &=& \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock price at expiration is $843.25 . You traded an OTM call at $855.00 for $2.35 , an OTM put at $810.00 for $2.75 , an ATM call at $832.50 for $8.10 , and an ATM put at $832.50 for $7.40 .

The following chart shows the payoff at expiration:



The maximum profit is K^C_{OTM} - K^C_{ATM} - C^{ATM}_0 - P^{ATM}_0 + C^{OTM}_0 + P^{OTM}_0. It occurs when the underlying price is below the OTM put strike price or above the OTM call strike price at expiration.

The maximum loss is the net debit paid, C^{OTM}_0 + P^{OTM}_0 - C^{ATM}_0 - P^{ATM}_0. It occurs when the underlying price stays the same as when you opened the trade.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
OTM call	2.35	855.00
OTM put	2.75	810.00
ATM call	8.10	832.50
ATM put	7.40	832.50
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^C_{OTM})^{+}\\ & = & (843.25-855.00)^{+}\\ & = & 0\\ C^{ATM}_T & = & (S_T - K^C_{ATM})^{+}\\ & = & (843.25-832.50)^{+}\\ & = & 10.75\\ P^{OTM}_T & = & (K^P_{OTM} - S_T)^{+}\\ & = & (810.00-843.25)^{+}\\ & = & 0\\ P^{ATM}_T & = & (K^P_{ATM} - S_T)^{+}\\ & = & (832.50.00-843.25)^{+}\\ & = & 0\\ P_T & = & (C^{OTM}_T + P^{OTM}_T - C^{ATM}_T - P^{ATM}_T - C^{OTM}_0 - P^{OTM}_0 + C^{ATM}_0 + P^{ATM}_0)\times m - fee\\ & = & (0+0-10.75-0-2.35-2.75+8.10+7.40)\times100-1\times4\\ & = & -39 \end{array}

So, the strategy losses $39.

The following algorithm implements a short iron butterfly Option strategy:

```py
class ShortButterflyOptionStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self._symbol = option.symbol

        # set our strike/expiry filter for this option chain
        option.set_filter(lambda x: x.iron_butterfly(30, 5))

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested:
            return

        # Get the OptionChain
        chain = slice.option_chains.get(self._symbol, None)
        if not chain:
            return

        # Select expiry
        expiry = max([x.expiry for x in chain])

        # Separate the call and put contracts
        calls = [i for i in chain if i.right == OptionRight.CALL and i.expiry == expiry]
        puts = [i for i in chain if i.right == OptionRight.PUT and i.expiry == expiry]
        if not calls or not puts:
            return

        # Get the ATM and OTM strike prices
        atm_strike = sorted(calls, key = lambda x: abs(x.strike - chain.underlying.price))[0].strike
        otm_put_strike = min([x.strike for x in puts])
        otm_call_strike = 2 * atm_strike - otm_put_strike

        short_iron_butterfly = OptionStrategies.short_iron_butterfly(self._symbol, otm_put_strike, atm_strike, otm_call_strike, expiry)
        self.buy(short_iron_butterfly, 1)
```

Option Strategies

Long Iron Condor

Introduction

The Long Iron Condor is an Option strategy that consists of four contracts. All the contracts have the same underlying Equity and expiration, but the order of strike prices is A>B>C>D. The following table describes the strike prices of each contract:

Position	Strike
1 far-OTM call	A
-1 near-OTM call	B, where B > underlying\ price
-1 near-OTM put	C, where C < underlying\ price
1 far-OTM put	D, where C-D = A-B

The long iron condor consists of buying a far OTM call, buying a far OTM put, selling a near ATM call, and selling a near ATM put. This strategy profits from an decrease in price movement (implied volatility) and time decay since ATM options decay sharper.

Implementation

Follow these steps to implement the long iron condor strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```py
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(500000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG")
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.iron_condor(30, 5, 10))
```

   The `iron_condor` filter narrows the universe down to just the four contracts you need to form a long iron condor.

2. In the `on_data` method, select the contracts in the strategy legs.

```py
def on_data(self, slice: Slice) -> None:
    if self.portfolio[self._symbol.underlying].invested:
        self.liquidate()

    if self.portfolio.invested or not self.is_market_open(self._symbol):
        return

    chain = slice.option_chains.get(self._symbol)
    if not chain:
        return

    # Find put and call contracts with the farthest expiry
    expiry = max([x.expiry for x in chain])
    chain = sorted([x for x in chain if x.expiry == expiry], key = lambda x: x.strike)

    put_contracts = [x for x in chain if x.right == OptionRight.PUT]
    call_contracts = [x for x in chain if x.right == OptionRight.CALL]

    if len(call_contracts) < 2 or len(put_contracts) < 2:
        return

    # Select the strategy legs
    near_call = call_contracts[0]
    far_call = call_contracts[1]
    near_put = put_contracts[1]
    far_put = [x for x in put_contracts if x.Strike == near_put.strike - far_call.strike + near_call.strike][0]
```

3. In the `on_data` method, place the orders.

   Approach A: Call the `OptionStrategies.iron_condor` method with the details of each leg and then pass the result to the `buy` method.

```
PY
iron_condor = OptionStrategies.iron_condor(
    self._symbol,
    far_put.strike,
    near_put.strike,
    near_call.strike,
    far_call.strike,
    expiry)

self.buy(iron_condor, 2)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
PY
legs = [
    Leg.create(far_put.symbol, 1),
    Leg.create(near_put.symbol, -1),
    Leg.create(far_call.symbol, 1),
    Leg.create(near_call.symbol, -1)
]
self.combo_market_order(legs, 1)
```

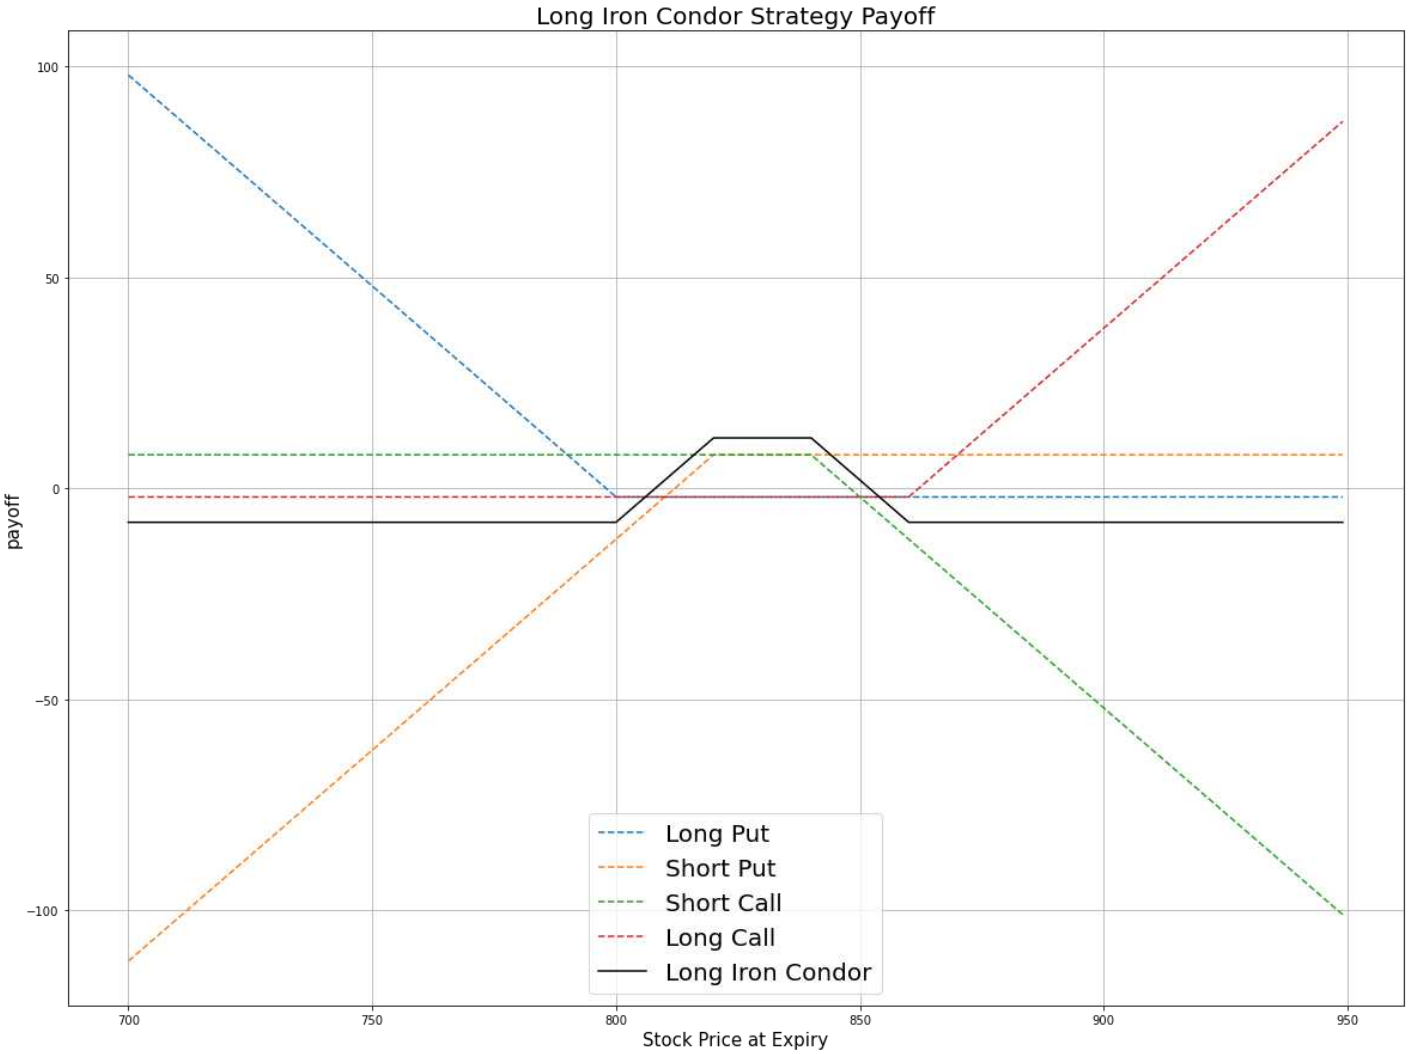
Strategy Payoff

This is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{far}_T & = & (S_T - K^C_{far})^{+}\\ C^{near}_T & = & (S_T - K^C_{near})^{+}\\ P^{far}_T & = & (K^P_{far} - S_T)^{+}\\ P^{near}_T & = & (K^P_{near} - S_T)^{+}\\ P_T & = & (C^{far}_T + P^{far}_T - C^{near}_T - P^{near}_T - C^{far}_0 - P^{far}_0 + C^{near}_0 + P^{near}_0)\times m - fee \end{array} \begin{array}{rcll} \textrm{where} & & & \\ C^{far}_T & = & \textrm{Far OTM call value at time T}\\ C^{near}_T & = & \textrm{Near OTM call value at time T}\\ P^{far}_T & = & \textrm{Far OTM put value at time T}\\ P^{near}_T & = & \textrm{Near ATM put value at time T}\\ S_T & = & \textrm{Underlying asset price at time T}\\ K^C_{far} & = & \textrm{Far OTM call strike price}\\ K^C_{near} & = & \textrm{Near OTM call strike price}\\ K^P_{far} & = & \textrm{Far OTM put strike price}\\ K^P_{near} & = & \textrm{Near OTM put strike price}\\ P_T & = & \textrm{Payout total at time T}\\ C^{far}_0 & = & \textrm{Far OTM call value at position opening (credit received)}\\ C^{near}_0 & = & \textrm{Near OTM call value at position opening (debit paid)}\\ P^{far}_0 & = & \textrm{Far OTM put value at position opening (credit received)}\\ P^{near}_0 & = & \textrm{Near OTM put value at position opening (debit paid)}\\ m & = & \textrm{Contract multiplier}\\ T & = & \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock price at expiration is $843.25 . You traded a far-OTM call at $857.50 for $1.85 , a near-OTM call at $852.50 for $1.65 , a far-OTM put at $815.00 for $3.80 , and a near-OTM put at $820.00 for $3.50 .

The following chart shows the payoff at expiration:



The maximum profit is the net credit received after commission when opening the trade, where K^P_{OTM} < S_T < K^C_{OTM}.

The maximum loss is K^C_{far} - K^C_{near} + C^{near}_0 + P^{near}_0 - C^{far}_0 - P^{far}_0, where K^P_{OTM} > S_T or S_T > K^C_{OTM}.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Far-OTM call	1.85	857.50
Far-OTM put	3.80	815.00
Near-OTM call	1.65	852.50
Near-OTM put	3.50	820.00
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

\begin{array}{rcll} C^{far}_T & = & (S_T - K^C_{far})^{+}\\ & = & (843.25-857.50)^{+}\\ & = & 0\\ C^{near}_T & = & (S_T - K^C_{near})^{+}\\ & = & (843.25-852.50)^{+}\\ & = & 0\\ P^{far}_T & = & (K^P_{far} - S_T)^{+}\\ & = & (815.00-843.25)^{+}\\ & = & 0\\ P^{near}_T & = & (K^P_{near} - S_T)^{+}\\ & = & (820.00-843.25)^{+}\\ & = & 0\\ P_T & = & (C^{near}_T + P^{near}_T - C^{far}_T - P^{far}_T - C^{near}_0 - P^{near}_0 + C^{far}_0 + P^{far}_0)\times m - fee\\ & = & (0+0-0-0+1.65+3.50-1.85-3.80)\times100-1\times4\\ & = & -54 \end{array}

So, the strategy loses $54.

The following algorithm implements a long iron condor Option strategy:

```
class LongIronCondorOptionStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self._symbol = option.symbol

        # set our strike/expiry filter for this option chain
        option.set_filter(lambda x: x.iron_condor(30, 5, 10))

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested or not self.is_market_open(self._symbol):
            return

        chain = slice.option_chains.get(self._symbol)
        if not chain:
            return

        # Find put and call contracts with the farthest expiry
        expiry = max([x.expiry for x in chain])
        chain = sorted([x for x in chain if x.expiry == expiry], key = lambda x: x.strike)

        put_contracts = [x for x in chain if x.right == OptionRight.PUT]
        call_contracts = [x for x in chain if x.right == OptionRight.CALL]

        if len(call_contracts) < 2 or len(put_contracts) < 2:
            return

        # Select the strategy legs
        near_call = call_contracts[0]
        far_call = call_contracts[1]
        near_put = put_contracts[1]
        far_put = [x for x in put_contracts if x.Strike == near_put.strike - far_call.strike + near_call.strike][0]

        iron_condor = OptionStrategies.iron_condor(
            self._symbol,
            far_put.strike,
            near_put.strike,
            near_call.strike,
            far_call.strike,
            expiry)

        self.buy(iron_condor, 2)
```

Option Strategies

Short Iron Condor

Introduction

The Short Iron Condor is an Option strategy that consists of four contracts. All the contracts have the same underlying Equity and expiration, but the order of strike prices is A>B>C>D. The following table describes the strike prices of each contract:

Position	Strike
-1 far-OTM call	A
1 near-OTM call	B, where B > underlying\ price
1 near-OTM put	C, where C < underlying\ price
-1 far-OTM put	D, where C-D = A-B

The short iron condor consists of selling a far OTM call, selling a far OTM put, buying a near OTM call, and buying a near OTM put. This strategy profits from a increase in price movement (implied volatility).

Implementation

Follow these steps to implement the short iron condor strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(500000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG")
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.iron_condor(30, 5, 10))
```

   The `iron_condor` filter narrows the universe down to just the four contracts you need to form a short iron condor.

2. In the `on_data` method, select the contracts in the strategy legs.

```
def on_data(self, slice: Slice) -> None:
    if self.portfolio[self._symbol.underlying].invested:
        self.liquidate()

    if self.portfolio.invested or not self.is_market_open(self._symbol):
        return

    chain = slice.option_chains.get(self._symbol)
    if not chain:
        return

    # Find put and call contracts with the farthest expiry
    expiry = max([x.expiry for x in chain])
    chain = sorted([x for x in chain if x.expiry == expiry], key = lambda x: x.strike)

    put_contracts = [x for x in chain if x.right == OptionRight.PUT]
    call_contracts = [x for x in chain if x.right == OptionRight.CALL]

    if len(call_contracts) < 2 or len(put_contracts) < 2:
        return

    # Select the strategy legs
    far_put = put_contracts[0]
    near_put = put_contracts[1]
    near_call = call_contracts[0]
    far_call = call_contracts[1]
```

3. In the `on_data` method, place the orders.

   Approach A: Call the `OptionStrategies.short_iron_condor` method with the details of each leg and then pass the result to the `buy` method.

```
PY
short_iron_condor = OptionStrategies.short_iron_condor(
    self._symbol,
    far_put.strike,
    near_put.strike,
    near_call.strike,
    far_call.strike,
    expiry)

self.buy(short_iron_condor, 2)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
PY
legs = [
    Leg.create(far_put.symbol, -1),
    Leg.create(near_put.symbol, 1),
    Leg.create(far_call.symbol, -1),
    Leg.create(near_call.symbol, 1)
]
self.combo_market_order(legs, 1)
```

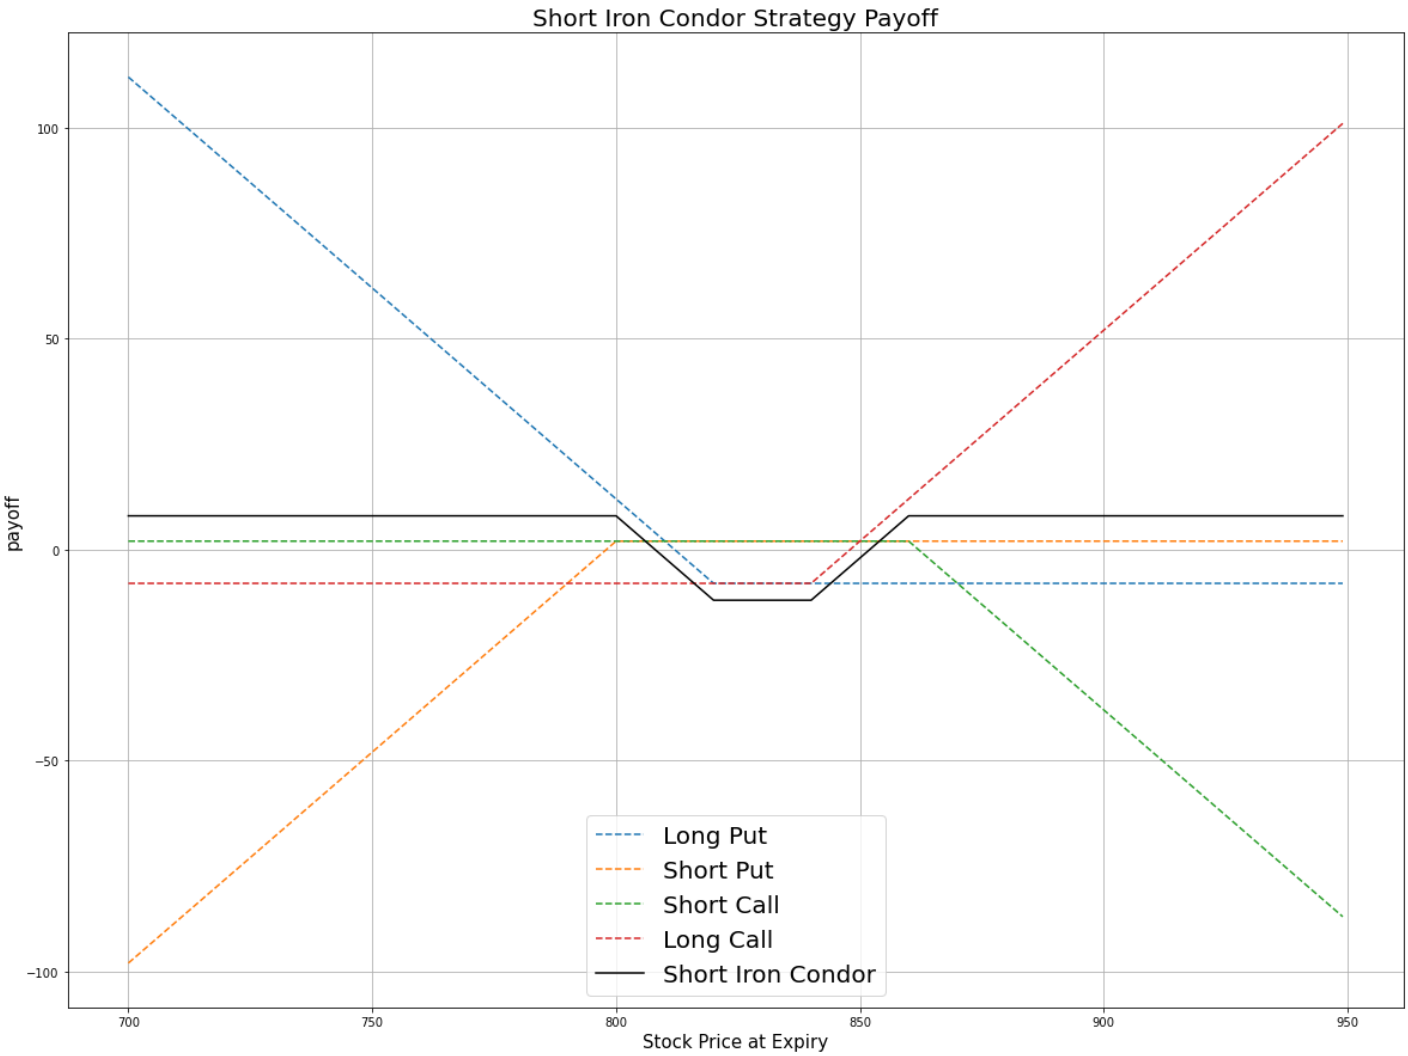
Strategy Payoff

This is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{far}_T & = & (S_T - K^C_{far})^{+}\\ C^{near}_T & = & (S_T - K^C_{near})^{+}\\ P^{far}_T & = & (K^P_{far} - S_T)^{+}\\ P^{near}_T & = & (K^P_{near} - S_T)^{+}\\ P_T & = & (C^{near}_T + P^{near}_T - C^{far}_T - P^{far}_T - C^{near}_0 - P^{near}_0 + C^{far}_0 + P^{far}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & C^{far}_T & = & \textrm{Far OTM call value at time T}\\ & C^{near}_T & = & \textrm{Near OTM call value at time T}\\ & P^{far}_T & = & \textrm{Far OTM put value at time T}\\ & P^{near}_T & = & \textrm{Near ATM put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^C_{far} & = & \textrm{Far OTM call strike price}\\ & K^C_{near} & = & \textrm{Near OTM call strike price}\\ & K^P_{far} & = & \textrm{Far OTM put strike price}\\ & K^P_{near} & = & \textrm{Near OTM put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{far}_0 & = & \textrm{Far OTM call value at position opening (credit received)}\\ & C^{near}_0 & = & \textrm{Near OTM call value at position opening (debit paid)}\\ & P^{far}_0 & = & \textrm{Far OTM put value at position opening (credit received)}\\ & P^{near}_0 & = & \textrm{Near OTM put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock price at expiration is $843.25 . You traded a far-OTM call at $857.50 for $1.05 , a near-OTM call at $852.50 for $2.75 , a far-OTM put at $815.00 for $2.15 , and a near-OTM put at $820.00 for $4.80 .

The following chart shows the payoff at expiration:



The maximum profit is K^C_{far} - K^C_{near} - C^{near}_0 - P^{near}_0 + C^{far}_0 + P^{far}_0, where K^P_{OTM} > S_T or S_T > K^C_{OTM}.

The maximum loss is the net debit paid: C^{far}_0 + P^{far}_0 - C^{near}_0 - P^{near}_0, where K^P_{OTM} < S_T < K^C_{OTM}.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Far-OTM call	1.05	857.50
Far-OTM put	2.15	815.00
Near-OTM call	2.75	852.50
Near-OTM put	4.80	820.00
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

\begin{array}{rcll} C^{far}_T & = & (S_T - K^C_{far})^{+}\\ & = & (843.25-857.50)^{+}\\ & = & 0\\ C^{near}_T & = & (S_T - K^C_{near})^{+}\\ & = & (843.25-852.50)^{+}\\ & = & 0\\ P^{far}_T & = & (K^P_{far} - S_T)^{+}\\ & = & (815.00-843.25)^{+}\\ & = & 0\\ P^{near}_T & = & (K^P_{near} - S_T)^{+}\\ & = & (820.00-843.25)^{+}\\ & = & 0\\ P_T & = & (C^{near}_T + P^{near}_T - C^{far}_T - P^{far}_T - C^{near}_0 - P^{near}_0 + C^{far}_0 + P^{far}_0)\times m - fee\\ & = & (0+0-0-0-2.75-4.80+1.05+2.15)\times100-1\times4\\ & = & -439 \end{array}

So, the strategy loses $439.

The following algorithm implements a short iron condor Option strategy:

PY

```
class ShortIronCondorOptionStrategy(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self._symbol = option.symbol

        # set our strike/expiry filter for this option chain
        option.set_filter(lambda x: x.iron_condor(30, 5, 10))

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested or not self.is_market_open(self._symbol):
            return

        chain = slice.option_chains.get(self._symbol)
        if not chain:
            return

        # Find put and call contracts with the farthest expiry
        expiry = max([x.expiry for x in chain])
        chain = sorted([x for x in chain if x.expiry == expiry], key = lambda x: x.strike)

        put_contracts = [x for x in chain if x.right == OptionRight.PUT]
        call_contracts = [x for x in chain if x.right == OptionRight.CALL]

        if len(call_contracts) < 2 or len(put_contracts) < 2:
            return

        # Select the strategy legs
        near_call = call_contracts[0]
        far_call = call_contracts[1]
        near_put = put_contracts[1]
        far_put = [x for x in put_contracts if x.Strike == near_put.strike - far_call.strike + near_call.strike][0]

        short_iron_condor = OptionStrategies.short_iron_condor(
            self._symbol,
            far_put.strike,
            near_put.strike,
            near_call.strike,
            far_call.strike,
            expiry)

        self.buy(short_iron_condor, 2)
```

Option Strategies

Naked Call

Introduction

A Naked Call , also known as an uncovered call , consists of selling call Options without owning the underlying asset. It's called "naked" because you don't have any cover or protection in the form of owning the underlying asset, which exposes you to potentially unlimited risk. Naked calls aim to profit from the Option premium by selling calls. At any time for American Options or at expiration for European Options, if the stock moves below the strike price, you keep the premium. If the underlying price moves above the strike, the Option buyer can exercise the Options contract , which means you need buy the underlying at market price to fulfill your obligation to sell it at the strike price and keep the premium.

Implementation

Follow these steps to implement the naked call strategy:

1. In the `initialize` method, set the start date, end date, starting cash, and Options universe .

```
PY
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(100000)

    self.universe_settings.asynchronous = True
    option = self.add_option("IBM")
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.naked_call(30, 0))
```

   The `naked_call` filter narrows the universe down to just the one contract you need to form a naked call.

2. In the `on_data` method, select the Option contract.

```
PY
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    chain = slice.option_chains.get(self._symbol)
    if not chain:
        return

    # Find ATM call with the farthest expiry
    expiry = max([x.expiry for x in chain])
    call_contracts = sorted([x for x in chain
        if x.right == OptionRight.CALL and x.expiry == expiry],
        key=lambda x: abs(chain.underlying.price - x.strike))

    if not call_contracts:
        return

    atm_call = call_contracts[0]
```

3. In the `on_data` method, place the orders.

   Approach A: Call the `OptionStrategies.naked_call` method with the details of each leg and then pass the result to the `buy` method.

```
PY
naked_call = OptionStrategies.naked_call(self._symbol, atm_call.strike, expiry)
self.buy(naked_call, 1)
```

   Approach B: Call the market_order or limit_order method.

```
PY
self.market_order(atm_call.symbol, -1)
```

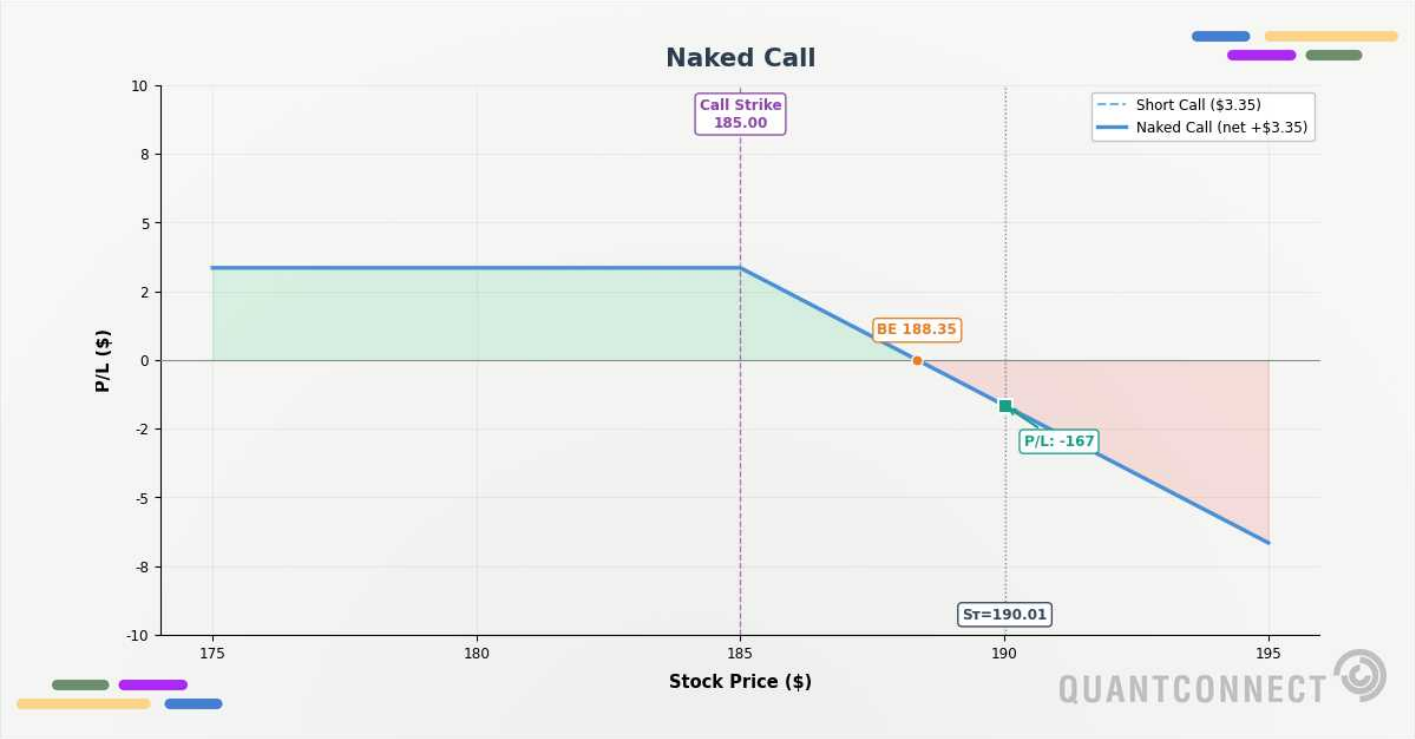
Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcll} C^{K}_T & = & (S_T - K)^{+}\\ P_T & = & (C^{K}_0 - C^{K}_T)\times m - fee \end{array} \begin{array}{rcll} \textrm{where} & & & \\ C^{K}_T & = & \textrm{Call value at time T}\\ S_T & = & \textrm{Underlying asset price at time T}\\ K & = & \textrm{Call strike price}\\ P_T & = & \textrm{Payout total at time T}\\ C^{K}_0 & = & \textrm{Call price when the trade opened (credit received)}\\ m & = & \textrm{Contract multiplier}\\ T & = & \textrm{Time of expiration} \end{array}$$

In this example, you sold a call at a strike of $185.00 for $3.35 .

The following chart shows the payoff at expiration:



The maximum profit is C^{K}_0, which occurs when the underlying price is at or below the strike price of the call at expiration.

The maximum loss is unlimited because there is no limit to how high the underlying asset's price can rise.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Call	3.35	185.00
Underlying Equity at expiration	190.01	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{K}_T & = & (S_T - K)^{+}\\ & = & (190.01 - 185)^{+}\\ & = & 5.01\\ P_T & = & (C^{K}_0 - C^{K}_T)\times m - fee\\ & = & (3.35 - 5.01)\times m - fee\\ & = & -1.66 \times 100 - 1\\ & = & -167 \end{array}$$

So, the strategy loses $167.

The following algorithm implements a naked call Option strategy:

PY

```
class NakedCallAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        option = self.add_option("IBM")
        self.symbol = option.symbol
        option.set_filter(lambda universe: universe.naked_call(30, 0))

        self.call = None

        # use the underlying equity as the benchmark
        self.set_benchmark(self.symbol.underlying)

    def on_data(self, slice: Slice) -> None:
        if self.call and self.portfolio[self.call].invested:
            return

        chain = slice.option_chains.get(self.symbol)
        if not chain:
            return

        # Find ATM call with the farthest expiry
        expiry = max([x.expiry for x in chain])
        call_contracts = sorted([x for x in chain
            if x.right == OptionRight.CALL and x.expiry == expiry],
            key=lambda x: abs(chain.underlying.price - x.strike))

        if not call_contracts:
            return

        atm_call = call_contracts[0]

        naked_call = OptionStrategies.naked_call(self.symbol, atm_call.strike, expiry)
        self.buy(naked_call, 1)

        self.call = atm_call.symbol
```

Option Strategies

Naked Put

Introduction

A Naked Put , also known as an uncovered put , consists of selling put Options without having a corresponding short position in the underlying security. It's called "naked" because you don't have any cover or protection in the form of a short position in the underlying asset, which exposes you to potentially unlimited risk. Naked puts aim to profit from the Option premium by selling puts. At any time for American Options or at expiration for European Options, if the stock moves above the strike price, you keep the premium. If the underlying price moves below the strike, the Option buyer can exercise the Options contract , which means you need sell the underlying at market price to fulfill your obligation to buy it at the strike price and keep the premium.

Implementation

Follow these steps to implement the naked put strategy:

1. In the `initialize` method, set the start date, end date, starting cash, and Options universe .

```
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(100000)

    self.universe_settings.asynchronous = True
    option = self.add_option("IBM")
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.naked_put(30, 0))
```

   The `naked_put` filter narrows the universe down to just the one contract you need to form a naked put.

2. In the `on_data` method, select the Option contract.

```
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    chain = slice.option_chains.get(self._symbol)
    if not chain:
        return

    # Find ATM put with the farthest expiry
    expiry = max([x.expiry for x in chain])
    put_contracts = sorted([x for x in chain
        if x.right == OptionRight.PUT and x.expiry == expiry],
        key=lambda x: abs(chain.underlying.price - x.strike))

    if not put_contracts:
        return

    atm_put = put_contracts[0]
```

3. In the `on_data` method, place the orders.

   Approach A: Call the `OptionStrategies.naked_put` method with the details of each leg and then pass the result to the `buy` method.

```
naked_put = OptionStrategies.naked_put(self._symbol, atm_put.strike, expiry)
self.buy(naked_put, 1)
```

   Approach B: Call the market_order or limit_order method.

```
self.market_order(atm_put.symbol, -1)
```

Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcll} P^{K}_T & = & (K - S_T)^{+}\\ P_T & = & (P^{K}_0 - P^{K}_T)\times m - fee \end{array} \begin{array}{rcll} \textrm{where} & P^{K}_T & = & \textrm{Put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & P^{K}_0 & = & \textrm{Put price when the trade opened (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

In this example, you sold a put at a strike of $185.00 for $1.37 .

The following chart shows the payoff at expiration:

The maximum profit is P^{K}_0, which occurs when the underlying price is at or above the strike price of the put at expiration.

The maximum loss is $K - P^{K}_0$, which ocurrs when the underlying price drops to zero.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Put	1.37	185.00
Underlying Equity at expiration	190.01	-

Therefore, the payoff is

$$\begin{array}{rcll} P^{K}_T & = & (K - S_T)^{+}\\ & = & (185 - 190.01)^{+}\\ & = & 0.0\\ P_T & = & (P^{K}_0 - P^{K}_T)\times m - fee\\ & = & (1.37 - 0.0)\times m - fee\\ & = & 1.37 \times 100 - 1\\ & = & 136 \end{array}$$

So, the strategy gains $136.

The following algorithm implements a naked put Option strategy:

PY

```
class NakedPutAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        option = self.add_option("IBM")
        self.symbol = option.symbol
        option.set_filter(lambda universe: universe.naked_put(30, 0))

        self.put = None

        # use the underlying equity as the benchmark
        self.set_benchmark(self.symbol.underlying)

    def on_data(self, slice: Slice) -> None:
        if self.put and self.portfolio[self.put].invested:
            return

        chain = slice.option_chains.get(self.symbol)
        if not chain:
            return

        # Find ATM put with the farthest expiry
        expiry = max([x.expiry for x in chain])
        put_contracts = sorted([x for x in chain
            if x.right == OptionRight.PUT and x.expiry == expiry],
            key=lambda x: abs(chain.underlying.price - x.strike))

        if not put_contracts:
            return

        atm_put = put_contracts[0]

        naked_put = OptionStrategies.naked_put(self.symbol, atm_put.strike, expiry)
        self.buy(naked_put, 1)

        self.put = atm_put.symbol
```

Option Strategies

Protective Call

Introduction

A Protective Call consists of a short position in a stock and a long position in a call Option for the same amount of stock. Protective calls aim to hedge the short position of a stock with a long ATM or slightly OTM call Option. At any time for American Options or at expiration for European Options, if the stock moves below the strike price, the Option contract becomes worthless but the short position acquires an unrealized gain. If the underlying price moves above the strike, you can exercise the Options contract and receive the underlying Equity, which closes your short position.

Implementation

Follow these steps to implement the protective call strategy:

1. In the `initialize` method, set the start date, end date, cash, and Options universe .

```py
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(100000)

    self.universe_settings.asynchronous = True
    option = self.add_option("IBM")
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.naked_call(30, 0))
```

   The `naked_call` filter narrows the universe down to just the one contract you need to form a protective call.

2. In the `on_data` method, select the Option contract.

```py
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    chain = slice.option_chains.get(self._symbol)
    if not chain:
        return

    # Find ATM call with the farthest expiry
    expiry = max([x.expiry for x in chain])
    call_contracts = sorted([x for x in chain
        if x.right == OptionRight.CALL and x.expiry == expiry],
        key=lambda x: abs(chain.underlying.price - x.strike))

    if not call_contracts:
        return

    atm_call = call_contracts[0]
```

3. In the `on_data` method, place the orders.

   Approach A: Call the `OptionStrategies.protective_call` method with the details of each leg and then pass the result to the `buy` method.

```py
protective_call = OptionStrategies.protective_call(self._symbol, atm_call.strike, expiry)
self.buy(protective_call, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```py
legs = [
    Leg.create(atm_call.symbol, 1),
    Leg.create(chain.underlying.symbol, -chain.underlying.symbol_properties.contract_multiplier)
]
self.combo_market_order(legs, 1)
```

Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcll} C^{K}_T & = & (S_T - K)^{+}\\ P_T & = & (S_0 - S_T + C^{K}_T - C^{K}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & C^{K}_T & = & \textrm{Call value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Call strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & S_0 & = & \textrm{Underlying asset price when the trade opened}\\ & C^{K}_0 & = & \textrm{Call price when the trade opened (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock traded at $186.94 at expiration. You held the underlying position and bought a call at a strike of $185.00 for $3.50 .

The following chart shows the payoff at expiration:

The maximum profit is $S_0 - C^{K}_0$, which occurs when the underlying price is 0.

The maximum loss is $S_0 - K - C^{K}_0$, which occurs when the underlying price is above the strike price.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Call	3.50	185.00
Underlying Equity at start of the trade	186.94	-
Underlying Equity at expiration	190.01	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{K}_T & = & (S_T - K)^{+}\\ & = & (190.01 - 185)^{+}\\ & = & 5.01\\ P_T & = & (S_0 - S_T + C^{K}_T - C^{K}_0)\times m - fee\\ & = & (186.94 - 190.01 + 5.01 - 3.50)\times m - fee\\ & = & -1.56 \times 100 - 2\\ & = & -158 \end{array}$$

So, the strategy loses $158.

The following algorithm implements a protective call Option strategy:

PY

```
class ProtectiveCallAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        option = self.add_option("IBM")
        self.symbol = option.symbol
        option.set_filter(lambda universe: universe.naked_call(30, 0))

        self.call = None

        # use the underlying equity as the benchmark
        self.set_benchmark(self.symbol.underlying)

    def on_data(self, slice: Slice) -> None:
        if self.call and self.portfolio[self.call].invested:
            return

        chain = slice.option_chains.get(self.symbol)
        if not chain:
            return

        # Find ATM call with the farthest expiry
        expiry = max([x.expiry for x in chain])
        call_contracts = sorted([x for x in chain
            if x.right == OptionRight.CALL and x.expiry == expiry],
            key=lambda x: abs(chain.underlying.price - x.strike))

        if not call_contracts:
            return

        atm_call = call_contracts[0]

        protective_call = OptionStrategies.protective_call(self.symbol, atm_call.strike, expiry)
        self.buy(protective_call, 1)

        self.call = atm_call.symbol
```

Option Strategies

Protective Put

Introduction

A Protective Put consists of buying a long position in a stock and a long position in put Options for the same amount of stock. Protective puts aim to hedge the long position of a stock with a long ATM or slightly OTM put Option. At any time for American Options or at expiration for European Options, if the stock moves above the strike price, the Option contract becomes worthless but the long stock position acquires an unrealized gain. If the underlying price moves below the strike, you can exercise the Options contract , which sells your underlying position at the put Option strike price.

Implementation

Follow these steps to implement the protective put strategy:

1. In the `initialize` method, set the start date, end date, starting cash, and Options universe .

```
PY
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(100000)

    self.universe_settings.asynchronous = True
    option = self.add_option("IBM")
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.naked_put(30, 0))
```

   The `naked_put` filter narrows the universe down to just the one contract you need to form a protective put.

2. In the `on_data` method, select the Option contract.

```
PY
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    chain = slice.option_chains.get(self._symbol)
    if not chain:
        return

    # Find ATM put with the farthest expiry
    expiry = max([x.expiry for x in chain])
    put_contracts = sorted([x for x in chain
        if x.right == OptionRight.PUT and x.expiry == expiry],
        key=lambda x: abs(chain.underlying.price - x.strike))

    if not put_contracts:
        return

    atm_put = put_contracts[0]
```

3. In the `on_data` method, place the orders.

   Approach A: Call the `OptionStrategies.protective_put` method with the details of each leg and then pass the result to the `buy` method.

```
PY
protective_put = OptionStrategies.protective_put(self._symbol, atm_put.strike, expiry)
self.buy(protective_put, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
legs = [
    Leg.create(atm_put.symbol, 1),
    Leg.create(chain.underlying.symbol, chain.underlying.symbol_properties.contract_multiplier)
]
self.combo_market_order(legs, 1)
```

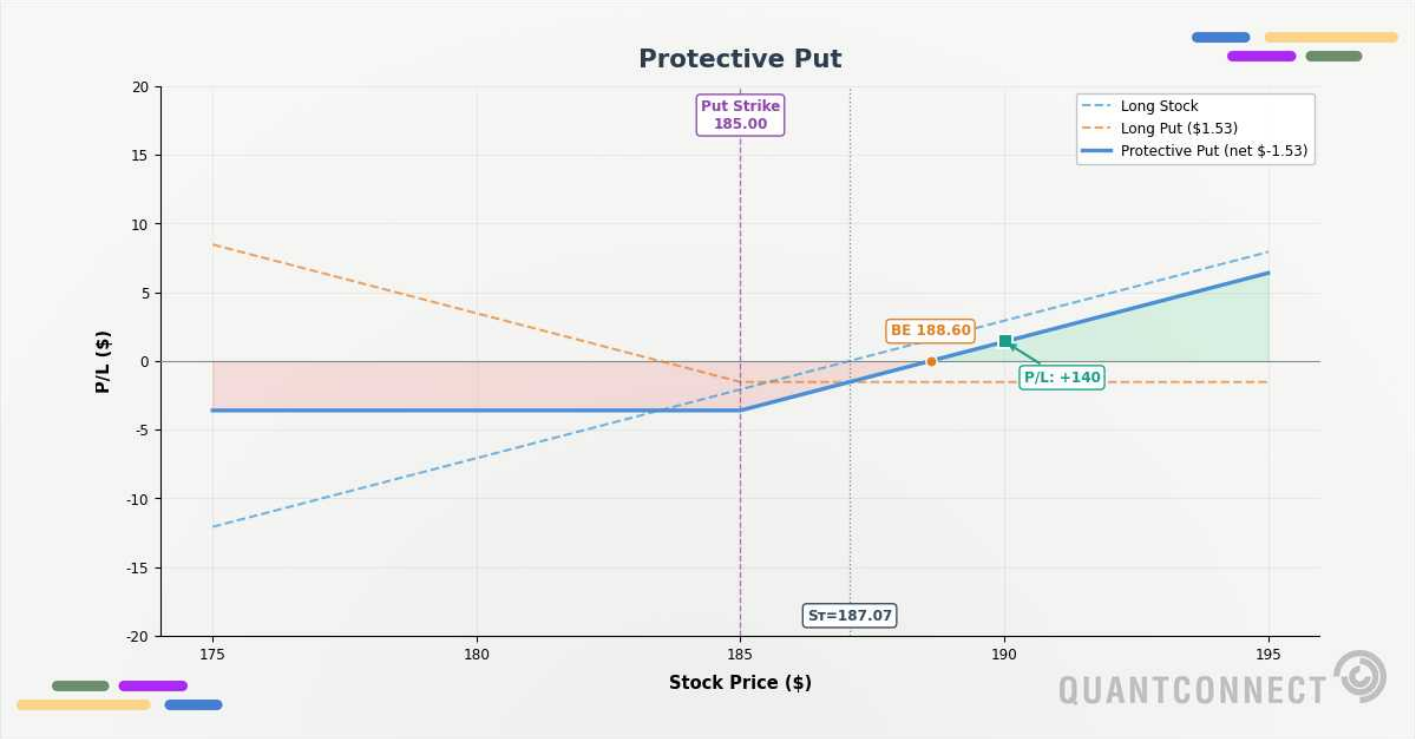
Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcl} P^{K}_T & = & (K - S_T)^{+}\\ P_T & = & (S_T - S_0 + P^{K}_T - P^{K}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & P^{K}_T & = & \textrm{Put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & S_0 & = & \textrm{Underlying asset price when the trade opened}\\ & P^{K}_0 & = & \textrm{Put price when the trade opened (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock traded at $187.07 at expiration. You held the underlying position and bought a put at a strike of $185.00 for $1.53 .

The following chart shows the payoff at expiration:



The maximum profit is $S_T - S_0 - P^{K}_0$, which occurs when the underlying price is above the $S_0 + P^{K}_0$.

The maximum loss is P^{K}_0, which occurs when the underlying price drops.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Put	1.53	185.00
Underlying Equity at start of the trade	187.07	-
Underlying Equity at expiration	190.01	-

Therefore, the payoff is

$$\begin{array}{rcl} P^{K}_T & = & (K - S_T)^{+}\\ & = & (185 - 190.1)^{+}\\ & = & 0\\ P_T & = & (S_T - S_0 + P^{K}_T - P^{K}_0)\times m - fee\\ & = & (190.01 - 187.07 + 0 - 1.53)\times m - fee\\ & = & 1.41 \times 100 - 2\\ & = & 139 \end{array}$$

So, the strategy gains $139.

The following algorithm implements a protective put Option strategy:

```py
class ProtectivePutAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        option = self.add_option("IBM")
        self.symbol = option.symbol
        option.set_filter(lambda universe: universe.naked_put(30, 0))

        self.put = None

        # use the underlying equity as the benchmark
        self.set_benchmark(self.symbol.underlying)

    def on_data(self, slice: Slice) -> None:
        if self.put and self.portfolio[self.put].invested:
            return

        chain = slice.option_chains.get(self.symbol)
        if not chain:
            return

        # Find ATM put with the farthest expiry
        expiry = max([x.expiry for x in chain])
        put_contracts = sorted([x for x in chain
            if x.right == OptionRight.Put and x.expiry == expiry],
            key=lambda x: abs(chain.underlying.price - x.strike))

        if not put_contracts:
            return

        atm_put = put_contracts[0]

        protective_put = OptionStrategies.protective_put(self.symbol, atm_put.strike, expiry)
        self.buy(protective_put, 1)

        self.put = atm_put.symbol
```

Option Strategies

Protective Collar

Introduction

A Protective Collar is an Options strategy that consists of a covered call and a long put (protective put) with a lower strike price than the short call contract. In contrast to the covered call, the protective put component limits the drawdown of the strategy when the underlying price decreases too much.

Implementation

Follow these steps to implement the protective collar strategy:

1. In the `initialize` method, set the start date, set the end date, subscribe to the underlying Equity , and create an Option universe .

```
PY
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(100000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.protective_collar(30, -1, -10))
```

   The `protective_collar` filter narrows the universe down to just the two contracts you need to form a protective collar.

2. In the `on_data` method, select the Option contracts.

```
PY
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Select an expiry date
    expiry = max([x.expiry for x in chain])

    # Select the call and put contracts that expire on the selected date
    calls = [x for x in chain if x.right == OptionRight.CALL and x.expiry == expiry]
    puts = [x for x in chain if x.right == OptionRight.PUT and x.expiry == expiry]
    if not calls or not puts:
        return

    # Select the OTM contracts
    call = sorted(calls, key = lambda x: x.strike)[-1]
    put = sorted(puts, key = lambda x: x.strike)[0]
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.protective_collar` method with the details of each leg and then pass the result to the `buy` method.

```
PY
protective_collar = OptionStrategies.protective_collar(self._symbol, call.strike, put.strike, expiry)
self.buy(protective_collar, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
legs = [
    Leg.create(call.symbol, -1),
    Leg.create(put.symbol, 1),
    Leg.create(chain.underlying.symbol, chain.underlying.symbol_properties.contract_multiplier)
]
self.combo_market_order(legs, 1)
```

Strategy Payoff

This is a limited-profit-limited-loss strategy. The payoff is

$$\begin{array}{rcll} C_T & = & (S_T - K^{C})^{+}\\ P_T & = & (K^{P} - S_T)^{+}\\ Payoff_T & = & (S_T - S_0 - C_T + P_T + C_0 - P_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & C_T & = & \textrm{Call value at time T}\\ & P_T & = & \textrm{Put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{C} & = & \textrm{Call strike price}\\ & K^{P} & = & \textrm{Put strike price}\\ & Payoff_T & = & \textrm{Payout total at time T}\\ & S_0 & = & \textrm{Underlying asset price when the trade opened}\\ & C_0 & = & \textrm{Call price when the trade opened (credit received)}\\ & P_0 & = & \textrm{Put price when the trade opened (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock traded at $833.17 at expiration. You held the underlying, bought a put at a strike of $822.50 for $6.00 , and sold a call at a strike of $845.00 for $2.85 .

The following chart shows the payoff at expiration:

The maximum profit is $K^{C} - S_T + C_0 - P_0$. It occurs when the underlying price is at or above the strike price of the call at expiration.

The maximum profit is $S_T - K^{P} + C_0 - P_0$. It occurs when the underlying price is at or below the strike price of the put at expiration.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Call	2.85	845.00
Put	6.00	822.50
Underlying Equity at position opens	833.17	-
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

$$\begin{array}{rcll} C_T & = & (S_T - K^{C})^{+}\\ & = & (843.365 - 845.00)^{+}\\ & = & 0\\ P_T & = & (K^{P} - S_T)^{+}\\ & = & (822.50 - 843.365)^{+}\\ & = & 0\\ Payoff_T & = & (S_T - S_0 - C_T + P_T + C_0 - P_0)\times m - fee\\ & = & (843.25 - 833.17 - 0 + 0 + 2.85 - 6.00)\times100-1.00\times3\\ & = & 690\\ \end{array}$$

So, the strategy gains $690.

The following algorithm implements a protective collar Option strategy:

```py
class ProtectiveCollarOptionStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        equity = self.add_equity("GOOG", Resolution.MINUTE)
        option = self.add_option("GOOG", Resolution.MINUTE)
        self.symbol = option.symbol
        option.set_filter(lambda universe: universe.protective_collar(30, -1, -10))

    def on_data(self, data: Slice) -> None:
        # avoid extra orders
        if self.portfolio.invested: return

        # Get the OptionChain of the self.symbol
        chain = data.option_chains.get(self.symbol, None)
        if not chain: return

        # choose the furthest expiration date within 30 days from now on
        expiry = sorted(chain, key = lambda x: x.expiry)[-1].expiry
        # filter the call options contracts
        call = [x for x in chain if x.right == OptionRight.CALL and x.expiry == expiry]
        # filter the put options contracts
        put = [x for x in chain if x.right == OptionRight.PUT and x.expiry == expiry]

        if not call or not put: return

        # select the strike prices of call and put contracts
        call_strike = sorted(call, key = lambda x: x.strike)[-1].strike
        put_strike = sorted(put, key = lambda x: x.strike)[0].strike

        protective_collar = OptionStrategies.protective_collar(self.symbol, call_strike, put_strike, expiry)
        self.buy(protective_collar, 1)

    def on_end_of_day(self, symbol):
        if symbol.value == "GOOG":
            self.log(f"{self.time}::{symbol}::{self.securities[symbol].price}")
```

Option Strategies

Long Straddle

Introduction

Long Straddle is an Options trading strategy that consists of buying an ATM call and an ATM put, where both contracts have the same underlying asset, strike price, and expiration date. This strategy aims to profit from volatile movements in the underlying stock, either positive or negative.

Implementation

Follow these steps to implement the long straddle strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```py
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(100000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG")
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.straddle(30))
```

   The `straddle` filter narrows the universe down to just the two contracts you need to form a long straddle.

2. In the `on_data` method, select the expiration date and strike price of the contracts in the strategy legs.

```py
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Find ATM options with the nearest expiry
    expiry = min([x.expiry for x in chain])
    strike = sorted(chain, key=lambda x: abs(x.strike - chain.underlying.price))[0].strike
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.straddle` method with the details of each leg and then pass the result to the `buy` method.

```py
long_straddle = OptionStrategies.straddle(self._symbol, strike, expiry)
self.buy(long_straddle, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```py
contracts = [x for x in chain if x.expiry == expiry and x.strike == strike]
if len(contracts) < 2:
    return

atm_call = [x for x in contracts if x.right == OptionRight.CALL][0]
atm_put = [x for x in contracts if x.right == OptionRight.PUT][0]

legs = [
    Leg.create(atm_call.symbol, 1),
    Leg.create(atm_put.symbol, 1)
]
self.combo_market_order(legs, 1)
```

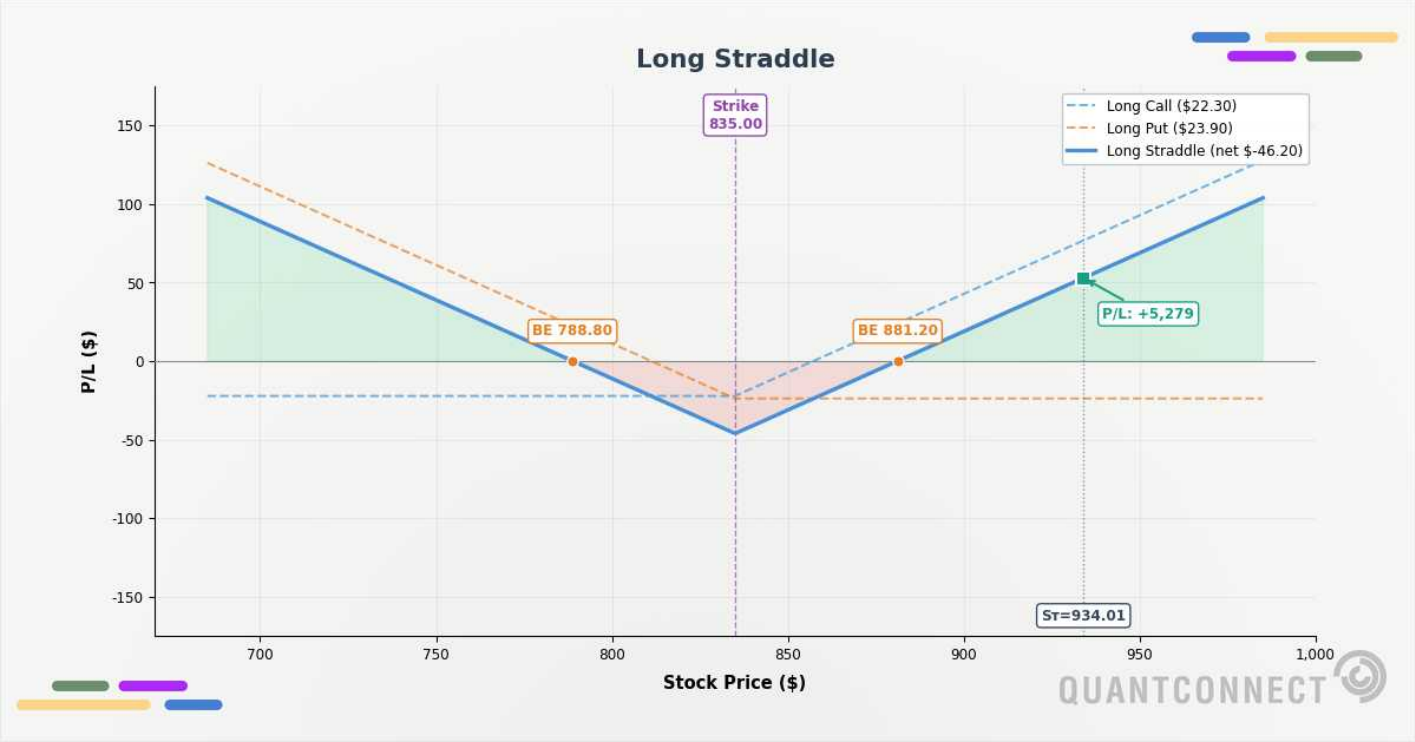
Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcll} C^{ATM}_T & = & (S_T - K^{C})^{+}\\ P^{ATM}_T & = & (K^{P} - S_T)^{+}\\ P_T & = & (C^{ATM}_T + P^{ATM}_T - C^{ATM}_0 - P^{ATM}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & C^{ATM}_T & = & \textrm{ATM call value at time T}\\ & P^{ATM}_T & = & \textrm{ATM put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{C} & = & \textrm{ATM call strike price}\\ & K^{P} & = & \textrm{ATM put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{ATM}_0 & = & \textrm{ATM call value at position opening (debit paid)}\\ & P^{ATM}_0 & = & \textrm{ATM put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

In this example, you traded a call and a put, both at a strike of $835.00 , for $22.30 and $23.90 respectively.

The following chart shows the payoff at expiration:



The maximum profit is unlimited if the underlying price rises to infinity or substantial, $K^{P} - C^{OTM}_0 - P^{OTM}_0$, if it drops to zero at expiration.

The maximum loss is the net debit paid, $C^{ATM}_0 + P^{ATM}_0$. It occurs when the underlying price is the same at expiration as it was when you opened the trade. In this case, both Options expire worthless.

Example

The following table shows the price details of the assets in the algorithm at Option expiration (2017-05-20):

Asset	Price ($)	Strike ($)
Call	22.30	835.00
Put	23.90	835.00
Underlying Equity at expiration	934.01	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{ATM}_T & = & (S_T - K^{C})^{+}\\ & = & (934.01-835.00)^{+}\\ & = & 99.01\\ P^{ATM}_T & = & (K^{P} - S_T)^{+}\\ & = & (835.00-934.01)^{+}\\ & = & 0\\ P_T & = & (C^{ATM}_T + P^{ATM}_T - C^{ATM}_0 - P^{ATM}_0)\times m - fee\\ & = & (99.01+0-22.3-23.9)\times100-1.00\times2\\ & = & 5279 \end{array}$$

So, the strategy gains $5,279.

The following algorithm implements a long straddle Option strategy:

PY

```
class LongStraddleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        option = self.add_option("GOOG")
        self.symbol = option.symbol
        option.set_filter(lambda universe: universe.straddle(30))

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested:
            return

        chain = slice.option_chains.get(self.symbol, None)
        if not chain:
            return

        # Find ATM options with the nearest expiry
        expiry = min([x.expiry for x in chain])
        contracts = sorted([x for x in chain if x.expiry == expiry],
            key=lambda x: abs(chain.underlying.price - x.strike))

        if len(contracts) < 2:
            return

        # The first two contracts are the ATM Call and the ATM Put
        contracts = contracts[0:2]

        long_straddle = OptionStrategies.straddle(self.symbol, contracts[0].strike, expiry)
        self.buy(long_straddle, 1)
```

Option Strategies

Short Straddle

Introduction

A Short Straddle consists of selling a call and a put, where both contracts have the same underlying asset, strike price (normally at-the-money), and expiration date. If you enter a short straddle, you bet that the underlying asset will remain relatively stable and not experience significant price movements before the Option expires.

Implementation

Follow these steps to implement the short straddle strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```py
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(100000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG")
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.straddle(30))
```

   The `straddle` filter narrows the universe down to just the two contracts you need to form a short straddle.

2. In the `on_data` method, select the expiration date and strike price of the contracts in the strategy legs.

```py
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Find ATM options with the nearest expiry
    expiry = min([x.expiry for x in chain])
    strike = sorted(chain, key=lambda x: abs(x.strike - chain.underlying.price))[0].strike
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.short_straddle` method with the details of each leg and then pass the result to the `buy` method.

```py
short_straddle = OptionStrategies.short_straddle(self._symbol, contracts[0].strike, expiry)
self.buy(short_straddle, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```py
contracts = [x for x in chain if x.expiry == expiry and x.strike == strike]
if len(contracts) < 2:
    return

atm_call = [x for x in contracts if x.right == OptionRight.CALL][0]
atm_put = [x for x in contracts if x.right == OptionRight.PUT][0]

legs = [
    Leg.create(atm_call.symbol, -1),
    Leg.create(atm_put.symbol, -1)
]
self.combo_market_order(legs, 1)
```

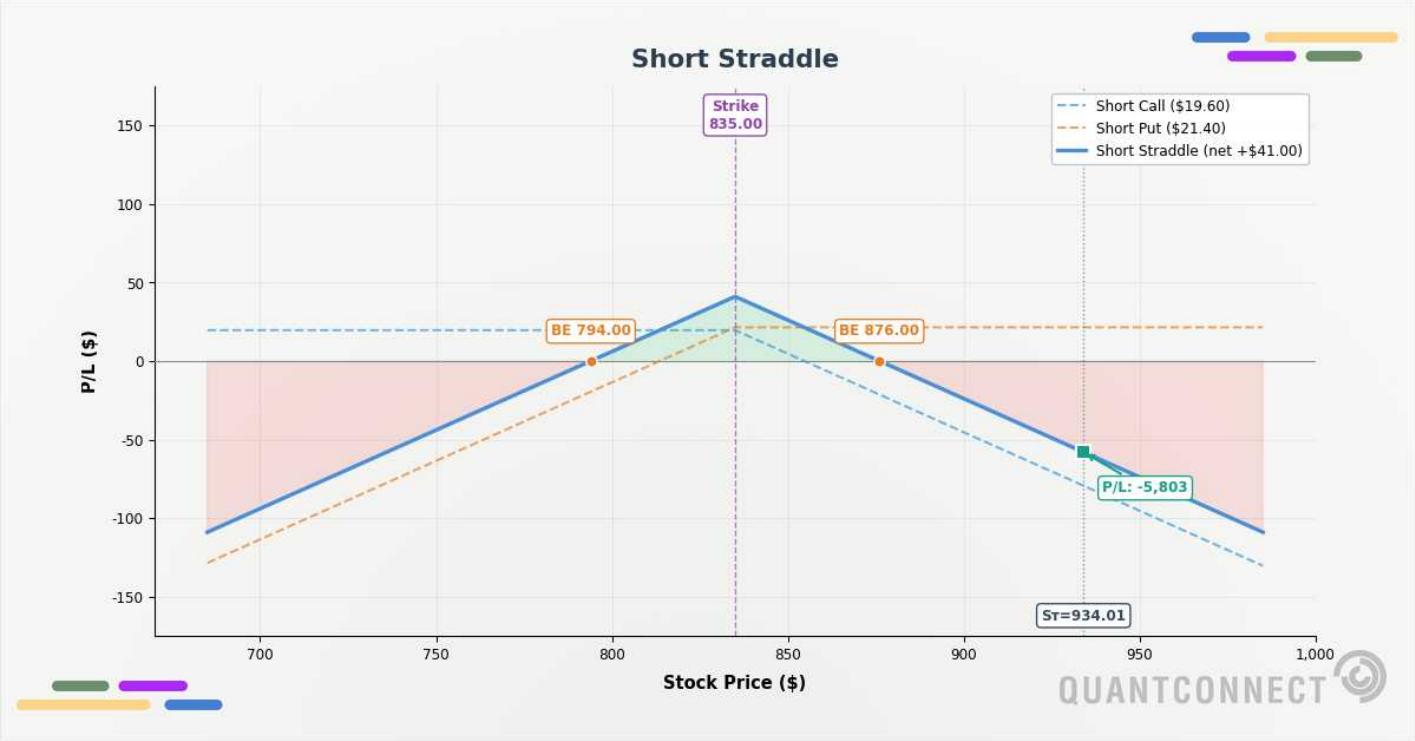
Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcll} C^{ATM}_T & = & (S_T - K^{C})^{+}\\ P^{ATM}_T & = & (K^{P} - S_T)^{+}\\ P_T & = & (-C^{ATM}_T - P^{ATM}_T + C^{ATM}_0 + P^{ATM}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & C^{ATM}_T & = & \textrm{ATM call value at time T}\\ & P^{ATM}_T & = & \textrm{ATM put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{C} & = & \textrm{ATM call strike price}\\ & K^{P} & = & \textrm{ATM put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{ATM}_0 & = & \textrm{ATM call value at position opening (debit paid)}\\ & P^{ATM}_0 & = & \textrm{ATM put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

In this example, you traded a call and a put, both at a strike of $835.00 , for $19.60 and $21.40 respectively.

The following chart shows the payoff at expiration:



The maximum profit is $C^{ATM}_0 + P^{ATM}_0$. It occurs when the price of the underlying asset remains exactly at the strike price upon expiration.

The maximum loss is unlimited if the underlying price rises to infinity or drops to zero at expiration.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the algorithm at Option expiration (2017-05-20):

Asset	Price ($)	Strike ($)
Call	19.6	835.00
Put	21.4	835.00
Underlying Equity at early (2017-05-15) call assignment	932.22	-
Underlying Equity at expiration	934.01	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{ATM}_T & = & (S_T - K^{C})^{+}\\ & = & (934.01-835.00)^{+}\\ & = & 99.01\\ P^{ATM}_T & = & (K^{P} - S_T)^{+}\\ & = & (835.00-934.01)^{+}\\ & = & 0\\ P_T & = & (-C^{ATM}_T - P^{ATM}_T + C^{ATM}_0 + P^{ATM}_0)\times m - fee\\ & = & (-99.01-0+19.6+21.4)\times 100 - 2.00\\ & = & -5803 \end{array}$$

So, the strategy loses $5,803. The early assigment doesn't influence the payoff.

The following algorithm implements a short straddle Option strategy:

PY

```
class LongStraddleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        option = self.add_option("GOOG")
        self.symbol = option.symbol
        option.set_filter(lambda universe: universe.straddle(30))

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested:
            return

        chain = slice.option_chains.get(self.symbol, None)
        if not chain:
            return

        # Find ATM options with the nearest expiry
        expiry = min([x.expiry for x in chain])
        contracts = sorted([x for x in chain if x.expiry == expiry],
            key=lambda x: abs(chain.underlying.price - x.strike))

        if len(contracts) < 2:
            return

        # The first two contracts are the ATM Call and the ATM Put
        contracts = contracts[0:2]

        short_straddle = OptionStrategies.short_straddle(self.symbol, contracts[0].strike, expiry)
        self.buy(short_straddle, 1)
```

Option Strategies

Long Strangle

Introduction

Long Strangle is an Options trading strategy that consists of simultaneously buying an OTM put and an OTM call, where both contracts have the same underlying asset and expiration date. This strategy aims to profit from volatile movements in the underlying stock, either positive or negative.

Compared to a long straddle , the net debit of a long strangle is lower since OTM Options are cheaper. Additionally, the losing range of a long straddle is wider and the strike spread is wider.

Implementation

Follow these steps to implement the long strangle strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```py
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(100000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG")
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.strangle(30, 5, -10))
```

   The `strangle` filter narrows the universe down to just the two contracts you need to form a long strangle.

2. In the `on_data` method, select the contracts of the strategy legs.

```py
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    chain = slice.option_chain.get(self._symbol)
    if not chain:
        return

    # Find options with the farthest expiry
    expiry = max([x.expiry for x in chain])
    contracts = [contract for contract in chain if contract.expiry == expiry]

    # Order the OTM calls by strike to find the nearest to ATM
    call_contracts = sorted([contract for contract in contracts
        if contract.right == OptionRight.CALL and
            contract.strike > chain.underlying.price],
        key=lambda x: x.Strike)
    if not call_contracts:
        return

    # Order the OTM puts by strike to find the nearest to ATM
    put_contracts = sorted([contract for contract in contracts
        if contract.right == OptionRight.PUT and
           contract.strike < chain.underlying.price],
        key=lambda x: x.Strike, reverse=True)
    if not put_contracts:
        return

    call = call_contracts[0]
    put = put_contracts[0]
```

3. In the `on_data` method, place the orders.

   Approach A: Call the `OptionStrategies.strangle` method with the details of each leg and then pass the result to the `buy` method.

```
long_strangle = OptionStrategies.strangle(self._symbol, call.strike, put.strike, expiry)
self.buy(long_strangle, 1)
```

Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
legs = [
    Leg.create(call.symbol, 1),
    Leg.create(put.symbol, 1)
]
self.combo_market_order(legs, 1)
```

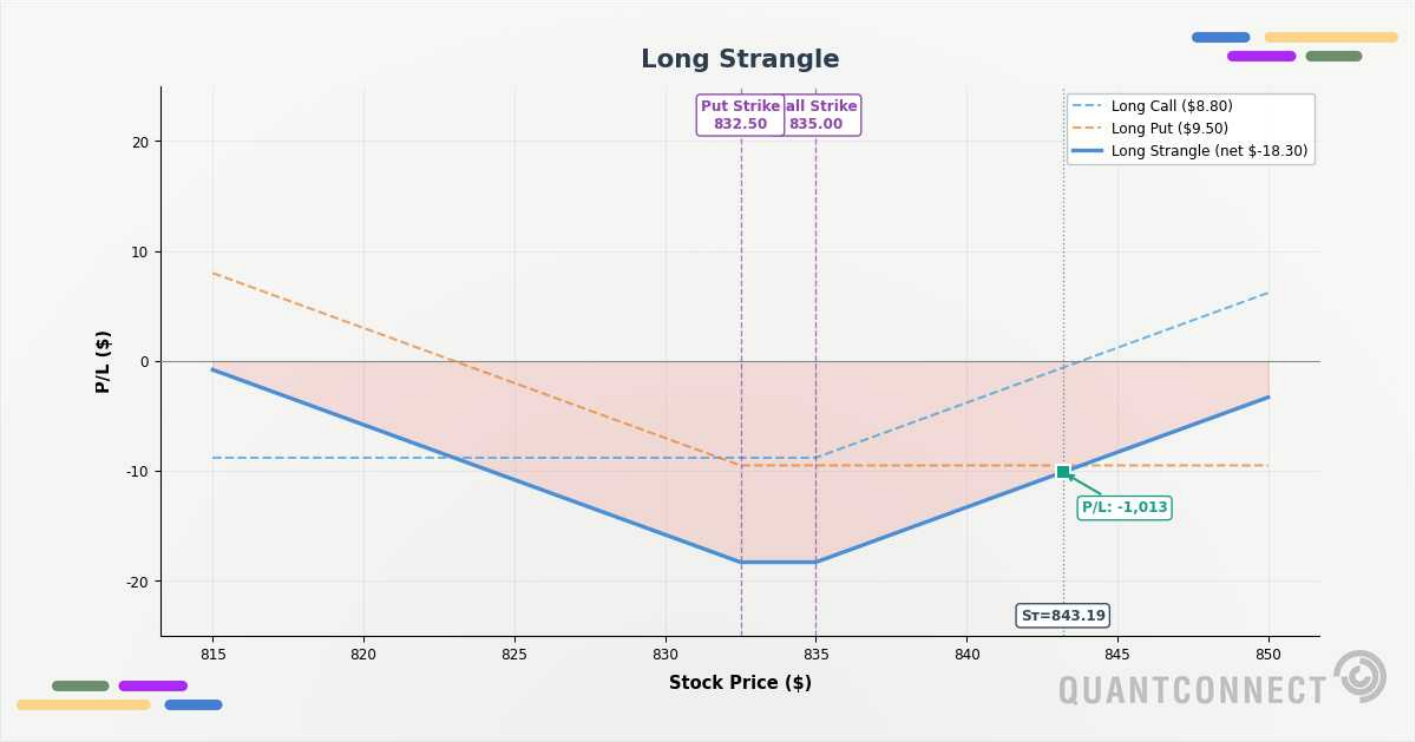
Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^{C})^{+}\\ P^{OTM}_T & = & (K^{P} - S_T)^{+}\\ P_T & = & (C^{OTM}_T + P^{OTM}_T - C^{OTM}_0 - P^{OTM}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & & \\ C^{OTM}_T & = & \textrm{OTM call value at time T}\\ P^{OTM}_T & = & \textrm{OTM put value at time T}\\ S_T & = & \textrm{Underlying asset price at time T}\\ K^{C} & = & \textrm{OTM call strike price}\\ K^{P} & = & \textrm{OTM put strike price}\\ P_T & = & \textrm{Payout total at time T}\\ C^{OTM}_0 & = & \textrm{OTM call value at position opening (debit paid)}\\ P^{OTM}_0 & = & \textrm{OTM put value at position opening (debit paid)}\\ m & = & \textrm{Contract multiplier}\\ T & = & \textrm{Time of expiration} \end{array}$$

In this example, you traded a call at a strike of $835.00 for $8.80 and a put at a strike of $832.50 for $9.50 .

The following chart shows the payoff at expiration:



The maximum profit is unlimited if the underlying price rises to infinity at expiration.

The maximum loss is the net debit paid, $C^{OTM}_0 + P^{OTM}_0$. It occurs when the underlying price at expiration is the same as when you opened the trade. In this case, both Options expire worthless.

Example

The following table shows the price details of the assets in the algorithm at Option expiration (04/22/2017):

Asset	Price ($)	Strike ($)
Call	8.80	835.00
Put	9.50	832.50
Underlying Equity at expiration	843.19	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^{C})^{+}\\ & = & (843.19-835.00)^{+}\\ & = & 8.19\\ P^{OTM}_T & = & (K^{P} - S_T)^{+}\\ & = & (832.50-843.19)^{+}\\ & = & 0\\ P_T & = & (C^{OTM}_T + P^{OTM}_T - C^{OTM}_0 - P^{OTM}_0)\times m - fee\\ & = & (8.19+0-8.80-9.50)\times100-1.00\times2\\ & = & -1013 \end{array}$$

So, the strategy loses $1,013.

The following algorithm implements a long strangle Option strategy:

```py
class LongStrangleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        option = self.add_option("GOOG")
        self.symbol = option.symbol
        option.set_filter(lambda universe: universe.strangle(30, 5, -10))

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested:
            return

        # Get the OptionChain
        chain = slice.option_chains.get(self.symbol)
        if not chain:
            return

        # Find options with the nearest expiry
        expiry = max([x.expiry for x in chain])
        contracts = [contract for contract in chain if contract.expiry == expiry]

        # Order the OTM calls by strike to find the nearest to ATM
        call_contracts = sorted([contract for contract in contracts
            if contract.right == OptionRight.CALL and
               contract.strike > chain.underlying.price],
            key=lambda x: x.strike)
        if not call_contracts:
            return

        # Order the OTM puts by strike to find the nearest to ATM
        put_contracts = sorted([contract for contract in contracts
            if contract.right == OptionRight.PUT and
               contract.strike < chain.underlying.price],
            key=lambda x: x.strike, reverse=True)
        if not put_contracts:
            return

        call_strike = call_contracts[0].strike
        put_strike = put_contracts[0].strike

        long_strangle = OptionStrategies.strangle(self.symbol, call_strike, put_strike, expiry)
        self.buy(long_strangle, 1)
```

Option Strategies

Short Strangle

Introduction

Short Strangle is an Options trading strategy that consists of simultaneously selling an OTM put and an OTM call, where both contracts have the same underlying asset and expiration date. By doing so, the trader is essentially betting that the underlying asset will remain relatively stable and not experience significant price movements before the Options' expiration.

Compared to a short straddle , the net debit of a short strangle is lower since OTM Options are cheaper. Additionally, the winning range of a short straddle is wider and the strike spread is wider.

Implementation

Follow these steps to implement the short strangle strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```py
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(100000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG")
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.strangle(30, 5, -10))
```

   The `strangle` filter narrows the universe down to just the two contracts you need to form a short strangle.

2. In the `on_data` method, select the contracts of the strategy legs.

```py
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    chain = slice.option_chains.get(self._symbol)
    if not chain:
        return

    # Find options with the farthest expiry
    expiry = max([x.expiry for x in chain])
    contracts = [contract for contract in chain if contract.expiry == expiry]

    # Order the OTM calls by strike to find the nearest to ATM
    call_contracts = sorted([contract for contract in contracts
        if contract.right == OptionRight.CALL and
            contract.strike > chain.underlying.price],
        key=lambda x: x.strike)
    if not call_contracts:
        return

    # Order the OTM puts by strike to find the nearest to ATM
    put_contracts = sorted([contract for contract in contracts
        if contract.right == OptionRight.PUT and
           contract.strike < chain.underlying.price],
        key=lambda x: x.strike, reverse=True)
    if not put_contracts:
        return

    call = call_contracts[0]
    put = put_contracts[0]
```

3. In the `on_data` method, place the orders.

   Approach A: Call the `OptionStrategies.short_strangle` method with the details of each leg and then pass the result to the `buy` method.

```
short_strangle = OptionStrategies.short_strangle(self._symbol, call.strike, put.strike, expiry)
self.buy(short_strangle, 1)
```

Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
legs = [
    Leg.create(call.symbol, -1),
    Leg.create(put.symbol, -1)
]
self.combo_market_order(legs, 1)
```

Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^{C})^{+}\\ P^{OTM}_T & = & (K^{P} - S_T)^{+}\\ P_T & = & (-C^{OTM}_T - P^{OTM}_T + C^{OTM}_0 + P^{OTM}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & & \\ C^{OTM}_T & = & \textrm{OTM call value at time T}\\ P^{OTM}_T & = & \textrm{OTM put value at time T}\\ S_T & = & \textrm{Underlying asset price at time T}\\ K^{C} & = & \textrm{OTM call strike price}\\ K^{P} & = & \textrm{OTM put strike price}\\ P_T & = & \textrm{Payout total at time T}\\ C^{OTM}_0 & = & \textrm{OTM call value at position opening (debit paid)}\\ P^{OTM}_0 & = & \textrm{OTM put value at position opening (debit paid)}\\ m & = & \textrm{Contract multiplier}\\ T & = & \textrm{Time of expiration} \end{array}$$

In this example, you traded a call at a strike of $835.00 for $8.00 and a put at a strike of $832.50 for $7.40 .

The following chart shows the payoff at expiration:

The maximum profit $C^{OTM}_0 + P^{OTM}_0$. It occurs when the underlying price at expiration remains within the range of the strike prices. In this case, both Options expire worthless.

The maximum loss is unlimited if the underlying price rises to infinity or substantial, $C^{OTM}_0 + P^{OTM}_0 - K^{P}$, if it drops to zero at expiration.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the algorithm at Option expiration (2017-04-22):

Asset	Price ($)	Strike ($)
Call	8.00	835.00
Put	7.40	832.50
Underlying Equity at expiration	843.19	-

Therefore, the payoff is

\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^{C})^{+}\\ & = & (843.19-835.00)^{+}\\ & = & 8.19\\ P^{OTM}_T & = & (K^{P} - S_T)^{+}\\ & = & (832.50-843.19)^{+}\\ & = & 0\\ P_T & = & (-C^{OTM}_T - P^{OTM}_T + C^{OTM}_0 + P^{OTM}_0)\times m - fee\\ & = & (-8.19-0+8.00+7.40)\times100-1.00\times2\\ & = & 719 \end{array}

So, the strategy gains $719.

The following algorithm implements a short strangle Option strategy:

```py
class ShortStrangleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        option = self.add_option("GOOG")
        self.symbol = option.symbol
        option.set_filter(lambda universe: universe.strangle(30, 5, -10))

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested:
            return

        # Get the OptionChain
        chain = slice.option_chains.get(self.symbol)
        if not chain:
            return

        # Find options with the nearest expiry
        expiry = max([x.expiry for x in chain])
        contracts = [contract for contract in chain if contract.expiry == expiry]

        # Order the OTM calls by strike to find the nearest to ATM
        call_contracts = sorted([contract for contract in contracts
            if contract.right == OptionRight.CALL and
               contract.strike > chain.underlying.price],
            key=lambda x: x.strike)
        if not call_contracts:
            return

        # Order the OTM puts by strike to find the nearest to ATM
        put_contracts = sorted([contract for contract in contracts
            if contract.right == OptionRight.PUT and
               contract.strike < chain.underlying.price],
            key=lambda x: x.strike, reverse=True)
        if not put_contracts:
            return

        call_strike = call_contracts[0].strike
        put_strike = put_contracts[0].strike

        short_strangle = OptionStrategies.short_strangle(self.symbol, call_strike, put_strike, expiry)
        self.buy(short_strangle, 1)
```

Option Strategies

Conversion

Introduction

A Conversion is a special case of a protective collar . It consist of holding one lot of the underlying security, shorting a call, and longing a put with lower strike price. However, the strategy now serves as an delta-neutral arbitration from Option mispricing instead of a hedge strategy. Note that it only attains a true profit when the risk-free return is greater than the risk-free interest rate .

Implementation

Follow these steps to implement the conversion strategy:

1. In the `initialize` method, set the start date, set the end date, subscribe to the underlying Equity , and create an Option universe .

```
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(100000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.conversion(30, -5))
```

   The `conversion` filter narrows the universe down to just the two contracts you need to form a conversion.

2. In the `on_data` method, select the strike and expiry of the contracts in the strategy legs.

```
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Select an expiry date and ATM strike price
    expiry = max([x.expiry for x in chain])
    strike = sorted(chain, key = lambda x: abs(x.strike - chain.underlying.price))[0].strike
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.conversion` method with the details of each leg and then pass the result to the `buy` method.

```
conversion = OptionStrategies.conversion(self._symbol, strike, expiry)
self.buy(conversion, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
# Select the call and put contracts
call = [x for x in chain if x.right == OptionRight.CALL and x.expiry == expiry and x.strike == strike][0]
put = [x for x in chain if x.right == OptionRight.PUT and x.expiry == expiry and x.strike == strike][0]

legs = [
    Leg.create(call.symbol, -1),
    Leg.create(put.symbol, 1),
    Leg.create(chain.underlying.symbol, chain.underlying.symbol_properties.contract_multiplier)
]
self.combo_market_order(legs, 1)
```

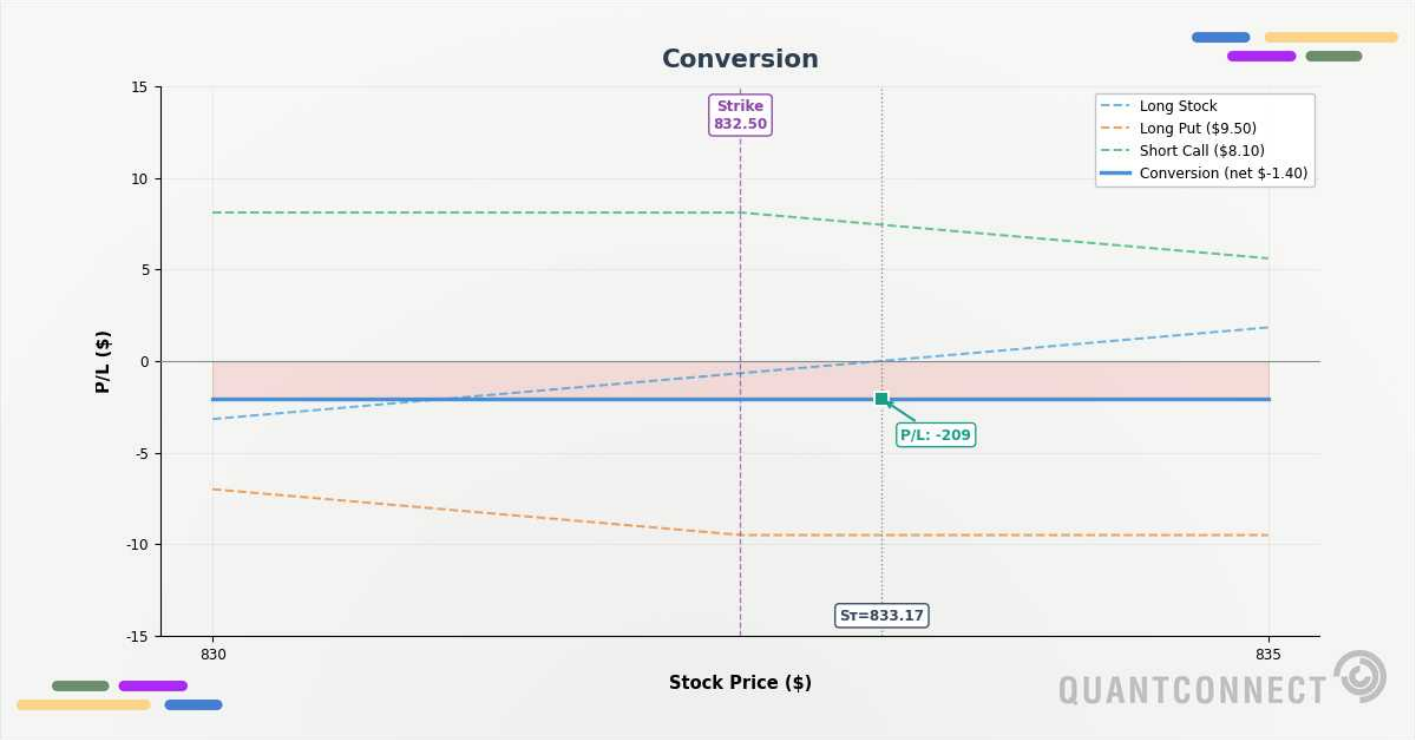
Strategy Payoff

This is a fixed payoff, delta-neutral strategy. The payoff is

$$\begin{array}{rcll} C_T & = & (S_T - K)^{+}\\ P_T & = & (K - S_T)^{+}\\ Payoff_T & = & (S_T - S_0 - C_T + P_T + C_0 - P_0)\times m - fee\\ & = & (K - S_0 + C_0 - P_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & C_T & = & \textrm{Call value at time T}\\ & P_T & = & \textrm{Put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Strike price}\\ & Payoff_T & = & \textrm{Payout total at time T}\\ & S_0 & = & \textrm{Underlying asset price when the trade opened}\\ & C_0 & = & \textrm{Call price when the trade opened (credit received)}\\ & P_0 & = & \textrm{Put price when the trade opened (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock traded at $833.17 at expiration. You traded a call and a put at a strike of $832.50 for $8.10 and $9.50 respectively, and held the underlying.

The following chart shows the payoff at expiration:



The payoff is only dependent on the strike price and the initial asset prices.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Call	8.10	832.50
Put	9.50	832.50
Underlying Equity at position opens	833.17	-

Therefore, the payoff is

$$\begin{array}{rcll} Payoff_T & = & (K - S_0 + C_0 - P_0)\times m - fee\\ & = & (832.50 - 833.17 + 8.10 - 9.50)\times100-1.00\times3\\ & = & -210.00\\ \end{array}$$

So, the strategy loses $210.

The following algorithm implements a conversion Option strategy:

PY

```
class ConversionOptionStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        equity = self.add_equity("GOOG", Resolution.MINUTE)
        option = self.add_option("GOOG", Resolution.MINUTE)
        self.symbol = option.symbol

        # set our strike/expiry filter for this option chain
        option.set_filter(lambda universe: universe.conversion(30, -5))

    def on_data(self, data: Slice) -> None:
        # avoid extra orders
        if self.portfolio.invested: return

        # Get the OptionChain of the self.symbol
        chain = data.option_chains.get(self.symbol, None)
        if not chain: return

        # choose the furthest expiration date within 30 days from now on
        expiry = sorted(chain, key = lambda x: x.expiry)[-1].expiry

        # select ATM strike price
        strike = sorted(chain, key = lambda x: abs(x.Strike - chain.underlying.price))[0].strike

        # Order Strategy
        conversion = OptionStrategies.conversion(self.symbol, strike, expiry)
        self.buy(conversion, 1)

    def on_end_of_day(self, symbol: Symbol) -> None:
        if symbol.value == "GOOG":
            self.log(f"{self.time}::{symbol}::{self.securities[symbol].price}")
```

Option Strategies

Reverse Conversion

Introduction

A Reverse Conversion , or Reversal , is the inverse of a conversion and also a special case of a protective collar . It consist of shorting one lot of the underlying security, buying a call, and selling a put with lower strike price. However, the strategy now serves as an delta-neutral arbitration from Option mispricing instead of a hedge strategy. Note that it only attains a true profit when the risk-free return is greater than the risk-free interest rate .

Implementation

Follow these steps to implement the reverse conversion strategy:

1. In the `initialize` method, set the start date, set the end date, subscribe to the underlying Equity , and create an Option universe .

```
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(100000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.conversion(30, -5))
```

   The `conversion` filter narrows the universe down to just the two contracts you need to form a reverse conversion.

2. In the `on_data` method, select the strike and expiry of the contracts in the strategy legs.

```
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Select an expiry date and ATM strike price
    expiry = max([x.expiry for x in chain])
    strike = sorted(chain, key = lambda x: abs(x.strike - chain.underlying.price))[0].strike
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.reverse_conversion` method with the details of each leg and then pass the result to the `buy` method.

```
reverse_conversion = OptionStrategies.reverse_conversion(self._symbol, strike, expiry)
self.buy(reverse_conversion, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
# Select the call and put contracts
call = [x for x in chain if x.right == OptionRight.CALL and x.expiry == expiry and x.strike == strike][0]
put = [x for x in chain if x.right == OptionRight.PUT and x.expiry == expiry and x.strike == strike][0]

legs = [
    Leg.create(call.symbol, 1),
    Leg.create(put.symbol, -1),
    Leg.create(chain.underlying.symbol, -chain.underlying.symbol_properties.contract_multiplier)
]
self.combo_market_order(legs, 1)
```

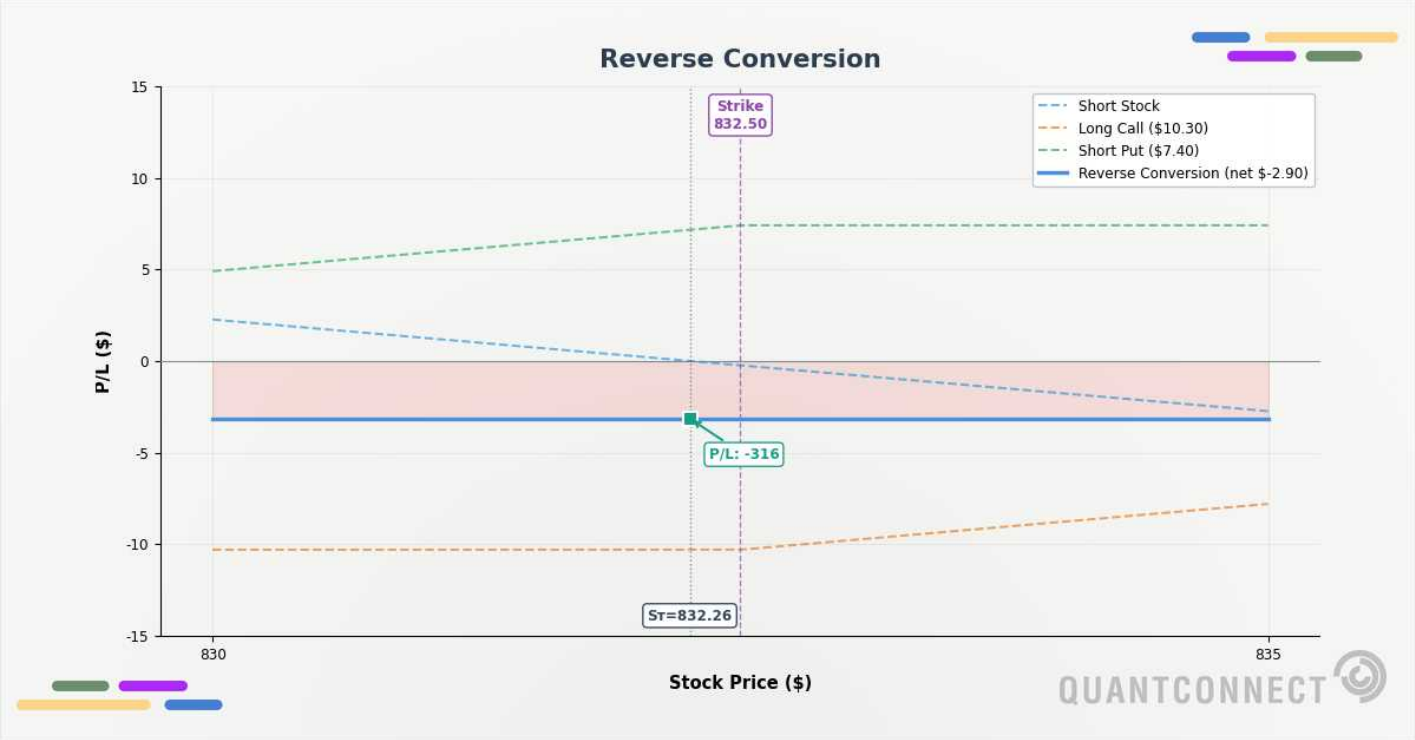
Strategy Payoff

This is a fixed payoff, delta-neutral strategy. The payoff is

$$\begin{array}{rcll} C_T & = & (S_T - K)^{+}\\ P_T & = & (K - S_T)^{+}\\ Payoff_T & = & (S_0 - S_T + C_T - P_T - C_0 + P_0)\times m - fee\\ & = & (S_0 - K - C_0 + P_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & C_T & = & \textrm{Call value at time T}\\ & P_T & = & \textrm{Put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Strike price}\\ & Payoff_T & = & \textrm{Payout total at time T}\\ & S_0 & = & \textrm{Underlying asset price when the trade opened}\\ & C_0 & = & \textrm{Call price when the trade opened (credit received)}\\ & P_0 & = & \textrm{Put price when the trade opened (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock traded at $832.26 at expiration. You traded a call and a put at a strike of $832.50 for $10.30 and $7.40 respectively, and held the underlying.

The following chart shows the payoff at expiration:



The payoff is only dependent on the strike price and the initial asset prices.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Call	10.30	832.50
Put	7.40	832.50
Underlying Equity at position opens	832.26	-

Therefore, the payoff is

$$\begin{array}{rcll} Payoff_T & = & (S_0 - K - C_0 + P_0)\times m - fee\\ & = & (832.26 - 832.50 - 10.30 + 7.40)\times100-1.00\times3\\ & = & -317.00\\ \end{array}$$

So, the strategy loses $317.

The following algorithm implements a reverse conversion Option strategy:

PY

```
class ReverseConversionOptionStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        equity = self.add_equity("GOOG", Resolution.MINUTE)
        option = self.add_option("GOOG", Resolution.MINUTE)
        self.symbol = option.symbol

        # set our strike/expiry filter for this option chain
        option.set_filter(lambda universe: universe.conversion(30, -5))

    def on_data(self, data: Slice) -> None:
        # avoid extra orders
        if self.portfolio.invested: return

        # Get the OptionChain of the self.symbol
        chain = data.option_chains.get(self.symbol, None)
        if not chain: return

        # choose the furthest expiration date within 30 days from now on
        expiry = sorted(chain, key = lambda x: x.expiry)[-1].expiry

        # select ATM strike price
        strike = sorted(chain, key = lambda x: abs(x.Strike - chain.underlying.price))[0].strike

        # Order Strategy
        reverse_conversion = OptionStrategies.reverse_conversion(self.symbol, strike, expiry)
        self.buy(reverse_conversion, 1)

    def on_end_of_day(self, symbol: Symbol) -> None:
        if symbol.value == "GOOG":
            self.log(f"{self.time}::{symbol}::{self.securities[symbol].price}")
```

Option Strategies

Long Box Spread

Introduction

A long Box Spread is the combination of a bull call spread and a bear put spread . It consist of buying an ITM call at strike A, selling an OTM put at strike A, buying an ITM put at strike B < A, and selling an OTM call at strike B, where all of the contracts have the same expiry date. This strategy serves as an delta-neutral arbitration from Option mispricing. Note that it only attains a true profit when the risk-free return is greater than the risk-free interest rate .

Implementation

Follow these steps to implement the long box spread strategy:

1. In the `initialize` method, set the start date, set the end date, subscribe to the underlying Equity , and create an Option universe .

```py
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(100000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.box_spread(30, 5))
```

   The `box_spread` filter narrows the universe down to just the four contracts you need to form a box spread.

2. In the `on_data` method, select the expiry and strikes of the contracts in the strategy legs.

```py
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Select an expiry date and ITM & OTM strike prices
    expiry = max([x.expiry for x in chain])
    contracts = [x for x in chain if x.expiry == expiry]
    lower_strike = min([x.strike for x in contracts])
    higher_strike = max([x.strike for x in contracts])
```

3. In the `on_data` method, select the contracts and place the order.

   Approach A: Call the `OptionStrategies.box_spread` method with the details of each leg and then pass the result to the `buy` method.

```py
box_spread = OptionStrategies.box_spread(self._symbol, higher_strike, lower_strike, expiry)
self.buy(box_spread, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```py
# Select the call and put contracts
itm_call = next(filter(lambda x: x.right == OptionRight.CALL and x.strike == lower_strike, contracts))
otm_call = next(filter(lambda x: x.right == OptionRight.CALL and x.strike == higher_strike, contracts))
itm_put = next(filter(lambda x: x.right == OptionRight.PUT and x.strike == higher_strike, contracts))
otm_put = next(filter(lambda x: x.right == OptionRight.PUT and x.strike == lower_strike, contracts))

legs = [
    Leg.create(itm_call.symbol, 1),
    Leg.create(itm_put.symbol, 1),
    Leg.create(otm_call.symbol, -1),
    Leg.create(otm_put.symbol, -1),
]
self.combo_market_order(legs, 1)
```

Strategy Payoff

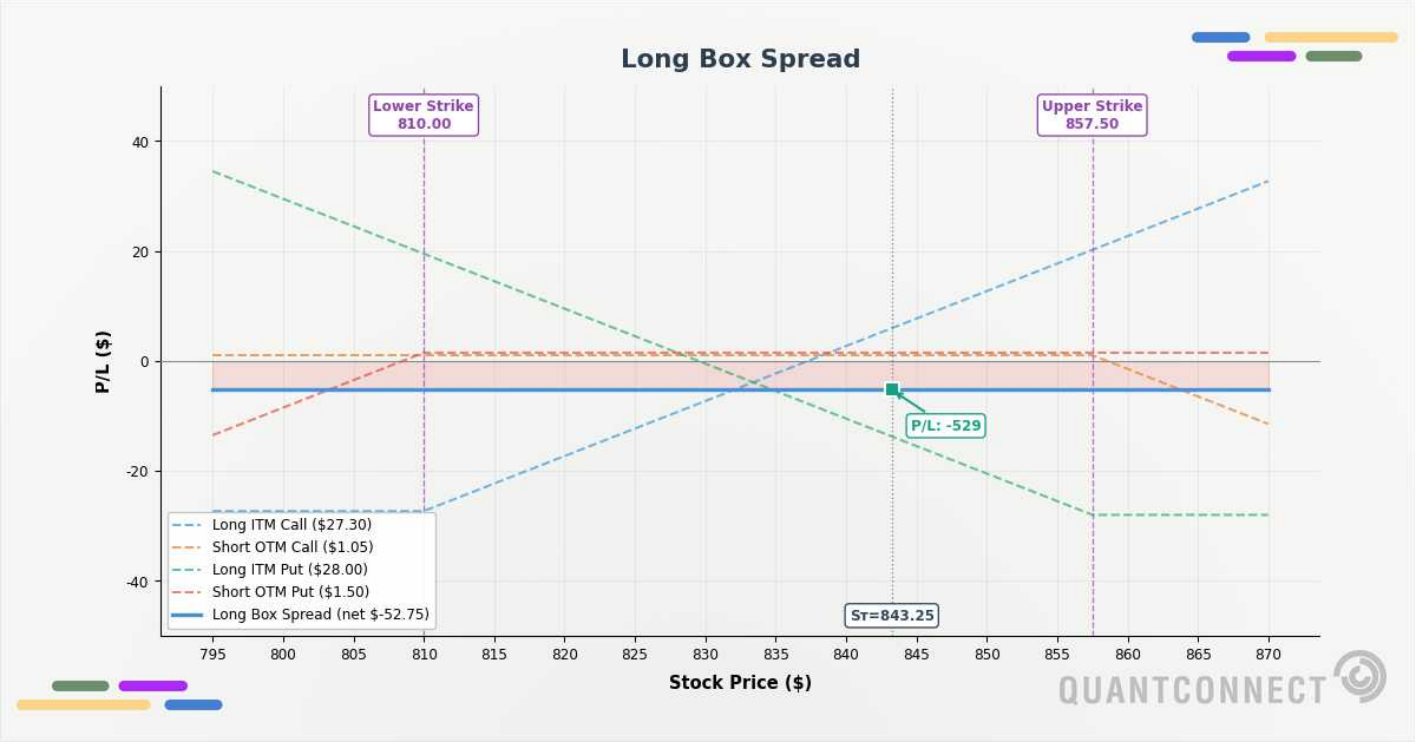
This is a fixed payoff, delta-neutral strategy. The payoff is

$$\begin{array}{rcll} C_T^{ITM} & = & (S_T - K_{-})^{+}\\ C_T^{OTM} & = & (S_T - K_{+})^{+}\\ P_T^{ITM} & = & (K_{+} - S_T)^{+}\\ P_T^{OTM} & = & (K_{-} - S_T)^{+}\\ Payoff_T & = & (C_T^{ITM} - C_{T_0}^{ITM} + P_T^{ITM} - P_{T_0}^{ITM} - C_T^{OTM} + C_{T_0}^{OTM} - P_T^{OTM} + P_{T_0}^{OTM})\times m - fee\\ & = & (K_{+} - K_{-} + C_{T_0}^{OTM} + P_{T_0}^{OTM} - C_{T_0}^{ITM} - P_{T_0}^{ITM})\times m - fee \end{array}$$

$$\begin{array}{rcll} \textrm{where} & & & \\ C_T^{ITM} & = & \textrm{ITM Call value at time T}\\ C_T^{OTM} & = & \textrm{OTM Call value at time T}\\ P_T^{ITM} & = & \textrm{ITM Put value at time T}\\ P_T^{OTM} & = & \textrm{OTM Put value at time T}\\ S_T & = & \textrm{Underlying asset price at time T}\\ K_{+} & = & \textrm{Higher strike price}\\ K_{-} & = & \textrm{Lower strike price}\\ Payoff_{T_1} & = & \textrm{Payout total at time T1}\\ C_{T_0}^{ITM} & = & \textrm{ITM Call price when the trade opened (debit paid)}\\ C_{T_0}^{OTM} & = & \textrm{OTM Call price when the trade opened (credit received)}\\ P_{T_0}^{ITM} & = & \textrm{ITM Put price when the trade opened (debit paid)}\\ P_{T_0}^{OTM} & = & \textrm{OTM Put price when the trade opened (credit received)}\\ m & = & \textrm{Contract multiplier}\\ T & = & \textrm{Time of expiration} \end{array}$$

In this example, you traded an ITM call at $810.00 for $27.30 , an OTM call at $857.50 for $1.05 , an ITM put at $857.50 for $28.00 , and an OTM put at $810.00 for $1.50 .

The following chart shows the payoff at expiration:



The payoff is only dependent on the strike price and the initial asset prices.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
ITM Call	27.30	810.00
ITM Put	28.00	857.50
OTM Call	1.05	857.50
OTM Put	1.50	810.00
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

$$\begin{array}{rcll} Payoff_T & = & (K_{+} - K_{-} + C_0^{OTM} + P_0^{OTM} - C_0^{ITM} - P_0^{ITM})\times m - fee\\ & = & (857.50 - 810.00 + 1.05 + 1.50 - 27.30 - 28.00)\times100 - 1.00\times4\\ & = & -529.00\\ \end{array}$$

So, the strategy loses $529.

The following algorithm implements a long box spread Option strategy:

```py
class BoxSpreadStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        self.universe_settings.asynchronous = True

        option = self.add_option("GOOG", Resolution.MINUTE)
        self._symbol = option.Symbol
        option.set_filter(lambda universe: universe.box_spread(30, 5))

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested:
            return

        # Get the OptionChain
        chain = slice.option_chains.get(self._symbol, None)
        if not chain:
            return

        # Select an expiry date
        expiry = max([x.expiry for x in chain])

        # Select the strike prices of the contracts
        contracts = [x for x in chain if x.expiry == expiry]
        higher_strike = max([x.strike for x in contracts])
        lower_strike = min([x.strike for x in contracts])

        box_spread = OptionStrategies.box_spread(self._symbol, higher_strike, lower_strike, expiry)
        self.buy(box_spread, 1)

    def on_end_of_day(self, symbol: Symbol) -> None:
        if symbol == self._symbol.underlying:
            self.Log(f"{self.time}::{symbol}::{self.securities[symbol].price}")
```

Option Strategies

Short Box Spread

Introduction

A Short Box Spread is the inverse of a box spread , as well as the combination of a bear call spread and a bull put spread . It consists of buying an OTM call at strike A, selling an ITM put at strike A, buying an OTM put and strike B < A, and selling an ITM call at strike B, where all of the contracts have the same expiry date. This strategy serves as an delta-neutral arbitration from Option mispricing. Note that it only attains a true profit when the risk-free return is greater than the risk-free interest rate .

Implementation

Follow these steps to implement the short box spread strategy:

1. In the `initialize` method, set the start date, set the end date, subscribe to the underlying Equity , and create an Option universe .

```
PY
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(100000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.box_spread(30, 5))
```

   The `box_spread` filter narrows the universe down to just the four contracts you need to form a short box spread.

2. In the `on_data` method, select the strike and expiry of the contracts in the strategy legs.

```
PY
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Select an expiry date and ITM & OTM strike prices
    expiry = max([x.expiry for x in chain])
    contracts = [x for x in chain if x.expiry == expiry]
    lower_strike = min([x.strike for x in contracts])
    higher_strike = max([x.strike for x in contracts])
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.short_box_spread` method with the details of each leg and then pass the result to the `buy` method.

```
PY
short_box_spread = OptionStrategies.short_box_spread(self._symbol, higher_strike, lower_strike, expiry)
self.buy(short_box_spread, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```py
# Select the call and put contracts
itm_call = [x for x in chain if x.right == OptionRight.CALL and x.expiry == expiry and x.strike == lower_strike][0]
otm_call = [x for x in chain if x.right == OptionRight.CALL and x.expiry == expiry and x.strike == higher_strike][0]
itm_put = [x for x in chain if x.right == OptionRight.PUT and x.expiry == expiry and x.strike == higher_strike][0]
otm_put = [x for x in chain if x.right == OptionRight.PUT and x.expiry == expiry and x.strike == lower_strike][0]

legs = [
    Leg.create(itm_call.symbol, -1),
    Leg.create(itm_put.symbol, -1),
    Leg.create(otm_call.symbol, 1),
    Leg.create(otm_put.symbol, 1),
]
self.combo_market_order(legs, 1)
```

Strategy Payoff

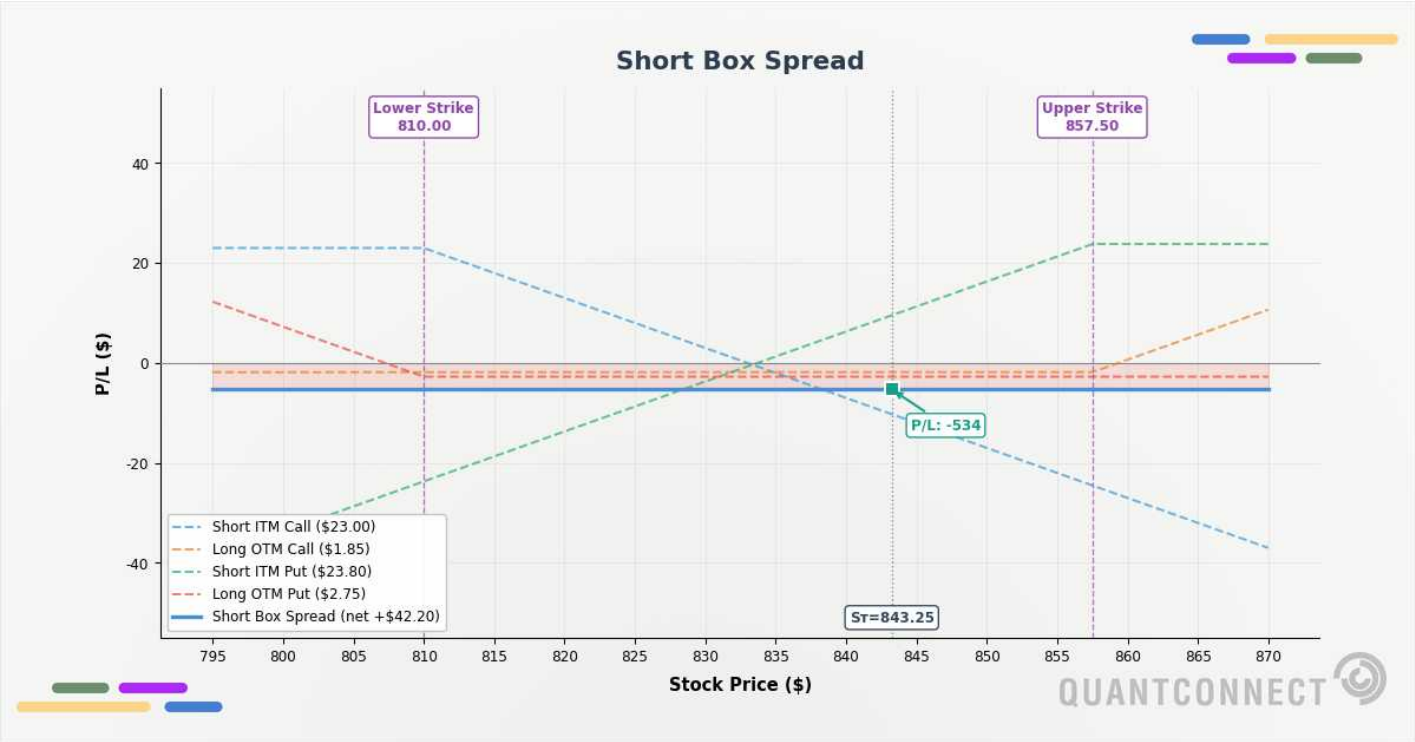
This is a fixed payoff, delta-neutral strategy. The payoff is

$$\begin{array}{rcl} C_T^{ITM} & = & (S_T - K_{-})^{+}\\ C_T^{OTM} & = & (S_T - K_{+})^{+}\\ P_T^{ITM} & = & (K_{+} - S_T)^{+}\\ P_T^{OTM} & = & (K_{-} - S_T)^{+}\\ Payoff_T & = & (C_{T_0}^{ITM} - C_T^{ITM} + P_{T_0}^{ITM} - P_T^{ITM} - C_{T_0}^{OTM} + C_T^{OTM} - P_{T_0}^{OTM} + P_T^{OTM})\times m - fee\\ & = & (K_{-} - K_{+} + C_{T_0}^{ITM} + P_{T_0}^{ITM} - C_{T_0}^{OTM} - P_{T_0}^{OTM})\times m - fee \end{array}$$

$$\begin{array}{rcl} \textrm{where} & C_T^{ITM} & = & \textrm{ITM Call value at time T}\\ & C_T^{OTM} & = & \textrm{OTM Call value at time T}\\ & P_T^{ITM} & = & \textrm{ITM Put value at time T}\\ & P_T^{OTM} & = & \textrm{OTM Put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K_{+} & = & \textrm{Higher strike price}\\ & K_{-} & = & \textrm{Lower strike price}\\ & Payoff_T & = & \textrm{Payout total at time T}\\ & C_{T_0}^{ITM} & = & \textrm{ITM Call price when the trade opened (debit paid)}\\ & C_{T_0}^{OTM} & = & \textrm{OTM Call price when the trade opened (credit received)}\\ & P_{T_0}^{ITM} & = & \textrm{ITM Put price when the trade opened (debit paid)}\\ & P_{T_0}^{OTM} & = & \textrm{OTM Put price when the trade opened (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

In this example, you traded an ITM call at $810.00 for $23.00 , an OTM call at $857.50 for $1.85 , an ITM put at $857.50 for $23.80 , and an OTM put at $810.00 for $2.75 .

The following chart shows the payoff at expiration:



The payoff is only dependent on the strike price and the initial asset prices.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
ITM Call	23.00	810.00
ITM Put	23.80	857.50
OTM Call	1.85	857.50
OTM Put	2.75	810.00
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

$$\begin{array}{rcll} Payoff_T & = & (K_{-} - K_{+} + C_0^{ITM} + P_0^{ITM} - C_0^{OTM} - P_0^{OTM})\times m - fee\\ & = & (810.00 - 857.50 + 23.00 + 23.80 - 1.85 - 2.75)\times100 - 1.00\times4\\ & = & -534.00\\ \end{array}$$

So, the strategy loses $534.

The following algorithm implements a short box spread Option strategy:

```py
class ProtectiveCollarOptionStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1);
        self.set_end_date(2024, 12, 31);
        self.set_cash(100000)

        self.universe_settings.asynchronous = True
        self.equity_symbol = self.add_equity("GOOG").symbol

        option = self.add_option("GOOG", Resolution.Minute)
        self.option_symbol = option.symbol
        option.set_filter(lambda universe: universe.box_spread(30, 5))

        self.invest_ever = False

    def on_data(self, slice: Slice) -> None:
        if self.invest_ever: return

        # Get the OptionChain
        chain = slice.option_chains.get(self.option_symbol, None)
        if not chain: return

        # Select an expiry date
        expiry = sorted(chain, key = lambda x: x.expiry)[-1].expiry

        # Select the strike prices of the contracts
        ordered_contracts = sorted(chain, key = lambda x: x.strike)
        higher_strike = ordered_contracts[-1].strike
        lower_strike = ordered_contracts[0].strike

        box_spread = OptionStrategies.short_box_spread(self.option_symbol, higher_strike, lower_strike, expiry)
        self.buy(box_spread, 1)

        self.invest_ever = True

    def on_end_of_day(self, symbol: Symbol) -> None:
        if symbol == self.equity_symbol:
            self.log(f"{self.time}::{symbol}::{self.securities[symbol].price}")
```

Option Strategies

Long Jelly Roll

Introduction

A long Jelly Roll , or simply Roll , is a combination of a long call calendar spread and a short put calendar spread . It consists of buying a put and selling a call of the same expiry, as well as buying a call and selling a put with a further expiry, where all of the contracts have the same strike price. This strategy serves as an arbitrage on Option mispricing due to the temporary disparity between the call spread and the put spread synthetic portfolios. It is a delta -, gamma -, vega -, and theta -neutral strategy, but sensitive to rho (interest rate) and phi (dividend yield).

Implementation

Follow these steps to implement the long jelly roll strategy:

1. In the `initialize` method, set the start date, set the end date, and create an Option universe .

```py
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(100000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda x: x.jelly_roll(5.0, 30, 60))
```

2. In the `on_data` method, select the expiry and strikes of the contracts in the strategy legs.

```py
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Select an expiry date and ITM & OTM strike prices
    strike = sorted([x.strike for x in chain], key=lambda x: abs(x - chain.underlying.price))[0]
    contracts = [x for x in chain if x.strike == strike]
    far_expiry = max([x.expiry for x in contracts])
    near_expiry = min([x.expiry for x in contracts])
```

3. In the `on_data` method, select the contracts and place the order.

   Approach A: Call the `OptionStrategies.jelly_roll` method with the details of each leg and then pass the result to the `buy` method.

```py
jelly_roll = OptionStrategies.jelly_roll(self._symbol, strike, near_expiry, far_expiry)
self.buy(jelly_roll, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```py
# Select the call and put contracts
near_call = next(filter(lambda x: x.right == OptionRight.CALL and x.expiry == near_expiry, contracts))
far_call = next(filter(lambda x: x.right == OptionRight.CALL and x.expiry == far_expiry, contracts))
near_put = next(filter(lambda x: x.right == OptionRight.PUT and x.expiry == near_expiry, contracts))
call_put = next(filter(lambda x: x.right == OptionRight.PUT and x.expiry == far_expiry, contracts))

legs = [
    Leg.create(near_call.symbol, -1),
    Leg.create(far_call.symbol, 1),
    Leg.create(near_put.symbol, 1),
    Leg.create(call_put.symbol, -1),
]
self.combo_market_order(legs, 1)
```

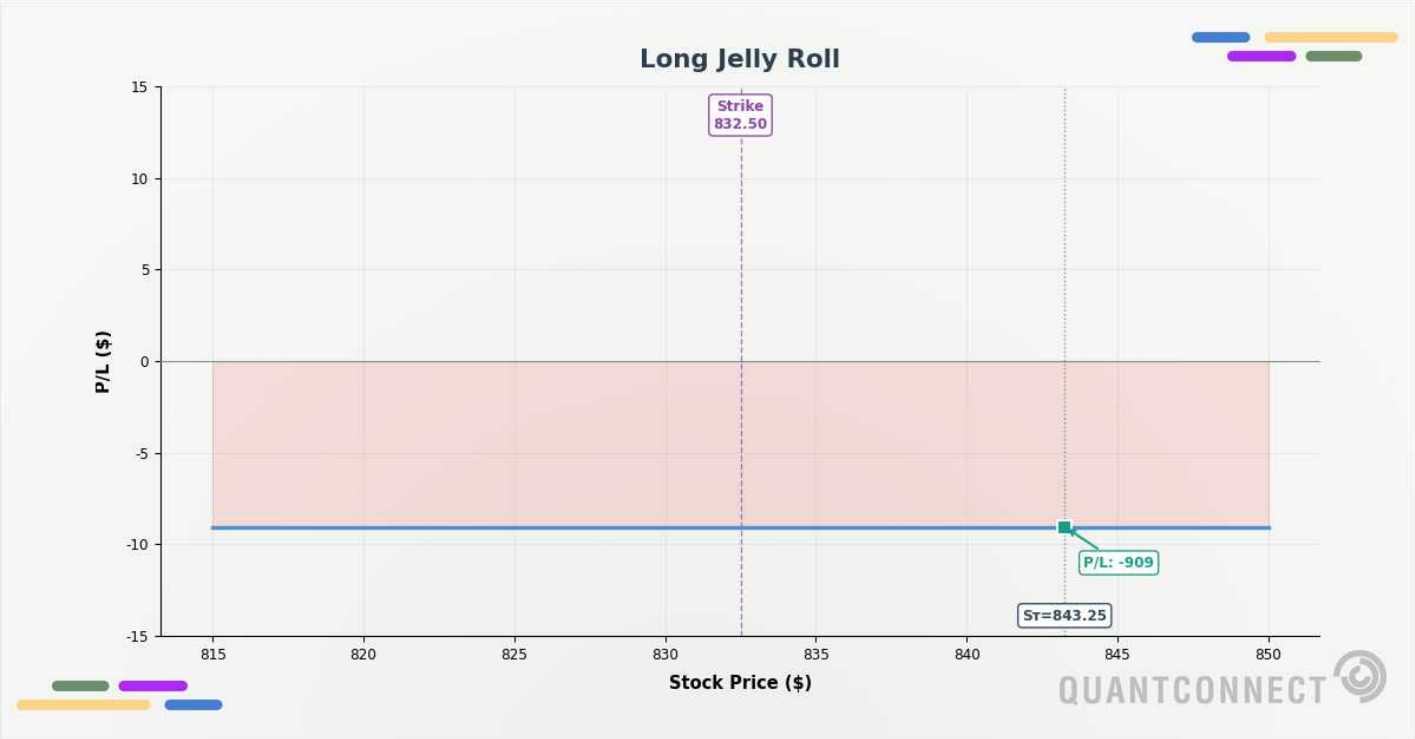
Strategy Payoff

This is a delta-, gamma-, vega-, and theta-neutral strategy. The payoff is

$$\begin{array}{rcll} C_{T_1}^{T_1} & = & (S_{T_1} - K)^{+}\\ P_{T_1}^{T_1} & = & (K - S_{T_1})^{+}\\ Payoff_{T_1} & = & (P_{T_1}^{T_1} - P_{T_0}^{T_1} - C_{T_1}^{T_1} + C_{T_0}^{T_1} + C_{T_1}^{T_2} - C_{T_0}^{T_2} - P_{T_1}^{T_2} + P_{T_0}^{T_2})\times m - fee\\ \end{array} \begin{array}{rcl} \textrm{where} & C_{T_1}^{T_1} & = & \textrm{Market value of Call with expiry at T1 at time T1}\\ C_{T_1}^{T_2} & = & \textrm{Market value of Call with expiry at T2 at time T1}\\ P_{T_1}^{T_1} & = & \textrm{Market value of Put with expiry at T1 at time T1}\\ P_{T_1}^{T_2} & = & \textrm{Market value of Put with expiry at T2 at time T1}\\ S_{T_1} & = & \textrm{Underlying asset price at time T1}\\ K & = & \textrm{Strike price}\\ Payoff_T & = & \textrm{Payout total at time T}\\ C_{T_0}^{T_1} & = & \textrm{Market value of Call with expiry at T1 when the trade opened}\\ C_{T_0}^{T_2} & = & \textrm{Market value of Call with expiry at T2 when the trade opened}\\ P_{T_0}^{T_1} & = & \textrm{Market value of Put with expiry at T2 when the trade opened}\\ P_{T_0}^{T_2} & = & \textrm{Market value of Put with expiry at T2 when the trade opened}\\ m & = & \textrm{Contract multiplier}\\ T_1 & = & \textrm{Time T1 as the near expiration}\\ T_2 & = & \textrm{Time T2 as the far expiration} \end{array}$$

In this example, you traded near-expiry and far-expiry calls and puts at a strike of $832.50 .

The following chart shows the payoff at expiration:



The payoff is dependent on the market prices of the Options, but in theory, if assuming call-put parity exists, the expected payoff would be

$$\begin{array}{rcll} Payoff_{T_1} & = & Payoff_{\textrm{call calendar spread}} - Payoff_{\textrm{put calendar spread}}\\ & = & K \times (T_2 - T_1) \times r - D \end{array} \begin{array}{rcl} \textrm{where} & r & = & \textrm{Continuous compounding interest rate}\\ D & = & \textrm{Dividend payment during the life of the option} \end{array}$$

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price at position open ($)	Price at the first expiry ($)	Strike ($)
Near-expiry Call	18.50	23.75	832.50
Near-expiry Put	22.50	12.85	832.50
Far-expiry Call	23.90	24.45	832.50
Far-expiry Put	19.00	13.70	832.50
Underlying Equity	-	843.2500	-

Therefore, the payoff is

$$\begin{array}{rcll} Payoff_{T_1} & = & (P_{T_1}^{T_1} - P_0^{T_1} - C_{T_1}^{T_1} + C_0^{T_1} + C_{T_1}^{T_2} - C_0^{T_2} - P_{T_1}^{T_2} + P_0^{T_2})\times m - fee\\ & = & (12.85 - 22.50 - 23.75 + 18.50 + 24.45 - 23.90 - 13.70 + 19.00)\times100 - 1.00\times4\\ & = & -909.00\\ \end{array}$$

So, the strategy loses $909.

The following algorithm implements a long jelly roll Option strategy:

```py
class JellyRollOptionStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self._symbol = option.symbol

        # set our strike/expiry filter for this option chain
        option.set_filter(lambda x: x.jelly_roll(5.0, 30, 60))

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested:
            return

        # Get the OptionChain
        chain = slice.option_chains.get(self._symbol, None)
        if not chain:
            return

        # Select an expiry date and ITM & OTM strike prices
        strike = sorted([x.strike for x in chain], key=lambda x: abs(x - chain.underlying.price))[0]
        contracts = [x for x in chain if x.strike == strike]
        far_expiry = max([x.expiry for x in contracts])
        near_expiry = min([x.expiry for x in contracts])

        jelly_roll = OptionStrategies.jelly_roll(self._symbol, strike, near_expiry, far_expiry)
        self.buy(jelly_roll, 1)
```

Option Strategies

Short Jelly Roll

Introduction

A Short Jelly Roll , or simply Short Roll , is a combination of a short call calendar spread and a long put calendar spread . It is the inverse of a jelly roll . It consist of selling a put and buying a call of the same expiry, as well as buying a put and selling a call with a further expiry, where all of the contracts have the same strike prices. This strategy serves as an arbitrage on Option mispricing due to the temporary disparity between the call spread and the put spread synthetic portfolios. It is a delta -, gamma -, vega -, and theta -neutral strategy, but sensitive to rho (interest rate) and phi (dividend yield).

Implementation

Follow these steps to implement the short jelly roll strategy:

1. In the `initialize` method, set the start date, set the end date, and create an Option universe .

```py
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(100000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda x: x.jelly_roll(5.0, 30, 60))
```

2. In the `on_data` method, select the expiry and strikes of the contracts in the strategy legs.

```py
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Select an expiry date and ITM & OTM strike prices
    strike = sorted([x.strike for x in chain], key=lambda x: abs(x - chain.underlying.price))[0]
    contracts = [x for x in chain if x.strike == strike]
    far_expiry = max([x.expiry for x in contracts])
    nearer_expiries = [x.expiry for x in contracts if x.expiry < far_expiry]
    if not nearer_expiries:
        return
    near_expiry = min(nearer_expiries)
```

3. In the `on_data` method, select the contracts and place the order.

   Approach A: Call the `OptionStrategies.jelly_roshort_jelly_rollll` method with the details of each leg and then pass the result to the `buy` method.

```py
short_jelly_roll = OptionStrategies.short_jelly_roll(self._symbol, strike, near_expiry, far_expiry)
self.buy(short_jelly_roll, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
# Select the call and put contracts
near_call = next(filter(lambda x: x.right == OptionRight.CALL and x.expiry == near_expiry, contracts))
far_call = next(filter(lambda x: x.right == OptionRight.CALL and x.expiry == far_expiry, contracts))
near_put = next(filter(lambda x: x.right == OptionRight.PUT and x.expiry == near_expiry, contracts))
call_put = next(filter(lambda x: x.right == OptionRight.PUT and x.expiry == far_expiry, contracts))

legs = [
    Leg.create(near_call.symbol, 1),
    Leg.create(far_call.symbol, -1),
    Leg.create(near_put.symbol, -1),
    Leg.create(call_put.symbol, 1),
]
self.combo_market_order(legs, 1)
```

Strategy Payoff

This is a delta-, gamma-, vega-, and theta-neutral strategy. The payoff is

$$\begin{array}{rcll} C_{T_1}^{T_1} & = & (S_{T_1} - K)^{+}\\ P_{T_1}^{T_1} & = & (K - S_{T_1})^{+}\\ Payoff_{T_1} & = & (C_{T_1}^{T_1} - C_{T_0}^{T_1} - P_{T_1}^{T_1} + P_{T_0}^{T_1} + P_{T_1}^{T_2} - P_{T_0}^{T_2} - C_{T_1}^{T_2} + C_{T_0}^{T_2})\times m - fee\\ \end{array} \begin{array}{rcl} \textrm{where} & C_{T_1}^{T_1} & = & \textrm{Market value of Call with expiry at T1 at time T1}\\ C_{T_1}^{T_2} & = & \textrm{Market value of Call with expiry at T2 at time T1}\\ P_{T_1}^{T_1} & = & \textrm{Market value of Put with expiry at T1 at time T1}\\ P_{T_1}^{T_2} & = & \textrm{Market value of Put with expiry at T2 at time T1}\\ S_{T_1} & = & \textrm{Underlying asset price at time T1}\\ K & = & \textrm{Strike price}\\ Payoff_{T_1} & = & \textrm{Payout total at time T1}\\ C_{T_0}^{T_1} & = & \textrm{Market value of Call with expiry at T1 when the trade opened}\\ C_{T_0}^{T_2} & = & \textrm{Market value of Call with expiry at T2 when the trade opened}\\ P_{T_0}^{T_1} & = & \textrm{Market value of Put with expiry at T2 when the trade opened}\\ P_{T_0}^{T_2} & = & \textrm{Market value of Put with expiry at T2 when the trade opened}\\ m & = & \textrm{Contract multiplier}\\ T_1 & = & \textrm{Time T1 as the near expiration}\\ T_2 & = & \textrm{Time T2 as the far expiration} \end{array}$$

In this example, you traded near-expiry and far-expiry calls and puts at a strike of $832.50 .

The following chart shows the payoff at expiration:

The payoff is dependent on the market prices of the options, but in theory, if assuming call-put parity exists, the expected payoff would be

$$\begin{array}{rcll} Payoff_{T_1} & = & Payoff_{\textrm{put calendar spread}} - Payoff_{\textrm{call calendar spread}}\\ & = & D - K \times (T_2 - T_1) \times r \end{array} \begin{array}{rcl} \textrm{where} & r & = & \textrm{Continuous compounding interest rate}\\ D & = & \textrm{Dividend payment during the life of the option} \end{array}$$

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price at position open ($)	Price at the first expiry ($)	Strike ($)
Near-expiry Call	22.80	23.75	832.50
Near-expiry Put	18.10	12.85	832.50
Far-expiry Call	19.50	24.45	832.50
Far-expiry Put	23.50	13.70	832.50
Underlying Equity	-	843.2500	-

Therefore, the payoff is

$$\begin{array}{rcll} Payoff_{T_1} & = & (C_{T_1}^{T_1} - C_0^{T_1} - P_{T_1}^{T_1} + P_0^{T_1} + P_{T_1}^{T_2} - P_0^{T_2} - C_{T_1}^{T_2} + C_0^{T_2})\times m - fee\\ & = & (23.75 - 22.80 - 12.85 + 18.10 + 13.70 - 23.50 - 24.45 + 19.50)\times100 - 1.00\times4\\ & = & -859.00\\ \end{array}$$

So, the strategy loses $859.

The following algorithm implements a short jelly roll Option strategy:

```py
class ShortJellyRollOptionStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self._symbol = option.symbol

        # set our strike/expiry filter for this option chain
        option.set_filter(lambda x: x.jelly_roll(5.0, 30, 60))

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested:
            return

        # Get the OptionChain
        chain = slice.option_chains.get(self._symbol, None)
        if not chain:
            return

        # Select an expiry date and ITM & OTM strike prices
        strike = sorted([x.strike for x in chain], key=lambda x: abs(x - chain.underlying.price))[0]
        contracts = [x for x in chain if x.strike == strike]
        far_expiry = max([x.expiry for x in contracts])
        near_expiry = min([x.expiry for x in contracts])

        short_jelly_roll = OptionStrategies.short_jelly_roll(self._symbol, strike, near_expiry, far_expiry)
        self.buy(short_jelly_roll, 1)
```

Option Strategies

Bear Call Ladder

Introduction

Bear call ladder , also known as short call ladder , is a combination of a bear call spread and a long call with a higher strike price than the 2 legs of the call spread. All calls have the same underlying Equity and expiration date. This strategy profits from increasing volatility of the underlying asset. For instance, the underlying price moves away from its current price.

Implementation

Follow these steps to implement the bear call ladder strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```
PY
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(1000000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.call_ladder(30, 5, 0, -5))
```

2. In the `on_data` method, select the expiration and strikes of the contracts in the strategy legs.

```
PY
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Select the call Option contracts with the furthest expiry
    expiry = max([x.expiry for x in chain])
    calls = [i for i in chain if i.expiry == expiry and i.right == OptionRight.CALL]
    if not calls:
        return

    # Select the strike prices from the remaining contracts
    strikes = sorted(set(x.strike for x in calls))
    if len(strikes) < 3:
        return

    low_strike = strikes[0]
    middle_strike = strikes[1]
    high_strike = strikes[2]
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.bear_call_ladder` method with the details of each leg and then pass the result to the `buy` method.

```
PY
option_strategy = OptionStrategies.bear_call_ladder(self._symbol, low_strike, middle_strike, high_strike, expiry)
self.buy(option_strategy, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```py
low_strike_call = next(filter(lambda x: x.strike == low_strike, calls))
middle_strike_call = next(filter(lambda x: x.strike == middle_strike, calls))
high_strike_call = next(filter(lambda x: x.strike == high_strike, calls))

legs = [
    Leg.create(low_strike_call.symbol, -1),
    Leg.create(middle_strike_call.symbol, 1),
    Leg.create(high_strike_call.symbol, 1)
]
self.combo_market_order(legs, 1)
```

Strategy Payoff

The bear call ladding is an unlimited-profit-limited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{low}_T & = & (S_T - K^{low})^{+}\\ C^{mid}_T & = & (S_T - K^{mid})^{+}\\ C^{high}_T & = & (S_T - K^{high})^{+}\\ Payoff_T & = & (C^{low}_0 - C^{low}_T + C^{mid}_T - C^{mid}_0 + C^{high}_T - C^{high}_0)\times m - fee\\ \end{array} \begin{array}{rcl} \textrm{where} & & \\ C^{low}_T & = & \textrm{Lower-strike call value at time T}\\ C^{mid}_T & = & \textrm{Middle-strike call value at time T}\\ C^{high}_T & = & \textrm{Higher-strike call value at time T}\\ S_T & = & \textrm{Underlying asset price at time T}\\ K^{low} & = & \textrm{Lower-strike call strike price}\\ K^{mid} & = & \textrm{Middle-strike call strike price}\\ K^{high} & = & \textrm{Higher-strike call strike price}\\ C^{low}_0 & = & \textrm{Lower-strike call value at position opening (credit received)}\\ C^{mid}_0 & = & \textrm{Middle-strikeTM call value at position opening (debit paid)}\\ C^{high}_0 & = & \textrm{Higher-strike call value at position opening (debit paid)}\\ m & = & \textrm{Contract multiplier}\\ T & = & \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock price at expiration is $843.25 . You traded a lower-strike call at $822.50 for $13.80 , a middle-strike call at $825.00 for $15.10 , and a higher-strike call at $827.50 for $13.10 .

The following chart shows the payoff at expiration:

The maximum profit is unlimited, which occurs when the underlying price increases indefinitely.

The maximum loss is $K^{low} - K^{mid} + C^{low}_0 - C^{mid}_0 - C^{high}_0$, which occurs when the underlying price is between the two higher strike prices.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Lower-Strike call	13.80	822.50
Middle-strike call	15.10	825.00
Higher-strike call	13.10	827.50
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

\begin{array}{rcll} C^{low}_T & = & (S_T - K^{low})^{+}\\ & = & (843.25-822.50)^{+}\\ & = & 20.75\\ C^{mid}_T & = & (S_T - K^{mid})^{+}\\ & = & (843.25-825.00)^{+}\\ & = & 18.25\\ C^{high}_T & = & (S_T - K^{high})^{+}\\ & = & (843.25-827.50)^{+}\\ & = & 15.75\\ Payoff_T & = & (C^{low}_0 - C^{low}_T + C^{mid}_T - C^{mid}_0 + C^{high}_T - C^{high}_0)\times m - fee\\ & = & (13.80 - 20.75 + 18.25 - 15.10 + 15.75 - 13.10)\times100-1.00\times3\\ & = & -118\\ \end{array}

So, the strategy loses $118.

The following algorithm implements a bear call ladder Option strategy:

```py
class BearCallLadderOptionStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self._symbol = option.symbol

        # set our strike/expiry filter for this option chain
        option.set_filter(lambda x: x.call_ladder(30, 5, 0, -5))

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested:
            return

        # Get the OptionChain
        chain = slice.option_chains.get(self._symbol, None)
        if not chain:
            return

        # Select the call Option contracts with the furthest expiry
        expiry = max([x.expiry for x in chain])
        calls = [i for i in chain if i.expiry == expiry and i.right == OptionRight.CALL]
        if not calls:
            return

        # Select the strike prices from the remaining contracts
        strikes = sorted(set(x.strike for x in calls))
        if len(strikes) < 3:
            return

        low_strike = strikes[0]
        middle_strike = strikes[1]
        high_strike = strikes[2]

        option_strategy = OptionStrategies.bear_call_ladder(self._symbol, low_strike, middle_strike, high_strike, expiry)
        self.buy(option_strategy, 1)
```

Option Strategies

Bear Put Ladder

Introduction

Bear put ladder , also known as long put ladder , is a combination of a bear put spread and short put with a lower strike price than the 2 legs of the put spread. All puts have the same underlying Equity and expiration date. This strategy profits from low volatility of the underlying asset. For instance, the underlying price stays similar to its current price.

Implementation

Follow these steps to implement the bear put ladder strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(1000000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.put_ladder(30, 5, 0, -5))
```

2. In the `on_data` method, select the expiration and strikes of the contracts in the strategy legs.

```
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Select the put Option contracts with the furthest expiry
    expiry = max([x.expiry for x in chain])
    puts = [i for i in chain if i.expiry == expiry and i.right == OptionRight.PUT]
    if not puts:
        return

    # Select the strike prices from the remaining contracts
    strikes = sorted(set(x.strike for x in puts))
    if len(strikes) < 3:
        return

    low_strike = strikes[0]
    middle_strike = strikes[1]
    high_strike = strikes[2]
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Put the `OptionStrategies.bear_put_ladder` method with the details of each leg and then pass the result to the `buy` method.

```
option_strategy = OptionStrategies.bear_put_ladder(self._symbol, high_strike, middle_strike, low_strike, expiry)
self.buy(option_strategy, 1)
```

   Approach B: Create a list of `Leg` objects and then put the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
low_strike_put = next(filter(lambda x: x.strike == low_strike, puts))
middle_strike_put = next(filter(lambda x: x.strike == middle_strike, puts))
high_strike_put = next(filter(lambda x: x.strike == high_strike, puts))

legs = [
    Leg.create(low_strike_put.symbol, -1),
    Leg.create(middle_strike_put.symbol, -1),
    Leg.create(high_strike_put.symbol, 1)
]
self.combo_market_order(legs, 1)
```

Strategy Payoff

The bear put ladding is an limited-profit strategy. The payoff is

$$\begin{array}{rcll} P^{low}_T &=& (K^{low} - S_T)^{+}\\ P^{mid}_T &=& (K^{mid} - S_T)^{+}\\ P^{high}_T &=& (K^{high} - S_T)^{+}\\ Payoff_T &=& (P^{low}_0 - P^{low}_T + P^{mid}_0 - P^{mid}_T + P^{high}_T - P^{high}_0)\times m - fee\\ \end{array} \begin{array}{rcl} \textrm{where} & & \\ P^{low}_T &=& \textrm{Lower-strike put value at time T}\\ P^{mid}_T &=& \textrm{Middle-strike put value at time T}\\ P^{high}_T &=& \textrm{Higher-strike put value at time T}\\ S_T &=& \textrm{Underlying asset price at time T}\\ K^{low} &=& \textrm{Lower-strike put strike price}\\ K^{mid} &=& \textrm{Middle-strike put strike price}\\ K^{high} &=& \textrm{Higher-strike put strike price}\\ P^{low}_0 &=& \textrm{Lower-strike put value at position opening (credit received)}\\ P^{mid}_0 &=& \textrm{Middle-strikeTM put value at position opening (debit paid)}\\ P^{high}_0 &=& \textrm{Higher-strike put value at position opening (debit paid)}\\ m &=& \textrm{Contract multiplier}\\ T &=& \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock price at expiration is $843.25 . You traded a lower-strike put at $822.50 for $3.80 , a middle-strike put at $825.00 for $4.70 , and a higher-strike put at $827.50 for $7.80 .

The following chart shows the payoff at expiration:

The maximum profit is $K^{high} - K^{mid} + P^{low}_0 + P^{mid}_0 - P^{high}_0$, which occurs when the underlying price is between the two lower strike prices.

The maximum loss is $K^{high} - K^{mid} - K^{low} + P^{low}_0 + P^{mid}_0 - P^{high}_0$, which occurs when the underlying price decreases to $0 .

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Lower-Strike put	3.80	822.50
Middle-strike put	4.70	825.00
Higher-strike put	7.80	827.50
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

\begin{array}{rcll} P^{low}_T & = & (K^{low} - S_T)^{+}\\ & = & (822.50-843.25)^{+}\\ & = & 0\\ P^{mid}_T & = & (K^{mid} - S_T)^{+}\\ & = & (825.00-843.25)^{+}\\ & = & 0\\ P^{high}_T & = & (K^{high} - S_T)^{+}\\ & = & (827.50-843.25)^{+}\\ & = & 0\\ Payoff_T & = & (P^{low}_0 - P^{low}_T + P^{mid}_0 - P^{mid}_T + P^{high}_T - P^{high}_0)\times m - fee\\ & = & (3.80 - 0 + 4.70 - 0 + 0 - 7.80)\times100-1.00\times3\\ & = & 67\\ \end{array}

So, the strategy gains $67.

The following algorithm implements a bear put ladder Option strategy:

```py
class BearPutLadderOptionStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self._symbol = option.symbol

        # set our strike/expiry filter for this option chain
        option.set_filter(lambda x: x.put_ladder(30, 5, 0, -5))

    def on_data(self, slice) -> None:
        if self.portfolio.invested:
            return

        # Get the OptionChain
        chain = slice.option_chains.get(self._symbol, None)
        if not chain:
            return

        # Select the call Option contracts with the furthest expiry
        expiry = max([x.expiry for x in chain])
        puts = [i for i in chain if i.expiry == expiry and i.right == OptionRight.PUT]
        if not puts:
            return

        # Select the strike prices from the remaining contracts
        strikes = sorted(set(x.strike for x in puts))
        if len(strikes) < 3:
            return

        low_strike = strikes[0]
        middle_strike = strikes[1]
        high_strike = strikes[2]

        option_strategy = OptionStrategies.bear_put_ladder(self._symbol, high_strike, middle_strike, low_strike, expiry)
        self.buy(option_strategy, 1)
```

Option Strategies

Bull Call Ladder

Introduction

Bull call ladder , also known as long call ladder , is a combination of a bull call spread and a short call with a higher strike price than the 2 legs of the call spread. All calls have the same underlying Equity and expiration date. This strategy profits from low volatility of the underlying asset. For instance, the underlying price stays similar to its current price.

Implementation

Follow these steps to implement the bull call ladder strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(1000000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.call_ladder(30, 5, 0, -5))
```

2. In the `on_data` method, select the expiration and strikes of the contracts in the strategy legs.

```
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Select the call Option contracts with the furthest expiry
    expiry = max([x.expiry for x in chain])
    calls = [i for i in chain if i.expiry == expiry and i.right == OptionRight.CALL]
    if not calls:
        return

    # Select the strike prices from the remaining contracts
    strikes = sorted(set(x.strike for x in calls))
    if len(strikes) < 3:
        return

    low_strike = strikes[0]
    middle_strike = strikes[1]
    high_strike = strikes[2]
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.bull_call_ladder` method with the details of each leg and then pass the result to the `buy` method.

```
option_strategy = OptionStrategies.bull_call_ladder(self._symbol, low_strike, middle_strike, high_strike, expiry)
self.buy(option_strategy, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
low_strike_call = next(filter(lambda x: x.strike == low_strike, calls))
middle_strike_call = next(filter(lambda x: x.strike == middle_strike, calls))
high_strike_call = next(filter(lambda x: x.strike == high_strike, calls))

legs = [
    Leg.create(low_strike_call.symbol, 1),
    Leg.create(middle_strike_call.symbol, -1),
    Leg.create(high_strike_call.symbol, -1)
]
self.combo_market_order(legs, 1)
```

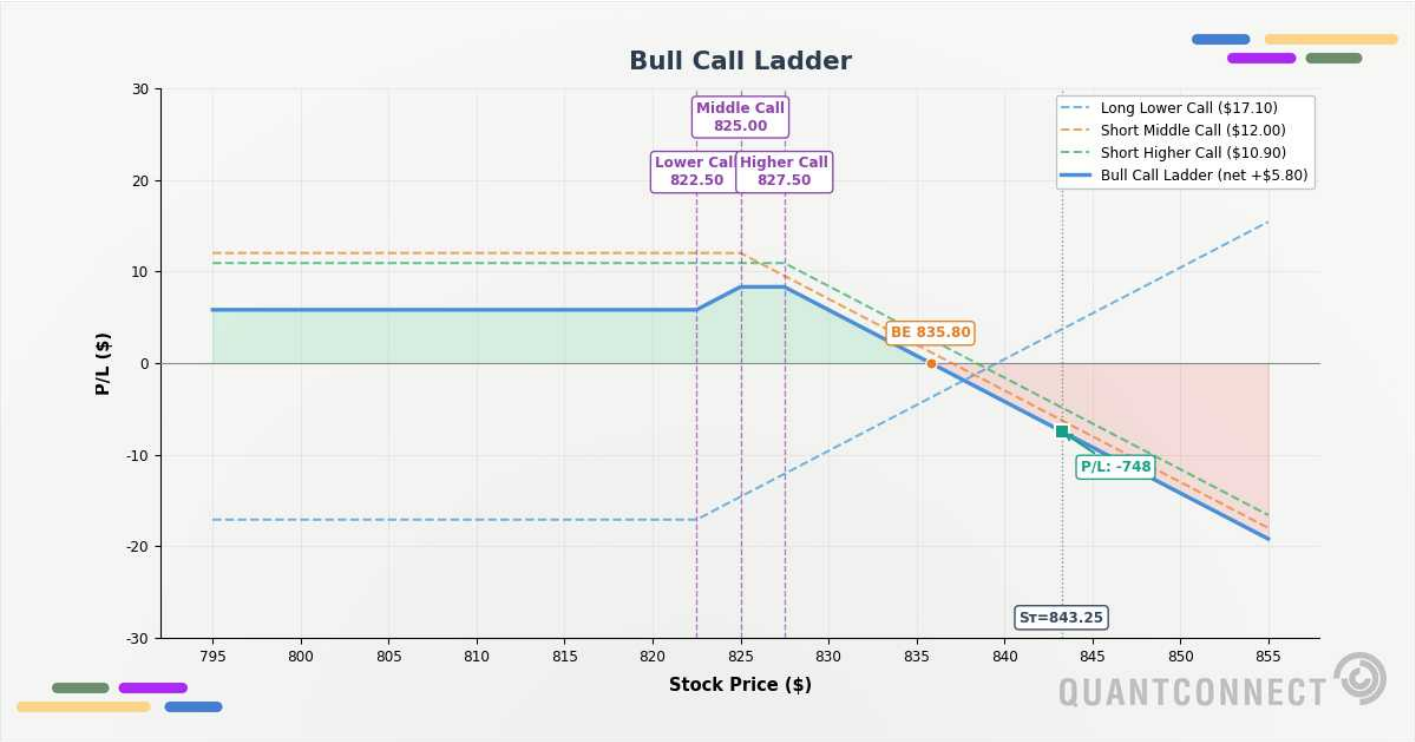
Strategy Payoff

The bull call spread is an limited-profit strategy. The payoff is

$$\begin{array}{rcll} C^{low}_T &=& (S_T - K^{low})^{+}\\ C^{mid}_T &=& (S_T - K^{mid})^{+}\\ C^{high}_T &=& (S_T - K^{high})^{+}\\ Payoff_T &=& (C^{low}_T - C^{low}_0 + C^{mid}_0 - C^{mid}_T + C^{high}_0 - C^{high}_T)\times m - fee\\ \end{array} \begin{array}{rcl} \textrm{where} & & \\ C^{low}_T &=& \textrm{Lower-strike call value at time T}\\ C^{mid}_T &=& \textrm{Middle-strike call value at time T}\\ C^{high}_T &=& \textrm{Higher-strike call value at time T}\\ S_T &=& \textrm{Underlying asset price at time T}\\ K^{low} &=& \textrm{Lower-strike call strike price}\\ K^{mid} &=& \textrm{Middle-strike call strike price}\\ K^{high} &=& \textrm{Higher-strike call strike price}\\ C^{low}_0 &=& \textrm{Lower-strike call value at position opening (credit received)}\\ C^{mid}_0 &=& \textrm{Middle-strikeTM call value at position opening (debit paid)}\\ C^{high}_0 &=& \textrm{Higher-strike call value at position opening (debit paid)}\\ m &=& \textrm{Contract multiplier}\\ T &=& \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock price at expiration is $843.25 . You traded a lower-strike call at $822.50 for $17.10 , a middle-strike call at $825.00 for $12.00 , and a higher-strike call at $827.50 for $10.90 .

The following chart shows the payoff at expiration:



The maximum profit is $K^{mid} - K^{low} - C^{low}_0 + C^{mid}_0 + C^{high}_0$, which occurs when the underlying price is between the two higher strike prices.

The maximum loss is unlimited, which occurs when the underlying price increases indefinitely.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Lower-Strike call	17.10	822.50
Middle-strike call	12.00	825.00
Higher-strike call	10.90	827.50
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{low}_T & = & (S_T - K^{low})^{+}\\ & = & (843.25-822.50)^{+}\\ & = & 20.75\\ C^{mid}_T & = & (S_T - K^{mid})^{+}\\ & = & (843.25-825.00)^{+}\\ & = & 18.25\\ C^{high}_T & = & (S_T - K^{high})^{+}\\ & = & (843.25-827.50)^{+}\\ & = & 15.75\\ Payoff_T & = & (C^{low}_T - C^{low}_0 + C^{mid}_0 - C^{mid}_T + C^{high}_0 - C^{high}_T)\times m - fee\\ & = & (20.75 - 17.10 + 12.00 - 18.25 + 10.90 - 15.75)\times100-1.00\times3\\ & = & -748\\ \end{array}$$

So, the strategy loses $748.

The following algorithm implements a bull call ladder Option strategy:

```py
class BullCallLadderOptionStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self._symbol = option.symbol

        # set our strike/expiry filter for this option chain
        option.set_filter(lambda x: x.call_ladder(30, 5, 0, -5))

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested:
            return

        # Get the OptionChain
        chain = slice.option_chains.get(self._symbol, None)
        if not chain:
            return

        # Select the call Option contracts with the furthest expiry
        expiry = max([x.expiry for x in chain])
        calls = [i for i in chain if i.expiry == expiry and i.right == OptionRight.CALL]
        if not calls:
            return

        # Select the strike prices from the remaining contracts
        strikes = sorted(set(x.strike for x in calls))
        if len(strikes) < 3:
            return

        low_strike = strikes[0]
        middle_strike = strikes[1]
        high_strike = strikes[2]

        option_strategy = OptionStrategies.bull_call_ladder(self._symbol, low_strike, middle_strike, high_strike, expiry)
        self.buy(option_strategy, 1)
```

Option Strategies

Bull Put Ladder

Introduction

Bull put ladder , also known as short put ladder , is a combination of a bull put spread and short put with a lower strike price than the 2 legs of the put spread. All puts have the same underlying Equity and expiration date. This strategy profits from increasing volatility of the underlying asset. For instance, the underlying price moves away from its current price.

Implementation

Follow these steps to implement the bull put ladder strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe .

```
PY
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(1000000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.put_ladder(30, 5, 0, -5))
```

2. In the `on_data` method, select the expiration and strikes of the contracts in the strategy legs.

```
PY
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Select the put Option contracts with the furthest expiry
    expiry = max([x.expiry for x in chain])
    puts = [i for i in chain if i.expiry == expiry and i.right == OptionRight.PUT]
    if not puts:
        return

    # Select the strike prices from the remaining contracts
    strikes = sorted(set(x.strike for x in puts))
    if len(strikes) < 3:
        return

    low_strike = strikes[0]
    middle_strike = strikes[1]
    high_strike = strikes[2]
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Put the `OptionStrategies.bull_put_ladder` method with the details of each leg and then pass the result to the `buy` method.

```
PY
option_strategy = OptionStrategies.bull_put_ladder(self._symbol, high_strike, middle_strike, low_strike, expiry)
self.buy(option_strategy, 1)
```

   Approach B: Create a list of `Leg` objects and then put the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
low_strike_put = next(filter(lambda x: x.strike == low_strike, puts))
middle_strike_put = next(filter(lambda x: x.strike == middle_strike, puts))
high_strike_put = next(filter(lambda x: x.strike == high_strike, puts))

legs = [
    Leg.create(low_strike_put.symbol, 1),
    Leg.create(middle_strike_put.symbol, 1),
    Leg.create(high_strike_put.symbol, -1)
]
self.combo_market_order(legs, 1)
```

Strategy Payoff

The bull put spread is an limited-risk strategy. The payoff is

$$\begin{array}{rcll} P^{low}_T &=& (K^{low} - S_T)^{+}\\ P^{mid}_T &=& (K^{mid} - S_T)^{+}\\ P^{high}_T &=& (K^{high} - S_T)^{+}\\ Payoff_T &=& (P^{low}_T - P^{low}_0 + P^{mid}_T - P^{mid}_0 + P^{high}_0 - P^{high}_T)\times m - fee\\ \end{array} \begin{array}{rcl} \textrm{where} & & \\ P^{low}_T &=& \textrm{Lower-strike put value at time T}\\ P^{mid}_T &=& \textrm{Middle-strike put value at time T}\\ P^{high}_T &=& \textrm{Higher-strike put value at time T}\\ S_T &=& \textrm{Underlying asset price at time T}\\ K^{low} &=& \textrm{Lower-strike put strike price}\\ K^{mid} &=& \textrm{Middle-strike put strike price}\\ K^{high} &=& \textrm{Higher-strike put strike price}\\ P^{low}_0 &=& \textrm{Lower-strike put value at position opening (credit received)}\\ P^{mid}_0 &=& \textrm{Middle-strikeTM put value at position opening (debit paid)}\\ P^{high}_0 &=& \textrm{Higher-strike put value at position opening (debit paid)}\\ m &=& \textrm{Contract multiplier}\\ T &=& \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock price at expiration is $843.25 . You traded a lower-strike put at $822.50 for $6.00 , a middle-strike put at $825.00 for $4.70 , and a higher-strike put at $827.50 for $5.60 .

The following chart shows the payoff at expiration:

The maximum profit is $K^{mid} + K^{low} - K^{high} - P^{low}_0 - P^{mid}_0 + P^{high}_0$, which occurs when the underlying price decreases to $0 .

The maximum loss is $K^{mid} - K^{high} - P^{low}_0 - P^{mid}_0 + P^{high}_0$, which occurs when the underlying price is between the two lower strike prices.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Lower-Strike put	6.00	822.50
Middle-strike put	4.70	825.00
Higher-strike put	5.60	827.50
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

$$\begin{array}{rcll} P^{low}_T & = & (K^{low} - S_T)^{+}\\ & = & (822.50-843.25)^{+}\\ & = & 0\\ P^{mid}_T & = & (K^{mid} - S_T)^{+}\\ & = & (825.00-843.25)^{+}\\ & = & 0\\ P^{high}_T & = & (K^{high} - S_T)^{+}\\ & = & (827.50-843.25)^{+}\\ & = & 0\\ Payoff_T & = & (P^{low}_T - P^{low}_0 + P^{mid}_T - P^{mid}_0 + P^{high}_0 - P^{high}_T)\times m - fee\\ & = & (0 - 6.00 + 0 - 4.70 + 5.60 - 0)\times100-1.00\times3\\ & = & -513\\ \end{array}$$

So, the strategy loses $513.

The following algorithm implements a bull put ladder Option strategy:

```py
class BullPutLadderOptionStrategy(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        option = self.add_option("GOOG", Resolution.MINUTE)
        self._symbol = option.symbol

        # set our strike/expiry filter for this option chain
        option.set_filter(lambda universe: universe.put_ladder(30, 5, 0, -5))

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested:
            return

        # Get the OptionChain
        chain = slice.option_chains.get(self._symbol, None)
        if not chain:
            return

        # Select the call Option contracts with the furthest expiry
        expiry = max([x.expiry for x in chain])
        puts = [i for i in chain if i.expiry == expiry and i.right == OptionRight.PUT]
        if not puts:
            return

        # Select the strike prices from the remaining contracts
        strikes = sorted(set(x.strike for x in puts))
        if len(strikes) < 3:
            return

        low_strike = strikes[0]
        middle_strike = strikes[1]
        high_strike = strikes[2]

        option_strategy = OptionStrategies.bull_put_ladder(self._symbol, high_strike, middle_strike, low_strike, expiry)
        self.buy(option_strategy, 1)
```

Option Strategies

Long Call Backspread

Introduction

Long Call Backspread , consists of short 1 lower-strike call and long 2 higher strike calls. It is a combination of a bear call spread and a long call with the same strike price as the higher-strike leg the call spread. All calls have the same underlying Equity and expiration date. This strategy profits from increasing volatility of the underlying asset. For instance, the underlying price moves away from its current price.

Implementation

Follow these steps to implement the long call backspread strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe . You can use the `call_spread` helper method in option universe filtering, since a call backspread consists of the same contracts as a call spread.

```py
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(1000000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.call_spread(20, 5))
```

2. In the `on_data` method, select the expiration and strikes of the contracts in the strategy legs.

```py
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Select the call Option contracts with the furthest expiry
    expiry = max([x.expiry for x in chain])
    calls = [i for i in chain if i.expiry == expiry and i.right == OptionRight.CALL]
    if not calls:
        return

    # Select the strike prices from the remaining contracts
    strikes = sorted(set(x.strike for x in calls))
    if len(strikes) < 2:
        return

    low_strike = strikes[0]
    high_strike = strikes[1]
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.call_backspread` method with the details of each leg and then pass the result to the `buy` method.

```py
option_strategy = OptionStrategies.call_backspread(self._symbol, low_strike, high_strike, expiry)
self.buy(option_strategy, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
low_strike_call = next(filter(lambda x: x.strike == low_strike, calls))
high_strike_call = next(filter(lambda x: x.strike == high_strike, calls))

legs = [
    Leg.create(low_strike_call.symbol, -1),
    Leg.create(high_strike_call.symbol, 2)
]
self.combo_market_order(legs, 1)
```

Strategy Payoff

The long call backspread is an unlimited-profit-limited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{low}_T & = & (S_T - K^{low})^{+}\\ C^{high}_T & = & (S_T - K^{high})^{+}\\ Payoff_T & = & (C^{low}_0 - C^{low}_T + C^{high}_T \times 2 - C^{high}_0 \times 2)\times m - fee\\ \end{array} \begin{array}{rcl} \textrm{where} & & \\ C^{low}_T & = & \textrm{Lower-strike call value at time T}\\ C^{high}_T & = & \textrm{Higher-strike call value at time T}\\ S_T & = & \textrm{Underlying asset price at time T}\\ K^{low} & = & \textrm{Lower-strike call strike price}\\ K^{high} & = & \textrm{Higher-strike call strike price}\\ C^{low}_0 & = & \textrm{Lower-strike call value at position opening (credit received)}\\ C^{high}_0 & = & \textrm{Higher-strike call value at position opening (debit paid)}\\ m & = & \textrm{Contract multiplier}\\ T & = & \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock price at expiration is $843.19 . You traded a lower-strike call at $825.00 for $12.00 and two higher-strike calls at $835.00 for $8.80 each.

The following chart shows the payoff at expiration:

The maximum profit is unlimited, which occurs when the underlying price increases indefinitely.

The maximum loss is $K^{low} - K^{high} + C^{low}_0 - C^{high}_0 \times 2$, which occurs when the underlying price is exactly at the higher strike at expiry.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Lower-Strike call	12.00	825.00
Higher-strike call	8.80	835.00
Underlying Equity at expiration	843.19	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{low}_T & = & (S_T - K^{low})^{+}\\ & = & (843.19-825.00)^{+}\\ & = & 18.19\\ C^{high}_T & = & (S_T - K^{high})^{+}\\ & = & (843.19-835.00)^{+}\\ & = & 8.19\\ Payoff_T & = & (C^{low}_0 - C^{low}_T + C^{high}_T \times 2 - C^{high}_0 \times 2)\times m - fee\\ & = & (12.00 - 18.19 + 8.19\times2 - 8.80\times2)\times100-2.30\\ & = & -743.30\\ \end{array}$$

So, the strategy loses $743.30.

The following algorithm implements a long call backspread Option strategy:

```py
class BackspreadOptionStrategyAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000000)

        self.universe_settings.asynchronous = True
        option = self.add_option("GOOG", Resolution.MINUTE)
        self._symbol = option.symbol
        option.set_filter(lambda universe: universe.call_spread(20, 5))

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested:
            return

        # Get the OptionChain
        chain = slice.option_chains.get(self._symbol, None)
        if not chain:
            return

        # Select the call Option contracts with the furthest expiry
        expiry = max([x.expiry for x in chain])
        calls = [i for i in chain if i.expiry == expiry and i.right == OptionRight.CALL]
        if not calls:
            return

        # Select the strike prices from the remaining contracts
        strikes = sorted(set(x.strike for x in calls))
        if len(strikes) < 2:
            return

        low_strike = strikes[0]
        high_strike = strikes[1]

        option_strategy = OptionStrategies.call_backspread(self._symbol, low_strike, high_strike, expiry)
        self.buy(option_strategy, 1)
```

Option Strategies

Short Call Backspread

Introduction

Short Call Backspread , consists of long 1 lower-strike call and short 2 higher strike calls. It is a combination of a bull call spread and a short call with the same strike price as the higher-strike leg the call spread. All calls have the same underlying Equity and expiration date. This strategy profits from stable, consistent price of the underlying asset. For instance, the underlying price stays at its current price.

Implementation

Follow these steps to implement the short call backspread strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe . You can use the `call_spread` helper method in option universe filtering, since a call backspread consists of the same contracts as a call spread.

```py
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(1000000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.call_spread(20, 5))
```

2. In the `on_data` method, select the expiration and strikes of the contracts in the strategy legs.

```py
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Select the call Option contracts with the furthest expiry
    expiry = max([x.expiry for x in chain])
    calls = [i for i in chain if i.expiry == expiry and i.right == OptionRight.CALL]
    if not calls:
        return

    # Select the strike prices from the remaining contracts
    strikes = sorted(set(x.strike for x in calls))
    if len(strikes) < 2:
        return

    low_strike = strikes[0]
    high_strike = strikes[1]
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.short_call_backspread` method with the details of each leg and then pass the result to the `buy` method.

```py
option_strategy = OptionStrategies.short_call_backspread(self._symbol, low_strike, high_strike, expiry)
self.buy(option_strategy, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
low_strike_call = next(filter(lambda x: x.strike == low_strike, calls))
high_strike_call = next(filter(lambda x: x.strike == high_strike, calls))

legs = [
    Leg.create(low_strike_call.symbol, 1),
    Leg.create(high_strike_call.symbol, -2)
]
self.combo_market_order(legs, 1)
```

Strategy Payoff

The short call backspread is an limited-profit-unlimited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{low}_T & = & (S_T - K^{low})^{+}\\ C^{high}_T & = & (S_T - K^{high})^{+}\\ Payoff_T & = & (C^{low}_T - C^{low}_0 + C^{high}_0 \times 2 - C^{high}_T \times 2)\times m - fee\\ \end{array} \begin{array}{rcl} \textrm{where} & & \\ C^{low}_T & = & \textrm{Lower-strike call value at time T}\\ C^{high}_T & = & \textrm{Higher-strike call value at time T}\\ S_T & = & \textrm{Underlying asset price at time T}\\ K^{low} & = & \textrm{Lower-strike call strike price}\\ K^{high} & = & \textrm{Higher-strike call strike price}\\ C^{low}_0 & = & \textrm{Lower-strike call value at position opening (credit received)}\\ C^{high}_0 & = & \textrm{Higher-strike call value at position opening (debit paid)}\\ m & = & \textrm{Contract multiplier}\\ T & = & \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock price at expiration is $843.19 . You traded a lower-strike call at $825.00 for $15.10 and two higher-strike calls at $835.00 for $8.00 each.

The following chart shows the payoff at expiration:

The maximum profit is $K^{high} - K^{low} - C^{low}_0 + C^{high}_0 \times 2$, which occurs when the underlying price is exactly at the higher strike at expiry.

The maximum loss is unlimited, which occurs when the underlying price increases indefinitely.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Lower-Strike call	15.10	825.00
Higher-strike call	8.00	835.00
Underlying Equity at expiration	843.19	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{low}_T & = & (S_T - K^{low})^{+}\\ & = & (843.19-825.00)^{+}\\ & = & 18.19\\ C^{high}_T & = & (S_T - K^{high})^{+}\\ & = & (843.19-835.00)^{+}\\ & = & 8.19\\ Payoff_T & = & (C^{low}_T - C^{low}_0 - C^{high}_T \times 2 + C^{high}_0 \times 2)\times m - fee\\ & = & (18.19 - 15.10 - 8.19\times2 + 8.00\times2)\times100-2.30\\ & = & 268.70\\ \end{array}$$

So, the strategy gains $268.70.

The following algorithm implements a short call backspread Option strategy:

```py
class BackspreadOptionStrategyAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000000)

        self.universe_settings.asynchronous = True
        option = self.add_option("GOOG", Resolution.MINUTE)
        self._symbol = option.symbol
        option.set_filter(lambda universe: universe.call_spread(20, 5))

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested:
            return

        # Get the OptionChain
        chain = slice.option_chains.get(self._symbol, None)
        if not chain:
            return

        # Select the call Option contracts with the furthest expiry
        expiry = max([x.expiry for x in chain])
        calls = [i for i in chain if i.expiry == expiry and i.right == OptionRight.CALL]
        if not calls:
            return

        # Select the strike prices from the remaining contracts
        strikes = sorted(set(x.strike for x in calls))
        if len(strikes) < 2:
            return

        low_strike = strikes[0]
        high_strike = strikes[1]

        option_strategy = OptionStrategies.short_call_backspread(self._symbol, low_strike, high_strike, expiry)
        self.buy(option_strategy, 1)
```

Option Strategies

Long Put Backspread

Introduction

Long Put Backspread , consists of short 1 higher-strike put and long 2 lower-strike puts. It is a combination of a bull put spread and a long put with the same strike price as the lower-strike leg the put spread. All puts have the same underlying Equity and expiration date. This strategy profits from increasing volatility of the underlying asset. For instance, the underlying price moves away from its current price.

Implementation

Follow these steps to implement the long put backspread strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe . You can use the `put_spread` helper method in option universe filtering, since a put backspread consists of the same contracts as a put spread.

```py
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(1000000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.put_spread(20, 5))
```

2. In the `on_data` method, select the expiration and strikes of the contracts in the strategy legs.

```py
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Select the put Option contracts with the furthest expiry
    expiry = max([x.expiry for x in chain])
    puts = [i for i in chain if i.expiry == expiry]
    if not puts:
        return

    # Select the strike prices from the remaining contracts
    strikes = sorted(set(x.strike for x in puts))
    if len(strikes) < 2:
        return

    low_strike = strikes[0]
    high_strike = strikes[1]
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.put_backspread` method with the details of each leg and then pass the result to the `buy` method.

```py
option_strategy = OptionStrategies.put_backspread(self._symbol, high_strike, low_strike, expiry)
self.buy(option_strategy, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
low_strike_put = next(filter(lambda x: x.strike == low_strike, puts))
high_strike_put = next(filter(lambda x: x.strike == high_strike, puts))

legs = [
    Leg.create(low_strike_put.symbol, 2),
    Leg.create(high_strike_put.symbol, -1)
]
self.combo_market_order(legs, 1)
```

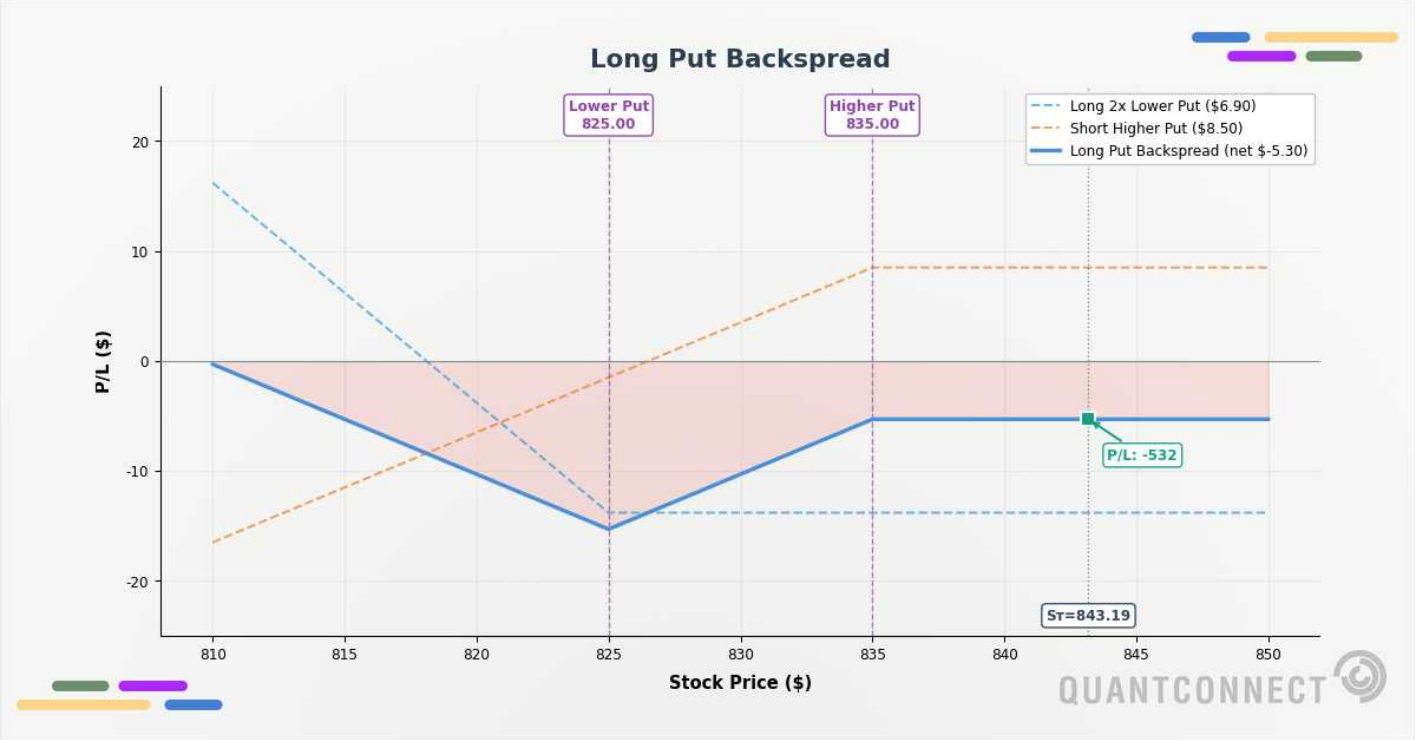
Strategy Payoff

The long put backspread is an unlimited-profit-limited-risk strategy. The payoff is

$$\begin{array}{rcll} P^{low}_T & = & (K^{low} - S_T)^{+}\\ P^{high}_T & = & (K^{high} - S_T)^{+}\\ Payoff_T & = & (P^{high}_0 - P^{high}_T + P^{low}_T \times 2 - P^{low}_0 \times 2)\times m - fee\\ \end{array} \begin{array}{rcl} \textrm{where} & & \\ P^{low}_T & = & \textrm{Lower-strike put value at time T}\\ P^{high}_T & = & \textrm{Higher-strike put value at time T}\\ S_T & = & \textrm{Underlying asset price at time T}\\ K^{low} & = & \textrm{Lower-strike put strike price}\\ K^{high} & = & \textrm{Higher-strike put strike price}\\ P^{low}_0 & = & \textrm{Lower-strike put value at position opening (credit received)}\\ P^{high}_0 & = & \textrm{Higher-strike put value at position opening (debit paid)}\\ m & = & \textrm{Contract multiplier}\\ T & = & \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock price at expiration is $843.19 . You traded two lower-strike puts at $825.00 for $6.90 each and a higher-strike put at $835.00 for $8.50 .

The following chart shows the payoff at expiration:



The maximum profit is unlimited, which occurs when the underlying price increases indefinitely.

The maximum loss is $K^{low} - K^{high} + P^{high}_0 - P^{low}_0 \times 2$, which occurs when the underlying price is exactly at the lower strike at expiry.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Lower-Strike put	6.90	825.00
Higher-strike put	8.50	835.00
Underlying Equity at expiration	843.19	-

Therefore, the payoff is

$$\begin{array}{rcll} P^{low}_T & = & (K^{low} - S_T)^{+}\\ & = & (825.00-843.19)^{+}\\ & = & 0.00\\ P^{high}_T & = & (K^{high} - S_T)^{+}\\ & = & (835.00-843.19)^{+}\\ & = & 0.00\\ Payoff_T & = & (P^{high}_0 - P^{high}_T + P^{low}_T \times 2 - P^{low}_0 \times 2)\times m - fee\\ & = & (8.50 - 0.00 + 0.00\times2 - 6.90\times2)\times100-2.30\\ & = & -532.30\\ \end{array}$$

So, the strategy loses $532.30.

The following algorithm implements a long put backspread Option strategy:

```py
class BackspreadOptionStrategyAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000000)

        self.universe_settings.asynchronous = True
        option = self.add_option("GOOG", Resolution.MINUTE)
        self._symbol = option.symbol
        option.set_filter(lambda universe: universe.put_spread(20, 5))

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested:
            return

        # Get the OptionChain
        chain = slice.option_chains.get(self._symbol, None)
        if not chain:
            return

        # Select the call Option contracts with the furthest expiry
        expiry = max([x.expiry for x in chain])
        puts = [i for i in chain if i.expiry == expiry]
        if not puts:
            return

        # Select the strike prices from the remaining contracts
        strikes = sorted(set(x.strike for x in puts))
        if len(strikes) < 2:
            return

        low_strike = strikes[0]
        high_strike = strikes[1]

        option_strategy = OptionStrategies.put_backspread(self._symbol, high_strike, low_strike, expiry)
        self.buy(option_strategy, 1)
```

Option Strategies

Short Put Backspread

Introduction

Short Put Backspread , consists of short 1 higher-strike put and short 2 lower-strike puts. It is a combination of a bear put spread and a short put with the same strike price as the lower-strike leg the put spread. All puts have the same underlying Equity and expiration date. This strategy profits from stable, consistent price of the underlying asset. For instance, the underlying price stays at its current price.

Implementation

Follow these steps to implement the short put backspread strategy:

1. In the `initialize` method, set the start date, end date, cash, and Option universe . You can use the `put_spread` helper method in option universe filtering, since a put backspread consists of the same contracts as a put spread.

```py
def initialize(self) -> None:
    self.set_start_date(2024, 9, 1)
    self.set_end_date(2024, 12, 31)
    self.set_cash(1000000)

    self.universe_settings.asynchronous = True
    option = self.add_option("GOOG", Resolution.MINUTE)
    self._symbol = option.symbol
    option.set_filter(lambda universe: universe.put_spread(20, 5))
```

2. In the `on_data` method, select the expiration and strikes of the contracts in the strategy legs.

```py
def on_data(self, slice: Slice) -> None:
    if self.portfolio.invested:
        return

    # Get the OptionChain
    chain = slice.option_chains.get(self._symbol, None)
    if not chain:
        return

    # Select the put Option contracts with the furthest expiry
    expiry = max([x.expiry for x in chain])
    puts = [i for i in chain if i.expiry == expiry]
    if not puts:
        return

    # Select the strike prices from the remaining contracts
    strikes = sorted(set(x.strike for x in puts))
    if len(strikes) < 2:
        return

    low_strike = strikes[0]
    high_strike = strikes[1]
```

3. In the `on_data` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.short_put_backspread` method with the details of each leg and then pass the result to the `buy` method.

```py
option_strategy = OptionStrategies.short_put_backspread(self._symbol, high_strike, low_strike, expiry)
self.buy(option_strategy, 1)
```

   Approach B: Create a list of `Leg` objects and then call the combo_market_order , combo_limit_order , or combo_leg_limit_order method.

```
low_strike_put = next(filter(lambda x: x.strike == low_strike, puts))
high_strike_put = next(filter(lambda x: x.strike == high_strike, puts))

legs = [
    Leg.create(low_strike_put.symbol, -2),
    Leg.create(high_strike_put.symbol, 1)
]
self.combo_market_order(legs, 1)
```

Strategy Payoff

The short put backspread is an unlimited-profit-limited-risk strategy. The payoff is

$$\begin{array}{rcll} P^{low}_T & = & (K^{low} - S_T)^{+}\\ P^{high}_T & = & (K^{high} - S_T)^{+}\\ Payoff_T & = & (P^{high}_T - P^{high}_0 - P^{low}_T \times 2 + P^{low}_0 \times 2)\times m - fee\\ \end{array} \begin{array}{rcll} \textrm{where} & P^{low}_T & = & \textrm{Lower-strike put value at time T}\\ & P^{high}_T & = & \textrm{Higher-strike put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{low} & = & \textrm{Lower-strike put strike price}\\ & K^{high} & = & \textrm{Higher-strike put strike price}\\ & P^{low}_0 & = & \textrm{Lower-strike put value at position opening (credit received)}\\ & P^{high}_0 & = & \textrm{Higher-strike put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

In this example, the underlying stock price at expiration is $843.19 . You traded two lower-strike puts at $825.00 for $4.70 each and a higher-strike put at $835.00 for $10.90 .

The following chart shows the payoff at expiration:

The maximum profit is $K^{high} - K^{low} - P^{high}_0 + P^{low}_0 \times 2$, which occurs when the underlying price is exactly at the lower strike at expiry.

The maximum loss is $P^{low}_0 \times 2 - P^{high}_0 - S_T$, which occurs when the underlying price drops to zero.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Lower-Strike put	4.70	825.00
Higher-strike put	10.90	835.00
Underlying Equity at expiration	843.19	-

Therefore, the payoff is

$$\begin{array}{rcll} P^{low}_T & = & (K^{low} - S_T)^{+}\\ & = & (825.00-843.19)^{+}\\ & = & 0.00\\ P^{high}_T & = & (K^{high} - S_T)^{+}\\ & = & (835.00-843.19)^{+}\\ & = & 0.00\\ Payoff_T & = & (P^{high}_T - P^{high}_0 - P^{low}_T \times 2 + P^{low}_0 \times 2)\times m - fee\\ & = & (0 - 10.90 - 0.00\times2 + 4.70\times2)\times100-2.30\\ & = & -152.30\\ \end{array}$$

So, the strategy loses $152.30.

The following algorithm implements a short put backspread Option strategy:

```
class BackspreadOptionStrategyAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000000)

        self.universe_settings.asynchronous = True
        option = self.add_option("GOOG", Resolution.MINUTE)
        self._symbol = option.symbol
        option.set_filter(lambda universe: universe.put_spread(20, 5))

    def on_data(self, slice: Slice) -> None:
        if self.portfolio.invested:
            return

        # Get the OptionChain
        chain = slice.option_chains.get(self._symbol, None)
        if not chain:
            return

        # Select the call Option contracts with the furthest expiry
        expiry = max([x.expiry for x in chain])
        puts = [i for i in chain if i.expiry == expiry]
        if not puts:
            return

        # Select the strike prices from the remaining contracts
        strikes = sorted(set(x.strike for x in puts))
        if len(strikes) < 2:
            return

        low_strike = strikes[0]
        high_strike = strikes[1]

        option_strategy = OptionStrategies.short_put_backspread(self._symbol, high_strike, low_strike, expiry)
        self.buy(option_strategy, 1)
```

Trading and Orders

Order Properties

Introduction

Order properties enable you to customize how the brokerage executes your orders. The `default_order_properties` of your algorithm sets the order properties for all of your orders. To adjust the order properties of an order, you can change the `default_order_properties` or pass an order properties object to the order method.

Time In Force

The `time_in_force` property determines how long an order should remain open if it doesn't fill. This property doesn't apply to market orders since they usually fill immediately. Time in force is useful to automatically cancel old trades. The following table describes the available `TimeInForce` options:

Member	Example	Description
`GOOD_TIL_CANCELED`	`TimeInForce.GOOD_TIL_CANCELED`	Order is valid until filled (default)
`DAY`	`TimeInForce.DAY`	Order is valid until filled or the market closes
`good_til_date(expiry: datetime)`	`time_in_force.good_til_date(datetime(2019, 6, 19, 12, 0, 0))`	Order is valid until filled or the specified expiration time

By default, orders remain open until they are canceled (`TimeInForce.GOOD_TIL_CANCELED`). To update the value, set the `default_order_properties.time_in_force` before you place an order or pass an `order_properties` argument to the order method.

PY

```
# Set a Limit Order to be good until market close
self.default_order_properties.time_in_force = TimeInForce.DAY
self.limit_order("IBM", 100, 120)

# Set a Limit Order to be good until noon
order_properties = OrderProperties()
order_properties.time_in_force = TimeInForce.good_til_date(datetime(2019, 6, 19, 12, 0, 0))
self.limit_order("IBM", 100, 120, order_properties=order_properties)
```

If you trade a market that's open 24 hours a day with daily data, `TimeInForce.DAY` won't work because the order cancels at the market close time but your algorithm receives daily data at midnight.

Market on open (MOO) and market on close (MOC) orders don't support the `good_til_date` time in force. If you submit a MOO or MOC order with the `good_til_date` time in force, LEAN automatically adjusts the time in force to be `GoodTilCanceled` .

The brokerage you use may not support all of the `TimeInForce` options. To see the options that your brokerage supports, see the Orders section of the brokerage model documentation .

Brokerage-Specific Properties

Some brokerages support additional order properties so you can customize how your orders execute. Some examples include the following order properties:

- Financial Advisor group orders
- An `outside_regular_trading_hours` property to let orders fill during pre-market and post-market trading hours
- A `post_only` property to force an order to only add liquidity to a market
- A `hidden` property to make an order not show on the order book
- A `reduce_only` property to signal the order must only decrease your position size
- `fee_in_base` and `fee_in_quote` properties to set which currency you pay fees in for a Crypto trade

To view the order properties your brokerage supports, see the Orders section of the brokerage model documentation .

Tags

You can tag orders to aid your strategy development. Tags can be any string of up to 100 characters. Tags aren't part of the `OrderProperties` object, but they are a property of the `Order` class you can set. To set an order tag, pass it as an argument when you create the order or use the order update methods. This is useful for debugging your algorithm's trading logic because you can include the indicator values or conditions that triggered the order.

```py
 # Tag an order on creation
ticket = self.limit_order("SPY", 100, 221.05, tag="Original tag")

# Update the tag with UpdateTag
ticket.update_tag("Updated tag")

# Update the tag with UpdateOrderFields
update_settings = UpdateOrderFields()
update_settings.tag = "Another tag"
ticket.update(update_settings)
```

Examples

The following examples demonstrate some common practices for utilizing order properties.

Example 1: Extended Market Hour Orders

The following algorithm trades buys or sells SPY during pre-market to capture momentum in the overnight gap. It exits the positions at 15 minutes after the market opens. To trade in the extended market hours without stale fills, it set the respective order properties.

```py
class OrderPropertiesAlgorithm(QCAlgorithm):
    _last_price = None

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Add extended market hour SPY data for trading.
        self._spy = self.add_equity("SPY", extended_market_hours=True).symbol

        # Add a Scheduled Event to trade 2 hours enter a position during pre-market.
        self.schedule.on(
            self.date_rules.every_day(self._spy),
            self.time_rules.before_market_open(self._spy, 120),
            self._open_position
        )
        # Add a Scheduled Event to exit the position 15 minutes after market open.
        self.schedule.on(
            self.date_rules.every_day(self._spy),
            self.time_rules.after_market_open(self._spy, 15),
            self.liquidate
        )
        # Add a Scheduled Event to cache the daily close price so you can generate signals the next day.
        self.schedule.on(
            self.date_rules.every_day(self._spy),
            self.time_rules.before_market_close(self._spy),
            self._get_last_price
        )
        # Add a warm-up period so the algorithm trades on the first day in live mode.
        self.set_warm_up(timedelta(1))

    def _open_position(self) -> None:
        if self._last_price:
            current_price = self.securities[self._spy].price

            # Define the order properties to trade in pre-market. The order will only valid for 3 minutes to avoid
            # stale fills.
            order_properties = OrderProperties()
            order_properties.time_in_force = TimeInForce.good_til_date(self.time + timedelta(minutes=3))
            order_properties.outside_regular_trading_hours = True

            # Buy if the overnight direction is upward, indicating positive market sentiment.
            # Sell if the overnight direction is downward, indicating negative market sentiment.
            # Note that pre-market orders do not accept market order.
            quantity = 10 if current_price > self._last_price else -10
            self.limit_order(self._spy, quantity, current_price, order_properties=order_properties)

    def _get_last_price(self) -> None:
        self._last_price = self.securities[self._spy].price
```

Example 2: Financial Advisor Managing Client Funds

The following algorithm forms an equal-weight portfolio at the start of each week with the 10 most liquid US Equities. It demonstrates how order properties can give financial advisors easy control over client funds.

```py
class OrderPropertiesAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Define the order properties to trade with an FA group.
        self.default_order_properties = InteractiveBrokersOrderProperties()
        self.default_order_properties.fa_group = "TestGroupEQ"          # FA group
        self.default_order_properties.fa_method = "EqualQuantity"       # Allocation by net liquidation
        self.default_order_properties.account = "DU123456"              # FA account

        # Add a universe that selects the 10 most liquid US Equities at the start of each week.
        spy = Symbol.create('SPY', SecurityType.EQUITY, Market.USA)
        self.universe_settings.schedule.on(self.date_rules.week_start(spy))
        universe = self.add_universe(self.universe.top(10))

        # Add a Scheduled Event to rebalance at the start of each week.
        self.schedule.on(
            self.date_rules.week_start(spy),
            self.time_rules.at(10, 0),
            lambda: self.set_holdings(
                # Form an equal-weighted portfolio of the universe constituents.
                [PortfolioTarget(symbol, 0.1) for symbol in universe.selected],
                # Liquidate the assets that aren't in the universe anymore.
                liquidate_existing_holdings=True
            )
        )
```

Trading and Orders

Order Events

Introduction

An `OrderEvent` object represents an update to the state of an order. As the state of your orders change, we notify your algorithm with `OrderEvent` objects through the `on_order_event` and `on_assignment_order_event` event handlers.

Track Order Events

Each order generates events over its life as its status changes. Your algorithm receives these events through the `on_order_event` and `on_assignment_order_event` methods. The `on_order_event` event handler receives all order events. The `on_assignment_order_event` receives order events for Option assignments. The event handlers receive an `OrderEvent` object, which contains information about the order status.

```
PY
def on_order_event(self, order_event: OrderEvent) -> None:
    order = self.transactions.get_order_by_id(order_event.order_id)
    if order_event.status == OrderStatus.FILLED:
        self.debug(f"{self.time}: {order.type}: {order_event}")

def on_assignment_order_event(self, assignment_event: OrderEvent) -> None:
    self.log(str(assignment_event))
```

To get a list of all `OrderEvent` objects for an order, call the `order_events` method of the order ticket .

```
PY
order_events = order_ticket.order_events()
```

If you don't have the order ticket, get the order ticket from the TransactionManager .

Order States

Orders can have any of the following states:

Event Attributes

The `on_order_event` and `on_assignment_order_event` event handlers in your algorithm receive `OrderEvent` objects, which have the following attributes:

Examples

The following examples demonstrate some common practices for using order events.

Example 1: Illiquid Stock Partial Fill

The following algorithm trades EMA cross on CARZ, an illiquid ETF. To realistically simulate the fill behavior, we set a fill model to partially fill the orders with at most 50% of the previous bar's volume per fill. We cancel the remaining open order after the partial fill since we only trade on the updated information.

```py
class OrderEventsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Request CARZ data to feed indicator and trade.
        equity = self.add_equity("CARZ")
        self.carz = equity.symbol
        # Set a custom partial fill model for the illiquid CARZ stock since it is more realistic.
        equity.set_fill_model(CustomPartialFillModel(self))

        # Create EMA indicator to generate trade signals.
        self._ema = self.ema(self.carz, 60, Resolution.DAILY)
        # Warm-up indicator for immediate readiness to use.
        self.warm_up_indicator(self.carz, self._ema, Resolution.DAILY)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self.carz)
        if bar and self._ema.is_ready:
            ema = self._ema.current.value
            # Trade EMA cross on CARZ for trend-following strategy.
            if bar.close > ema and not self.portfolio[self.carz].is_long:
                self.set_holdings(self.carz, 0.5)
            elif bar.close < ema and not self.portfolio[self.carz].is_short:
                self.set_holdings(self.carz, -0.5)

    def on_order_event(self, order_event: OrderEvent) -> None:
        # If an order is only partially filled, we cancel the rest to avoid trade on non-updated information.
        if order_event.status == OrderStatus.PARTIALLY_FILLED:
            self.transactions.cancel_open_orders()

# Implements a custom fill model that partially fills each order with a ratio of the previous trade bar.
class CustomPartialFillModel(FillModel):
    def __init__(self, algorithm: QCAlgorithm, ratio: float = 0.5) -> None:
        self.algorithm = algorithm
        self.absolute_remaining_by_order_id = {}
        # Save the ratio of the volume of the previous bar to fill the order.
        self.ratio = ratio

    def market_fill(self, asset: Security, order: MarketOrder) -> None:
        absolute_remaining = self.absolute_remaining_by_order_id.get(order.id, order. AbsoluteQuantity)

        fill = super().market_fill(asset, order)

        # Partially fill each order with at most 50% of the previous bar.
        fill.fill_quantity = np.sign(order.quantity) * asset.volume * self.ratio
        if (min(abs(fill.fill_quantity), absolute_remaining) == absolute_remaining):
            fill.fill_quantity = np.sign(order.quantity) * absolute_remaining
            fill.status = OrderStatus.FILLED
            self.absolute_remaining_by_order_id.pop(order.id, None)
        else:
            fill.status = OrderStatus.PARTIALLY_FILLED
            # Save the remaining quantity after it is partially filled.
            self.absolute_remaining_by_order_id[order.id] = absolute_remaining - abs(fill.fill_quantity)
            price = fill.fill_price

        return fill
```

Example 2: Price Actions

The following algorithm saves the trailing 3 `TradeBar` objects into a `RollingWindow` . When it identifies a volume contraction breakout price action pattern on the SPY, it buys to ride on the capital inflow. To exit positions, it places a 2% take profit and 1% stop loss order in the `on_order_event` method.

PY

```
class RollingWindowAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Add SPY data for signal generation and trading.
        self.spy = self.add_equity("SPY", Resolution.MINUTE).symbol

        # Set up a rolling window to hold the last 3 trade bars for price action detection as the trade signal.
        self.windows = RollingWindow(3)
        # Warm up the rolling window.
        history = self.history[TradeBar](self.spy, 3, Resolution.MINUTE)
        for bar in history:
            self.windows.add(bar)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self.spy)
        if bar:
            # Trade the price action if the previous bars fulfill a contraction breakout.
            if self.contraction_action and self.breakout(bar.close):
                self.set_holdings(self.spy, 0.5)

            # Add the current bar to the window.
            self.windows.add(bar)

    def contraction_action(self) -> None:
        # We trade contraction type price action, where the buying preesure is increasing.
        # 1. The last 3 bars are green.
        # 2. The price is increasing in trend.
        # 3. The trading volume is increasing as well.
        # 4. The range of the bars are decreasing.
        return (
            self.windows[2].close > self.windows[2].open and
            self.windows[1].close > self.windows[1].open and
            self.windows[0].close > self.windows[0].open and
            self.windows[0].close > self.windows[1].close > self.windows[2].close and
            self.windows[0].volume > self.windows[1].volume > self.windows[2].volume and
            self.windows[2].close - self.windows[2].open > self.windows[1].close - self.windows[1].open > self.windows[0].close -
self.windows[0].open
        )

    def breakout(self, current_close: float) -> None:
        # Trade breakout from contraction: the breakout should be much greater than the contracted range of the last bar.
        return current_close - self.windows[0].close > (self.windows[0].close - self.windows[0].open) * 2

    def on_order_event(self, order_event: OrderEvent) -> None:
        if order_event.status == OrderStatus.FILLED:
            if order_event.ticket.order_type == OrderType.MARKET:
                # Stop loss order at 1%.
                stop_price = order_event.fill_price * (0.99 if order_event.fill_quantity > 0 else 1.01)
                self.stop_market_order(self.spy, -self.portfolio[self.spy].quantity, stop_price)
                # Take profit order at 2%.
                take_profit_price = order_event.fill_price * (1.02 if order_event.fill_quantity > 0 else 0.98)
                self.limit_order(self.spy, -self.portfolio[self.spy].quantity, take_profit_price)
            elif order_event.ticket.order_type == OrderType.STOP_MARKET or order_event.ticket.order_type == OrderType.LIMIT:
                # Cancel open orders if stop loss or take profit order fills.
                self.transactions.cancel_open_orders()
```

Trading and Orders

Order Errors

Introduction

If an error occurs with one of your orders, LEAN logs the error message and stops executing.

Types of Order Errors

Errors can occur when you place orders or after you place them.

Errors at Order Submission

The following errors can occur when you submit an order:

- `ALGORITHM_WARMING_UP`
- `BROKERAGE_FAILED_TO_SUBMIT_ORDER`
- `BROKERAGE_MODEL_REFUSED_TO_UPDATE_ORDER`
- `CONVERSION_RATE_ZERO`
- `EUROPEAN_OPTION_NOT_EXPIRED_ON_EXERCISE`
- `EXCEEDED_MAXIMUM_ORDERS`
- `EXCEEDS_SHORTABLE_QUANTITY`
- `EXCHANGE_NOT_OPEN`
- `FOREX_BASE_AND_QUOTE_CURRENCIES_REQUIRED`
- `FOREX_CONVERSION_RATE_ZERO`
- `INSUFFICIENT_BUYING_POWER`
- `MARKET_ON_CLOSE_ORDER_TOO_LATE`
- `MISSING_SECURITY`
- `NON_EXERCISABLE_SECURITY`
- `NON_TRADABLE_SECURITY`
- `OPTION_ORDER_ON_STOCK_SPLIT`
- `ORDER_ALREADY_EXISTS`
- `ORDER_QUANTITY_LESS_THAN_LOT_SIZE`
- `ORDER_QUANTITY_ZERO`
- `PRE_ORDER_CHECKS_ERROR`
- `QUOTE_CURRENCY_REQUIRED`
- `SECURITY_HAS_NO_DATA`
- `UNSUPPORTED_REQUEST_TYPE`

Errors After Order Submission

The following errors can occur for active orders:

- `BROKERAGE_FAILED_TO_UPDATE_ORDER`
- `BROKERAGE_MODEL_REFUSED_TO_SUBMIT_ORDER`
- `INVALID_NEW_ORDER_STATUS`
- `INVALID_ORDER_STATUS`
- `INVALID_REQUEST`
- `REQUEST_CANCELED`
- `UNABLE_TO_FIND_ORDER`

Common Errors

There are a few common order errors you may experience.

Why is my order converted to a market on open order?

If you place a market order when the market is closed, LEAN automatically converts the order into market on open order. This most commonly happens when you use daily or hourly data, which your algorithm can receive when the market is closed. With the `daily_precise_end_time` setting enabled, your algorithm receives daily bars and the last hourly bar of each day at 4 PM Eastern Time (ET). To avoid LEAN from converting your market order to market on open orders, submit your market orders when the market is open. To check if the market is open, call the `is_market_open` method.

```py
# Check the market status before placing an order to avoid unintended market-on-open trades.
if self.is_market_open(self._symbol):
    self.market_order(self._symbol, quantity)
```

Why am I seeing the "stale price" warning?

Stale fills occur when you fill an order with price data that is timestamped an hour or more into the past. Stale fills usually only occur if you trade illiquid assets or if your algorithm uses daily data but you trade intraday with Scheduled Events. If your order is filled with stale data, the fill price may not be realistic. The pre-built fill models can only fill market orders with stale data. To adjust the length of time that needs to pass before an order is considered stale, set the `stale_price_time_span` setting.

```py
def initialize(self) -> None:
    # Adjust the stale price time span to be 10 minutes.
    self.settings.stale_price_time_span = timedelta(minutes=10)
```

Why do I get "Backtest Handled Error: The security with symbol '/ES' is marked as non-tradable"?

This error occurs when you place an order for a continuous Futures contract, which isn't a tradable security. To fix the issue, place the order for a specific Futures contract. To access the currently selected contract in the continuous contract series, use the `mapped` property of the `Future` object.

Why do I get "Backtest Handled Error: Order Error: ids: [1], Insufficient buying power to complete orders" from a Crypto order?

When you place Crypto trades, ensure you have a sufficient balance of the base or quote currency before each trade. If you hold multiple assets and you want to put all of your capital into BTCUSDT, you need to first convert all your non-BTC assets into USDT and then purchase BTCUSDT.

By default, the account currency is USD and your starting cash is 100,000. Some Crypto exchanges don't support fiat currencies, which means you can't convert the 100,000 USD to the pair's quote currency . In this case, set your account currency to the quote currency with a positive quantity.

```py
self.set_account_currency("USDT", 1000)   # Set the account currency to Tether and its quantity to 1,000 USDT
```

Error Code Reference

The `OrderError` enumeration has the following members:

Order Response Error Reference

The following sections explain why each `OrderResponseErrorCode` occurs and how to avoid it.

None

The `OrderResponseErrorCode.NONE` (0) error means there is no order response error.

Processing Error

The `OrderResponseErrorCode.PROCESSING_ERROR` (-1) error occurs in the following situations:

- When you submit a new order, but LEAN throws an exception while checking if you have sufficient buying power for the order.
- When you try to update or cancel an order, but LEAN throws an exception.

To investigate this order response error further, see the `HandleSubmitOrderRequest` , `UpdateOrder` , and `CancelOrder` methods of the BrokerageTransactionHandler in the LEAN GitHub repository.

Order Already Exists

The `OrderResponseErrorCode.ORDER_ALREADY_EXISTS` (-2) error occurs when you submit a new order but you already have an open order or a

completed order with the same order ID. This order response error usually comes from a concurrency issue.

To avoid this order response, don't place two asynchronous orders at the same time.

Insufficient Buying Power

The `OrderResponseErrorCode.INSUFFICIENT_BUYING_POWER` (-3) error occurs when you place an order but the buying power model determines you can't afford it.

To avoid this order response error, ensure you have enough margin remaining to cover the initial margin requirements of the order before placing it.

This error also commonly occurs when you place a market on open order with daily data. If you place the order with `set_holdings` or use `calculate_order_quantity` to determine the order quantity, LEAN calculates the order quantity based on the market close price. If the open price on the following day makes your order more expensive, then you may have insufficient buying power. To avoid the order response error in this case, either use intraday data and place trades when the market is open or adjust your buying power buffer .

```
self.settings.free_portfolio_value_percentage = 0.05
```

Brokerage Model Refused to Submit Order

The `OrderResponseErrorCode.BROKERAGE_MODEL_REFUSED_TO_SUBMIT_ORDER` (-4) error occurs when you place an order but the brokerage model determines it's invalid. The brokerage model usually checks your order meets the following requirements before sending it to the brokerage:

- Supported security types
- Supported order types and their respective requirements
- Supported time in force options
- The order size is larger than the minimum order size

Each brokerage model can have additional order requirements that the brokerage declares. To avoid this order response error, see the Orders section of the brokerage model documentation .

To investigate this order response error further, see the `CanSubmitOrder` method definition of your brokerage model . This order response error occurs when the `CanSubmitOrder` method returns `False` .

Brokerage Failed to Submit Order

The `OrderResponseErrorCode.BROKERAGE_FAILED_TO_SUBMIT_ORDER` (-5) error occurs when you place an order but the brokerage implementation fails to submit the order to your brokerage.

To investigate this order response error further, see the `PlaceOrder` method definition of your brokerage or the BacktestingBrokerage in the LEAN GitHub repository. This order response error occurs when the `PlaceOrder` method throws an error or returns `false` .

Brokerage Failed to Update Order

The `OrderResponseErrorCode.BROKERAGE_FAILED_TO_UPDATE_ORDER` (-6) error occurs when you try to update an order but the brokerage implementation fails to submit the order update request to your brokerage.

To avoid this order response error, see the Orders section of the brokerage model documentation .

To investigate this order response error further, see the `UpdateOrder` method definition of your brokerage or the BacktestingBrokerage in the LEAN GitHub repository. This order response error occurs when the `UpdateOrder` method throws an error or returns `false` .

Brokerage Failed to Cancel Order

The `OrderResponseErrorCode.BROKERAGE_FAILED_TO_CANCEL_ORDER` (-8) error occurs when you try to cancel an order but the brokerage implementation fails to submit the cancel request to your brokerage.

To investigate this order response error further, see the `CancelOrder` method definition of your brokerage or the BacktestingBrokerage in the LEAN GitHub repository. This order response error occurs when `CancelOrder` method throws an error or returns `false` .

Invalid Order Status

The `OrderResponseErrorCode.INVALID_ORDER_STATUS` (-9) error occurs when you try to update or cancel an order but the order is already complete.

An order is complete if it has `OrderStatus.FILLED` , `OrderStatus.CANCELED` , or `OrderStatus.INVALID` .

To avoid this order response error, check the `Status` of an order ticket or order event before you update or cancel the order.

```
if not OrderExtensions.is_closed(order_ticket.status):
    order_ticket.cancel()
```

Unable to Find Order

The `OrderResponseErrorCode.UNABLE_TO_FIND_ORDER` (-10) error occurs when you try to place, update, or cancel an order, but the `BrokerageTransactionHandler` doesn't have a record of the order ID.

To investigate this order response error further, see BrokerageTransactionHandler.cs in the LEAN GitHub repository. This order response error occurs when the `BrokerageTransactionHandler` can't find the order ID in it's `_completeOrders` or `_completeOrderTickets` dictionaries.

Order Quantity Zero

The `OrderResponseErrorCode.ORDER_QUANTITY_ZERO` (-11) error occurs when you place an order that has zero quantity or when you update an order to have a zero quantity. This error commonly occurs if you use the SetHoldings method but the portfolio weight you provide to the method is too small to translate into a non-zero order quantity.

To avoid this order response error, check if the quantity of the order is non-zero before you place the order. If you use the `set_holdings` method, replace it with a combination of the CalculateOrderQuantity and MarketOrder methods.

```
quantity = self.calculate_order_quantity(self._symbol, 0.05)
if quantity:
    self.market_order(self._symbol, quantity)
```

Unsupported Request Type

The `OrderResponseErrorCode.UNSUPPORTED_REQUEST_TYPE` (-12) error occurs in the following situations:

- When you try to exercise an Option contract for which you hold a short position
- When you try to exercise more Option contracts than you hold

To avoid this order response error, check the quantity of your holdings before you try to exercise an Option contract.

```
holding_quantity = self.portfolio[self._contract_symbol].quantity
if holding_quantity > 0:
    self.exercise_option(self._contract_symbol, max(holding_quantity, exercise_quantity))
```

Missing Security

The `OrderResponseErrorCode.MISSING_SECURITY` (-14) error occurs when you place an order for a security but you don't have a subscription for the security in your algorithm.

To avoid this order response error, create a subscription for each security you want to trade. To create subscriptions, see the Requesting Data page of the documentation for each asset class .

Exchange Not Open

The `OrderResponseErrorCode.EXCHANGE_NOT_OPEN` (-15) error occurs in the following situations:

- When you try to exercise an Option while the exchange is not open

  To avoid the order response error in this case, check if the exchange is open before you exercise an Option contract.

  ```
  if self.is_market_open(self.contract_symbol):
      self.exercise_option(self.contract_symbol, quantity)
  ```

- When you try to place a market on open order for a Futures contract or a Future Option contract

Security Price Zero

The `OrderResponseErrorCode.SECURITY_PRICE_ZERO` (-16) error occurs when you place an order or exercise an Option contract while the security price is 0. The security price can be 0 for the following reasons:

- The data is missing

  Investigate if it's a data issue. If it is a data issue, report it .

- The algorithm hasn't received data for the security yet

  If you subscribe to a security and place an order for the security in the same time step , you'll get this error. To avoid this order response error, enable the `seed_initial_prices` setting to seed new assets with their last known price.

  ```
  self.settings.seed_initial_prices = True
  ```
  PY

Forex Base and Quote Currencies Required

The `OrderResponseErrorCode.FOREX_BASE_AND_QUOTE_CURRENCIES_REQUIRED` (-17) error occurs when you place a trade for a Forex or Crypto pair but you don't have the base currency and quote currency in your cash book . This error should never occur. If it does, create a bug report.

Forex Conversion Rate Zero

The `OrderResponseErrorCode.FOREX_CONVERSION_RATE_ZERO` (-18) error occurs when you place a trade for a Forex or Crypto pair and LEAN can't convert the value of the base currency to your account currency. This error usually indicates a lack of data. Investigate the data and if there is some missing, report it .

Security Has No Data

The `OrderResponseErrorCode.SECURITY_HAS_NO_DATA` (-19) error occurs when you place an order for a security before your algorithm receives any data for it. If you subscribe to a security and place an order for the security in the same time step , you'll get this error. To avoid this order response error, enable the `seed_initial_prices` setting to seed new assets with their last known price.

```
self.settings.seed_initial_prices = True
```
PY

Exceeded Maximum Orders

The `OrderResponseErrorCode.EXCEEDED_MAXIMUM_ORDERS` (-20) error occurs when exceed your order quota in a backtest. The number of orders you can place in a single backtest depends on the tier of your organization . The following table shows the number of orders you can place on each tier:

Tier	**Orders Quota**
Free	10K
Quant Researcher	10M
Team	Unlimited
Trading Firm	Unlimited
Institution	Unlimited

To avoid this order response error, reduce the number of orders in your backtest or upgrade your organization .

Market on Close Order Too Late

The `OrderResponseErrorCode.MARKET_ON_CLOSE_ORDER_TOO_LATE` (-21) error occurs when you try to place a market on close (MOC) order too early in the trading day.

To avoid this order response error, place the MOC order closer to the market close or adjust the submission time buffer. By default, you must place

MOC orders at least 15.5 minutes before the close, but some exchanges let you submit them closer to the market closing time. To adjust the buffer period that's required, set the `MarketOnCloseOrder.submission_time_buffer` property.

```
MarketOnCloseOrder.submission_time_buffer = timedelta(minutes=10)
```

Invalid Request

The `OrderResponseErrorCode.INVALID_REQUEST` (-22) error occurs when you try to cancel an order multiple times.

To avoid this order response error, only try to cancel an order one time.

Request Canceled

The `OrderResponseErrorCode.REQUEST_CANCELED` (-23) error occurs when you try to cancel an order multiple times.

To avoid this order response error, only try to cancel an order one time.

Algorithm Warming Up

The `OrderResponseErrorCode.ALGORITHM_WARMING_UP` (-24) error occurs in the following situations:

- When you try to place, update, or cancel an order during the warm-up period
- When the Option assignment simulator assigns you to an Option during the warm-up period

To avoid this order response error, only manage orders after the warm-up period ends. To avoid trading during the warm-up period, add an `is_warming_up` guard to the top of the `on_data` method.

```
if self.is_warming_up: return
```

Brokerage Model Refused to Update Order

The `OrderResponseErrorCode.BROKERAGE_MODEL_REFUSED_TO_UPDATE_ORDER` (-25) error occurs in backtests when you try to update an order in a way that the brokerage model doesn't support.

To avoid this issue, see the Orders section of the brokerage model documentation to check its order requirements.

To investigate this order response error further, see the `CanUpdateOrder` method definition of your brokerage model .

Quote Currency Required

The `OrderResponseErrorCode.QUOTE_CURRENCY_REQUIRED` (-26) error occurs when you place an order for a Forex or Crypto pair and don't have the quote currency of the pair in your cash book . This error should never occur. If it does, create a bug report.

Conversion Rate Zero

The `OrderResponseErrorCode.CONVERSION_RATE_ZERO` (-27) error occurs when you place an order for a Forex or Crypto pair and LEAN can't convert the value of the quote currency in the pair to your account currency. This order response error usually indicates a lack of data. Investigate the data and if there is data missing, report it .

Non-Tradable Security

The `OrderResponseErrorCode.NON_TRADABLE_SECURITY` (-28) error occurs when you place an order for a security that's not tradable . To avoid this order response error, check if a security is tradable before you trade it.

```
if self.securities[self._symbol].is_tradable:
    self.market_order(self._symbol, quantity)
```

Non-Exercisable Security

The `OrderResponseErrorCode.NON_EXERCISABLE_SECURITY` (-29) error occurs when you call the exercise_option method with a `Symbol` that doesn't reference an Option contract.

Order Quantity Less Than Lot Size

The `OrderResponseErrorCode.ORDER_QUANTITY_LESS_THAN_LOT_SIZE` (-30) error occurs when you place an order with a quantity that's less than the lot size of the security.

To avoid this order response error, check if the order quantity is greater than or equal to the security lot size before you place an order.

```
lot_size = self.securities[self._symbol].symbol_properties.lot_size
if quantity >= lot_size:
    self.market_order(self._symbol, quantity)
```

Exceeds Shortable Quantity

The `OrderResponseErrorCode.EXCEEDS_SHORTABLE_QUANTITY` (-31) error occurs when you place an order to short a security but the shortable provider of the brokerage model states there isn't enough shares to borrow. The following algorithm demonstrates this error by using a custom shortable provider that limits shorts to 10 shares and then trying to short 12 shares.

```
# Demonstrate ExceedsShortableQuantity error with a custom shortable provider.
class ExceedsShortableQuantityAlgorithm(QCAlgorithm):
    def initialize(self):
        self.set_start_date(2021, 7, 23)
        self.set_end_date(2021, 7, 30)
        self.set_cash(100000)
        self.set_brokerage_model(CustomShortBrokerageModel())
        self.add_equity("SPY", Resolution.MINUTE)

    def on_data(self, data):
        if not self.portfolio.invested:
            self.market_order("SPY", 1)
        else:
            # Try to short 12 shares, which exceeds the shortable quantity of 10.
            self.market_order("SPY", -12)

    def on_order_event(self, order_event):
        self.debug(f"{self.time} -- {order_event.message}")

# Custom shortable provider that limits shorts to 10 shares.
class CustomShortableProvider:
    def all_shortable_symbols(self, local_time):
        return None
    def shortable_quantity(self, symbol, local_time):
        return 10

# Custom brokerage model using the shortable provider.
class CustomShortBrokerageModel(DefaultBrokerageModel):
    def __init__(self):
        super().__init__(AccountType.MARGIN)
        self.shortable_provider = CustomShortableProvider()
```

To avoid this order response error, check if there are enough shares available before you place an order to short a security.

```
if quantity_to_borrow <= self.shortable_quantity(self._symbol):
    self.market_order(self._symbol, -quantity_to_borrow)
```

Invalid New Order Status

The `OrderResponseErrorCode.INVALID_NEW_ORDER_STATUS` (-32) error occurs in live trading when you try to update or cancel an order while it still has `OrderStatus.NEW` status.

To avoid this order response error, check the `status` property of the order ticket or order event before you update or cancel an order.

```
if self.order_ticket.status != OrderStatus.NEW:
    self.order_ticket.cancel()
```

European Option Not Expired on Exercise

The `OrderResponseErrorCode.EUROPEAN_OPTION_NOT_EXPIRED_ON_EXERCISE` (-33) error occurs when you try to exercise a European Option contract before its expiry date.

To avoid this order response error, check the type and expiry date of the contract before you exercise it.

```py
if self.contract_symbol.id.option_style == OptionStyle.EUROPEAN && self.contract_symbol.id.date == self.time.date:
    self.exercise_option(self.contract_symbol, quantity)
```

Option Order on Stock Split

The `OrderResponseErrorCode.OPTION_ORDER_ON_STOCK_SPLIT` (-34) error occurs when you try to submit an order for an Equity Option contract when the current time slice contains a split for the underlying Equity.

To avoid this order response error, check if the time slice has a split event for the underlying Equity of the contract before you place an order for the contract.

```py
if self.contract_symbol.underlying not in slice.splits:
    self.market_order(self.contract_symbol, quantity)
```

Market on Open Not Allowed During Regular Hours

The `OrderResponseErrorCode.MARKET_ON_OPEN_NOT_ALLOWED_DURING_REGULAR_HOURS` (-35) error occurs when you try to place a market on open order for an asset when it's during regular trading hours.

To avoid this order response error, place the order when the market is closed.

```py
if not self.is_market_open(self._symbol):
    self.market_on_open_order(self._symbol, quantity)
```

Warnings

The following sections explain why each some warnings occur and how to avoid them.

Limit Price Exceeds Precision Requirements

Limit prices must be a multiple of the security's `minimum_price_variation` property . Otherwise, LEAN rounds the limit price for you and throws the following warning message:

Backtest Handled Error: Warning: To meet brokerage precision requirements, order LimitPrice was rounded to 6136.00 from 6136.125

To avoid the warning, round the limit price to the nearest value that respects the `minimum_price_variation` before you place the order.

```py
def _adjust_limit_price(self, security, price, round_up=True):
    pip = security.price_variation_model.get_minimum_price_variation(
        GetMinimumPriceVariationParameters(security, price)
    )
    return (int(price / pip) + int(round_up)) * pip
```

Examples

The following examples demonstrate common practices for handling order errors.

Example 1: Pre-Open Order Error

The following algorithm simulate extended market hour trading on Tradier Brokerage . We place a market-on-open order at 7:30am and expect the order cannot submit to the broker since it is not supported, resulting into an error.

PY

```
class OrderErrorsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Simulate Tradier brokerage, which does not support the market-on-open orders.
        self.set_brokerage_model(BrokerageName.TRADIER_BROKERAGE, AccountType.CASH)

        # Request extended market hour SPY data for trading.
        self.spy = self.add_equity("SPY", extended_market_hours=True).symbol

        # Set a scheduled event to trade 2 hours pre-open to place the market-on-open-order.
        self.schedule.on(
            self.date_rules.every_day(self.spy),
            self.time_rules.before_market_open(self.spy, 120),
            self.open_position
        )

    def open_position(self) -> None:
        # Buy on market open will result in an error since Tradier does not support it.
        self.market_on_open_order(self.spy, 10)

    # It will be triggered on live trading.
    def on_brokerage_message(self, message: BrokerageMessageEvent) -> None:
        if message.type == BrokerageMessageType.ERROR:
            self.log(f"{self.time}: {message.type}: Message: {message.message}")
```

Trading and Orders

Trade Statistics

Introduction

The `TradeBuilder` tracks the trades of your algorithm and calculates some statistics. Some of these statistics are a function of the risk free interest rate and the number of trading days per year . You can adjust how the `TradeBuilder` defines a trade and how it matches offsetting order fills.

Set Trade Builder

To set the `TradeBuilder` , in the `initialize` method, call the `set_trade_builder` method.

```
self.set_trade_builder(TradeBuilder(grouping_method, matching_method))
```

The following table describes the arguments the `TradeBuilder` constructor accepts:

Argument	Data Type	Description	Default Value
`grouping_method`	`FillGroupingMethod`	The method used to group order fills into trades	
`matching_method`	`FillMatchingMethod`	The method used to match offsetting order fills	

The `FillGroupingMethod` enumeration has the following members:

The `FillMatchingMethod` enumeration has the following members:

Default Behavior

The default `TradeBuilder` uses `FillGroupingMethod.FILL_TO_FILL` and `FillMatchingMethod.FIFO` .

Check Open Positions

To check if you have a position open for a security as defined by the `FillGroupingMethod` , call the `has_open_position` method.

```
# Check if the trade builder has recorded any active trades (unclosed positions)
# for a security.
has_open_position = self.trade_builder.has_open_position(self._symbol)
```

Get Closed Trades

To get your closed trades, use the `closed_trades` property.

```
trades = self.trade_builder.closed_trades
```

This property returns a list of `Trade` objects, which have the following attributes:

Examples

The following examples demonstrate some common practices for making use of trade statistics.

Example 1: Kelly Criterion Sizing Using Previous Trades

The following algorithm uses the previous trades to update the win probability and expected return of each trade of the EMA cross strategy of SPY, by the concept of Bayes Theorem. The updated figures are used for position sizing through Kelly Criterion.

PY

```
class TradeStatisticsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 12)
        self.set_end_date(2024, 10, 1)
        self.set_cash(1000000)

        # Request SPY data to trade.
        self.spy = self.add_equity("SPY").symbol
        # Create an EMA indicator to generate trade signals.
        self._ema = self.ema(self.spy, 20, Resolution.DAILY)
        # Warm-up indicator for immediate readiness.
        self.warm_up_indicator(self.spy, self._ema, Resolution.DAILY)

        # Set up a trade builder to track the trade statistics; we are interested in open-to-close round trade.
        self.set_trade_builder(TradeBuilder(FillGroupingMethod.FLAT_TO_FLAT, FillMatchingMethod.FIFO))

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self.spy)
        if not bar:
            return
        # Trend-following strategy using price and EMA.
        # If the price is above EMA, SPY is in an uptrend, and we buy it.
        sign = 0
        if bar.close > self._ema.current.value and not self.portfolio[self.spy].is_long:
            sign = 1
        elif bar.close < self._ema.current.value and not self.portfolio[self.spy].is_short:
            sign = -1
        else:
            return

        size = 1
        trades = self.trade_builder.closed_trades

        if len(trades) > 4:
            # Use the trade builder to obtain the win rate and % return of the last five trades to calculate position size.
            last_five_trades = sorted(trades, key=lambda x: x.exit_time)[-5:]
            prob_win = len([x for x in last_five_trades if x.is_win]) / 5
            win_size = np.mean([x.profit_loss / x.entry_price for x in last_five_trades])
            # Use the Kelly Criterion to calculate the order size.
            size = max(0, prob_win - (1 - prob_win) / win_size)

        self.set_holdings(self.spy, size * sign)
```

Trading and Orders

Trading Calendar

Introduction

The `trading_calendar` contains a variety of events relevant to the assets in your algorithm.

Trading Day Properties

`TradingDay` objects represent the trading events of a single day. They have the following properties:

Get a Single Trading Day

To get the trading events of the current day, call the `get_trading_day` method with no arguments.

```py
trading_day = self.trading_calendar.get_trading_day()
```

To get the trading events of a specific day, pass a `datetime` object to the `get_trading_day` method.

```py
trading_day = self.trading_calendar.get_trading_day(datetime(2022, 6, 1))
```

Get Trading Days

To get all the trading events across a range of dates, pass start and end `datetime` objects to the `get_trading_days` method.

```py
start_date = datetime(2022, 6, 1)
end_date = datetime(2022, 7, 1)
trading_days = self.trading_calendar.get_trading_days(start_date, end_date)
```

To get specific trading events across a range of dates, pass a `TradingDayType` enumeration member and the dates to the `get_days_by_type` method.

```py
trading_days = self.TradingCalendar.get_days_by_type(TradingDayType.OPTION_EXPIRATION, start_date, end_date)
```

The `TradingDayType` enumeration has the following members:

Trading and Orders

Financial Advisors

Introduction

Financial Advisor accounts enable certified professionals to use a single trading algorithm to manage several client accounts. Our Interactive Brokers integration enables you to place FA group orders if your IB account code starts with F, FA, or I.

Group Routing

To place trades using a subset of client accounts, create Account Groups in Trader Workstation and then define the `InteractiveBrokersOrderProperties` when you create orders.

```
self.default_order_properties = InteractiveBrokersOrderProperties()
self.default_order_properties.fa_group = "TestGroupEQ"
self.default_order_properties.fa_method = "Equal"
self.default_order_properties.account = "DU123456"
```

SecurityHolding objects aggregate your positions across all the account groups. If you have two groups where group A has 10 shares of SPY and group B has -10 shares of SPY, then `self.portfolio["SPY"].quantity` is zero.

Allocation Methods

LEAN supports several allocation methods for FA group orders. If you intend to use the same group allocation method for every order, set the `default_order_properties` of your algorithm, which sets the order properties for all of your orders.

```
def initialize(self) -> None:
    # Set the default order properties
    self.default_order_properties = InteractiveBrokersOrderProperties()
    self.default_order_properties.fa_group = "TestGroupEQ"
    self.default_order_properties.fa_method = "Equal"
    self.default_order_properties.account = "DU123456"

def on_data(self, slice: Slice) -> None:
    # Use default order order properties
    LimitOrder(_symbol, quantity, limitPrice);
```

To adjust the order properties of an order, change the `default_order_properties` or pass an order properties object to the order method . The following sections explain the FA group allocation methods.

Equal

This group allocation method distributes shares equally between all accounts in the group. When you use this method, you need to specify an order quantity.

For example, say your Account Group includes four accounts and you place an order to buy 400 shares of a stock. In this case, each account receives 100 shares. If your Account Group includes six accounts, each account receives 66 shares, and then 1 share is allocated to each account until all are distributed. After you submit the order, your algorithm receives order events to track the order progress. When all the shares are bought, the order status is `OrderStatus.FILLED` . If one of the accounts in the group can't afford 10 of the shares it needs to buy, 10 shares are cancelled and you'll only end up buying 390 shares in total.

```
order_properties = InteractiveBrokersOrderProperties()
order_properties.fa_method = "Equal"
self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Net Liquidation Value

This group allocation method distributes shares based on the net liquidation value of each account. The system calculates ratios based on the net

liquidation value in each account and allocates shares based on these ratios. When you use this method, you need to specify an order quantity.

For example, say your account group includes three accounts, A, B and C with Net Liquidation values of 25,000, 50,000 and $100,000, respectively. In this case, the system calculates a ratio of 1:2:4. If you place an order for 700 shares of a stock, it allocates 100 shares to Client A, 200 shares to Client B, and 400 shares to Client C.

```py
order_properties = InteractiveBrokersOrderProperties()
order_properties.fa_method = "NetLiq"
self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Available Equity

This group allocation method distributes shares based on the amount of available equity in each account. The system calculates ratios based on the available equity in each account and allocates shares based on these ratios. When you use this method, you need to specify an order quantity.

For example, say your account group includes three accounts, A, B and C with available equity of 25,000, 50,000 and $100,000, respectively. In this case, the system calculates a ratio of 1:2:4. If you place an order for 700 shares of a stock, it allocates 100 shares to Client A, 200 shares to Client B, and 400 shares to Client C.

```py
order_properties = InteractiveBrokersOrderProperties()
order_properties.fa_method = "AvailableEquity"
self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Subscription Requirements

To use FA group orders through our Interactive Brokers integration, you need to connect as a member of a Trading Firm and Institution organization. If you aren't currently on either of these tiers, upgrade your organization .

Reality Modeling

Reality Modeling

Key Concepts

Introduction

Reality models make backtests as realistic as possible to how the strategy would perform in live trading. These reality models model the behavior of things like the portfolio, brokerage, fills, slippage, options, and strategy capacity . Some reality models are set on a security basis and some are set at the portfolio level. The default models assume you trade highly liquid assets. If you trade high volumes or on illiquid assets, you should create custom reality models to be more realistic.

Security Level Models

LEAN's philosophy is to make the models customizable per security as much as possible. The following models are security-level models:

- Fill
- Slippage
- Fee
- Brokerages
- Buying Power
- Settlement
- Short availability
- Option models
  - Pricing
  - Volatility
  - Exercise
  - Assignment
- Margin Interest Rate
- Dividend Yield

To set a security-level reality model, call the set reality model method on the `Security` object. To get the correct method, see the preceding documentation page for each type of model.

```py
# Set IBM to have a constant $1 transaction fee
self.securities["IBM"].set_fee_model(ConstantFeeModel(1))
```

You can also set the security-specific models inside a security initializer .

```py
class AddSecurityInitializerExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the security initializer to set models of assets.
        self.add_security_initializer(self._custom_security_initializer)

    def _custom_security_initializer(self, security: Security) -> None:
        # Overwrite some of the reality models
        security.set_fee_model(ConstantFeeModel(1))
```

Portfolio Level Models

A portfolio is a semi-closed system where the state updates over time as the value and quantity of assets in the portfolio fluctuate. It's a semi-closed system because the portfolio usually incurs transaction fees and you can add and deposit capital from the portfolio. LEAN models the portfolio

holdings to track and update the average price of each asset with every transaction.

You can set the following portfolio-level models:

- Margin call model

```
self.portfolio.set_margin_call_model(DefaultMarginCallModel(self.portfolio, self.default_order_properties))
```

- Risk free interest rate model

```
self.set_risk_free_interest_rate_model(InterestRateProvider())
```

Reality Modeling

Trade Fills

Trade Fills

Key Concepts

Introduction

A trade fill is the quantity and price at which your brokerage executes your order in the market. Fill models model how each type of order fills to accurately simulate the behavior of a real brokerage. Fill models determine the price and quantity of your fills, can incorporate spread costs, and work with the slippage model to add slippage into the fill price. If you trade US Equities, our built-in fill models can fill your orders at the official opening and closing auction prices .

Set Models

The brokerage model of your algorithm automatically sets the fill model for each security, but you can override it. To manually set the fill model of a security, call the `set_fill_model` method on the Security object.

PY

```
def initialize(self) -> None:
    security = self.add_equity("SPY")
    # Set the fill model for the requested security to backtest with the most realistic scenario
    # ImmediateFillModel provide no delay from network issue or brokerage rules
    security.set_fill_model(ImmediateFillModel())
```

You can also set the fill model in a security initializer . If your algorithm has a dynamic universe, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `add_security_initializer` before you create the subscriptions.

PY

```
class AddSecurityInitializerExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the security initializer to set models of assets.
        self.add_security_initializer(self._custom_security_initializer)

    def _custom_security_initializer(self, security: Security) -> None:
        # Overwrite some of the reality models
        security.set_fill_model(ImmediateFillModel())
```

To view all the pre-built fill models, see Supported Models .

Default Behavior

The brokerage model of your algorithm automatically sets the fill model of each security. The default brokerage model is the `DefaultBrokerageModel` , which sets the EquityFillModel for Equities, the FutureFillModel for Futures, the FutureOptionFillModel for Future Options, and the ImmediateFillModel for all other asset classes.

Model Structure

Fill Models should extend the `FillModel` class. To implement your own fill model, override the methods in the `FillModel` class you wish to change. The class has a dedicated method for each order type. Most of the methods receive a `Security` and `Order` object and return an `OrderEvent` object that contains information about the order status, fill quantity, and errors.

```py
class CustomFillModelExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # In the Initialize method, set the custom fill model for an added security to use the custom model
        security = self.add_equity("SPY")
        security.set_fill_model(MyFillModel())

# Define the custom fill model outside of the algorithm
class MyFillModel(FillModel):

    def market_fill(self, asset: Security, order: MarketOrder) -> OrderEvent:
        return super().market_fill(asset, order)

    def limit_fill(self, asset: Security, order: LimitOrder) -> OrderEvent:
        return super().limit_fill(asset, order)

    def limit_if_touched_fill(self, asset: Security, order: LimitIfTouchedOrder) -> OrderEvent:
        return super().limit_if_touched_fill(asset, order)

    def stop_market_fill(self, asset: Security, order: StopMarketOrder) -> OrderEvent:
        return super().stop_market_fill(asset, order)

    def stop_limit_fill(self, asset: Security, order: StopLimitOrder) -> OrderEvent:
        return super().stop_limit_fill(asset, order)

    def trailing_stop_fill(self, asset: Security, order: TrailingStopOrder) -> OrderEvent:
        return super().trailing_stop_fill(asset, order)

    def market_on_open_fill(self, asset: Security, order: MarketOnOpenOrder) -> OrderEvent:
        return super().market_on_open_fill(asset, order)

    def market_on_close_fill(self, asset: Security, order: MarketOnCloseOrder) -> OrderEvent:
        return super().market_on_close_fill(asset, order)

    def combo_market_fill(self, order: Order, parameters: FillModelParameters) -> List[OrderEvent]:
        return super().combo_market_fill(order, parameters)

    def combo_limit_fill(self, order: Order, parameters: FillModelParameters) -> List[OrderEvent]:
        return super().combo_limit_fill(order, parameters)

    def combo_leg_limit_fill(self, order: Order, parameters: FillModelParameters) -> List[OrderEvent]:
        return super().combo_leg_limit_fill(order, parameters)
```

The `FillModelParameters` class has the following properties:

Partial Fills

In live trading, your orders can partially fill. For example, if you have a buy limit order at the bid price for 100 shares and someone sells 10 shares with a market order, your order is partially filled. In backtests, the pre-built fill models assume orders completely fill. To simulate partial fills in backtests, create a custom fill model.

Stale Fills

Stale fills occur when you fill an order with price data that is timestamped an hour or more into the past. Stale fills usually only occur if you trade illiquid assets or if your algorithm uses daily data but you trade intraday with Scheduled Events. If your order is filled with stale data, the fill price may not be realistic. The pre-built fill models can only fill market orders with stale data. To adjust the length of time that needs to pass before an order is considered stale, set the `stale_price_time_span` setting.

```py
def initialize(self) -> None:
    # Adjust the stale price time span to be 10 minutes.
    self.settings.stale_price_time_span = timedelta(minutes=10)
```

Examples

The following examples demonstrate common practices for implementing a custom fill model.

Example 1: Default Model Wrapper

The following algorithm defines a subclass of the default `FillModel` and overrides its built-in members so you can easily customize the parts you need.

```py
class CustomFillModelAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 10, 15)
        self.set_cash(100000)
        security = self.add_equity('SPY', Resolution.DAILY)
        security.set_fill_model(MyFillModel())

    def on_data(self, data: Slice) -> None:
        if not self.portfolio.invested:
            self.set_holdings('SPY', 1)

class MyFillModel(FillModel):

    def market_fill(self, asset: Security, order: MarketOrder) -> OrderEvent:
        return super().market_fill(asset, order)

    def limit_fill(self, asset: Security, order: LimitOrder) -> OrderEvent:
        return super().limit_fill(asset, order)

    def limit_if_touched_fill(self, asset: Security, order: LimitIfTouchedOrder) -> OrderEvent:
        return super().limit_if_touched_fill(asset, order)

    def stop_market_fill(self, asset: Security, order: StopMarketOrder) -> OrderEvent:
        return super().stop_market_fill(asset, order)

    def stop_limit_fill(self, asset: Security, order: StopLimitOrder) -> OrderEvent:
        return super().stop_limit_fill(asset, order)

    def trailing_stop_fill(self, asset: Security, order: TrailingStopOrder) -> OrderEvent:
        return super().trailing_stop_fill(asset, order)

    def market_on_open_fill(self, asset: Security, order: MarketOnOpenOrder) -> OrderEvent:
        return super().market_on_open_fill(asset, order)

    def market_on_close_fill(self, asset: Security, order: MarketOnCloseOrder) -> OrderEvent:
        return super().market_on_close_fill(asset, order)

    def combo_market_fill(self, order: Order, parameters: FillModelParameters) -> List[OrderEvent]:
        return super().combo_market_fill(order, parameters)

    def combo_limit_fill(self, order: Order, parameters: FillModelParameters) -> List[OrderEvent]:
        return super().combo_limit_fill(order, parameters)

    def combo_leg_limit_fill(self, order: Order, parameters: FillModelParameters) -> List[OrderEvent]:
        return super().combo_leg_limit_fill(order, parameters)
```

Example 2: Volume Share Fill

The following algorithm longs the top 10 liquid constituents and short the bottom 10 liquid constituents of QQQ. To realistically fill the less liquid stocks, we implement a fill model that only fills with at most 30% of the previous second bar.

```py
class VolumeShareFillModelAlgorithm(QCAlgorithm):
    longs = []
    shorts = []

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # The security initializer applies the VolumeShareFillModel to all assets.
        self.settings.seed_initial_prices = True
        self.add_security_initializer(self._volume_share_fill_security_initializer)

        # Request extended market hour SPY data for trading.
        qqq = self.add_equity("QQQ").symbol

        # Weekly portfolio updating to allow time to capitalize on the popularity gap.
        self.universe_settings.schedule.on(self.date_rules.week_start())
        # Set the resolution to second since the fill model is based on the second bar.
        self.universe_settings.resolution = Resolution.SECOND
        # Add universe to trade on the most and least liquid stocks among QQQ constituents.
        self.add_universe(
            self.universe.etf(qqq, Market.USA, self.universe_settings, lambda constituents: [c.symbol for c in constituents]),
            self.fundamental_selection
        )

        # Set a scheduled event to rebalance the portfolio at the start of every week.
        self.schedule.on(
            self.date_rules.week_start(qqq),
            self.time_rules.after_market_open(qqq),
            self.rebalance
        )

    def fundamental_selection(self, fundamentals: List[Fundamental]) -> List[Symbol]:
        sorted_by_dollar_volume = sorted(fundamentals, key=lambda f: f.dollar_volume)
        # Add the 10 most liquid stocks to the universe to long later.
        self.longs = [f.symbol for f in sorted_by_dollar_volume[-10:]]
        # Add the 10 least liquid stocks to the universe to short later.
        self.shorts = [f.symbol for f in sorted_by_dollar_volume[:10]]

        return self.longs + self.shorts

    def rebalance(self) -> None:
        # Equally invest in the selected stocks to dissipate capital risk evenly.
        # Dollar neutral of long and short stocks to eliminate systematic risk, only capitalize the popularity gap.
        targets = [PortfolioTarget(symbol, 0.05) for symbol in self.longs]
        targets += [PortfolioTarget(symbol, -0.05) for symbol in self.shorts]

        # Liquidate the ones not being the most and least popular stocks to release funds for higher expected return trades.
        self.set_holdings(targets, liquidate_existing_holdings=True)

    def _volume_share_fill_security_initializer(self, security: Security) -> None:
        # Create a slippage model to fill only 30% of the volume of the previous second bar to fill illiquid stocks realistically.
        security.set_fill_model(VolumeShareFillModel(self, 0.3))

class VolumeShareFillModel(FillModel):
    def __init__(self, algorithm: QCAlgorithm, maximum_ratio: float = 0.3):
        self.algorithm = algorithm
        self.maximum_ratio = maximum_ratio
        self.absolute_remaining_by_order_id = {}

    def market_fill(self, asset, order):
        absolute_remaining = self.absolute_remaining_by_order_id.get(order.id, order. AbsoluteQuantity)

        fill = super().market_fill(asset, order)
        # Set the fill amount to 30% of the previous second trade bar.
        fill.fill_quantity = np.sign(order.quantity) * asset.volume * self.maximum_ratio

        if (min(abs(fill.fill_quantity), absolute_remaining) == absolute_remaining):
            fill.fill_quantity = np.sign(order.quantity) * absolute_remaining
            fill.status = OrderStatus.FILLED
            self.absolute_remaining_by_order_id.pop(order.id, None)
        else:
            fill.status = OrderStatus.PARTIALLY_FILLED
            self.absolute_remaining_by_order_id[order.id] = absolute_remaining - abs(fill.fill_quantity)
            price = fill.fill_price

        return fill
```

Equity Model

Introduction

The `EquityFillModel` is the default fill model if you trade Equity assets with the DefaultBrokerageModel . This fill model fills trades completely and immediately.

```
security.set_fill_model(EquityFillModel())
```

PY

The fill logic of each order depends on the order type, the data format of the security subscription, and the order direction. The following sections explain the fill logic of each order given these factors.

For more information about this model, see the class reference and implementation .

Market Orders

The model fills buy market orders at the best effort ask price plus slippage and fills sell market orders at the best effort bid price minus slippage.

To get the best effort bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the best effort ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the best effort bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

The model only fills market orders during regular trading hours.

Limit Orders

To fill limit orders, the model first gets the best effort `TradeBar` . To get the best effort `TradeBar` , the model checks the resolution of your security subscription. If your subscription provies `Tick` data, it gets the most recent batch of trade ticks and consolidates them to build a `TradeBar` . If your subscription provies `TradeBar` data, it gets the most recent `TradeBar` . If the `end_time` of the best effort `TradeBar` is less than or equal to the time you placed the order, the model waits until the next best effort `TradeBar` to fill the order.

Once the model has a valid best effort `TradeBar` , it can fill the order. The following table shows the fill condition and fill price of limit orders. The model only fills the order once the fill condition is met.

Order Direction	Fill Condition	Fill Price
Buy	low price < limit price	min(open price, limit price)
Sell	high price > limit price	max(open price, limit price)

The model only fills limit orders when the exchange is open.

The model won't fill limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Limit if Touched Orders

To fill limit if touched orders, the model first gets the best effort `TradeBar` . To get the best effort `TradeBar` , the model checks the resolution of your

security subscription. If your subscription provies `Tick` data, it gets the most recent batch of trade ticks and consolidates them to build a `TradeBar` . If your subscription provies `TradeBar` data, it gets the most recent `TradeBar` . If the `end_time` of the best effort `TradeBar` is less than or equal to the time you placed the order, the model waits until the next best effort `TradeBar` to fill the order.

After the model has a valid best effort `TradeBar` , it can check if the trigger price has been touched. The following table describes the trigger condition of limit if touched orders for each order direction:

Order Direction	Trigger Condition
Buy	low price <= trigger price
Sell	high price >= trigger price

Once the limit if touched order triggers, the model starts to check if it should fill the order. The following table shows the fill condition and fill price of limit if touched orders. The model only fills the order once the fill condition is met

Order Direction	Fill Condition	Fill Price
Buy	Best effort ask price <= limit price	min(best effort ask price, limit price)
Sell	Best effort bid price >= limit price	max(best effort bid price, limit price)

To get the best effort bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the best effort ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the best effort bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

The model only fills limit orders when the exchange is open.

The model won't trigger or fill limit if touched orders with stale data .

Stop Market Orders

To fill stop market orders, the model first gets the best effort `TradeBar` . To get the best effort `TradeBar` , the model checks the resolution of your security subscription. If your subscription provies `Tick` data, it gets the most recent batch of trade ticks and consolidates them to build a `TradeBar` . If your subscription provies `TradeBar` data, it gets the most recent `TradeBar` . If the `end_time` of the best effort `TradeBar` is less than or equal to the time you placed the order, the model waits until the next best effort `TradeBar` to fill the order.

Once the stop condition is met, the model fills the orders and sets the fill price.

Once the model has a valid best effort `TradeBar` , it can fill the order. The following table shows the stop condition and fill price of stop market orders. The model only fills the order once the stop condition is met.

Order Direction	Fill Condition	Fill Price
Buy	high price >= stop price	max(open price, stop price) + slippage
Sell	low price <= stop price	min(open price, stop price) - slippage

The model only fills stop market orders during regular trading hours.

The model won't fill stop market orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Limit Orders

The fill logic of stop limit orders depends on the data format of the security subscription and the order direction. The following table shows the fill price of stop limit orders given these factors. To determine the fill price of the order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If your security subscription doesn't provide quote data, the fill model checks the most recent `TradeBar` .

The following table describes how the fill model processes the order given the data format and order direction. Once the stop condition is met, the model starts to check the fill condition. Once the fill condition is met, the model fills the orders and sets the fill price.

Data Format	`TickType`	Order Direction	Stop Condition	Fill Condition	Fill Price
`Tick`	`Quote`	Buy	quote price > stop price	quote price < limit price	min(quote price, limit price)
`Tick`	`Quote`	Sell	quote price < stop price	quote price > limit price	max(quote price, limit price)
`Tick`	`Trade`	Buy	trade price > stop price	trade price < limit price	min(trade price, limit price)
`Tick`	`Trade`	Sell	trade price < stop price	trade price > limit price	max(trade price, limit price)
`QuoteBar`		Buy	ask high price > stop price	ask close price < limit price	min(ask high price, limit price)
`QuoteBar`		Sell	bid low price < stop price	bid close price > limit price	max(bid low price, limit price)
`TradeBar`		Buy	high price > stop price	close price < limit price	min(high price, limit price)
`TradeBar`		Sell	low price < stop price	close price > limit price	max(low price, limit price)

The model won't fill stop limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

The model only fills stop limit orders when the exchange is open.

Trailing Stop Orders

To fill trailing stop orders, the model first gets the best effort `TradeBar` . To get the best effort `TradeBar` , the model checks the resolution of your security subscription. If your subscription provies `Tick` data, it gets the most recent batch of trade ticks and consolidates them to build a `TradeBar` . If your subscription provies `TradeBar` data, it gets the most recent `TradeBar` . If the `end_time` of the best effort `TradeBar` is less than or equal to the time you placed the order, the model waits until the next best effort `TradeBar` to fill the order.

Once the stop condition is met, the model fills the orders and sets the fill price.

Once the model has a valid best effort `TradeBar` , it can fill the order. The following table shows the stop condition and fill price of trailing stop orders. The model only fills the order once the stop condition is met.

Order Direction	Fill Condition	Fill Price
Buy	high price >= stop price	max(open price, stop price) + slippage
Sell	low price <= stop price	min(open price, stop price) - slippage

While the stop condition is not met, the model updates the stop price under certain conditions. The following table shows the update condition and stop price value for currency-based trailing amounts:

Order Direction	Update Condition	Stop Price
Buy	stop price - low price <= trailing amount	low price + trailing amount
Sell	high price - stop price <= trailing amount	high price - trailing amount

The following table shows the update condition and stop price value for percentage-based trailing amounts:

Order Direction	Update Condition	Stop Price
Buy	stop price - low price <= low price * trailing amount	low price * (1 + trailing amount)
Sell	high price - stop price <= high price * trailing amount	high price * (1 - trailing amount)

The model only fills trailing stop orders during regular trading hours.

The model won't fill trailing stop orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Open Orders

The following table describes the fill price of market on open orders for each data format and order direction:

Data Format	Order Direction	Fill Price
`Tick`	Buy	If the model receives the official opening auction price within one minute, the order fills at official open price + slippage. After one minute, the order fills at the most recent trade price + slippage. If the security doesn't trade within the first two minutes, the order fills at the best effort ask price + slippage.
`Tick`	Sell	If the model receives the official opening auction price within one minute, the order fills at the official open price - slippage. After one minute, the order fills at the most recent trade price - slippage. If the security doesn't trade within the first two minutes, the order fills at the best effort bid price - slippage.
`TradeBar`	Buy	Open price + slippage
`TradeBar`	Sell	Open price - slippage
`QuoteBar`	Buy	Best effort ask price + slippage
`QuoteBar`	Sell	Best effort bid price - slippage

The model checks the data format in the following order:

1. `Tick`
2. `TradeBar`
3. `QuoteBar`

To get the best effort bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the best effort ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the best effort bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

Market on Close Orders

The following table describes the fill price of market on close orders for each data format and order direction:

Data Format	Order Direction	Fill Price
`Tick`	Buy	If the model receives the official closing auction price within one minute after the close, the order fills at official close price + slippage. After one minute, the order fills at the most recent trade price + slippage. If the security doesn't trade within the first two minutes, the order fills at the best effort ask price + slippage.
`Tick`	Sell	If the model receives the official closing auction price within one minute after the close, the order fills at the official close price - slippage. After one minute, the order fills at the most recent trade price - slippage. If the security doesn't trade within the first two minutes after the close, the order fills at the best effort bid price - slippage.
`TradeBar`	Buy	Open price + slippage
`TradeBar`	Sell	Open price - slippage
`QuoteBar`	Buy	Best effort ask price + slippage
`QuoteBar`	Sell	Best effort bid price - slippage

The model checks the data format in the following order:

1. `Tick`
2. `TradeBar`
3. `QuoteBar`

To get the best effort bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the best effort ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the best effort bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

Combo Market Orders

The fill logic of combo market orders depends on the data format of the security subscription and the order direction. The following table shows the fill price of combo market orders given these factors. To determine the fill price of the order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If your security subscription doesn't provide quote data, the fill model checks the most recent `TradeBar` .

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	Ask quote price + slippage
Tick	Quote	Sell	Bid quote price - slippage
Tick	Trade	Buy	Trade price + slippage
Tick	Trade	Sell	Trade price - slippage
QuoteBar		Buy	Ask close price + slippage
QuoteBar		Sell	Bid close price - slippage
TradeBar		Buy	Close price + slippage
TradeBar		Sell	Close price - slippage

The model only fills combo market orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity of each leg is the product of the leg order quantity and the combo market order quantity.

Combo Limit Orders

The fill logic of combo limit orders depends on the data format of the security subscription and the order direction. To determine the fill price of the order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If your security subscription doesn't provide quote data, the fill model checks the most recent `TradeBar` .

To fill combo limit orders, the fill model calculates the aggregate price of the combo order, which is the sum of prices for each security in the order legs. The price of each security is a function of the data format and order direction. Legs with a positive order quantity increase the aggregate price and legs with a negative quantity decrease the aggregate price. The following table shows how the fill model calculates the security prices.

Data Format	TickType	Combo Order Direction	Leg Order Direction	Price
Tick	Quote	Buy or sell	Buy	Ask price
Tick	Quote	Buy or sell	Sell	Bid price
Tick	Trade	Buy or sell	Buy or sell	Trade price
QuoteBar		Buy	Buy	Ask low price
QuoteBar		Buy	Sell	Bid low price
QuoteBar		Sell	Buy	Ask high price
QuoteBar		Sell	Sell	Bid high price
TradeBar		Buy	Buy or sell	Low price
TradeBar		Sell	Buy or sell	High price

After the fill model calculates the aggregate price of the combo order, it checks if it should fill the order. The following table describes the fill condition of the combo order and the fill price price of each leg:

Data Format	TickType	Combo Order Direction	Fill Condition	Leg Order Direction	Fill Price
Tick	Quote	Buy	Aggregate price < combo limit price	Buy or sell	Quote price
Tick	Quote	Sell	Aggregate price > combo limit price	Buy or sell	Quote price
Tick	Trade	Buy	Aggregate price < combo limit price	Buy or sell	Trade price
Tick	Trade	Sell	Aggregate price > combo limit price	Buy or sell	Trade price
QuoteBar		Buy	Aggregate price < combo limit price	Buy	Ask low price
QuoteBar		Buy	Aggregate price < combo limit price	Sell	Bid low price
QuoteBar		Sell	Aggregate price > combo limit price	Buy	Ask high price
QuoteBar		Sell	Aggregate price > combo limit price	Sell	Bid high price
TradeBar		Buy	Aggregate price < combo limit price	Buy or sell	Low price
TradeBar		Sell	Aggregate price > combo limit price	Buy or sell	High price

The model only fills combo limit orders if the data isn't stale and all the legs can fill in the same time step after the order time step. The fill quantity of each leg is the product of the leg order quantity and the combo order quantity.

Combo Leg Limit Orders

The fill logic of combo leg limit orders depends on the data format of the security subscription and the order direction. The following table shows the fill price of combo leg limit orders given these factors. To determine the fill price of the order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If your security subscription doesn't provide quote data, the fill model checks the most recent `TradeBar` .

The order direction in the table represents the order direction of the order leg, not the order direction of the combo order.

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	Ask price < limit price	min(ask price, limit price)
Tick	Quote	Sell	Bid price > limit price	max(bid price, limit price)
Tick	Trade	Buy	Trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	Trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	Ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	Bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	Low price < limit price	min(high price, limit price)
TradeBar		Sell	High price > limit price	max(low price, limit price)

The model only fills combo leg limit orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity is the product of the leg order quantity and the combo order quantity.

Supported Models

Future Model

Introduction

The `FutureFillModel` is the default fill model if you trade Futures contracts with the DefaultBrokerageModel . This fill model fills trades completely and immediately.

```
security.set_fill_model(FutureFillModel())
```

PY

The fill logic of each order depends on the order type, the data format of the security subscription, and the order direction. The following tables show the fill price of each order given these factors. To determine the fill price of an order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If your security subscription doesn't provide quote data, the fill model checks the most recent `TradeBar` .

For more information about this model, see the class reference and implementation .

Market Orders

The following table describes the fill price of market orders for each data format and order direction:

Data Format	`TickType`	Order Direction	Fill Price
`Tick`	`Quote`	Buy	quote price + slippage
`Tick`	`Quote`	Sell	quote price - slippage
`Tick`	`Trade`	Buy	trade price + slippage
`Tick`	`Trade`	Sell	trade price - slippage
`QuoteBar`		Buy	ask close price + slippage
`QuoteBar`		Sell	bid close price - slippage
`TradeBar`		Buy	close price + slippage
`TradeBar`		Sell	close price - slippage

The model only fills market orders if the exchange is open and it immediately fills them. If your algorithm places a market order at 10 AM, it fills at 10 AM.

Limit Orders

The following table describes the fill logic of limit orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	low price < limit price	min(high price, limit price)
TradeBar		Sell	high price > limit price	max(low price, limit price)

The model won't fill limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Limit if Touched Orders

The model converts a limit if touched order to a limit order when the trigger condition is met. The following table describes the trigger condition of limit if touched orders for each data format and order direction:

Data Format	TickType	Order Direction	Trigger Condition
Tick	Quote	Buy	quote price <= trigger price
Tick	Quote	Sell	quote price >= trigger price
Tick	Trade	Buy	trade price <= trigger price
Tick	Trade	Sell	trade price >= trigger price
TradeBar		Buy	low price <= trigger price
TradeBar		Sell	high price >= trigger price

Once the limit if touched order triggers, to fill the order, the model checks the bid price for buy orders and the ask price for sell orders.

To get the bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

Buy orders fill when the bid price <= limit price and sell orders fill when the ask price >= limit price. The order fills at the limit price. The model won't trigger or fill limit if touched orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Market Orders

The following table describes the fill logic of stop market orders for each data format and order direction. Once the stop condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	max(stop price, quote price + slippage)
Tick	Quote	Sell	quote price < stop price	min(stop price, quote price - slippage)
Tick	Trade	Buy	trade price > stop price	max(stop price, last trade price + slippage)
Tick	Trade	Sell	trade price < stop price	min(stop price, last trade price - slippage)
QuoteBar		Buy	ask high price > stop price	max(stop price, ask close price + slippage)
QuoteBar		Sell	bid low price < stop price	min(stop price, bid close price - slippage)
TradeBar		Buy	high price > stop price	max(stop price, close price + slippage)
TradeBar		Sell	low price < stop price	min(stop price, close price - slippage)

The model only fills stop market orders when the exchange is open.

The model won't fill stop market orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Limit Orders

The following table describes the fill logic of stop limit orders for each data format and order direction. Once the stop condition is met, the model starts to check the fill condition. Once the fill condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price < stop price	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price > stop price	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price < stop price	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask high price > stop price	ask close price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid low price < stop price	bid close price > limit price	max(bid low price, limit price)
TradeBar		Buy	high price > stop price	close price < limit price	min(high price, limit price)
TradeBar		Sell	low price < stop price	close price > limit price	max(low price, limit price)

The model won't fill stop limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Trailing Stop Orders

The following table describes the fill logic of trailing stop orders for each data format and order direction. Once the stop condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	max(stop price, quote price + slippage)
Tick	Quote	Sell	quote price < stop price	min(stop price, quote price - slippage)
Tick	Trade	Buy	trade price > stop price	max(stop price, last trade price + slippage)
Tick	Trade	Sell	trade price < stop price	min(stop price, last trade price - slippage)
QuoteBar		Buy	ask high price > stop price	max(stop price, ask close price + slippage)
QuoteBar		Sell	bid low price < stop price	min(stop price, bid close price - slippage)
TradeBar		Buy	high price > stop price	max(stop price, close price + slippage)
TradeBar		Sell	low price < stop price	min(stop price, close price - slippage)

While the stop condition is not met, the model updates the stop price under certain conditions. The following table shows the update condition and stop price value for currency-based trailing amounts:

Data Format	TickType	Order Direction	Update Condition	Stop Price
Tick	Quote	Buy	stop price - quote price <= trailing amount	quote price + trailing amount
Tick	Quote	Sell	quote price - stop price <= trailing amount	quote price - trailing amount
Tick	Trade	Buy	stop price - trade price <= trailing amount	trade price + trailing amount
Tick	Trade	Sell	trade price - stop price <= trailing amount	trade price - trailing amount
QuoteBar		Buy	stop price - ask low price <= trailing amount	ask low price + trailing amount
QuoteBar		Sell	bid high price - stop price <= trailing amount	bid high price - trailing amount
TradeBar		Buy	stop price - low price <= trailing amount	low price + trailing amount
TradeBar		Sell	high price - stop price <= trailing amount	high price - trailing amount

The following table shows the update condition and stop price value for percentage-based trailing amounts.

Data Format	TickType	Order Direction	Update Condition	Stop Price
Tick	Quote	Buy	stop price - quote price <= quote price * trailing amount	quote price * (1 + trailing amount)
Tick	Quote	Sell	quote price - stop price <= quote price * trailing amount	quote price * (1 - trailing amount)
Tick	Trade	Buy	stop price - trade price <= trade price * trailing amount	trade price * (1 + trailing amount)
Tick	Trade	Sell	trade price - stop price <= trade price * trailing amount	trade price * (1 - trailing amount)
QuoteBar		Buy	stop price - ask low price <= ask low price * trailing amount	ask low price * (1 + trailing amount)
QuoteBar		Sell	bid high price - stop price <= bid high price * trailing amount	bid high price * (1 - trailing amount)
TradeBar		Buy	stop price - low price <= stop price * trailing amount	low price * (1 + trailing amount)
TradeBar		Sell	high price - stop price <= high price * trailing amount	high price * (1 - trailing amount)

The model only fills trailing stop orders when the exchange is open.

The model won't fill trailing stop orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Open Orders

The following table describes the fill price of market on open orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask open price + slippage
QuoteBar		Sell	bid open price - slippage
TradeBar		Buy	open price + slippage
TradeBar		Sell	open price - slippage

The model won't fill market on open orders during pre-market hours.

The model won't fill market on open orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Close Orders

The following table describes the fill price of market on close orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask close price + slippage
QuoteBar		Sell	bid close price - slippage
TradeBar		Buy	close price + slippage
TradeBar		Sell	close price - slippage

The model won't fill market on close orders with stale data or data with the order timestamp to avoid look-ahead bias.

Combo Market Orders

The following table describes the fill price of combo market orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	Ask quote price + slippage
Tick	Quote	Sell	Bid quote price - slippage
Tick	Trade	Buy	Trade price + slippage
Tick	Trade	Sell	Trade price - slippage
QuoteBar		Buy	Ask close price + slippage
QuoteBar		Sell	Bid close price - slippage
TradeBar		Buy	Close price + slippage
TradeBar		Sell	Close price - slippage

The model only fills combo market orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity of each leg is the product of the leg order quantity and the combo market order quantity.

Combo Limit Orders

To fill combo limit orders, the fill model calculates the aggregate price of the combo order, which is the sum of prices for each security in the order legs. The price of each security is a function of the data format and order direction. Legs with a positive order quantity increase the aggregate price and legs with a negative quantity decrease the aggregate price. The following table shows how the fill model calculates the security prices.

Data Format	TickType	Combo Order Direction	Leg Order Direction	Price
Tick	Quote	Buy or sell	Buy	Ask price
Tick	Quote	Buy or sell	Sell	Bid price
Tick	Trade	Buy or sell	Buy or sell	Trade price
QuoteBar		Buy	Buy	Ask low price
QuoteBar		Buy	Sell	Bid low price
QuoteBar		Sell	Buy	Ask high price
QuoteBar		Sell	Sell	Bid high price
TradeBar		Buy	Buy or sell	Low price
TradeBar		Sell	Buy or sell	High price

After the fill model calculates the aggregate price of the combo order, it checks if it should fill the order. The following table describes the fill condition of the combo order and the fill price price of each leg:

Data Format	TickType	Combo Order Direction	Fill Condition	Leg Order Direction	Fill Price
Tick	Quote	Buy	Aggregate price < combo limit price	Buy or sell	Quote price
Tick	Quote	Sell	Aggregate price > combo limit price	Buy or sell	Quote price
Tick	Trade	Buy	Aggregate price < combo limit price	Buy or sell	Trade price
Tick	Trade	Sell	Aggregate price > combo limit price	Buy or sell	Trade price
QuoteBar		Buy	Aggregate price < combo limit price	Buy	Ask low price
QuoteBar		Buy	Aggregate price < combo limit price	Sell	Bid low price
QuoteBar		Sell	Aggregate price > combo limit price	Buy	Ask high price
QuoteBar		Sell	Aggregate price > combo limit price	Sell	Bid high price
TradeBar		Buy	Aggregate price < combo limit price	Buy or sell	Low price
TradeBar		Sell	Aggregate price > combo limit price	Buy or sell	High price

The model only fills combo limit orders if the data isn't stale and all the legs can fill in the same time step after the order time step. The fill quantity of each leg is the product of the leg order quantity and the combo order quantity.

Combo Leg Limit Orders

The following table describes the fill logic of combo leg limit orders for each data format and order direction. The order direction in the table represents the order direction of the order leg, not the order direction of the combo order.

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	Ask price < limit price	min(ask price, limit price)
Tick	Quote	Sell	Bid price > limit price	max(bid price, limit price)
Tick	Trade	Buy	Trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	Trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	Ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	Bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	Low price < limit price	min(high price, limit price)
TradeBar		Sell	High price > limit price	max(low price, limit price)

The model only fills combo leg limit orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity is the product of the leg order quantity and the combo order quantity.

Supported Models

Future Option Model

Introduction

The `FutureOptionFillModel` is the default fill model if you trade Future Option contracts with the DefaultBrokerageModel . This fill model fills trades completely and immediately.

```
security.set_fill_model(FutureOptionFillModel())
```

PY

The fill logic of each order depends on the order type, the data format of the security subscription, and the order direction. The following tables show the fill price of each order given these factors. To determine the fill price of an order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If your security subscription doesn't provide quote data, the fill model checks the most recent `TradeBar` .

For more information about this model, see the class reference and implementation .

Market Orders

The following table describes the fill price of market orders for each data format and order direction:

Data Format	`TickType`	Order Direction	Fill Price
`Tick`	`Quote`	Buy	quote price + slippage
`Tick`	`Quote`	Sell	quote price - slippage
`Tick`	`Trade`	Buy	trade price + slippage
`Tick`	`Trade`	Sell	trade price - slippage
`QuoteBar`		Buy	ask close price + slippage
`QuoteBar`		Sell	bid close price - slippage
`TradeBar`		Buy	close price + slippage
`TradeBar`		Sell	close price - slippage

The model only fills market orders if the exchange is open and it immediately fills them. If your algorithm places a market order at 10 AM, it fills at 10 AM.

Limit Orders

The following table describes the fill logic of limit orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	low price < limit price	min(high price, limit price)
TradeBar		Sell	high price > limit price	max(low price, limit price)

The model won't fill limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Limit if Touched Orders

The model converts a limit if touched order to a limit order when the trigger condition is met. The following table describes the trigger condition of limit if touched orders for each data format and order direction:

Data Format	TickType	Order Direction	Trigger Condition
Tick	Quote	Buy	quote price <= trigger price
Tick	Quote	Sell	quote price >= trigger price
Tick	Trade	Buy	trade price <= trigger price
Tick	Trade	Sell	trade price >= trigger price
TradeBar		Buy	low price <= trigger price
TradeBar		Sell	high price >= trigger price

Once the limit if touched order triggers, to fill the order, the model checks the bid price for buy orders and the ask price for sell orders.

To get the bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

Buy orders fill when the bid price <= limit price and sell orders fill when the ask price >= limit price. The order fills at the limit price. The model won't trigger or fill limit if touched orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Market Orders

The following table describes the fill logic of stop market orders for each data format and order direction. Once the stop condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	max(stop price, quote price + slippage)
Tick	Quote	Sell	quote price < stop price	min(stop price, quote price - slippage)
Tick	Trade	Buy	trade price > stop price	max(stop price, last trade price + slippage)
Tick	Trade	Sell	trade price < stop price	min(stop price, last trade price - slippage)
QuoteBar		Buy	ask high price > stop price	max(stop price, ask close price + slippage)
QuoteBar		Sell	bid low price < stop price	min(stop price, bid close price - slippage)
TradeBar		Buy	high price > stop price	max(stop price, close price + slippage)
TradeBar		Sell	low price < stop price	min(stop price, close price - slippage)

The model only fills stop market orders when the exchange is open.

The model won't fill stop market orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Limit Orders

The following table describes the fill logic of stop limit orders for each data format and order direction. Once the stop condition is met, the model starts to check the fill condition. Once the fill condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price < stop price	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price > stop price	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price < stop price	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask high price > stop price	ask close price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid low price < stop price	bid close price > limit price	max(bid low price, limit price)
TradeBar		Buy	high price > stop price	close price < limit price	min(high price, limit price)
TradeBar		Sell	low price < stop price	close price > limit price	max(low price, limit price)

The model won't fill stop limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Trailing Stop Orders

The following table describes the fill logic of trailing stop orders for each data format and order direction. Once the stop condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	max(stop price, quote price + slippage)
Tick	Quote	Sell	quote price < stop price	min(stop price, quote price - slippage)
Tick	Trade	Buy	trade price > stop price	max(stop price, last trade price + slippage)
Tick	Trade	Sell	trade price < stop price	min(stop price, last trade price - slippage)
QuoteBar		Buy	ask high price > stop price	max(stop price, ask close price + slippage)
QuoteBar		Sell	bid low price < stop price	min(stop price, bid close price - slippage)
TradeBar		Buy	high price > stop price	max(stop price, close price + slippage)
TradeBar		Sell	low price < stop price	min(stop price, close price - slippage)

While the stop condition is not met, the model updates the stop price under certain conditions. The following table shows the update condition and stop price value for currency-based trailing amounts:

Data Format	TickType	Order Direction	Update Condition	Stop Price
Tick	Quote	Buy	stop price - quote price <= trailing amount	quote price + trailing amount
Tick	Quote	Sell	quote price - stop price <= trailing amount	quote price - trailing amount
Tick	Trade	Buy	stop price - trade price <= trailing amount	trade price + trailing amount
Tick	Trade	Sell	trade price - stop price <= trailing amount	trade price - trailing amount
QuoteBar		Buy	stop price - ask low price <= trailing amount	ask low price + trailing amount
QuoteBar		Sell	bid high price - stop price <= trailing amount	bid high price - trailing amount
TradeBar		Buy	stop price - low price <= trailing amount	low price + trailing amount
TradeBar		Sell	high price - stop price <= trailing amount	high price - trailing amount

The following table shows the update condition and stop price value for percentage-based trailing amounts.

Data Format	TickType	Order Direction	Update Condition	Stop Price
Tick	Quote	Buy	stop price - quote price <= quote price * trailing amount	quote price * (1 + trailing amount)
Tick	Quote	Sell	quote price - stop price <= quote price * trailing amount	quote price * (1 - trailing amount)
Tick	Trade	Buy	stop price - trade price <= trade price * trailing amount	trade price * (1 + trailing amount)
Tick	Trade	Sell	trade price - stop price <= trade price * trailing amount	trade price * (1 - trailing amount)
QuoteBar		Buy	stop price - ask low price <= ask low price * trailing amount	ask low price * (1 + trailing amount)
QuoteBar		Sell	bid high price - stop price <= bid high price * trailing amount	bid high price * (1 - trailing amount)
TradeBar		Buy	stop price - low price <= stop price * trailing amount	low price * (1 + trailing amount)
TradeBar		Sell	high price - stop price <= high price * trailing amount	high price * (1 - trailing amount)

The model only fills trailing stop orders when the exchange is open.

The model won't fill trailing stop orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Open Orders

The following table describes the fill price of market on open orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask open price + slippage
QuoteBar		Sell	bid open price - slippage
TradeBar		Buy	open price + slippage
TradeBar		Sell	open price - slippage

The model won't fill market on open orders during pre-market hours.

The model won't fill market on open orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Close Orders

The following table describes the fill price of market on close orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask close price + slippage
QuoteBar		Sell	bid close price - slippage
TradeBar		Buy	close price + slippage
TradeBar		Sell	close price - slippage

The model won't fill market on close orders with stale data or data with the order timestamp to avoid look-ahead bias.

Combo Market Orders

The following table describes the fill price of combo market orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	Ask quote price + slippage
Tick	Quote	Sell	Bid quote price - slippage
Tick	Trade	Buy	Trade price + slippage
Tick	Trade	Sell	Trade price - slippage
QuoteBar		Buy	Ask close price + slippage
QuoteBar		Sell	Bid close price - slippage
TradeBar		Buy	Close price + slippage
TradeBar		Sell	Close price - slippage

The model only fills combo market orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity of each leg is the product of the leg order quantity and the combo market order quantity.

Combo Limit Orders

To fill combo limit orders, the fill model calculates the aggregate price of the combo order, which is the sum of prices for each security in the order legs. The price of each security is a function of the data format and order direction. Legs with a positive order quantity increase the aggregate price and legs with a negative quantity decrease the aggregate price. The following table shows how the fill model calculates the security prices.

Data Format	TickType	Combo Order Direction	Leg Order Direction	Price
Tick	Quote	Buy or sell	Buy	Ask price
Tick	Quote	Buy or sell	Sell	Bid price
Tick	Trade	Buy or sell	Buy or sell	Trade price
QuoteBar		Buy	Buy	Ask low price
QuoteBar		Buy	Sell	Bid low price
QuoteBar		Sell	Buy	Ask high price
QuoteBar		Sell	Sell	Bid high price
TradeBar		Buy	Buy or sell	Low price
TradeBar		Sell	Buy or sell	High price

After the fill model calculates the aggregate price of the combo order, it checks if it should fill the order. The following table describes the fill condition of the combo order and the fill price price of each leg:

Data Format	TickType	Combo Order Direction	Fill Condition	Leg Order Direction	Fill Price
Tick	Quote	Buy	Aggregate price < combo limit price	Buy or sell	Quote price
Tick	Quote	Sell	Aggregate price > combo limit price	Buy or sell	Quote price
Tick	Trade	Buy	Aggregate price < combo limit price	Buy or sell	Trade price
Tick	Trade	Sell	Aggregate price > combo limit price	Buy or sell	Trade price
QuoteBar		Buy	Aggregate price < combo limit price	Buy	Ask low price
QuoteBar		Buy	Aggregate price < combo limit price	Sell	Bid low price
QuoteBar		Sell	Aggregate price > combo limit price	Buy	Ask high price
QuoteBar		Sell	Aggregate price > combo limit price	Sell	Bid high price
TradeBar		Buy	Aggregate price < combo limit price	Buy or sell	Low price
TradeBar		Sell	Aggregate price > combo limit price	Buy or sell	High price

The model only fills combo limit orders if the data isn't stale and all the legs can fill in the same time step after the order time step. The fill quantity of each leg is the product of the leg order quantity and the combo order quantity.

Combo Leg Limit Orders

The following table describes the fill logic of combo leg limit orders for each data format and order direction. The order direction in the table represents the order direction of the order leg, not the order direction of the combo order.

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	Ask price < limit price	min(ask price, limit price)
Tick	Quote	Sell	Bid price > limit price	max(bid price, limit price)
Tick	Trade	Buy	Trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	Trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	Ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	Bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	Low price < limit price	min(high price, limit price)
TradeBar		Sell	High price > limit price	max(low price, limit price)

The model only fills combo leg limit orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity is the product of the leg order quantity and the combo order quantity.

Supported Models

Immediate Model

Introduction

The `ImmediateFillModel` is the default fill model if you trade non-Equity assets with the DefaultBrokerageModel . This fill model fills trades completely and immediately.

```
security.set_fill_model(ImmediateFillModel())
```

PY

The fill logic of each order depends on the order type, the data format of the security subscription, and the order direction. The following tables show the fill price of each order given these factors. To determine the fill price of an order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If your security subscription doesn't provide quote data, the fill model checks the most recent `TradeBar` .

For more information about this model, see the class reference and implementation .

Market Orders

The following table describes the fill price of market orders for each data format and order direction:

Data Format	`TickType`	Order Direction	Fill Price
`Tick`	`Quote`	Buy	quote price + slippage
`Tick`	`Quote`	Sell	quote price - slippage
`Tick`	`Trade`	Buy	trade price + slippage
`Tick`	`Trade`	Sell	trade price - slippage
`QuoteBar`		Buy	ask close price + slippage
`QuoteBar`		Sell	bid close price - slippage
`TradeBar`		Buy	close price + slippage
`TradeBar`		Sell	close price - slippage

The model only fills market orders if the exchange is open and it immediately fills them. If your algorithm places a market order at 10 AM, it fills at 10 AM.

Limit Orders

The following table describes the fill logic of limit orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	low price < limit price	min(high price, limit price)
TradeBar		Sell	high price > limit price	max(low price, limit price)

The model won't fill limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Limit if Touched Orders

The model converts a limit if touched order to a limit order when the trigger condition is met. The following table describes the trigger condition of limit if touched orders for each data format and order direction:

Data Format	TickType	Order Direction	Trigger Condition
Tick	Quote	Buy	quote price <= trigger price
Tick	Quote	Sell	quote price >= trigger price
Tick	Trade	Buy	trade price <= trigger price
Tick	Trade	Sell	trade price >= trigger price
TradeBar		Buy	low price <= trigger price
TradeBar		Sell	high price >= trigger price

Once the limit if touched order triggers, to fill the order, the model checks the bid price for buy orders and the ask price for sell orders.

To get the bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

Buy orders fill when the bid price <= limit price and sell orders fill when the ask price >= limit price. The order fills at the limit price. The model won't trigger or fill limit if touched orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Market Orders

The following table describes the fill logic of stop market orders for each data format and order direction. Once the stop condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	max(stop price, quote price + slippage)
Tick	Quote	Sell	quote price < stop price	min(stop price, quote price - slippage)
Tick	Trade	Buy	trade price > stop price	max(stop price, last trade price + slippage)
Tick	Trade	Sell	trade price < stop price	min(stop price, last trade price - slippage)
QuoteBar		Buy	ask high price > stop price	max(stop price, ask close price + slippage)
QuoteBar		Sell	bid low price < stop price	min(stop price, bid close price - slippage)
TradeBar		Buy	high price > stop price	max(stop price, close price + slippage)
TradeBar		Sell	low price < stop price	min(stop price, close price - slippage)

The model only fills stop market orders when the exchange is open.

The model won't fill stop market orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Limit Orders

The following table describes the fill logic of stop limit orders for each data format and order direction. Once the stop condition is met, the model starts to check the fill condition. Once the fill condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price < stop price	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price > stop price	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price < stop price	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask high price > stop price	ask close price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid low price < stop price	bid close price > limit price	max(bid low price, limit price)
TradeBar		Buy	high price > stop price	close price < limit price	min(high price, limit price)
TradeBar		Sell	low price < stop price	close price > limit price	max(low price, limit price)

The model won't fill stop limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Trailing Stop Orders

The following table describes the fill logic of trailing stop orders for each data format and order direction. Once the stop condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	max(stop price, quote price + slippage)
Tick	Quote	Sell	quote price < stop price	min(stop price, quote price - slippage)
Tick	Trade	Buy	trade price > stop price	max(stop price, last trade price + slippage)
Tick	Trade	Sell	trade price < stop price	min(stop price, last trade price - slippage)
QuoteBar		Buy	ask high price > stop price	max(stop price, ask close price + slippage)
QuoteBar		Sell	bid low price < stop price	min(stop price, bid close price - slippage)
TradeBar		Buy	high price > stop price	max(stop price, close price + slippage)
TradeBar		Sell	low price < stop price	min(stop price, close price - slippage)

While the stop condition is not met, the model updates the stop price under certain conditions. The following table shows the update condition and stop price value for currency-based trailing amounts:

Data Format	TickType	Order Direction	Update Condition	Stop Price
Tick	Quote	Buy	stop price - quote price <= trailing amount	quote price + trailing amount
Tick	Quote	Sell	quote price - stop price <= trailing amount	quote price - trailing amount
Tick	Trade	Buy	stop price - trade price <= trailing amount	trade price + trailing amount
Tick	Trade	Sell	trade price - stop price <= trailing amount	trade price - trailing amount
QuoteBar		Buy	stop price - ask low price <= trailing amount	ask low price + trailing amount
QuoteBar		Sell	bid high price - stop price <= trailing amount	bid high price - trailing amount
TradeBar		Buy	stop price - low price <= trailing amount	low price + trailing amount
TradeBar		Sell	high price - stop price <= trailing amount	high price - trailing amount

The following table shows the update condition and stop price value for percentage-based trailing amounts.

Data Format	TickType	Order Direction	Update Condition	Stop Price
Tick	Quote	Buy	stop price - quote price <= quote price * trailing amount	quote price * (1 + trailing amount)
Tick	Quote	Sell	quote price - stop price <= quote price * trailing amount	quote price * (1 - trailing amount)
Tick	Trade	Buy	stop price - trade price <= trade price * trailing amount	trade price * (1 + trailing amount)
Tick	Trade	Sell	trade price - stop price <= trade price * trailing amount	trade price * (1 - trailing amount)
QuoteBar		Buy	stop price - ask low price <= ask low price * trailing amount	ask low price * (1 + trailing amount)
QuoteBar		Sell	bid high price - stop price <= bid high price * trailing amount	bid high price * (1 - trailing amount)
TradeBar		Buy	stop price - low price <= stop price * trailing amount	low price * (1 + trailing amount)
TradeBar		Sell	high price - stop price <= high price * trailing amount	high price * (1 - trailing amount)

The model only fills trailing stop orders when the exchange is open.

The model won't fill trailing stop orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Open Orders

The following table describes the fill price of market on open orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask open price + slippage
QuoteBar		Sell	bid open price - slippage
TradeBar		Buy	open price + slippage
TradeBar		Sell	open price - slippage

The model won't fill market on open orders during pre-market hours.

The model won't fill market on open orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Close Orders

The following table describes the fill price of market on close orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask close price + slippage
QuoteBar		Sell	bid close price - slippage
TradeBar		Buy	close price + slippage
TradeBar		Sell	close price - slippage

The model won't fill market on close orders with stale data or data with the order timestamp to avoid look-ahead bias.

Combo Market Orders

The following table describes the fill price of combo market orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	Ask quote price + slippage
Tick	Quote	Sell	Bid quote price - slippage
Tick	Trade	Buy	Trade price + slippage
Tick	Trade	Sell	Trade price - slippage
QuoteBar		Buy	Ask close price + slippage
QuoteBar		Sell	Bid close price - slippage
TradeBar		Buy	Close price + slippage
TradeBar		Sell	Close price - slippage

The model only fills combo market orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity of each leg is the product of the leg order quantity and the combo market order quantity.

Combo Limit Orders

To fill combo limit orders, the fill model calculates the aggregate price of the combo order, which is the sum of prices for each security in the order legs. The price of each security is a function of the data format and order direction. Legs with a positive order quantity increase the aggregate price and legs with a negative quantity decrease the aggregate price. The following table shows how the fill model calculates the security prices.

Data Format	TickType	Combo Order Direction	Leg Order Direction	Price
Tick	Quote	Buy or sell	Buy	Ask price
Tick	Quote	Buy or sell	Sell	Bid price
Tick	Trade	Buy or sell	Buy or sell	Trade price
QuoteBar		Buy	Buy	Ask low price
QuoteBar		Buy	Sell	Bid low price
QuoteBar		Sell	Buy	Ask high price
QuoteBar		Sell	Sell	Bid high price
TradeBar		Buy	Buy or sell	Low price
TradeBar		Sell	Buy or sell	High price

After the fill model calculates the aggregate price of the combo order, it checks if it should fill the order. The following table describes the fill condition of the combo order and the fill price price of each leg:

Data Format	TickType	Combo Order Direction	Fill Condition	Leg Order Direction	Fill Price
Tick	Quote	Buy	Aggregate price < combo limit price	Buy or sell	Quote price
Tick	Quote	Sell	Aggregate price > combo limit price	Buy or sell	Quote price
Tick	Trade	Buy	Aggregate price < combo limit price	Buy or sell	Trade price
Tick	Trade	Sell	Aggregate price > combo limit price	Buy or sell	Trade price
QuoteBar		Buy	Aggregate price < combo limit price	Buy	Ask low price
QuoteBar		Buy	Aggregate price < combo limit price	Sell	Bid low price
QuoteBar		Sell	Aggregate price > combo limit price	Buy	Ask high price
QuoteBar		Sell	Aggregate price > combo limit price	Sell	Bid high price
TradeBar		Buy	Aggregate price < combo limit price	Buy or sell	Low price
TradeBar		Sell	Aggregate price > combo limit price	Buy or sell	High price

The model only fills combo limit orders if the data isn't stale and all the legs can fill in the same time step after the order time step. The fill quantity of each leg is the product of the leg order quantity and the combo order quantity.

Combo Leg Limit Orders

The following table describes the fill logic of combo leg limit orders for each data format and order direction. The order direction in the table represents the order direction of the order leg, not the order direction of the combo order.

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	Ask price < limit price	min(ask price, limit price)
Tick	Quote	Sell	Bid price > limit price	max(bid price, limit price)
Tick	Trade	Buy	Trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	Trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	Ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	Bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	Low price < limit price	min(high price, limit price)
TradeBar		Sell	High price > limit price	max(low price, limit price)

The model only fills combo leg limit orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity is the product of the leg order quantity and the combo order quantity.

Supported Models

Latest Price Model

Introduction

The `LatestPriceFillModel` fills trades completely and immediately.

```
security.set_fill_model(LatestPriceFillModel())
```
PY

The fill logic of each order depends on the order type, the data format of the security subscription, and the order direction. The following tables show the fill price of each order given these factors. To determine the fill price of an order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If there is no `QuoteBar` available, it uses the OHLC prices from the `Security` object. If there is a `QuoteBar` available, the fill model gets the most recent `TradeBar` . If the `TradeBar` is more recent, it uses the `TradeBar` data. Otherwise, it uses the `QuoteBar` data.

For more information about this model, see the class reference and implementation .

Market Orders

The following table describes the fill price of market orders for each data format and order direction:

Data Format	`TickType`	Order Direction	Fill Price
`Tick`	`Quote`	Buy	quote price + slippage
`Tick`	`Quote`	Sell	quote price - slippage
`Tick`	`Trade`	Buy	trade price + slippage
`Tick`	`Trade`	Sell	trade price - slippage
`QuoteBar`		Buy	ask close price + slippage
`QuoteBar`		Sell	bid close price - slippage
`TradeBar`		Buy	close price + slippage
`TradeBar`		Sell	close price - slippage

The model only fills market orders if the exchange is open and it immediately fills them. If your algorithm places a market order at 10 AM, it fills at 10 AM.

Limit Orders

The following table describes the fill logic of limit orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	low price < limit price	min(high price, limit price)
TradeBar		Sell	high price > limit price	max(low price, limit price)

The model won't fill limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Limit if Touched Orders

The model converts a limit if touched order to a limit order when the trigger condition is met. The following table describes the trigger condition of limit if touched orders for each data format and order direction:

Data Format	TickType	Order Direction	Trigger Condition
Tick	Quote	Buy	quote price <= trigger price
Tick	Quote	Sell	quote price >= trigger price
Tick	Trade	Buy	trade price <= trigger price
Tick	Trade	Sell	trade price >= trigger price
TradeBar		Buy	low price <= trigger price
TradeBar		Sell	high price >= trigger price

Once the limit if touched order triggers, to fill the order, the model checks the bid price for buy orders and the ask price for sell orders.

To get the bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

Buy orders fill when the bid price <= limit price and sell orders fill when the ask price >= limit price. The order fills at the limit price. The model won't trigger or fill limit if touched orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Market Orders

The following table describes the fill logic of stop market orders for each data format and order direction. Once the stop condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	max(stop price, quote price + slippage)
Tick	Quote	Sell	quote price < stop price	min(stop price, quote price - slippage)
Tick	Trade	Buy	trade price > stop price	max(stop price, last trade price + slippage)
Tick	Trade	Sell	trade price < stop price	min(stop price, last trade price - slippage)
QuoteBar		Buy	ask high price > stop price	max(stop price, ask close price + slippage)
QuoteBar		Sell	bid low price < stop price	min(stop price, bid close price - slippage)
TradeBar		Buy	high price > stop price	max(stop price, close price + slippage)
TradeBar		Sell	low price < stop price	min(stop price, close price - slippage)

The model only fills stop market orders when the exchange is open.

The model won't fill stop market orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Limit Orders

The following table describes the fill logic of stop limit orders for each data format and order direction. Once the stop condition is met, the model starts to check the fill condition. Once the fill condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price < stop price	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price > stop price	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price < stop price	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask high price > stop price	ask close price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid low price < stop price	bid close price > limit price	max(bid low price, limit price)
TradeBar		Buy	high price > stop price	close price < limit price	min(high price, limit price)
TradeBar		Sell	low price < stop price	close price > limit price	max(low price, limit price)

The model won't fill stop limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Trailing Stop Orders

The following table describes the fill logic of trailing stop orders for each data format and order direction. Once the stop condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	max(stop price, quote price + slippage)
Tick	Quote	Sell	quote price < stop price	min(stop price, quote price - slippage)
Tick	Trade	Buy	trade price > stop price	max(stop price, last trade price + slippage)
Tick	Trade	Sell	trade price < stop price	min(stop price, last trade price - slippage)
QuoteBar		Buy	ask high price > stop price	max(stop price, ask close price + slippage)
QuoteBar		Sell	bid low price < stop price	min(stop price, bid close price - slippage)
TradeBar		Buy	high price > stop price	max(stop price, close price + slippage)
TradeBar		Sell	low price < stop price	min(stop price, close price - slippage)

While the stop condition is not met, the model updates the stop price under certain conditions. The following table shows the update condition and stop price value for currency-based trailing amounts:

Data Format	TickType	Order Direction	Update Condition	Stop Price
Tick	Quote	Buy	stop price - quote price <= trailing amount	quote price + trailing amount
Tick	Quote	Sell	quote price - stop price <= trailing amount	quote price - trailing amount
Tick	Trade	Buy	stop price - trade price <= trailing amount	trade price + trailing amount
Tick	Trade	Sell	trade price - stop price <= trailing amount	trade price - trailing amount
QuoteBar		Buy	stop price - ask low price <= trailing amount	ask low price + trailing amount
QuoteBar		Sell	bid high price - stop price <= trailing amount	bid high price - trailing amount
TradeBar		Buy	stop price - low price <= trailing amount	low price + trailing amount
TradeBar		Sell	high price - stop price <= trailing amount	high price - trailing amount

The following table shows the update condition and stop price value for percentage-based trailing amounts.

Data Format	TickType	Order Direction	Update Condition	Stop Price
Tick	Quote	Buy	stop price - quote price <= quote price * trailing amount	quote price * (1 + trailing amount)
Tick	Quote	Sell	quote price - stop price <= quote price * trailing amount	quote price * (1 - trailing amount)
Tick	Trade	Buy	stop price - trade price <= trade price * trailing amount	trade price * (1 + trailing amount)
Tick	Trade	Sell	trade price - stop price <= trade price * trailing amount	trade price * (1 - trailing amount)
QuoteBar		Buy	stop price - ask low price <= ask low price * trailing amount	ask low price * (1 + trailing amount)
QuoteBar		Sell	bid high price - stop price <= bid high price * trailing amount	bid high price * (1 - trailing amount)
TradeBar		Buy	stop price - low price <= stop price * trailing amount	low price * (1 + trailing amount)
TradeBar		Sell	high price - stop price <= high price * trailing amount	high price * (1 - trailing amount)

The model only fills trailing stop orders when the exchange is open.

The model won't fill trailing stop orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Open Orders

The following table describes the fill price of market on open orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask open price + slippage
QuoteBar		Sell	bid open price - slippage
TradeBar		Buy	open price + slippage
TradeBar		Sell	open price - slippage

The model won't fill market on open orders during pre-market hours.

The model won't fill market on open orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Close Orders

The following table describes the fill price of market on close orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask close price + slippage
QuoteBar		Sell	bid close price - slippage
TradeBar		Buy	close price + slippage
TradeBar		Sell	close price - slippage

The model won't fill market on close orders with stale data or data with the order timestamp to avoid look-ahead bias.

Combo Market Orders

The following table describes the fill price of combo market orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	Ask quote price + slippage
Tick	Quote	Sell	Bid quote price - slippage
Tick	Trade	Buy	Trade price + slippage
Tick	Trade	Sell	Trade price - slippage
QuoteBar		Buy	Ask close price + slippage
QuoteBar		Sell	Bid close price - slippage
TradeBar		Buy	Close price + slippage
TradeBar		Sell	Close price - slippage

The model only fills combo market orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity of each leg is the product of the leg order quantity and the combo market order quantity.

Combo Limit Orders

To fill combo limit orders, the fill model calculates the aggregate price of the combo order, which is the sum of prices for each security in the order legs. The price of each security is a function of the data format and order direction. Legs with a positive order quantity increase the aggregate price and legs with a negative quantity decrease the aggregate price. The following table shows how the fill model calculates the security prices.

Data Format	TickType	Combo Order Direction	Leg Order Direction	Price
Tick	Quote	Buy or sell	Buy	Ask price
Tick	Quote	Buy or sell	Sell	Bid price
Tick	Trade	Buy or sell	Buy or sell	Trade price
QuoteBar		Buy	Buy	Ask low price
QuoteBar		Buy	Sell	Bid low price
QuoteBar		Sell	Buy	Ask high price
QuoteBar		Sell	Sell	Bid high price
TradeBar		Buy	Buy or sell	Low price
TradeBar		Sell	Buy or sell	High price

After the fill model calculates the aggregate price of the combo order, it checks if it should fill the order. The following table describes the fill condition of the combo order and the fill price price of each leg:

Data Format	TickType	Combo Order Direction	Fill Condition	Leg Order Direction	Fill Price
Tick	Quote	Buy	Aggregate price < combo limit price	Buy or sell	Quote price
Tick	Quote	Sell	Aggregate price > combo limit price	Buy or sell	Quote price
Tick	Trade	Buy	Aggregate price < combo limit price	Buy or sell	Trade price
Tick	Trade	Sell	Aggregate price > combo limit price	Buy or sell	Trade price
QuoteBar		Buy	Aggregate price < combo limit price	Buy	Ask low price
QuoteBar		Buy	Aggregate price < combo limit price	Sell	Bid low price
QuoteBar		Sell	Aggregate price > combo limit price	Buy	Ask high price
QuoteBar		Sell	Aggregate price > combo limit price	Sell	Bid high price
TradeBar		Buy	Aggregate price < combo limit price	Buy or sell	Low price
TradeBar		Sell	Aggregate price > combo limit price	Buy or sell	High price

The model only fills combo limit orders if the data isn't stale and all the legs can fill in the same time step after the order time step. The fill quantity of each leg is the product of the leg order quantity and the combo order quantity.

Combo Leg Limit Orders

The following table describes the fill logic of combo leg limit orders for each data format and order direction. The order direction in the table represents the order direction of the order leg, not the order direction of the combo order.

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	Ask price < limit price	min(ask price, limit price)
Tick	Quote	Sell	Bid price > limit price	max(bid price, limit price)
Tick	Trade	Buy	Trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	Trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	Ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	Bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	Low price < limit price	min(high price, limit price)
TradeBar		Sell	High price > limit price	max(low price, limit price)

The model only fills combo leg limit orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity is the product of the leg order quantity and the combo order quantity.

Reality Modeling

Slippage

Slippage

Key Concepts

Introduction

Slippage is the difference between the fill price you expect to get for an order and the actual fill price. Since the price can move in the direction of your trade or against the direction of your trade while you wait for the order to fill, slippage can be positive or negative. Slippage models model slippage to make backtest results more realistic.

Factors Impacting Slippage

There are many factors that can impact slippage, including the trading engine, brokerage connection, and market dynamics.

Trading Engine

How long does it take from when you place an order to when it's sent to the brokerage? Longer delays lead to more slippage.

Brokerage Connection

How long does it take for your brokerage to receive an order that you send? Slow internet connections, long travel distances, and poor infrastructure lead to more slippage

Market Dynamics

How volatile is the current market environment? More volatility leads to more slippage.

Does the market consist of sophisticated microsecond arbitrageurs? If your order creates an arbitrage opportunity, it can cause more slippage.

Set Models

The brokerage model of your algorithm automatically sets the slippage model for each security, but you can override it. To manually set the slippage model of a security, call the `set_slippage_model` method on the `Security` object.

```py
def initialize(self) -> None:
    security = self.add_equity("SPY")
    # Set the slippage model for the requested security to backtest with the most realistic scenario
    # VolumeShareSlippageModel has slippage size affected by the volume of the order compared to the actual filled volume of the bar
    # It is only valid for the security with a volume property, while being more accurate with denser resolution
    security.set_slippage_model(VolumeShareSlippageModel())
```

You can also set the slippage model in a security initializer . If your algorithm has a dynamic universe, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `add_security_initializer` before you create the subscriptions.

```py
class AddSecurityInitializerExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the security initializer to set models of assets.
        self.add_security_initializer(self._custom_security_initializer)

    def _custom_security_initializer(self, security: Security) -> None:
        # Overwrite some of the reality models
        security.set_slippage_model(VolumeShareSlippageModel())
```

To view all the pre-built slippage models, see Supported Models .

Default Behavior

The brokerage model of your algorithm automatically sets the slippage model of each security. The default brokerage model is the `DefaultBrokerageModel`, which uses the NullSlippageModel to model zero slippage for all securities.

Model Structure

Slippage models should implement the `ISlippageModel` interface. Extensions of the `ISlippageModel` interface must implement the `get_slippage_approximation` method, which calculates the slippage quantity.

```
PY
class CustomSlippageModelExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the custom slippage model for an added security to use the custom model
        security = self.add_equity("SPY")
        security.set_slippage_model(MySlippageModel())

# Define the custom slippage model
class MySlippageModel:

    def get_slippage_approximation(self, asset: Security, order: Order) -> float:
        return asset.price * 0.0001 * np.log10(2*float(order.absolute_quantity))
```

Examples

The following examples demonstrate some common practices for implementing a custom slippage model.

Example 1: Logarithmic Scaling

The following algorithm defines a custom slippage model where the slippage increases logarithmically with order size, scaled by 0.01% of the asset price, modeling realistic market impact where larger orders have diminishing marginal price impact.

```
PY
class CustomSlippageModelAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        security = self.add_equity('SPY', Resolution.DAILY)
        security.set_slippage_model(MySlippageModel())

    def on_data(self, data: Slice) -> None:
        if not self.portfolio.invested:
            self.set_holdings('SPY', 1)

class MySlippageModel:

    def get_slippage_approximation(self, asset: Security, order: Order) -> float:
        return asset.price * 0.0001 * np.log10(2*float(order.absolute_quantity))
```

Example 2: Volume Ratio Capped Slippage Model

The following algorithm trades the microeconomic demand popularity gap between the top 10 and bottom 10 liquid constituents of QQQ. A custom slippage model simulates the slippage on less liquid stock fills. The slippage percent is set to be 2% multiplied by the ratio of the order quantity to the previous minute bar's volume, maximized at 2%.

```py
class RealityModelingSlippageAlgorithm(QCAlgorithm):
    longs = []
    shorts = []

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.settings.seed_initial_prices = True
        self.add_security_initializer(self._custom_security_initializer)

        # Request extended market hour QQQ data for trading.
        qqq = self.add_equity("QQQ").symbol

        # Weekly portfolio updating to allow time to capitalize on the popularity gap.
        self.universe_settings.schedule.on(self.date_rules.week_start())
        # Add universe to trade on the most and least liquid stocks among QQQ constituents.
        self.add_universe(
            self.universe.etf(qqq, Market.USA, self.universe_settings, lambda constituents: [c.symbol for c in constituents]),
            self.fundamental_selection
        )

        # Set a scheduled event to rebalance the portfolio at the start of every week.
        self.schedule.on(
            self.date_rules.every_day(qqq),
            self.time_rules.after_market_open(qqq),
            self.rebalance
        )

    def fundamental_selection(self, fundamentals: List[Fundamental]) -> List[Symbol]:
        sorted_by_dollar_volume = sorted(fundamentals, key=lambda f: f.dollar_volume)
        # Add the 10 most liquid stocks to the universe to long later.
        self.longs = [f.symbol for f in sorted_by_dollar_volume[-10:]]
        # Add the 10 least liquid stocks to the universe to short later.
        self.shorts = [f.symbol for f in sorted_by_dollar_volume[:10]]

        return self.longs + self.shorts

    def rebalance(self) -> None:
        # Equally invest in the selected stocks to dissipate capital risk evenly.
        # Dollar neutral of long and short stocks to eliminate systematic risk, only capitalize the popularity gap.
        targets = [PortfolioTarget(symbol, 0.05) for symbol in self.longs]
        targets += [PortfolioTarget(symbol, -0.05) for symbol in self.shorts]

        # Liquidate the stocks that are not the most and least popular to release funds for trades with higher expected returns.
        self.set_holdings(targets, liquidate_existing_holdings=True)

    def _custom_security_initializer(self, security):
        # To set the slippage model to the custom one for all stocks entering the universe.
        security.set_slippage_model(CustomSlippageModel())

class CustomSlippageModel:
    def get_slippage_approximation(self, asset: Security, order: Order) -> float:
        # We set a maximum 2% slippage that is linearly linked to the ratio of the order size versus the previous bar's volume.
        return asset.price * 0.02 * min(1, order.absolute_quantity / asset.volume)
```

Other Examples

For more examples, see the following algorithms:

Demonstration Algorithms
CustomModelsAlgorithm.py Python

Slippage

Supported Models

Introduction

This page describes the pre-built slippage models in LEAN. If none of these models perform exactly how you want, create a custom slippage model .

Null Model

The `NullSlippageModel` sets the slippage of each order to zero. It's the default slippage model of the DefaultBrokerageModel .

```
security.set_slippage_model(NullSlippageModel.INSTANCE)
```

PY

For more information about this model, see the class reference and implementation .

Constant Model

The `ConstantSlippageModel` applies a constant percentage of slippage to each order.

```
security.set_slippage_model(ConstantSlippageModel(0.01))
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`slippage_percent`	`float`	The slippage percent for each order. The value must be in the interval (0, 1).	

For more information about this model, see the class reference and implementation .

Volume Share Model

The `VolumeShareSlippageModel` calculates the slippage of each order by multiplying the price impact constant by the square of the ratio of the order to the total volume. If the volume of the current bar is zero, the slippage percent is

$$volumeLimit^2 * priceImpact$$

where volumeLimit and priceImpact are custom input variables. If the volume of the current bar is positive, the slippage percent is

$$\min(\frac{|orderQuantity|}{barVolume}, volumeLimit)^2 * priceImpact$$

where orderQuantity is the quantity of the order and barVolume is the volume of the current bar. If the security subscription provides `TradeBar` data, the barVolume is the volume of the current bar. If the security subscription provides `QuoteBar` data, the barVolume is the bid or ask size of the current bar. CFD, Forex, and Crypto data often doesn't include volume. If there is no volume reported for these asset classes, the model returns zero slippage.

```
security.set_slippage_model(VolumeShareSlippageModel())
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`volume_limit`	`float`	Maximum percent of historical volume that can fill in each bar. 0.5 means 50% of historical volume. 1.0 means 100%.	0.025
`price_impact`	`float`	Scaling coefficient for price impact. Larger values will result in more simulated price impact. Smaller values will result in less simulated price impact.	0.1

For more information about this model, see the class reference and implementation .

Market Impact Model

The `MarketImpactSlippageModel` calculates the slippage with perspective to the market impact created by an order, which mimics the consumption of the order book and disruption of the supply-demand relationship at the microeconomic scale. The model is divided into distinct parts, the market impact estimation and the slippage that results from it.

Factors to Consider

The model includes factors that create market impact. Almgren, Thum, Hauptmann & Li (2005) suggested the following factors:

1. Execution Time

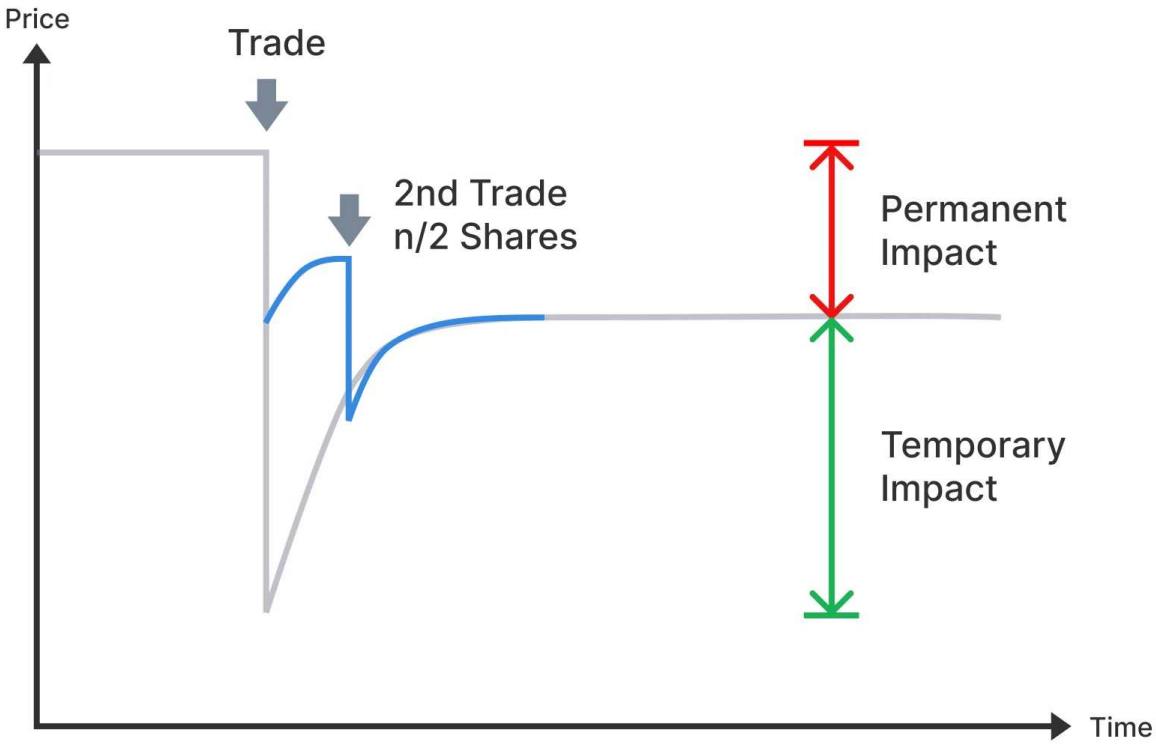
   Asset price time series is usually considered as Random walk (with/without drift) $S_t = S_{t-1} + f(S, t) + \epsilon$ or Brownian Motion $S_t = S_0 + exp((\mu-\frac{1}{2}\sigma^2)t + \sigma W_t)$ In either model, the variance of predictions increases over time ($Var(S)=\sigma\sqrt{t}$). In fact, this happens to most stock price models. Thus, time uncertainty should also apply to the concept of slippage. The longer it takes to go from order submission to execution, the further the fill price will be from the price at order submission.

2. Volatility of the Underlying Securities

   Like (1), the volatility also contributes to the uncertainty of the next price ($Var(S)=\sigma\sqrt{t}$). In most cases, volatility has a one-sided impact since the market's volatility is often introduced by overbuying or overselling from positive or negative sentiments.

3. Liquidity

   Liquidity plays a crucial role in the supply-demand resilience. When a stock is liquid, an order usually only takes a small fraction of the market depth. Hence, the gap between the bid and ask price can be refilled quickly due to high market participation and a small gap. However, when a stock is illiquid, a single order might already take the top few layers of the order book, creating a wide gap between the bid and ask price and volume, which makes a bigger shift in the equilibrium price. This will create an impact which is permanent in nature.

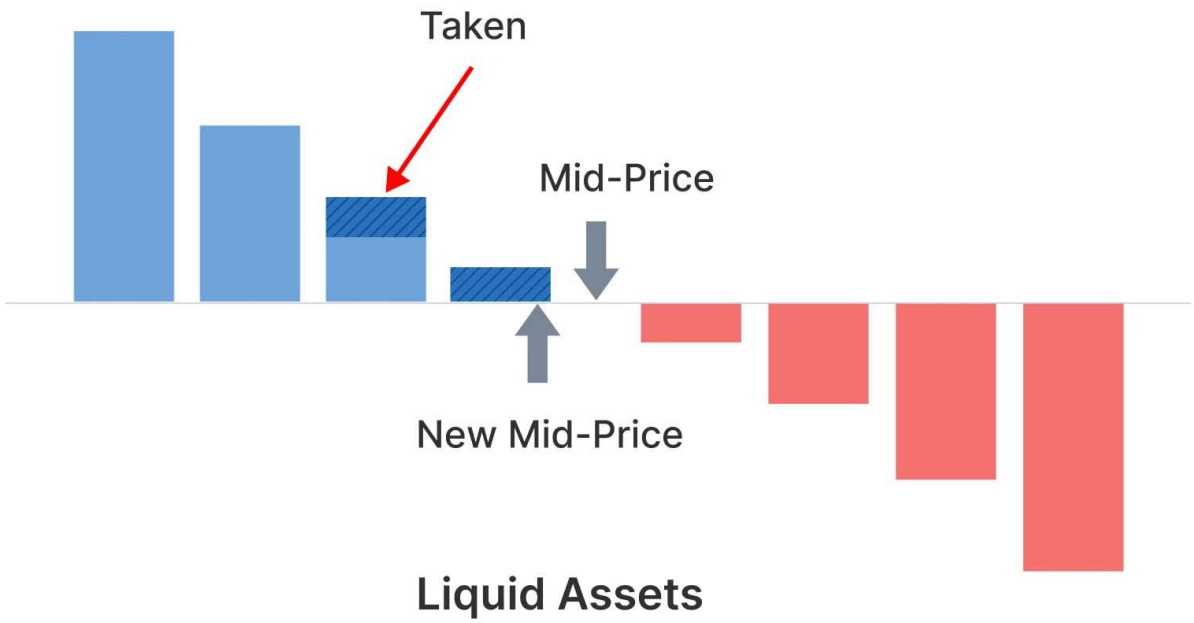


4. Order Size

   Last but not least, the order size directly affects the proportion of the order book/liquidity that the order consumes. Moreover, the larger the order is, the longer it takes to fill since the market might not have sufficient depth. This has interaction effects with the preceding factors.

Market Impact Decomposition

In the book "A Signal Processing Perspective on Financial Engineering", Feng & Palomer (2015) generalized scholars' opinions that market impact can be broken down into "permanent" and "temporary" components, with noise. The permanent impact of a trade refers to the price differences between equilibrium prices before and after the trade and the resilience of the order book. In contrast, temporary impact refers to the price difference between the instant price drop after a trade and the post-trade equilibrium.



Liquid Assets

Illiquid Assets

The model incorporates the preceding factors and estimates both the permanent and temporary impact components with two diffusion models as a function of $\nu=\frac{X}{VT}$, which is the normalized order size: $G\left(\nu\right)=\pm\gamma\left|\nu\right|^\alpha+\text{noise}$ $H\left(\nu\right)=\pm\eta\left|\nu\right|^\beta+\text{noise}$ where X is the order quantity, V is the average daily volume, and T is the time difference between order submission and filling (execution time). The other symbols are parameters that are calibrated from historical trade data. Together with the execution time, daily volatility σ, and liquidity factor δ, the complete models are as follows: $I=\sigma T \gamma\left|\frac{X}{VT}\right|^\alpha\left(\frac{\Theta}{V}\right)^\delta+\sigma\sqrt{T_{\text{post}}}\epsilon$ $J=\sigma T \eta\left|\frac{X}{VT}\right|^\beta+\sigma\sqrt{T_{\text{post}}}\epsilon$ where Θ is the share outstanding, T_{post} is the time difference between order

submission and the new equilibrium established, I is the permanent market impact, and J is the temporary market impact. The inverse of the turnover rate $\frac{\Theta}{V}$ contributes to the permanent impact. This relationship is reasonable since higher turnover means more market participants are in the market, so the order book depth is deeper.

Implementation

```
security.set_slippage_model(MarketImpactSlippageModel(self))
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`algorithm`	`IAlgorithm`	The algorithm instance	
`non_negative`	`bool`	Indicator whether only non-negative slippage allowed.	`True`
`latency`	`float`	Seconds between order submission and order fill	0.075
`impact_time`	`float`	Seconds between order fill and the establishment of the new equilibrium	1800
`alpha`	`float`	Exponent of the permanent impact function	0.891
`beta`	`float`	Exponent of the temporary impact function	0.600
`gamma`	`float`	Coefficient of the permanent impact function	0.314
`eta`	`float`	Coefficient of the temporary impact function	0.142
`delta`	`float`	Liquidity scaling factor for permanent impact	0.267
`random_seed`	`int`	Random seed for generating gaussian noise	50

The default parameters of the `MarketImpactSlippageModel` are the parameters that the authors calibrated and shared. However, you may want to reference the original paper and recalibrate the parameters because of the following reasons:

- The default parameters are calibrated around 2 decades ago
- The trading time effect is not accounted (volume near market open/close is larger)
- The market environment does not have many market makers at that time

For more information about this model, see the class reference and implementation .

Reality Modeling

Transaction Fees

Transaction Fees

Key Concepts

Introduction

Your orders incur a transaction fee when a brokerage fills them in the market. LEAN uses transaction fee models in backtesting to model the live trading fees you would incur with the strategy. Transaction fee models make backtest results more realistic. To give your backtests the most accurate fees, LEAN contains transaction fee models that model the fee structure of many popular brokerages.

Set Models

The brokerage model of your algorithm automatically sets the fee model for each security, but you can override it. To manually set the fee model of a security, call the `set_fee_model` method on the `Security` object.

```
PY
def initialize(self):
    security = self.add_equity("SPY")
    # Set the fee model for the requested security to backtest with the most realistic scenario
    # Constant fee model of 0 dollar is accurate for the commission-free brokerage
    security.set_fee_model(ConstantFeeModel(0))
```

You can also set the fee model in a security initializer . If your algorithm has a dynamic universe, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `add_security_initializer` before you create the subscriptions.

```
PY
class AddSecurityInitializerExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the security initializer to set models of assets.
        self.add_security_initializer(self._custom_security_initializer)

    def _custom_security_initializer(self, security: Security) -> None:
        # Overwrite some of the reality models
        security.set_fee_model(ConstantFeeModel(0))
```

In live trading, the `set_fee_model` method isn't ignored. If we use order helper methods like `set_holdings` , the fee model helps to calculate the order quantity. However, the algorithm doesn't update the cash book with the fee from the fee model. The algorithm uses the actual fee from the brokerage to update the cash book.

To view all the pre-built fee models, see Supported Models .

Default Behavior

The brokerage model of your algorithm automatically sets the fill model for each security. The default brokerage model is the `DefaultBrokerageModel` , which set the ConstantFeeModel with no fees for Forex, CFD, and Crypto assets and sets the InteractiveBrokersFeeModel for the remaining asset classes.

Model Structure

Fee models should extend the `FeeModel` class. Extensions of the `FeeModel` class must implement the `get_order_fee` method, which receives `OrderFeeParameters` and returns an `OrderFee` that represents a cash amount in a currency.

```py
class CustomFeeModelExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the custom fee model for an added security to use the custom model
        security = self.add_equity("SPY")
        security.set_fee_model(MyFeeModel())

# Define the custom fee model
class MyFeeModel(FeeModel):

    def get_order_fee(self, parameters: OrderFeeParameters) -> OrderFee:
        return OrderFee(CashAmount(0.5, 'USD'))
```

The `OrderFeeParameters` object has the following members:

Zero Transaction Fees

To model zero transaction fees, use the ConstantFeeModel with zero as `fee` and specify the `currency` .

```py
def initialize(self):
    security = self.add_equity("SPY")
    security.set_fee_model(ConstantFeeModel(fee=0, currency="USD"))
```

Negative Transaction Fees

If you short a security and receive interest payments, they are negative transaction fees.

Examples

The following examples demonstrate common practices for implementing a custom fee model.

Example 1: Fixed Fees

The following algorithm incurs a $0.50 fee for each order.

```py
class CustomFeeModelAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        security = self.add_equity('SPY', Resolution.DAILY)
        security.set_fee_model(MyFeeModel())

    def on_data(self, data: Slice) -> None:
        if not self.portfolio.invested:
            self.set_holdings('SPY', 1)

class MyFeeModel(FeeModel):

    def get_order_fee(self, parameters: OrderFeeParameters) -> OrderFee:
        return OrderFee(CashAmount(0.5, 'USD'))
```

Other Examples

For more examples, see the following algorithms:

Demonstration Algorithms
CustomModelsAlgorithm.py Python RawPricesCoarseUniverseAlgorithm.py Python

Transaction Fees

Supported Models

Introduction

This page describes some of the pre-built fee models in LEAN. For more brokerage-specific fee models, see the brokerage model documentation . If none of these models perform exactly how you want, create a custom fee model .

Constant Model

The `ConstantFeeModel` applies the absolute value of a constant fee to each order. It's the default fee model of the DefaultBrokerageModel if you trade Forex, CFD, or Crypto assets. Use this model to set zero transaction fees .

```
security.set_fee_model(ConstantFeeModel(0.05))
```
PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`fee`	`float`	The order fee quantity	
`currency`	`str`	The order fee currency	"USD"

For more information about this model, see the class reference and implementation .

Alpaca Model

The `AlpacaFeeModel` models the fees of Alpaca .

```
security.set_fee_model(AlpacaFeeModel())
```
PY

The `AlpacaFeeModel` charges zero fees for Equity and Equity Options trading. For Crypto trades, it charges a 0.15% maker and 0.25% taker fee. If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. Alpaca adjusts your fees based on your 30-day trading volume, but we don't currently model these metrics to adjust fees.

The `AlpacaFeeModel` charges fees in the currency you receive from a trade. For example, if you buy ETHBTC, you pay fees in ETH. If you sell ETHBTC, you pay fees in BTC.

For more information about this model, see the class reference and implementation .

Binance Model

The `BinanceFeeModel` models the fees of spot trades on Binance and Binance US .

```
security.set_fee_model(BinanceFeeModel())
```
PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`m_fee`	`float`	Maker fee value	0.001
`t_fee`	`float`	Taker fee value	0.001

The `BinanceFeeModel` charges the order fees of Binance and Binance US at the VIP 0 level, which is a 0.1% maker and taker fee. If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. Binance adjusts your fees based on your 30-day trading volume and BNB balance, but we don't currently model these metrics to adjust fees.

The `BinanceFeeModel` charges fees in the currency you receive from a trade. For example, if you buy ETHBTC, you pay fees in ETH. If you sell ETHBTC, you pay fees in BTC.

For more information about this model, see the class reference and implementation .

Binance Futures Model

The `BinanceFuturesFeeModel` models the Binance Futures live trading fees .

```
security.set_fee_model(BinanceFuturesFeeModel())
```
PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`m_usdt_fee`	`float`	Maker fee value for USDT pair contracts	0.0002
`t_usdt_fee`	`float`	Taker fee value for USDT pair contracts	0.0004
`m_busd_fee`	`float`	Maker fee value for BUSD pair contracts	0.00012
`t_busd_fee`	`float`	Taker fee value for BUSD pair contracts	0.00036

By default, the `BinanceFuturesFeeModel` charges the order fees of Binance Futures at the Regular User level. If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. Binance adjusts your fees based on your 30-day trading volume and BNB balance, but we don't currently model these metrics to adjust fees.

The `BinanceFuturesFeeModel` charges fees in the currency you receive from a trade. For example, if you buy BTCUSD, you pay fees in BTC. If you sell BTCUSD, you pay fees in USD.

For more information about this model, see the class reference and implementation .

Binance Coin Futures Model

The `BinanceCoinFuturesFeeModel` models the Binance Coin Futures live trading fees .

```
security.set_fee_model(BinanceCoinFuturesFeeModel())
```
PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`m_fee`	`float`	Maker fee value	0.0001
`t_fee`	`float`	Taker fee value	0.0005

By default, the `BinanceCoinFuturesFeeModel` charges the order fees of Binance Coin Futures at the Regular User level. If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. Binance adjusts your fees based on your 30-day trading volume and BNB balance, but we don't currently model these metrics to adjust fees.

The `BinanceCoinFuturesFeeModel` charges fees in the currency you receive from a trade. For example, if you buy BTCUSDT, you pay fees in BTC. If you sell BTCUSDT, you pay fees in USDT.

For more information about this model, see the class reference and implementation .

Bitfinex Model

The `BitfinexFeeModel` models the Bitfinex live trading fees .

```
PY
security.set_fee_model(BitfinexFeeModel())
```

The `BitfinexFeeModel` charges a 0.1% maker fee and a 0.2% taker fee. If you place a limit order that hits a hidden order or you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you place a hidden order or you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. Bitfinex adjusts your fees based on your 30-day trading volume and LEO balance, but we don't currently model these metrics to adjust fees.

The `BitfinexFeeModel` charges fees in the currency you receive from a trade. For example, if you buy ETHBTC, you pay fees in ETH. If you sell ETHBTC, you pay fees in BTC.

For more information about this model, see the class reference and implementation .

Bybit Model

The `BybitFeeModel` models the Bybit live trading fees .

```
PY
security.set_fee_model(BybitFeeModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`m_fee`	`float`	Maker fee value	0.001
`t_fee`	`float`	Taker fee value	0.001

The `BybitFeeModel` charges the order fees of Bybit at the VIP 0 level, which is a 0.1% maker and taker fee for spot trades. If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. Bybit adjusts your fees based on your 30-day trading volume, net borrowings, or asset balance, but we don't currently model these metrics to adjust fees. Bybit also charges different fees for fiat-Crypto pairs, (for example, USDT/EUR), but the `BybitFeeModel` charges the same fee rate for all pairs.

The `BybitFeeModel` charges fees in the currency you receive from a trade. For example, if you buy ETHBTC, you pay fees in ETH. If you sell ETHBTC, you pay fees in BTC.

For more information about this model, see the class reference and implementation .

Bybit Futures Model

The `BybitFuturesFeeModel` models the Bybit live trading fees .

```
PY
security.set_fee_model(BybitFuturesFeeModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`maker_fee`	`float`	Maker fee value	0.0002
`taker_fee`	`float`	Taker fee value	0.00055

The `BybitFuturesFeeModel` charges the order fees of Bybit at the VIP 0 level, which is a 0.02% maker and a 0.055% taker fee for Crypto Futures trades. If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. Bybit adjusts your fees based on your 30-day trading volume, net borrowings, or asset balance, but we don't currently model these metrics to adjust fees.

The `BybitFuturesFeeModel` charges fees in the currency you receive from a trade. For example, if you buy BTCUSDT, you pay fees in BTC. If you sell BTCUSDT, you pay fees in USDT.

For more information about this model, see the class reference and implementation .

Charles Schwab Model

The `CharlesSchwabFeeModel` models the fees of Charles Schwab .

```
security.set_fee_model(CharlesSchwabFeeModel())
```
PY

The `CharlesSchwabFeeModel` charges $0 USD for Equity trades.

For more information about this model, see the class reference and implementation .

Coinbase Model

The `CoinbaseFeeModel` models the Coinbase live trading fees .

```
security.set_fee_model(CoinbaseFeeModel())
```
PY

The `CoinbaseFeeModel` models the order fees of Coinbase at the $50K-100K pricing tier for all Crypto pairs, so it charges a 0.6% maker and a 0.8% taker fee for most pairs. The following table shows the Coinbase Stable Pairs, which charge a 0% maker fee and a 0.001% taker fee:

Stable Pairs			
DAIUSDC	DAIUSD	GYENUSD	PAXUSD
PAXUSDT	MUSDUSD	USDCEUR	USDCGBP
USDTEUR	USDTGBP	USDTUSD	USDTUSDC
USTEUR	USTUSD	USTUSDT	WBTCBTC

If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. Coinbase adjusts your fees based on your 30-day trading volume, but we don't currently model trading volume to adjust fees.

The `CoinbaseFeeModel` models the adjustments Coinbase has made to their fees over time. The following table shows the fees for each time period:

Time Period (UTC)	Maker Fee (%)	Taker Fee (%)	Stable Coin
Time < 3/23/2019 1:30AM	0	0.3	
3/23/2019 1:30AM <= Time < 10/8/2019 12:30AM	0.15	0.25	
10/8/2019 12:30AM <= Time	0.5	0.5	
Time < 6/1/2022 3/23/2019 12:00AM	0	0.1%	✓

The `CoinbaseFeeModel` charges fees in the quote currency .

For more information about this model, see the class reference and implementation .

dYdX Model

The `dYdXFeeModel` models the dYdX live trading fees .

```
security.set_fee_model(dYdXFeeModel())
```

The `dYdXFeeModel` models the order fees of dYdX at the lowest pricing tier for all Cryptofuture pairs, so it charges a 0.01% maker and a 0.05% taker fee.

If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. dYdX adjusts your fees based on your 30-day trading volume, but we don't currently model trading volume to adjust fees.

The `dYdXFeeModel` charges fees in the quote currency .

For more information about this model, see the class reference and implementation .

Interactive Brokers Model

The `InteractiveBrokersFeeModel` models the fees of Interactive Brokers .

```
security.set_fee_model(InteractiveBrokersFeeModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`monthly_forex_trade_amount_in_us_dollars`	`float`	Monthly Forex dollar volume traded	0
`monthly_options_trade_amount_in_contracts`	`float`	Monthly Option contracts traded	0

The following table describes which currency the `InteractiveBrokersFeeModel` charges fees in for each asset class:

Asset Class	Fee Currency
US Equity	USD
India Equity	INR
Equity Options	USD
Forex	USD
US Futures	USD
Hong Kong Futures	The contract quote currency (CNH, HKD, or USD)
US Future Options	USD
Hong Kong Future Options	The contract quote currency (CNH, HKD, or USD)
Index Options	USD
CFD	The contract quote currency

The following sections describe the trading fees of each asset class.

For more information about this model, see the class reference and implementation .

US Equities

US Equity trades cost 0.005/share with a 1 minimum fee and a 0.5% maximum fee.

Equity Options and Index Options

Equity Options and Index Options fees are a function of your monthly volume and the premium of the contract you trade. The following table shows the fees for each volume tier:

Monthly Volume (Contacts)	Premium ($)	Fee per Contract ($)
<= 10,000	< 0.05	0.25
<= 10,000	0.05 <= premium < 0.10	0.50
<= 10,000	>= 0.10	0.70
10,000 < volume <= 50,000	< 0.05	0.25
10,000 < volume <= 50,000	>= 0.05	0.50
50,000 < volume <= 100,000	Any	0.25
> 100,000	Any	0.15

By default, LEAN models your fees at the tier with the lowest monthly volume. To adjust the fee tier, manually set the fee model and provide a `monthly_options_trade_amount_in_contracts` argument.

The following table shows how the model determines the premium for each order type and direction:

Order Type	Buy Order Premium	Sell Order Premium
Market	Bid price	Ask price
Limit	Limit price	Limit price
Limit if touched	Limit price	Limit price
Stop market	Stop price	Stop price
Stop limit	Limit price	Limit price
Trailing stop	Stop price	Stop price
Market on open	Bid price	Ask price
Market on close	Bid price	Ask price
Combo market	Bid price	Ask price
Combo limit	Limit price	Limit price
Combo leg limit	Limit price	Limit price

There is no fee to exercise Option contracts.

Forex

Forex fees are a function of your monthly Forex trading volume. The following table shows the fee tiers:

Monthly Volume (USD)	Commission Rate (%)	Minimum Fee ($)
<= 1B	0.002	2
1B < volume <= 2B	0.0015	1.5
2B < volume <= 5B	0.001	1.25
> 5B	0.0008	1

By default, LEAN models your fees at the tier with the lowest monthly volume. To adjust the fee tier, manually set the fee model and provide a `monthly_forex_trade_amount_in_us_dollars` argument.

US Futures

US Futures fees depend on the contracts you trade. The following table shows the base fee per contract for each Future:

Contract Symbol	Market	Name	Base Fee Per Contract ($)	Exchange Fee Per Contract ($)
E-mini Futures				
ES	CME	E-mini S&P 500 Futures	0.85	1.28
NQ	CME	E-mini Nasdaq-100 Futures	0.85	1.28
YM	CBOT	E-mini Dow ($5) Futures	0.85	1.28
RTY	CME	E-mini Russell 2000 Index Futures	0.85	1.28
EMD	CME	E-mini S&P MidCap 400 Futures	0.85	1.28

Micro E-mini Futures				
MYM	CBOT	Micro E-mini Dow Jones Industrial Average Index Futures	0.25	0.3
M2K	CME	Micro E-mini Russell 2000 Index Futures	0.25	0.3
MES	CME	Micro E-mini Standard and Poor's 500 Stock Price Index Futures	0.25	0.3
MNQ	CME	Micro E-mini Nasdaq-100 Index Futures	0.25	0.3
2YY	CBOT	Micro 2-Year Yield Futures	0.25	0.3
5YY	CBOT	Micro 5-Year Yield Futures	0.25	0.3
10Y	CBOT	Micro 10-Year Yield Futures	0.25	0.3
30Y	CBOT	Micro 30-Year Yield Futures	0.25	0.3
MCL	NYMEX	Micro WTI Crude Oil Futures	0.25	0.3
MGC	COMEX	Micro Gold Futures	0.25	0.3
SIL	COMEX	Micro Silver Futures	0.25	0.3
Cryptocurrency Futures				
BTC	CME	Bitcoin Futures	5	6
MIB	CME	BTIC on Micro Bitcoin Futures	2.25	2.5
MBT	CME	Micro Bitcoin Futures	2.25	2.5
MET	CME	Micro Ether Futures	0.2	0.2
MRB	CME	BTIC on Micro Ether Futures	0.2	0.2
E-mini FX Futures				
E7	CME	E-mini Euro FX Futures	0.5	0.85
J7	CME	E-mini Japanese Yen Futures	0.5	0.85
Micro E-mini FX Futures				
M6E	CME	Micro Euro/U.S. Dollar (EUR/USD) Futures	0.15	0.24
M6A	CME	Micro Australian Dollar/U.S. Dollar (AUD/USD) Futures	0.15	0.24
M6B	CME	Micro British Pound Sterling/U.S. Dollar (GBP/USD) Futures	0.15	0.24

MCD	CME	Micro Canadian Dollar/U.S.Dollar(CAD/USD) Futures	0.15	0.24
MJY	CME	Micro Japanese Yen/U.S. Dollar (JPY/USD) Futures	0.15	0.24
MSF	CME	Micro Swiss Franc/U.S. Dollar (CHF/USD) Futures	0.15	0.24
M6J	CME	Micro USD/JPY Futures	0.15	0.24
MIR	CME	Micro INR/USD Futures	0.15	0.24
M6C	CME	Micro USD/CAD Futures	0.15	0.24
M6S	CME	Micro USD/CHF Futures	0.15	0.24
MNH	CME	Micro USD/CNH Futures	0.15	0.24

If you trade a contract that's not in the preceding table, the base fee is 0.85/contract and the exchange fee is 1.60/contract.

In addition to the base fee and exchange fee, there is a $0.02/contract regulatory fee.

Futures Options

Futures Options fees depend on the contracts you trade. The following table shows the base fee per contract for each Future:

Contract Symbol	Market	Underlying Futures Name	Base Fee Per Contract ($)	Exchange Fee Per Contract ($)
E-mini Futures Options				
ES	CME	E-mini S&P 500 Futures	0.85	0.55
NQ	CME	E-mini Nasdaq-100 Futures	0.85	0.55
YM	CBOT	E-mini Dow ($5) Futures	0.85	0.55
RTY	CME	E-mini Russell 2000 Index Futures	0.85	0.55
EMD	CME	E-mini S&P MidCap 400 Futures	0.85	0.55
Micro E-mini Futures Options				
MYM	CBOT	Micro E-mini Dow Jones Industrial Average Index Futures	0.25	0.2
M2K	CME	Micro E-mini Russell 2000 Index Futures	0.25	0.2
MES	CME	Micro E-mini Standard and Poor's 500 Stock Price Index Futures	0.25	0.2
MNQ	CME	Micro E-mini Nasdaq-100 Index Futures	0.25	0.2
2YY	CBOT	Micro 2-Year Yield Futures	0.25	0.2
5YY	CBOT	Micro 5-Year Yield Futures	0.25	0.2
10Y	CBOT	Micro 10-Year Yield Futures	0.25	0.2
30Y	CBOT	Micro 30-Year Yield Futures	0.25	0.2
MCL	NYMEX	Micro WTI Crude Oil Futures	0.25	0.2
MGC	COMEX	Micro Gold Futures	0.25	0.2
SIL	COMEX	Micro Silver Futures	0.25	0.2
Cryptocurrency Futures Options				
BTC	CME	Bitcoin Futures	5	5
MIB	CME	BTIC on Micro Bitcoin Futures	1.25	2.5
MBT	CME	Micro Bitcoin Futures	1.25	2.5
MET	CME	Micro Ether Futures	0.1	0.2
MRB	CME	BTIC on Micro Ether Futures	0.1	0.2

If you trade a contract that's not in the preceding table, the base fee is 0.85/contract and the exchange fee is 1.60/contract.

In addition to the base fee and exchange fee, there is a $0.02/contract regulatory fee.

CFD

CFD trades cost 0.002% of the trade value. The following table shows the minimum fee for each quote currency:

Quote Currency	Fee
JPY	¥40
MKD	HK$10
Other	1

CFD trading fees are denominated in the quote currency of the CFD product.

Kraken Model

The `KrakenFeeModel` models the fees of Kraken .

```
security.set_fee_model(KrakenFeeModel())
```

The `KrakenFeeModel` model the order fees of Kraken. For trading pairs that contain only Crypto assets, this fee model models the lowest tier in Kraken's tiered fee structure, which is a 0.16% maker fee and a 0.26% taker fee. If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. For trading pairs that have any of the following currencies as the base currency in the pair, the fee is 0.2%:

- CAD
- EUR
- GBP
- JPY
- USD
- USDT
- DAI
- USDC

The `KrakenFeeModel` charges fees in the quote currency for buy orders and in the base currency for sell orders. To override these settings, define the `KrakenOrderProperties` .

```
def initialize(self) -> None:
    # Set the default order properties
    self.default_order_properties = KrakenOrderProperties()
    self.default_order_properties.fee_in_base = True
    self.default_order_properties.fee_in_quote = False

def on_data(self, slice: Slice) -> None:
    # Override the default order properties
    order_properties = KrakenOrderProperties()
    order_properties.fee_in_quote = True
    order_properties.fee_in_base = False
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Kraken adjusts your fees based on your 30-day trading volume, but the `KrakenFeeModel` don't currently model trading volume to adjust fees.

For more information about this model, see the class reference and implementation .

Samco Model

The `SamcoFeeModel` models the fees of Samco .

```
security.set_fee_model(SamcoFeeModel())
```

The SamcoFeeModel models the order fees of Samco by its Equity Intraday fee structure. The following table shows the fees:

Charge Item	Fee
Brokerage Fee	₹20 per trade or 0.02% (whichever is lower)
Exchange Transaction Charge	0.00345%
Securities Transaction Tax	0.025%
Goods and Services Tax	18%
SEBI Charges	0.0001%
Stamp Duty	0.003%

The SamcoFeeModel charges fees in INR.

For more information about this model, see the class reference and implementation .

Tastytrade Model

The TastytradeFeeModel models the fees of Tastytrade .

```
security.set_fee_model(TastytradeFeeModel())
```
PY

The following sections describe the trading fees of each asset class.

For more information about this model, see the class reference and implementation .

US Equities

US Equity trades are free.

Equity Options

Equity Option trades cost $1 USD per contract to open a position, free to close.

Index Options

Index Option trades cost $1 USD per contract to open a position, free to close.

Futures

Futures trades cost $1.25 USD per contract.

Future Options

Future Option trades cost $2.5 USD per contract to open a position, free to close.

TradeStation Model

The TradeStationFeeModel models the fees of TradeStation .

```
security.set_fee_model(TradeStationFeeModel())
```
PY

The following sections describe the trading fees of each asset class.

For more information about this model, see the class reference and implementation .

US Equities

US Equity trades are free for US residents. For non-US residents, they cost $5 USD per order.

Equity Options

Equity Option trades cost 0.60 USD per contract. For non-US residents, they cost an extra 5 USD per order.

Index Options

Index Option trades cost 1.00 USD per contract. For non-US residents, they cost an extra 5 USD per order.

Futures

Futures trades cost $1.50 USD per contract.

Wolverine Model

The `WolverineFeeModel` models the fees of Wolverine Execution Services.

```
security.set_fee_model(WolverineFeeModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`fees_per_share`	`float` / `NoneType`	The fees per share to apply. If `None` , it uses 0.005.	`None`

The `WolverineFeeModel` charges fees in USD.

For more information about this model, see the class reference and implementation .

Zerodha Model

The `ZerodhaFeeModel` models the fees of Zerodha .

```
security.set_fee_model(ZerodhaFeeModel())
```

The `ZerodhaFeeModel` models the order fees of Zerodha with its Equity Intraday fee structure. The following table shows the fees:

Charge Item	Fee
Brokerage Fee	₹20 per trade or 0.03% (whichever is lower)
Exchange Transaction Charge	0.00345%
Securities Transaction Tax	0.025%
Goods and Services Tax	18%
SEBI Charges	0.0001%
Stamp Duty	0.003%

The `ZerodhaFeeModel` charges fees in INR.

For more information about this model, see the class reference and implementation .

Reality Modeling

Brokerages

Brokerages

Key Concepts

Introduction

Brokerages provide you with a connection to the market so you can fill trades. Brokerage models simulate the live behavior of a real brokerage. To avoid sending invalid orders for execution in live trading, the brokerage model validates your orders before LEAN sends them to the real brokerage. Brokerage models combine together all of the models relevant for a brokerage. If you set the appropriate brokerage model, the supported order types, default markets, and some of the security-level models are appropriately set in your algorithm.

Set Models

To set a brokerage model, in the `initialize` method, call the `set_brokerage_model` method with a `BrokerageName` and an `AccountType` . If you set a brokerage model, it overrides any security level models you manually set in your algorithm.

```
def initialize(self) -> None:
 # Set the brokerage model to backtest with the most realistic scenario to handle the order validity, margin rate and transaction fee
 self.set_brokerage_model(BrokerageName.OANDA_BROKERAGE) # Defaults to margin account
 self.set_brokerage_model(BrokerageName.BITFINEX, AccountType.MARGIN) # Overrides the default account type, which is AccountType.Cash
```

PY

In live trading, LEAN doesn't ignore your `set_brokerage_model` method calls. LEAN uses some of the brokerage model rules to catch invalid orders before they reach your real brokerage.

To view all the pre-built brokerage models, see Supported Models .

Default Behavior

The default brokerage model is the `DefaultBrokerageModel` , but LEAN has many other brokerage models you can use in your algorithms. For more information about the `DefaultBrokerageModel` , see QuantConnect Paper Trading .

Modeled Properties

Brokerage models model that following properties:

- Transaction fees
- Supported asset classes
- Account types
- Support for extended market hours
- Leverage for assets
- Trade settlement rules
- Order properties and updates

Model Structure

Brokerage models should extend the `DefaultBrokerageModel` class. Extensions of the `DefaultBrokerageModel` class should implement the following methods:

```py
class CustomBrokerageModelExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the custom brokerage model
        self.set_brokerage_model(MyBrokerageModel())

# Define the custom brokerage model outside of the algorithm
class MyBrokerageModel(DefaultBrokerageModel):
    default_markets = {SecurityType.EQUITY: Market.USA}
    required_free_buying_power_percent = 0

    def __init__(self, accountType: account_type = account_type.margin):
        self.account_type = accountType

    def can_submit_order(self, security: Security, order: Order,
         message: BrokerageMessageEvent) -> bool:
        return super().can_submit_order(security, order, message)

    def can_update_order(self, security: Security, order: Order,
         request: UpdateOrderRequest, message: BrokerageMessageEvent) -> bool:
        return super().can_update_order(security, order, request, message)

    def can_execute_order(self, security: Security, order: Order) -> bool:
        return super().can_execute_order(security, order)

    def apply_split(self, tickets: List[OrderTicket], split: Split) -> None:
        super().apply_split(tickets, split)

    def get_leverage(self, security: Security) -> float:
        return super().get_leverage(security)

    def get_benchmark(self, securities: SecurityManager) -> IBenchmark:
        return super().get_benchmark(securities)

    def get_fill_model(self, security: Security) -> IFillModel:
        return super().get_fill_model(security)

    def get_fee_model(self, security: Security) -> IFeeModel:
        return super().get_fee_model(security)

    def get_slippage_model(self, security: Security) -> ISlippageModel:
        return super().get_slippage_model(security)

    def get_settlement_model(self, security: Security) -> ISettlementModel:
        return super().get_settlement_model(security)

    def get_buying_power_model(self, security: Security) -> IBuyingPowerModel:
        return super().get_buying_power_model(security)

    def get_margin_interest_rate_model(self, security: Security) -> IMarginInterestRateModel:
        return super().get_margin_interest_rate_model(security)

    def get_shortable_provider(self, security: Security) -> IShortableProvider:
        return super().get_shortable_provider(security)
```

Custom brokerage models give you enormous control over your algorithm behavior and allow you to model virtually any brokerage in the world.

Live Trading Considerations

LEAN doesn't infer account type, leverage, margin requirements, or pattern day trading rules from your brokerage account. For example, if you have a cash account, and your algorithm doesn't set `AccountType.CASH`, LEAN will not automatically enforce cash account restrictions such as leverage of 1x or immediate settlement. You must manually configure your algorithm to adhere to these rules. If you set the leverage to 10x and you have a leverage of 2x, LEAN will place orders that can be rejected by your brokerage.

The default leverage of U.S. Equities is 2x. However, your brokerage can reduce the leverage of some securities based on market conditions. For example, leveraged ETFs such as TQQQ might have lower leverage during periods of high volatility. If your algorithm doesn't account for this, LEAN doesn't account for it and your orders can be rejected by your brokerage.

Examples

The following examples demonstrate common practices for implementing a custom brokerage model.

Example 1: Default Model Wrapper

The following algorithm defines a subclass of the `DefaultBrokerageModel` and overrides the built-in members so you can easily customize the parts you need.

PY

```
class CustomBrokerageModelAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.set_brokerage_model(MyBrokerageModel())
        self.add_equity('SPY', Resolution.DAILY)

    def on_data(self, data: Slice) -> None:
        if not self.portfolio.invested:
            self.set_holdings('SPY', 1)

class MyBrokerageModel(DefaultBrokerageModel):
    default_markets = {SecurityType.EQUITY: Market.USA}
    required_free_buying_power_percent = 0

    def __init__(self, account_type: AccountType = AccountType.MARGIN):
        self.account_type = account_type

    def can_submit_order(self, security: Security, order: Order,
         message: BrokerageMessageEvent) -> bool:
        return super().can_submit_order(security, order, message)

    def can_update_order(self, security: Security, order: Order,
         request: UpdateOrderRequest, message: BrokerageMessageEvent) -> bool:
        return super().can_update_order(security, order, request, message)

    def can_execute_order(self, security: Security, order: Order) -> bool:
        return super().can_execute_order(security, order)

    def apply_split(self, tickets: List[OrderTicket], split: Split) -> None:
        super().apply_split(tickets, split)

    def get_leverage(self, security: Security) -> float:
        return super().get_leverage(security)

    def get_benchmark(self, securities: SecurityManager) -> IBenchmark:
        return super().get_benchmark(securities)

    def get_fill_model(self, security: Security) -> IFillModel:
        return super().get_fill_model(security)

    def get_fee_model(self, security: Security) -> IFeeModel:
        return super().get_fee_model(security)

    def get_slippage_model(self, security: Security) -> ISlippageModel:
        return super().get_slippage_model(security)

    def get_settlement_model(self, security: Security) -> ISettlementModel:
        return super().get_settlement_model(security)

    def get_buying_power_model(self, security: Security) -> IBuyingPowerModel:
        return super().get_buying_power_model(security)

    def get_margin_interest_rate_model(self, security: Security) -> IMarginInterestRateModel:
        return super().get_margin_interest_rate_model(security)

    def get_shortable_provider(self, security: Security) -> IShortableProvider:
        return super().get_shortable_provider(security)
```

Other Examples

For more examples, see the following algorithms:

Demonstration Algorithms
BrokerageModelAlgorithm.py Python

Brokerages

Supported Models

Brokerage models combine together all of the models relevant for a brokerage. The following brokerage models are available:

QuantConnect Paper Trading

Interactive Brokers

TradeStation

Tastytrade

Alpaca

Charles Schwab

Binance

Bybit

Tradier

Kraken

Coinbase

Bitfinex

dYdX

Terminal Link

SSC Eze

Trading Technologies

Wolverine

Oanda

Live Trading Brokerages

Supported Models

QuantConnect Paper Trading

Introduction

This page explains the `DefaultBrokerageModel` , including the asset classes it supports, its default security-level models , and its default markets.

```
self.set_brokerage_model(BrokerageName.QUANT_CONNECT_BROKERAGE) # Defaults to margin account
self.set_brokerage_model(BrokerageName.QUANT_CONNECT_BROKERAGE, AccountType.MARGIN) # Overrides the default account type
```

PY

For more information about this model, see the class reference and implementation .

Asset Classes

The `DefaultBrokerageModel` supports trading for all asset classes .

Orders

The following sections describe how the `DefaultBrokerageModel` handles orders.

Order Types

The following table describes the available order types for each asset class that the `DefaultBrokerageModel` supports:

Order Type	US Equity	Equity Options	Crypto	Crypto Futures	Forex	CFD	Futures	Futures Options	Index Options
Market	✓	✓	✓	✓	✓	✓	✓	✓	✓
Limit	✓	✓	✓	✓	✓	✓	✓	✓	✓
Limit if touched	✓	✓	✓	✓	✓	✓	✓	✓	✓
Stop market	✓	✓	✓	✓	✓	✓	✓	✓	✓
Stop limit	✓	✓	✓	✓	✓	✓	✓	✓	✓
Market on open	✓	✓	✓		✓	✓			✓
Market on close	✓	✓	✓		✓	✓	✓	✓	✓
Combo market		✓						✓	✓
Combo limit		✓						✓	✓
Combo leg limit		✓						✓	✓
Exercise Option		✓ Not supported for cash-settled Options						✓	

In live trading, Option orders require a third-party data provider that supports Options. To view the data providers that support Options, see their respective documentation in Cloud Platform , Local Platform , or the CLI .

Time In Force

The `DefaultBrokerageModel` supports the following TimeInForce instructions:

- `DAY`
- `good_til_canceled`
- `good_til_date`

Updates

The `DefaultBrokerageModel` supports order updates .

Handling Splits

If you're using raw data normalization and you have active orders with a limit, stop, or trigger price in the market for a US Equity when a stock split occurs, the following properties of your orders automatically adjust to reflect the stock split:

- Quantity
- Limit price
- Stop price
- Trigger price

Fills

The following table shows the fill model that the `DefaultBrokerageModel` uses for each `SecurityType` :

`SecurityType`	**Fill Model**
`Equity`	EquityFillModel
`Future`	FutureFillModel
`FutureOption`	FutureOptionFillModel
Remaining `SecurityType` values	ImmediateFillModel

Slippage

The `DefaultBrokerageModel` uses the NullSlippageModel .

Fees

The `DefaultBrokerageModel` uses the ConstantFeeModel with no fees for Forex, CFD, Crypto, and Crypto Future assets and the InteractiveBrokersFeeModel for the remaining asset classes.

```
# For Forex, CFD, Crypto, and Crypto Future assets:
security.set_fee_model(ConstantFeeModel(0))

# For the remaining asset classes:
security.set_fee_model(InteractiveBrokersFeeModel())
```

Buying Power

The `DefaultBrokerageModel` sets the buying power model based on the asset class of the security. The following table shows the default buying power model of each asset class:

Asset Class	Model
Equity Options	`OptionMarginModel`
Futures	`FutureMarginModel`
Future Options	`FuturesOptionsMarginModel`
Index Options	`OptionMarginModel`
Crypto	`CashBuyingPowerModel` for cash accounts or `BuyingPowerModel` for margin accounts
CryptoFuture	`CryptoFutureMarginModel`
Forex	`CashBuyingPowerModel` for cash accounts or `BuyingPowerModel` for margin accounts
Other	`BuyingPowerModel`

If you have a margin account, the `DefaultBrokerageModel` allows 2x leverage for Equities, 50x leverage for Forex and CFDs, and 1x leverage for the remaining asset classes.

Settlement

The following table shows which settlement model the `DefaultBrokerageModel` uses based on the security type and your account type:

Security Type	Account Type	Settlement Model
Equity	Cash	DelayedSettlementModel with the default settlement rules
Option	Cash	DelayedSettlementModel with the default settlement rules
Future	Any	FutureSettlementModel

For all other cases, the `DefaultBrokerageModel` uses the ImmediateSettlementModel .

```py
# For US Equities with a cash account:
security.set_settlement_model(DelayedSettlementModel(Equity.DEFAULT_SETTLEMENT_DAYS, Equity.DEFAULT_SETTLEMENT_TIME))

# For Equity Options with a cash account:
security.set_settlement_model(DelayedSettlementModel(Option.DEFAULT_SETTLEMENT_DAYS, Option.DEFAULT_SETTLEMENT_TIME))

# For Futures
security.set_settlement_model(FutureSettlementModel())

# For remaining cases:
security.set_settlement_model(ImmediateSettlementModel())
```

Margin Interest Rate

The `DefaultBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The following table describes the default markets of each `SecurityType` for the `DefaultBrokerageModel` :

SecurityType	Market
Equity	USA
Option	USA
Future	CME
FutureOption	CME
Index	USA
IndexOption	USA
Forex	Oanda
Cfd	Oanda
Crypto	Coinbase
CryptoFuture	Binance

Account Currency

The `DefaultBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Interactive Brokers

Introduction

This page explains the `InteractiveBrokersBrokerageModel`, including the asset classes it supports, its default security-level models, and its default markets.

```
self.set_brokerage_model(BrokerageName.INTERACTIVE_BROKERS_BROKERAGE, AccountType.CASH)
self.set_brokerage_model(BrokerageName.INTERACTIVE_BROKERS_BROKERAGE, AccountType.MARGIN)
```

For more information about this model, see the class reference and implementation.

Asset Classes

The `InteractiveBrokersBrokerageModel` supports the following asset classes:

- US Equities
- Equity Options
- Forex
- Futures
- Future Options
- Indices
- Index Options
- CFD

Orders

The `InteractiveBrokersBrokerageModel` supports several order types, order properties, and order updates.

Order Types

The following table describes the order types that the `InteractiveBrokersBrokerageModel` supports: supports. For specific details about each order type, refer to the IB documentation.

Order Type	IB Documentation Page
Market	Market Orders
Limit	Limit Orders
Limit if touched	Limit if Touched Orders
Stop market	Stop Orders
Stop limit	Stop-Limit Orders
Trailing stop	Trailing Stop Orders
Market on open	Market-on-Open (MOO) Orders
Market on close	Market-on-Close (MOC) Orders
Combo market	Spread Orders
Combo limit	Spread Orders
Combo leg limit	Spread Orders
Exercise Option	Options Exercise

The following table describes the available order types for each asset class that the `InteractiveBrokersBrokerageModel` supports:

Order Type	US Equity	Equity Options	Forex	Futures	Futures Options	Index Options	CFD
Market	✓	✓	✓	✓	✓	✓	✓
Limit	✓	✓	✓	✓	✓	✓	✓
Limit if touched	✓	✓	✓	✓	✓	✓	✓
Stop market	✓	✓	✓	✓	✓	✓	✓
Stopl imit	✓	✓	✓	✓	✓	✓	✓
Trailing stop	✓	✓	✓	✓	✓	✓	✓
Market on open	✓	✓			✓	✓	✓
Market on close	✓			✓			✓
Combo market		✓			✓	✓	
Combo limit		✓			✓	✓	
Combo leg limit		✓			✓	✓	
Exercise Option		✓ Not supported for cash-settled Options			✓		

Order Properties

The `InteractiveBrokersBrokerageModel` supports custom order properties. The following table describes the members of the

`InteractiveBrokersOrderProperties` object that you can set to customize order execution. The table does not include the methods for FA accounts .

Property	Data Type	Description	Default Value
`time_in_force`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `DAY` • `GOOD_TIL_CANCELED` • `good_til_date`	`TimeInForce.GOOD_TIL_CANCELED`
`outside_regular_trading_hours`	`bool`	A flag to signal that the order may be triggered and filled outside of regular trading hours.	`False`

```py
def initialize(self) -> None:
    # Set the default order properties
    self.default_order_properties = InteractiveBrokersOrderProperties()
    self.default_order_properties.time_in_force = TimeInForce.GOOD_TIL_CANCELED
    self.default_order_properties.outside_regular_trading_hours = False

def on_data(self, slice: Slice) -> None:
    # Use default order order properties
    self.limit_order(self._symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = InteractiveBrokersOrderProperties()
    order_properties.time_in_force = TimeInForce.DAY
    order_properties.outside_regular_trading_hours = True
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)

    order_properties.time_in_force = TimeInForce.good_til_date(datetime(year, month, day))
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Updates

The `InteractiveBrokersBrokerageModel` supports order updates .

Financial Advisor Group Orders

To place FA group orders, see Financial Advisors .

Fractional Trading

The `InteractiveBrokersBrokerageModel` doesn't support fractional trading .

Handling Splits

If you're using raw data normalization and you have active orders with a limit, stop, or trigger price in the market for a US Equity when a stock split occurs, the following properties of your orders automatically adjust to reflect the stock split:

- Quantity
- Limit price
- Stop price
- Trigger price

Order Size Limits

The `InteractiveBrokersBrokerageModel` enforces the Spot Currency Minimum/Maximum Order Sizes from the IB website.

Fills

The following table shows the fill model that the `InteractiveBrokersBrokerageModel` uses for each `SecurityType` :

SecurityType	Fill Model
Equity	EquityFillModel
Future	FutureFillModel
FutureOption	FutureOptionFillModel
Remaining SecurityType values	ImmediateFillModel

Slippage

The InteractiveBrokersBrokerageModel uses the NullSlippageModel .

Fees

The InteractiveBrokersBrokerageModel uses the InteractiveBrokersFeeModel with the default argument values. We model current Interactive Brokers fees on all assets.

Buying Power

The InteractiveBrokersBrokerageModel sets the buying power model based on the asset class of the security. The following table shows the default buying power model of each asset class:

Asset Class	Model
Equity Options	OptionMarginModel
Futures	FutureMarginModel
Future Options	FuturesOptionsMarginModel
Index Options	OptionMarginModel
Crypto	CashBuyingPowerModel for cash accounts or BuyingPowerModel for margin accounts
CryptoFuture	CryptoFutureMarginModel
Forex	CashBuyingPowerModel for cash accounts or BuyingPowerModel for margin accounts
Other	BuyingPowerModel

If you have a margin account, the InteractiveBrokersBrokerageModel allows 2x leverage for Equities, 50x leverage for Forex, 10x leverage for CFDs, and 1x leverage for the remaining asset classes.

Settlement

The InteractiveBrokersBrokerageModel uses the ImmediateSettlementModel in most cases. If you trade US Equities or Equity Options with a cash account, it uses the DelayedSettlementModel with the default settlement rules .

The following table shows which settlement model the InteractiveBrokersBrokerageModel uses based on the security type and your account type:

Security Type	Account Type	Settlement Model
Equity	Cash	DelayedSettlementModel with the default settlement rules
Option	Cash	DelayedSettlementModel with the default settlement rules
Future	Any	FutureSettlementModel

For all other cases, the InteractiveBrokersBrokerageModel uses the ImmediateSettlementModel .

```py
# For US Equities with a cash account:
security.set_settlement_model(DelayedSettlementModel(Equity.DEFAULT_SETTLEMENT_DAYS, Equity.DEFAULT_SETTLEMENT_TIME))

# For Equity Options with a cash account:
security.set_settlement_model(DelayedSettlementModel(Option.DEFAULT_SETTLEMENT_DAYS, Option.DEFAULT_SETTLEMENT_TIME))

# For remaining cases:
security.set_settlement_model(ImmediateSettlementModel())
```

Interactive Brokers doesn't provide information on which assets aren't settled, so we assume each live trading session starts with its cash fully settled.

Margin Interest Rate

The `InteractiveBrokersBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The following table describes the default markets of each `SecurityType` for the `InteractiveBrokersBrokerageModel` :

SecurityType	Market
Equity	USA
Option	USA
Future	CME
FutureOption	CME
Index	USA
IndexOption	USA
Forex	Oanda
Cfd	InteractiveBrokers

Financial Advisors

IB supports FA accounts for Trading Firm and Institution organizations. FA accounts enable certified professionals to use a single trading algorithm to manage several client accounts.

To place trades using a subset of client accounts, create Account Groups in Trader Workstation and then define the `InteractiveBrokersOrderProperties` when you create orders.

```py
self.default_order_properties = InteractiveBrokersOrderProperties()
self.default_order_properties.fa_group = "TestGroupEQ"
self.default_order_properties.fa_method = "Equal"
self.default_order_properties.account = "DU123456"
```

SecurityHolding objects aggregate your positions across all the account groups. If you have two groups where group A has 10 shares of SPY and group B has -10 shares of SPY, then `self.portfolio["SPY"].quantity` is zero.

LEAN supports several allocation methods for FA group orders. If you intend to use the same group allocation method for every order, set the `default_order_properties` of your algorithm, which sets the order properties for all of your orders.

```
def initialize(self) -> None:
    # Set the default order properties
    self.default_order_properties = InteractiveBrokersOrderProperties()
    self.default_order_properties.fa_group = "TestGroupEQ"
    self.default_order_properties.fa_method = "Equal"
    self.default_order_properties.account = "DU123456"

def on_data(self, slice: Slice) -> None:
    # Use default order order properties
    LimitOrder(_symbol, quantity, limitPrice);
```

To adjust the order properties of an order, change the `default_order_properties` or pass an order properties object to the order method . The following sections explain the FA group allocation methods.

Equal

This group allocation method distributes shares equally between all accounts in the group. When you use this method, you need to specify an order quantity.

For example, say your Account Group includes four accounts and you place an order to buy 400 shares of a stock. In this case, each account receives 100 shares. If your Account Group includes six accounts, each account receives 66 shares, and then 1 share is allocated to each account until all are distributed. After you submit the order, your algorithm receives order events to track the order progress. When all the shares are bought, the order status is `OrderStatus.FILLED` . If one of the accounts in the group can't afford 10 of the shares it needs to buy, 10 shares are cancelled and you'll only end up buying 390 shares in total.

```
order_properties = InteractiveBrokersOrderProperties()
order_properties.fa_method = "Equal"
self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Net Liquidation Value

This group allocation method distributes shares based on the net liquidation value of each account. The system calculates ratios based on the net liquidation value in each account and allocates shares based on these ratios. When you use this method, you need to specify an order quantity.

For example, say your account group includes three accounts, A, B and C with Net Liquidation values of 25,000, 50,000 and $100,000, respectively. In this case, the system calculates a ratio of 1:2:4. If you place an order for 700 shares of a stock, it allocates 100 shares to Client A, 200 shares to Client B, and 400 shares to Client C.

```
order_properties = InteractiveBrokersOrderProperties()
order_properties.fa_method = "NetLiq"
self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Available Equity

This group allocation method distributes shares based on the amount of available equity in each account. The system calculates ratios based on the available equity in each account and allocates shares based on these ratios. When you use this method, you need to specify an order quantity.

For example, say your account group includes three accounts, A, B and C with available equity of 25,000, 50,000 and $100,000, respectively. In this case, the system calculates a ratio of 1:2:4. If you place an order for 700 shares of a stock, it allocates 100 shares to Client A, 200 shares to Client B, and 400 shares to Client C.

```
order_properties = InteractiveBrokersOrderProperties()
order_properties.fa_method = "AvailableEquity"
self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Account Currency

The `InteractiveBrokersBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

TradeStation

Introduction

This page explains the `TradeStationBrokerageModel`, including the asset classes it supports, its default security-level models, and its default markets.

```py
self.set_brokerage_model(BrokerageName.TRADE_STATION, AccountType.CASH)
self.set_brokerage_model(BrokerageName.TRADE_STATION, AccountType.MARGIN)
```

For more information about this model, see the class reference and implementation.

Asset Classes

The `TradeStationBrokerageModel` supports trading the following asset classes:

- US Equities
- Equity Options
- Futures
- Index
- Index Options

Orders

The `TradeStationBrokerageModel` supports several order types, order properties, and order updates.

Order Types

The following table describes the available order types for each asset class that the `TradeStationBrokerageModel` supports:

Order Type	Equity	Equity Options	Index Options	Futures
Market	✓	✓	✓	✓
Limit	✓	✓	✓	✓
Stop market	✓	✓	✓	✓
Stop limit	✓	✓	✓	✓
Trailing stop	✓	✓	✓	✓
Market on Open	✓			
Market on Close	✓			
Combo market	✓	✓	✓	✓
Combo limit	✓	✓	✓	✓

Order Properties

The `TradeStationBrokerageModel` supports custom order properties. The following table describes the members of the `TradeStationOrderProperties` object that you can set to customize order execution.

Property	Data Type	Description	Default Value
`time_in_force`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `DAY` • `GOOD_TIL_CANCELED` • `good_til_date`	`TimeInForce.GOOD_TIL_CANCELED`
`outside_regular_trading_hours`	`bool`	A flag to signal that the order may be triggered and filled outside of regular trading hours.	`False`
`post_only`	`bool`	This flag will ensure the limit order executes only as a maker (no fee) order. If part of the order results in taking liquidity rather than providing, it will be rejected and no part of the order will execute. Equities only.	`False`

PY

```
def initialize(self) -> None:
    # Set the default order properties
    self.default_order_properties = TradeStationOrderProperties()
    self.default_order_properties.outside_regular_trading_hours = False
    self.default_order_properties.time_in_force = TimeInForce.GOOD_TIL_CANCELED

def on_data(self, slice: Slice) -> None:
    # Use default order order properties
    self.limit_order(self._symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = TradeStationOrderProperties()
    order_properties.post_only = True
    order_properties.time_in_force = TimeInForce.DAY
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)

    order_properties.time_in_force = TimeInForce.good_til_date(datetime(year, month, day))
    order_properties.outside_regular_trading_hours = True
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Updates

The `TradeStationBrokerageModel` supports order updates .

Handling Splits

If you're using raw data normalization and you have active orders with a limit, stop, or trigger price in the market for a US Equity when a stock split occurs, the following properties of your orders automatically adjust to reflect the stock split:

- Quantity
- Limit price
- Stop price
- Trigger price

Fills

The following table shows the fill model that the `TradeStationBrokerageModel` uses for each `SecurityType` :

`SecurityType`	Fill Model
`Equity`	EquityFillModel
`Option`	ImmediateFillModel
`Future`	FutureFillModel

Slippage

The `TradeStationBrokerageModel` uses the NullSlippageModel .

Fees

The `TradeStationBrokersBrokerageModel` uses the TradeStationFeeModel with the default argument values. We model current TradeStation fees on all assets.

Buying Power

The `TradeStationBrokerageModel` sets the buying power model based on the asset class of the security. The following table shows the default buying power model of each asset class:

Asset Class	Model
Equities	`SecurityMarginModel`
Equity Options	`OptionMarginModel`
Futures	`FutureMarginModel`

If you have a margin account, the `TradeStationBrokerageModel` allows 2x leverage for Equities and and 1x leverage for Equity Options and Futures.

Settlement

The following table shows which settlement model the `TradeStationBrokerageModel` uses based on the security type and your account type:

Security Type	Account Type	Settlement Model
Equity	Cash	DelayedSettlementModel with the default settlement rules
Option	Cash	DelayedSettlementModel with the default settlement rules
Future	Any	FutureSettlementModel

For all other cases, the `TradeStationBrokerageModel` uses the ImmediateSettlementModel .

```py
# For US Equities with a cash account:
security.set_settlement_model(DelayedSettlementModel(Equity.DEFAULT_SETTLEMENT_DAYS, Equity.DEFAULT_SETTLEMENT_TIME))

# For Equity Options with a cash account:
security.set_settlement_model(DelayedSettlementModel(Option.DEFAULT_SETTLEMENT_DAYS, Option.DEFAULT_SETTLEMENT_TIME))

# For Futures
security.set_settlement_model(FutureSettlementModel())

# For remaining cases:
security.set_settlement_model(ImmediateSettlementModel())
```

Margin Interest Rate

The `TradeStationBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The following table describes the default markets of each `SecurityType` for the `TradeStationBrokerageModel` :

`SecurityType`	`Market`
`Equity`	`USA`
`Option`	`USA`
`Future`	`CME`

Account Currency

The `TradeStationBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Tastytrade

Introduction

This page explains the `TastytradeBrokerageModel`, including the asset classes it supports, its default security-level models, and its default markets.

```py
self.set_brokerage_model(BrokerageName.TASTYTRADE, AccountType.CASH)
self.set_brokerage_model(BrokerageName.TASTYTRADE, AccountType.MARGIN)
```

For more information about this model, see the class reference and implementation.

Asset Classes

The `TastytradeBrokerageModel` supports the following asset classes:

- US Equities
- Equity Options
- Futures
- Future Options
- Indices
- Index Options

Orders

The `TastytradeBrokerageModel` supports several order types, order properties, and order updates.

Order Types

The following table describes the available order types for each asset class that the `TastytradeBrokerageModel` supports:

Order Type	Equity	Equity Options	Futures	Future Options	Index Options
Market	✓	✓	✓	✓	✓
Limit	✓	✓	✓	✓	✓
Stop market	✓	✓	✓	✓	✓
Stop limit	✓	✓	✓	✓	✓
Combo limit	✓	✓	✓	✓	✓

Order Properties

The `TastytradeBrokerageModel` supports custom order properties. The following table describes the members of the `TastytradeOrderProperties` object that you can set to customize order execution.

Property	Data Type	Description	Default Value
`time_in_force`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `DAY` • `GOOD_TIL_CANCELED` • `good_til_date`	`TimeInForce.GOOD_TIL_CANCELED`

```py
def initialize(self) -> None:
    # Set the default order properties
    self.default_order_properties = TastytradeOrderProperties()
    self.default_order_properties.time_in_force = TimeInForce.GOOD_TIL_CANCELED

def on_data(self, slice: Slice) -> None:
    # Use default order order properties
    self.limit_order(self._symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = TastytradeOrderProperties()
    order_properties.time_in_force = TimeInForce.DAY
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Updates

The `TastytradeBrokerageModel` supports order updates .

Handling Splits

If you're using raw data normalization and you have active orders with a limit, stop, or trigger price in the market for a US Equity when a stock split occurs, the following properties of your orders automatically adjust to reflect the stock split:

- Quantity
- Limit price
- Stop price
- Trigger price

Fills

The following table shows the fill model that the `TastytradeBrokerageModel` uses for each `SecurityType` :

`SecurityType`	Fill Model
`Equity`	EquityFillModel
`Future`	FutureFillModel
`FutureOption`	FutureOptionFillModel
Remaining `SecurityType` values	ImmediateFillModel

Slippage

The `TastytradeBrokerageModel` uses the NullSlippageModel .

Fees

The `TastytradeBrokersBrokerageModel` uses the TastytradeFeeModel with the default argument values. We model current Tastytrade fees on all assets.

Buying Power

The `TastytradeBrokerageModel` sets the buying power model based on the asset class of the security. The following table shows the default buying power model of each asset class:

Asset Class	Model
Equities	`SecurityMarginModel`
Futures	`FutureMarginModel`
All Options Types	`OptionMarginModel`

If you have a margin account, the `TastytradeBrokerageModel` allows 2x leverage for Equities. The remaining asset classes are derivatives.

Settlement

The following table shows which settlement model the `TastytradeBrokerageModel` uses based on the security type and your account type:

Security Type	Account Type	Settlement Model
Equity	Cash	DelayedSettlementModel with the default settlement rules
Option	Cash	DelayedSettlementModel with the default settlement rules
Future	Any	FutureSettlementModel

For all other cases, the `TastytradeBrokerageModel` uses the ImmediateSettlementModel .

```py
# For US Equities with a cash account:
security.set_settlement_model(DelayedSettlementModel(Equity.DEFAULT_SETTLEMENT_DAYS, Equity.DEFAULT_SETTLEMENT_TIME))

# For Equity Options with a cash account:
security.set_settlement_model(DelayedSettlementModel(Option.DEFAULT_SETTLEMENT_DAYS, Option.DEFAULT_SETTLEMENT_TIME))

# For Futures
security.set_settlement_model(FutureSettlementModel())

# For remaining cases:
security.set_settlement_model(ImmediateSettlementModel())
```

Margin Interest Rate

The `TastytradeBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The following table describes the default markets of each `SecurityType` for the `TastytradeBrokerageModel` :

`SecurityType`	`Market`
`Equity`	`USA`
`Option`	`USA`
`Future`	`CME`
`FutureOption`	`CME`
`Index`	`USA`
`IndexOption`	`USA`

Supported Models

Alpaca

Introduction

This page explains the `AlpacaBrokerageModel` , including the asset classes it supports, its default security-level models , and its default markets.

```
self.set_brokerage_model(BrokerageName.ALPACA, AccountType.CASH)
self.set_brokerage_model(BrokerageName.ALPACA, AccountType.MARGIN)
```

For more information about this model, see the class reference and implementation .

Asset Classes

The `AlpacaBrokerageModel` supports the following asset classes:

- US Equities
- Equity Options
- Crypto

Orders

The `AlpacaBrokerageModel` supports several order types, order properties, and most order updates.

Order Types

The following table describes the available order types for each asset class that the `AlpacaBrokerageModel` supports:

Order Type	Equity	Equity Options	Crypto
Market	✓	✓	✓
Limit	✓	✓	✓
Stop market	✓	✓	✓
Stop limit	✓	✓	✓
Market on Open	✓		
Market on Close	✓		

Order Properties

The `AlpacaBrokerageModel` supports custom order properties. The following table describes the members of the `AlpacaOrderProperties` object that you can set to customize order execution.

Property	Data Type	Description	Default Value
`time_in_force`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `DAY` • `GOOD_TIL_CANCELED` • `good_til_date`	`TimeInForce.GOOD_TIL_CANCELED`
`outside_regular_trading_hours`	`bool`	A flag to signal that the order may be triggered and filled outside of regular trading hours.	`False`

PY

```
def initialize(self) -> None:
    # Set the default order properties
    self.default_order_properties = AlpacaOrderProperties()
    self.default_order_properties.outside_regular_trading_hours = False
    self.default_order_properties.time_in_force = TimeInForce.GOOD_TIL_CANCELED

def on_data(self, slice: Slice) -> None:
    # Use default order order properties
    self.limit_order(self._symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = AlpacaOrderProperties()
    order_properties.time_in_force = TimeInForce.DAY
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)

    order_properties.time_in_force = TimeInForce.good_til_date(datetime(year, month, day))
    order_properties.outside_regular_trading_hours = True
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Updates

The `AlpacaBrokerageModel` supports order updates .

Handling Splits

If you're using raw data normalization and you have active orders with a limit, stop, or trigger price in the market for a US Equity when a stock split occurs, the following properties of your orders automatically adjust to reflect the stock split:

- Quantity
- Limit price
- Stop price
- Trigger price

Fills

The `AlpacaBrokerageModel` uses the EquityFillModel for Equity trades and the ImmediateFillModel for Option and Crypto trades.

Slippage

The `AlpacaBrokerageModel` uses the NullSlippageModel .

Fees

The `AlpacaBrokerageModel` uses the AlpacaFeeModel with the default argument values. We model current Alpaca fees on all assets.

Buying Power

The `AlpacaBrokerageModel` uses the `CashBuyingPowerModel` for cash accounts, the `SecurityMarginModel` for margin accounts, and the `OptionMarginModel` for Option trades.

If you have a margin account, the `AlpacaBrokerageModel` allows 2x leverage for Equities and 3x leverage for Crypto.

Settlement

The `AlpacaBrokerageModel` uses the ImmediateSettlementModel for margin accounts and the DelayedSettlementModel with the default settlement

rules for cash accounts with Equity and Equity Options.

```py
# For US Equities with a cash account:
security.set_settlement_model(DelayedSettlementModel(Equity.DEFAULT_SETTLEMENT_DAYS, Equity.DEFAULT_SETTLEMENT_TIME))

# For Equity Options with a cash account:
security.set_settlement_model(DelayedSettlementModel(Option.DEFAULT_SETTLEMENT_DAYS, Option.DEFAULT_SETTLEMENT_TIME))

# For remaining cases:
security.set_settlement_model(ImmediateSettlementModel())
```

Margin Interest Rate

The `AlpacaBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `AlpacaBrokerageModel` is `Market.USA` for Equity and Equity Options. It's `Market.COINBASE` for Crypto.

Account Currency

The `AlpacaBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Charles Schwab

Introduction

This page explains the `CharlesSchwabBrokerageModel` , including the asset classes it supports, its default security-level models , and its default markets.

```py
self.set_brokerage_model(BrokerageName.CHARLES_SCHWAB, AccountType.CASH)
self.set_brokerage_model(BrokerageName.CHARLES_SCHWAB, AccountType.MARGIN)
```

For more information about this model, see the class reference and implementation .

Asset Classes

The `CharlesSchwabBrokerageModel` supports the following asset classes:

- US Equities
- Equity Options
- Index
- Index Options

Orders

The `CharlesSchwabBrokerageModel` supports several order types, order properties, and order updates.

Order Types

The following table describes the available order types for each asset class that the `CharlesSchwabBrokerageModel` supports:

Order Type	Equity	Equity Options	Index Options
Market	✓	✓	✓
Limit	✓	✓	✓
Stop market	✓	✓	
Market on open	✓		
Market on close	✓		
Combo market	✓	✓	✓
Combo limit	✓	✓	✓

Order Properties

The `CharlesSchwabBrokerageModel` supports custom order properties. The following table describes the members of the `CharlesSchwabOrderProperties` object that you can set to customize order execution.

Property	Data Type	Description	Default Value
`time_in_force`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `DAY` • `GOOD_TIL_CANCELED` • `good_til_date`	`TimeInForce.GOOD_TIL_CANCELED`
`extended_regular_trading_hours`	`bool`	If set to true, allows orders to also trigger or fill outside of regular trading hours.	`False`

PY

```
def initialize(self) -> None:
    # Set the default order properties
    self.default_order_properties.time_in_force = TimeInForce.GOOD_TIL_CANCELED

def on_data(self, slice: Slice) -> None:
    # Use default order order properties
    self.limit_order(self._symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = CharlesSchwabOrderProperties()
    order_properties.time_in_force = TimeInForce.DAY
    order_properties.extended_regular_trading_hours = True
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)

    order_properties.time_in_force = TimeInForce.good_til_date(datetime(year, month, day))
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Updates

The `CharlesSchwabBrokerageModel` supports order updates .

Handling Splits

If you're using raw data normalization and you have active orders with a limit, stop, or trigger price in the market for a US Equity when a stock split occurs, the following properties of your orders automatically adjust to reflect the stock split:

- Quantity
- Limit price
- Stop price
- Trigger price

Fills

The `CharlesSchwabBrokerageModel` uses the EquityFillModel for Equity trades and the ImmediateFillModel for Equity and Index Options trades.

Slippage

The `CharlesSchwabBrokerageModel` uses the NullSlippageModel .

Fees

The `CharlesSchwabBrokerageModel` uses the CharlesSchwabFeeModel .

Buying Power

The `CharlesSchwabBrokerageModel` uses the `SecurityMarginModel` . If you have a margin account, the `CharlesSchwabBrokerageModel` allows up to 2x leverage.

Settlement

The `CharlesSchwabBrokerageModel` uses the ImmediateSettlementModel for margin accounts and the DelayedSettlementModel with the default settlement rules for cash accounts.

```
# For cash accounts:
security.set_settlement_model(DelayedSettlementModel(Equity.DEFAULT_SETTLEMENT_DAYS, Equity.DEFAULT_SETTLEMENT_TIME))

# For margin accounts:
security.set_settlement_model(ImmediateSettlementModel())
```

Margin Interest Rate

The `CharlesSchwabBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `CharlesSchwabBrokerageModel` is `Market.USA` .

Account Currency

The `CharlesSchwabBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Binance

Introduction

This page explains the Binance brokerage models, including the asset classes they supports, their default security-level models , and their default markets.

```py
# Binance Spot
self.set_brokerage_model(BrokerageName.BINANCE, AccountType.CASH)
self.set_brokerage_model(BrokerageName.BINANCE, AccountType.MARGIN)

# Binance Futures
self.set_brokerage_model(BrokerageName.BINANCE_FUTURES, AccountType.MARGIN)
self.set_brokerage_model(BrokerageName.BINANCE_COIN_FUTURES, AccountType.MARGIN)

# Binance US Spot
self.set_brokerage_model(BrokerageName.BINANCE_US, AccountType.CASH)
```

For more information about these models, see their respective class reference and implementation.

Model	Class Reference	Implementation
BinanceBrokerageModel		
BinanceFuturesBrokerageModel		
BinanceCoinFuturesBrokerageModel		
BinanceUSBrokerageModel		

Asset Classes

The Binance brokerage models support trading Crypto and Crypto Futures .

```py
self.add_crypto("BTCUSDT", Resolution.MINUTE, Market.BINANCE)
self.add_crypto_future("BTCUSD", Resolution.MINUTE, Market.BINANCE)
```

The Binance US brokerage model supports trading Crypto .

```py
self.add_crypto("BTCUSDT", Resolution.MINUTE, Market.BINANCE_US)
```

Orders

The Binance and Binance US brokerage models support several order types and order properties, but don't support order updates.

Order Types

The following table describes the available order types for each asset class that the Binance and Binance US brokerage models support:

Order Type	Crypto	Crypto Futures
Market	✓	✓
Limit	✓	✓
Stop Market		✓
Stop limit	✓	✓

Order Properties

The Binance and Binance US brokerage models supports custom order properties. The following table describes the members of the `BinanceOrderProperties` object that you can set to customize order execution:

Property	Data Type	Description	Default Value
`time_in_force`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `DAY` • `GOOD_TIL_CANCELED` • `good_til_date`	`TimeInForce.GOOD_TIL_CANCELED`
`post_only`	`bool`	A flag to signal that the order must only add liquidity to the order book and not take liquidity from the order book. If part of the order results in taking liquidity rather than providing liquidity, the order is rejected without any part of it being filled.	

```py
def initialize(self) -> None:
    # Set the default order properties
    self.default_order_properties = BinanceOrderProperties()
    self.default_order_properties.time_in_force = TimeInForce.GOOD_TIL_CANCELED
    self.default_order_properties.post_only = False

def on_data(self, slice: Slice) -> None:
    # Use default order order properties
    self.limit_order(self._symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = BinanceOrderProperties()
    order_properties.time_in_force = TimeInForce.DAY
    order_properties.post_only = True
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)

    order_properties.time_in_force = TimeInForce.good_til_date(datetime(year, month, day))
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Updates

The Binance and Binance US brokerage models don't support order updates, but you can cancel an existing order and then create a new order with the desired arguments. For more information about this workaround, see the Workaround for Brokerages That Don't Support Updates .

Fills

The Binance brokerage models use the ImmediateFillModel .

Slippage

The Binance brokerage models use the NullSlippageModel .

Fees

The following table shows the fee model that each Binance brokerage model uses:

Brokerage Model	Fee Model
`BinanceBrokerageModel`	BinanceFeeModel
`BinanceFuturesBrokerageModel`	BinanceFuturesFeeModel
`BinanceCoinFuturesBrokerageModel`	BinanceCoinFuturesFeeModel
`BinanceUSBrokerageModel`	BinanceFeeModel

The Binance brokerage models use the default argument values for each fee model so that it models the current Binance fee schedule.

Buying Power

The Binance brokerage models use the `CashBuyingPowerModel` for cash accounts and the `SecurityMarginModel` for margin accounts.

The following table shows the maximum leverage each brokerage model allows for margin accounts:

Brokerage Model	Maximum Leverage
`BinanceBrokerageModel`	3
`BinanceFuturesBrokerageModel`	25
`BinanceCoinFuturesBrokerageModel`	25

The `BinanceUSBrokerageModel` doesn't currently support margin trading.

Settlement

The Binance brokerage models use the ImmediateSettlementModel .

Margin Interest Rate

The following table shows the margin interest rate model that the Binance brokerages use:

Brokerage Model	Margin Interest Rate Model
`BinanceBrokerageModel`	NullMarginInterestRateModel
`BinanceFuturesBrokerageModel`	BinanceFutureMarginInterestRateModel for Crypto Perpetual Futures and NullMarginInterestRateModel for other assets
`BinanceCoinFuturesBrokerageModel`	BinanceFutureMarginInterestRateModel for Crypto Perpetual Futures and NullMarginInterestRateModel for other assets
`BinanceUSBrokerageModel`	NullMarginInterestRateModel

Default Markets

The following table shows the default market of the Binance brokerage models:

Brokerage Model	Market
`BinanceBrokerageModel`	`Market.BINANCE`
`BinanceFuturesBrokerageModel`	`Market.BINANCE`
`BinanceCoinFuturesBrokerageModel`	`Market.BINANCE`
`BinanceUSBrokerageModel`	`Market.BINANCE_US`

Account Currency

Most of the Binance brokerage models support fiat currencies like USD, but the `BinanceBrokerageModel` doesn't. When you use this brokerage

model, set the account currency to USDT or another Cryptocurrency that Binance supports .

Supported Models

Bybit

Introduction

This page explains the `BybitBrokerageModel`, including the asset classes it supports, its default security-level models, and its default markets.

```
self.set_brokerage_model(BrokerageName.BYBIT, AccountType.CASH)
self.set_brokerage_model(BrokerageName.BYBIT, AccountType.MARGIN)
```

For more information about this model, see the class reference and implementation.

Asset Classes

The `BybitBrokerageModel` supports trading Crypto and Crypto Futures.

Orders

The `BybitBrokerageModel` supports several order types, order properties, and order updates.

Order Types

The following table describes the available order types for each asset class that the `BybitBrokerageModel` supports:

Order Type	Crypto	Crypto Futures
Market	✓	✓
Limit	✓	✓
Stop market	✓	✓
Stop limit	✓	✓

Order Properties

The `BybitBrokerageModel` supports custom order properties. The following table describes the members of the `BybitBrokerageModel` object that you can set to customize order execution:

Property	Data Type	Description	Default Value
`time_in_force`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `DAY` • `GOOD_TIL_CANCELED` • `good_til_date`	`TimeInForce.GOOD_TIL_CANCELED`
`post_only`	`bool`	A flag to signal that the order must only add liquidity to the order book and not take liquidity from the order book. If part of the order results in taking liquidity rather than providing liquidity, the order is rejected without any part of it being filled. This order property is only available for limit orders.	
`reduce_only`	`bool/NoneType`	A flag to signal that the order must only reduce your current position size. For more information about this order property, see Reduce-Only Order on the Bybit website.	

PY

```
def initialize(self) -> None:
    # Set the default order properties
    self.default_order_properties = BybitOrderProperties()
    self.default_order_properties.time_in_force = TimeInForce.GOOD_TIL_CANCELED
    self.default_order_properties.post_only = False
    self.default_order_properties.reduce_only = False

def on_data(self, slice: Slice) -> None:
    # Use default order order properties
    self.limit_order(self._symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = BybitOrderProperties()
    order_properties.time_in_force = TimeInForce.DAY
    order_properties.post_only = True
    self.default_order_properties.reduce_only = False
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)

    order_properties.time_in_force = TimeInForce.good_til_date(datetime(year, month, day))
    order_properties.post_only = False
    self.default_order_properties.reduce_only = True
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Updates

The `BybitBrokerageModel` supports order updates for Crypto Future assets that have one of the following order states :

- `OrderStatus.NEW`
- `OrderStatus.PARTIALLY_FILLED`
- `OrderStatus.SUBMITTED`
- `OrderStatus.FILLED`

In cases where you can't update an order, you can cancel the existing order and then create a new order with the desired arguments. For more information about this workaround, see the Workaround for Brokerages That Don't Support Updates .

Fills

The `BybitBrokerageModel` uses the ImmediateFillModel .

Slippage

The `BybitBrokerageModel` uses the NullSlippageModel .

Fees

The `BybitBrokerageModel` uses the BybitFeeModel for Crypto trades and the BybitFuturesFeeModel for Crypto Future trades. In both cases, the brokerage model uses the default argument values that models the Bybit fee schedule for VIP Level 0.

Buying Power

The `BybitBrokerageModel` sets the buying power model based on the asset class of the security. The following table shows the default buying power model of each asset class:

Asset Class	Model
Crypto	`CashBuyingPowerModel` for cash accounts or `SecurityMarginModel` for margin accounts
CryptoFuture	`CryptoFutureMarginModel`

If you have a margin account, the `BybitBrokerageModel` allows 10x leverage.

Settlement

The `BybitBrokerageModel` uses the ImmediateSettlementModel .

Margin Interest Rate

The `BybitBrokerageModel` uses the BybitFutureMarginInterestRateModel for perpetual Futures and the NullMarginInterestRateModel for every other asset.

Default Markets

The default market of the `BybitBrokerageModel` is `Market.BYBIT` .

Account Currency

The `BybitBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Tradier

Introduction

This page explains the `TradierBrokerageModel`, including the asset classes it supports, its default security-level models, and its default markets.

```py
self.set_brokerage_model(BrokerageName.TRADIER_BROKERAGE, AccountType.CASH)
self.set_brokerage_model(BrokerageName.TRADIER_BROKERAGE, AccountType.MARGIN)
```

For more information about this model, see the class reference and implementation.

Asset Classes

The `TradierBrokerageModel` supports trading US Equities and Equity Options.

Orders

The `TradierBrokerageModel` supports several order types, order properties, and most order updates.

Order Types

The following table describes the available order types for each asset class that the `TradierBrokerageModel` supports:

Order Type	Equity	Equity Options
Market	✓	✓
Limit	✓	✓
Stop market	✓	✓
Stop limit	✓	✓

Order Properties

The `TradierBrokerageModel` supports custom order properties. The following table describes the members of the `TradierOrderProperties` object that you can set to customize order execution.

Property	Data Type	Description	Default Value
`time_in_force`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `DAY` • `GOOD_TIL_CANCELED` • `good_til_date`	`TimeInForce.GOOD_TIL_CANCELED`
`outside_regular_trading_hours`	`bool`	A flag to signal that the order may be triggered and filled outside of regular trading hours.	`False`

```
def initialize(self) -> None:
    # Set the default order properties
    self.default_order_properties = TradierOrderProperties()
    self.default_order_properties.outside_regular_trading_hours = False
    self.default_order_properties.time_in_force = TimeInForce.GOOD_TIL_CANCELED

def on_data(self, slice: Slice) -> None:
    # Use default order order properties
    self.limit_order(self._symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = TradierOrderProperties()
    order_properties.time_in_force = TimeInForce.DAY
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)

    order_properties.time_in_force = TimeInForce.good_til_date(datetime(year, month, day))
    order_properties.outside_regular_trading_hours = True
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Updates

The `TradierBrokerageModel` supports most order updates . To update the quantity of an order, cancel the order and then submit a new order with the desired quantity. For more information about this workaround, see the Workaround for Brokerages That Don't Support Updates .

Extended Market Hours

The `TradierBrokerageModel` doesn't support extended market hours trading. If you place an order outside of regular trading hours, the order will be processed at market open.

Automatic Cancellations

If you have open orders for a security when it performs a reverse split, the `TradierBrokerageModel` automatically cancels your orders.

Errors

To view the order-related error codes from Tradier, see Error Responses in their documentation.

The `TradierBrokerageModel` validates your orders for the following errors before sending them to Tradier:

Error	Description
`ShortOrderIsGtc`	You can't short sell with the `GOOD_TIL_CANCELED` time in force
`SellShortOrderLastPriceBelow5`	You can't short sell stocks below $5
`IncorrectOrderQuantity`	The order quantity must be between 1 and 10,000,000 shares

Fills

The `TradierBrokerageModel` uses the EquityFillModel for Equity trades and the ImmediateFillModel for Option trades.

Slippage

The `TradierBrokerageModel` uses the NullSlippageModel .

Fees

The `TradierBrokerageModel` uses the ConstantFeeModel with zero fees.

```
security.set_fee_model(ConstantFeeModel(0))
```

Buying Power

The `TradierBrokerageModel` uses the `OptionMarginModel` for Option trades and the `SecurityMarginModel` for Equity trades.

If you have a margin account, the `TradierBrokerageModel` allows 2x leverage for Equities.

Settlement

The TradierBrokerageModel uses the ImmediateSettlementModel for margin accounts and the DelayedSettlementModel with the default settlement rules for cash accounts.

```py
# For US Equities with a cash account:
security.set_settlement_model(DelayedSettlementModel(Equity.DEFAULT_SETTLEMENT_DAYS, Equity.DEFAULT_SETTLEMENT_TIME))

# For Equity Options with a cash account:
security.set_settlement_model(DelayedSettlementModel(Option.DEFAULT_SETTLEMENT_DAYS, Option.DEFAULT_SETTLEMENT_TIME))

# For remaining cases:
security.set_settlement_model(ImmediateSettlementModel())
```

Margin Interest Rate

The TradierBrokerageModel uses the NullMarginInterestRateModel .

Default Markets

The default market of the TradierBrokerageModel is Market.USA .

Account Currency

The TradierBrokerageModel doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Kraken

Introduction

This page explains the `KrakenBrokerageModel` , including the asset classes it supports, its default security-level models , and its default markets.

```py
self.set_brokerage_model(BrokerageName.KRAKEN, AccountType.CASH)
self.set_brokerage_model(BrokerageName.KRAKEN, AccountType.MARGIN)
```

For more information about this model, see the class reference and implementation .

Asset Classes

The `KrakenBrokerageModel` supports trading Crypto .

Orders

The `KrakenBrokerageModel` supports several order types and order properties, but it doesn't support order updates.

Order Types

The following table describes the available order types for each asset class that the `KrakenBrokerageModel` supports:

Order Type	Crypto
Market	✓
Limit	✓
Limit if touched	✓
Stop market	✓
Stop limit	✓

Order Properties

The `KrakenBrokerageModel` supports custom order properties. The following table describes the members of the `KrakenOrderProperties` object that you can set to customize order execution:

Property	Data Type	Description	Default Value
`time_in_force`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `DAY` • `GOOD_TIL_CANCELED` • `good_til_date`	`TimeInForce.GOOD_TIL_CANCELED`
`post_only`	`bool`	A flag to signal that the order must only add liquidity to the order book and not take liquidity from the order book. If part of the order results in taking liquidity rather than providing liquidity, the order is rejected without any part of it being filled.	
`fee_in_base`	`bool`	A flag to signal that the order fees should be paid in the base currency, which is the default behavior when selling. This flag must be the opposite of the `fee_in_quote` flag.	
`fee_in_quote`	`bool`	A flag to signal that the order fees should be paid in the quote currency, which is the default behavior when buying. This flag must be the opposite of the `fee_in_base` flag.	
`no_market_price_protection`	`bool`	A flag to signal that no Market Price Protection should be used.	
`conditional_order`	`Order`	An `Order` that's submitted when the primary order is executed. The `conditional_order` quantity must match the primary order quantity and the `conditional_order` direction must be the opposite of the primary order direction. This order property is only available for live algorithms.	

PY

```
def initialize(self) -> None:
    # Set the default order properties
    self.default_order_properties = KrakenOrderProperties()
    self.default_order_properties.time_in_force = TimeInForce.GOOD_TIL_CANCELED
    self.default_order_properties.post_only = False
    self.default_order_properties.fee_in_base = True
    self.default_order_properties.fee_in_quote = False
    self.default_order_properties.no_market_price_protection = True

def on_data(self, slice: Slice) -> None:
    # Use default order order properties
    self.limit_order(self._symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = KrakenOrderProperties()
    order_properties.time_in_force = TimeInForce.DAY
    order_properties.post_only = True
    order_properties.fee_in_base = False
    order_properties.fee_in_quote = True
    order_properties.no_market_price_protection = True
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)

    order_properties.time_in_force = TimeInForce.good_til_date(datetime(year, month, day))
    order_properties.post_only = False
    order_properties.fee_in_base = True
    order_properties.fee_in_quote = False
    order_properties.no_market_price_protection = False
    order_properties.conditional_order = StopLimitOrder(self._symbol, -quantity, stop_limit_price, stop_price)
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Updates

The `KrakenBrokerageModel` doesn't support order updates, but you can cancel an existing order and then create a new order with the desired arguments. For more information about this workaround, see the Workaround for Brokerages That Don't Support Updates .

Fills

The `KrakenBrokerageModel` uses the ImmediateFillModel .

Slippage

The `KrakenBrokerageModel` uses the NullSlippageModel .

Fees

The `KrakenBrokerageModel` uses the KrakenFeeModel .

Buying Power

The `KrakenBrokerageModel` uses the `CashBuyingPowerModel` for cash accounts and the `SecurityMarginModel` for margin accounts.

If you have a margin account, the `KrakenBrokerageModel` allows 1x leverage for most Crypto pairs. The following table shows pairs that have additional leverage available:

Quote Currency	Base Currencies	Leverage
ADA	BTC, ETH, USD, EUR	3
BCH	BTC, USD, EUR	2
BTC	USD, EUR	5
DASH	BTC, USD, EUR	3
EOS	BTC, ETH, USD, EUR	3
ETH	BTC, USD, EUR	5
LINK	BTC, ETH, USD, EUR	3
LTC	BTC, USD, EUR	3
REP	BTC, ETH, USD, EUR	2
TRX	BTC, ETH, USD, EUR	3
USDC	USD, EUR	3
USDT	USD, EUR	2
XMR	BTC, USD, EUR	2
XRP	BTC, USD, EUR	3
XTZ	BTC, ETH, USD, EUR	2

Settlement

The `KrakenBrokerageModel` uses the ImmediateSettlementModel .

Margin Interest Rate

The `KrakenBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `KrakenBrokerageModel` is `Market.KRAKEN` .

Account Currency

The `KrakenBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Coinbase

Introduction

This page explains the `CoinbaseBrokerageModel`, including the asset classes it supports, its default security-level models, and its default markets.

```py
self.set_brokerage_model(BrokerageName.COINBASE, AccountType.CASH)
```

For more information about this model, see the class reference and implementation.

Asset Classes

The `CoinbaseBrokerageModel` supports trading Crypto.

Orders

The `CoinbaseBrokerageModel` supports several order types and order properties, but it doesn't support order updates.

Order Types

The following table describes the available order types for each asset class that the `CoinbaseBrokerageModel` supports:

Order Type	Crypto
Market	✓
Limit	✓
Stop market	✓ Supported before 2019-03-23 in backtests. For reference, see the Coinbase Market Structure Update on the Coinbase website.
Stop limit	✓

Order Properties

The `CoinbaseBrokerageModel` supports custom order properties. The following table describes the members of the `CoinbaseOrderProperties` object that you can set to customize order execution:

Property	Data Type	Description	Default Value
`time_in_force`	`TimeInForce`	A TimeInForce instruction to apply to the order. The `TimeInForce` is supported.	`TimeInForce.GOOD_TIL_CANCELED`
`post_only`	`bool`	A flag that signals the order must only add liquidity to the order book and not take liquidity from the order book. If part of the order results in taking liquidity rather than providing liquidity, the order is rejected without any part of it being filled.	
`self_trade_prevention_id`	`bool`	A flag that signals self-trade prevention is enabled for this order. Self-trade prevention helps prevent an order from crossing against the same user, reducing the risk of unintentional trades within the same account.	

```
def initialize(self) -> None:
    # Set the default order properties
    self.default_order_properties = CoinbaseOrderProperties()
    self.default_order_properties.time_in_force = TimeInForce.GOOD_TIL_CANCELED
    self.default_order_properties.post_only = False

def on_data(self, slice: Slice) -> None:
    # Use default order order properties
    self.limit_order(self._symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = CoinbaseOrderProperties()
    order_properties.time_in_force = TimeInForce.GOOD_TIL_CANCELED
    order_properties.post_only = True
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Updates

The `CoinbaseBrokerageModel` doesn't support limit order updates, but you can cancel an existing limit order and then create a new limit order with the desired arguments. For more information about this workaround, see the Workaround for Brokerages That Don't Support Updates .

Fills

The `CoinbaseBrokerageModel` uses the ImmediateFillModel .

Slippage

The `CoinbaseBrokerageModel` uses the NullSlippageModel .

Fees

The `CoinbaseBrokerageModel` uses the CoinbaseFeeModel .

Buying Power

The `CoinbaseBrokerageModel` uses the `CashBuyingPowerModel` . The brokerage model doesn't currently support margin trading.

Settlement

The `CoinbaseBrokerageModel` uses the ImmediateSettlementModel .

Margin Interest Rate

The `CoinbaseBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `CoinbaseBrokerageModel` is `Market.COINBASE` .

Account Currency

The `CoinbaseBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Bitfinex

Introduction

This page explains the `BitfinexBrokerageModel`, including the asset classes it supports, its default security-level models, and its default markets.

```py
self.set_brokerage_model(BrokerageName.BITFINEX, AccountType.CASH)
self.set_brokerage_model(BrokerageName.BITFINEX, AccountType.MARGIN)
```

For more information about this model, see the class reference and implementation.

Asset Classes

The `BitfinexBrokerageModel` supports trading Crypto.

Orders

The `BitfinexBrokerageModel` supports several order types, order properties, and order updates.

Order Types

The following table describes the available order types for each asset class that the `BitfinexBrokerageModel` supports:

Order Type	Crypto
Market	✓
Limit	✓
Stop market	✓
Stop limit	✓

Order Properties

The `BitfinexBrokerageModel` supports custom order properties. The following table describes the members of the `BitfinexOrderProperties` object that you can set to customize order execution:

Property	Data Type	Description	Default Value
`time_in_force`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `DAY` • `GOOD_TIL_CANCELED` • `good_til_date`	`TimeInForce.GOOD_TIL_CANCELED`
`hidden`	`bool`	A flag to signal that the order should be hidden. Hidden orders do not appear in the order book, so they do not influence other market participants. Hidden orders incur the taker fee.	
`post_only`	`bool`	A flag to signal that the order must only add liquidity to the order book and not take liquidity from the order book. If part of the order results in taking liquidity rather than providing liquidity, the order is rejected without any part of it being filled.	

PY

```
def initialize(self) -> None:
    # Set the default order properties
    self.default_order_properties = BitfinexOrderProperties()
    self.default_order_properties.time_in_force = TimeInForce.GOOD_TIL_CANCELED
    self.default_order_properties.hidden = False
    self.default_order_properties.post_only = False

def on_data(self, slice: Slice) -> None:
    # Use default order order properties
    self.limit_order(self._symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = BitfinexOrderProperties()
    order_properties.time_in_force = TimeInForce.DAY
    order_properties.hidden = True
    order_properties.post_only = False
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)

    order_properties.time_in_force = TimeInForce.good_til_date(datetime(year, month, day))
    order_properties.hidden = False
    order_properties.post_only = True
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Updates

The `BitfinexBrokerageModel` supports order updates .

Fills

The `BitfinexBrokerageModel` uses the ImmediateFillModel .

Slippage

The `BitfinexBrokerageModel` uses the NullSlippageModel .

Fees

The `BitfinexBrokerageModel` uses the BitfinexFeeModel with the default argument values that models the current Bitfinex fee schedule.

Buying Power

The `BitfinexBrokerageModel` uses the `CashBuyingPowerModel` for cash accounts and the `SecurityMarginModel` for margin accounts.

If you have a margin account, the `BitfinexBrokerageModel` allows 3.3x leverage.

Settlement

The `BitfinexBrokerageModel` uses the ImmediateSettlementModel .

Margin Interest Rate

The `BitfinexBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `BitfinexBrokerageModel` is `Market.BITFINEX` .

Account Currency

The `BitfinexBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

dYdX

Introduction

This page explains the `dYdXBrokerageModel`, including the asset classes it supports, its default security-level models, and its default markets.

```py
self.set_brokerage_model(BrokerageName.DYDX, AccountType.MARGIN)
```

For more information about this model, see the class reference and implementation.

Asset Classes

The `dYdXBrokerageModel` supports trading Crypto futures.

Orders

The `dYdXBrokerageModel` supports several order types, order properties, and order updates.

Order Types

The following table describes the available order types for each asset class that the `dYdXBrokerageModel` supports:

Order Type	Crypto Future
Market	✓
Limit	✓
Stop market	✓
Stop limit	✓

Order Properties

The `dYdXBrokerageModel` supports custom order properties. The following table describes the members of the `dYdXOrderProperties` object that you can set to customize order execution:

Property	Data Type	Description	Default Value
`time_in_force`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `DAY` • `GOOD_TIL_CANCELED` [1] • `good_til_date`	`TimeInForce.GOOD_TIL_CANCELED`
`gas_limit`	`int`	The maximum amount of gas to use for the order.	1_000_000
`good_til_block_offset`	`int`	The block height at which the order expires.	20
`IOC` [2]	`bool`	Enforces that an order only be placed on the book as a maker order. Note this means that validators will cancel any newly placed post only orders that would cross with other maker.	`False`
`post_only` [2]	`bool`	A flag to signal that the order must only add liquidity to the order book and not take liquidity from the order book. If part of the order results in taking liquidity rather than providing liquidity, the order is rejected without any part of it being filled. This order property is only available for limit orders.	`False`
`reduce_only`	`bool`	A flag to signal that the order must only reduce your current position size. For more information about this order property, see Reduce-Only Order on the dYdX website.	`False`

[1] `GOOD_TIL_CANCELED` is not fully supported. These orders expire in 90 days.

[2] You cannot set `post_only` when `IOC` is already set and vice-versa. Only one execution type can be active at a time.

PY

```
def initialize(self) -> None:
    # Set the default order properties
    self.default_order_properties = dYdXOrderProperties()
    self.default_order_properties.time_in_force = TimeInForce.GOOD_TIL_CANCELED
    self.default_order_properties.reduce_only = False
    self.default_order_properties.post_only = False

def on_data(self, slice: Slice) -> None:
    # Use default order order properties
    self.limit_order(self._symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = dYdXOrderProperties()
    order_properties.time_in_force = TimeInForce.DAY
    order_properties.reduce_only = True
    order_properties.post_only = False
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)

    order_properties.time_in_force = TimeInForce.good_til_date(datetime(year, month, day))
    order_properties.reduce_only = False
    order_properties.post_only = True
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Updates

The `dYdXBrokerageModel` doesn't support order updates, but you can cancel an existing order and then create a new order with the desired arguments. For more information about this workaround, see the Workaround for Brokerages That Don't Support Updates .

Fills

The `dYdXBrokerageModel` uses the ImmediateFillModel .

Slippage

The `dYdXBrokerageModel` uses the NullSlippageModel .

Fees

The `dYdXBrokerageModel` uses the dYdXFeeModel with the default argument values that models the current dYdX fee schedule.

Buying Power

The `dYdXBrokerageModel` uses the `SecurityMarginModel` and allows 3.3x leverage.

Settlement

The `dYdXBrokerageModel` uses the ImmediateSettlementModel .

Margin Interest Rate

The `dYdXBrokerageModel` uses the dYdXFutureMarginInterestRateModel .

Default Markets

The default market of the `dYdXBrokerageModel` is `Market.DYDX` .

Account Currency

The `dYdXBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Terminal Link

Introduction

This page explains the Terminal Link brokerage, including the asset classes it supports, its default security-level models , and its default markets.

Asset Classes

Terminal Link supports trading the following asset classes:

- Equities
- Equity Options
- Futures
- Index Options

Orders

Terminal Link enables you to create and manage Bloomberg™ orders.

Order Types

The following table describes the available order types for each asset class that Terminal Link supports:

Order Type	Equity	Equity Options	Futures	Index Options
Market	✓	✓	✓	✓
Limit	✓	✓	✓	✓
Stop market	✓	✓	✓	✓
Stop limit	✓	✓	✓	✓

Order Properties

We model custom order properties from the Bloomberg EMSX API. The following table describes the members of the `TerminalLinkOrderProperties` object that you can set to customize order execution:

Property	Data Type	Description	Default Value
`time_in_force`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `DAY` • `GOOD_TIL_CANCELED` • `good_til_date`	`TimeInForce.GOOD_TIL_CANCELED`
`notes`	`str`	The free form instructions that may be sent to the broker.	
`handling_instruction`	`str`	The instructions for handling the order or route. The values can be preconfigured or a value customized by the broker.	

`custom_notes_1`	`str`	Custom user order notes 1. For more information about custom order notes, see Custom Notes & Free Text Fields in the EMSX API documentation	
`custom_notes_2`	`str`	Custom user order notes 2.	
`custom_notes_3`	`str`	Custom user order notes 3.	
`custom_notes_4`	`str`	Custom user order notes 4.	
`custom_notes_5`	`str`	Custom user order notes 5.	
`account`	`str`	The EMSX account.	
`broker`	`str`	The EMSX broker code.	
`strategy`	`StrategyParameters`	An object that represents the EMSX order strategy details. You must append strategy parameters in the order that the EMSX API expects. The following strategy names are supported: "DMA", "DESK", "VWAP", "TWAP", "FLOAT", "HIDDEN", "VOLUMEINLINE", "CUSTOM", "TAP", "CUSTOM2", "WORKSTRIKE", "TAPNOW", "TIMED", "LIMITTICK", "STRIKE"	
`execution_instruction`	`str`	The execution instruction field.	
`automatic_position_sides`	`bool`	A flag that determines whether to automatically include the position side in the order direction (buy-to-open, sell-to-close, etc.) instead of the default (buy, sell).	
`position_side`	`OrderPosition/NoneType`	An `OrderPosition` object that specifies the position side in the order direction (buy-to-open, sell-to-close, etc.) instead of the default (buy, sell). This member has precedence over `automatic_position_sides` .	
`exchange`	`Exchange`	Defines the exchange name for sending the order to.	

```py
def initialize(self) -> None:
    # Set the default order properties
    self.default_order_properties = TerminalLinkOrderProperties()
    self.default_order_properties.time_in_force = TimeInForce.GOOD_TIL_CANCELED
    self.default_order_properties.strategy = TerminalLinkOrderProperties.StrategyParameters(
        "VWAP",
        [
            TerminalLinkOrderProperties.StrategyField("09:30:00"),
            TerminalLinkOrderProperties.StrategyField("10:30:00"),
            TerminalLinkOrderProperties.StrategyField(),
            TerminalLinkOrderProperties.StrategyField()
        ]
    )

def on_data(self, slice: Slice) -> None:
    # Use default order order properties
    self.limit_order(self._symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = TerminalLinkOrderProperties()
    order_properties.time_in_force = TimeInForce.DAY
    order_properties.account = "account1"
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)

    order_properties.time_in_force = TimeInForce.good_til_date(datetime(year, month, day))
    order_properties.account = "account2"
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

For more information about the format that the Bloomberg EMSX API expects, see Create Order and Route Extended Request in the EMSX API documentation and the createOrderAndRouteWithStrat documentation on the MathWorks website.

Get Open Orders

Terminal Link lets you access open orders .

Monitor Fills

Terminal Link allows you to monitor orders as they fill through order events .

Updates

Terminal Link doesn't support order updates , but you can cancel an existing order and then create a new order with the desired arguments. For more information about this workaround, see the Workaround for Brokerages That Don't Support Updates .

Cancellations

Terminal Link enables you to cancel open orders .

Handling Splits

If you're using raw data normalization and you have active orders with a limit, stop, or trigger price in the market for a US Equity when a stock split occurs, the following properties of your orders automatically adjust to reflect the stock split:

- Quantity
- Limit price
- Stop price
- Trigger price

Brokerage-Side Orders

By default, your algorithm doesn't record orders that you submit to your account by third-parties instead of through LEAN. To accept these orders, create a custom brokerage message handler .

Fills

To view how we model fills in backtests, see Fills .

Slippage

To view how we model slippage in backtests, see Slippage .

Fees

To view how we model fees in backtests, see Fees .

Buying Power

To view how we model buying power in backtests, see Buying Power .

Settlement

To view how we model settlements in backtests, see Settlement .

Margin Interest Rate

To view how we model margin interest rates in backtests, see Margin Interest Rate .

Default Markets

To view the default markets of each asset class when you use Terminal Link, see Default Markets .

Account Currency

The Terminal Link brokerage doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

SSC Eze

Introduction

This page explains the `EzeBrokerageModel` , including the asset classes it supports, its default security-level models , and its default markets.

```py
self.set_brokerage_model(BrokerageName.EZE, AccountType.MARGIN)
```

For more information about this model, see the class reference and implementation .

Asset Classes

The `EzeBrokerageModel` supports the following asset classes:

- US Equities
- Equity Options
- Futures
- Future Options
- Indices
- Index Options

Orders

The `EzeBrokerageModel` supports several order types, order properties, and order updates.

Order Types

The following table describes the available order types for each asset class that the `EzeBrokerageModel` supports:

Order Type	Equity	Equity Options	Futures	Future Options	Index Options
Market	✓	✓	✓	✓	✓
Limit	✓	✓	✓	✓	✓
Stop market	✓	✓	✓	✓	✓
Stop limit	✓	✓	✓	✓	✓
Market on Open	✓				
Market on Close	✓				

Order Properties

The `EzeBrokerageModel` supports custom order properties. The following table describes the members of the `EzeOrderProperties` object that you can set to customize order execution.

Property	Data Type	Description	Default Value
time_in_force	TimeInForce	A TimeInForce instruction to apply to the order. The following instructions are supported: • DAY • GOOD_TIL_CANCELED • good_til_date	TimeInForce.GOOD_TIL_CANCELED
account	str	Sets a semi-colon separated list of trade or neutral accounts the user has permission for, e.g., "TAL;TEST;USER1;TRADE" or "TAL;TEST;USER2;NEUTRAL".	
account_type	str	Sets the account type for the order. E.g., **"119"** for margin orders in Eze EMS.	
notes	str	Sets the user message or notes.	
route	str	Sets the route name as shown in SS&C Eze EMS.	

```py
def initialize(self) -> None:
    # Set the default order properties
    self.default_order_properties = EzeOrderProperties()
    self.default_order_properties.time_in_force = TimeInForce.GOOD_TIL_CANCELED
    self.default_order_properties.notes = "Default order properties"

def on_data(self, slice: Slice) -> None:
    # Use default order order properties
    self.limit_order(self._symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = EzeOrderProperties()
    order_properties.time_in_force = TimeInForce.DAY
    order_properties.notes = "Default order properties"
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Updates

The EzeBrokerageModel supports order updates .

Handling Splits

If you're using raw data normalization and you have active orders with a limit, stop, or trigger price in the market for a US Equity when a stock split occurs, the following properties of your orders automatically adjust to reflect the stock split:

- Quantity
- Limit price
- Stop price
- Trigger price

Fills

The following table shows the fill model that the EzeBrokerageModel uses for each SecurityType :

SecurityType	Fill Model
Equity	EquityFillModel
Future	FutureFillModel
FutureOption	FutureOptionFillModel
Remaining SecurityType values	ImmediateFillModel

Slippage

The EzeBrokerageModel uses the NullSlippageModel .

Fees

The EzeBrokerageModel uses the EzeFeeModel which extends the ConstantFeeModel with with zero as fee for all assets.

Buying Power

The EzeBrokerageModel sets the buying power model based on the asset class of the security. The following table shows the default buying power model of each asset class:

Asset Class	Model
Equities	SecurityMarginModel
Futures	FutureMarginModel
All Options Types	OptionMarginModel

If you have a margin account, the EzeBrokerageModel allows 2x leverage for Equities. The remaining asset classes are derivatives.

Settlement

The following table shows which settlement model the EzeBrokerageModel uses based on the security type and your account type:

Security Type	Account Type	Settlement Model
Equity	Cash	DelayedSettlementModel with the default settlement rules
Option	Cash	DelayedSettlementModel with the default settlement rules
Future	Any	FutureSettlementModel

For all other cases, the EzeBrokerageModel uses the ImmediateSettlementModel .

```py
# For US Equities with a cash account:
security.set_settlement_model(DelayedSettlementModel(Equity.DEFAULT_SETTLEMENT_DAYS, Equity.DEFAULT_SETTLEMENT_TIME))

# For Equity Options with a cash account:
security.set_settlement_model(DelayedSettlementModel(Option.DEFAULT_SETTLEMENT_DAYS, Option.DEFAULT_SETTLEMENT_TIME))

# For Futures
security.set_settlement_model(FutureSettlementModel())

# For remaining cases:
security.set_settlement_model(ImmediateSettlementModel())
```

Margin Interest Rate

The EzeBrokerageModel uses the NullMarginInterestRateModel .

Default Markets

The following table describes the default markets of each `SecurityType` for the `EzeBrokerageModel` :

SecurityType	Market
Equity	USA
Option	USA
Future	CME
FutureOption	CME
Index	USA
IndexOption	USA

Supported Models

Trading Technologies

Introduction

This page explains the `TradingTechnologiesBrokerageModel`, including the asset classes it supports, its default security-level models, and its default markets.

```
self.set_brokerage_model(BrokerageName.TRADING_TECHNOLOGIES, AccountType.CASH)
self.set_brokerage_model(BrokerageName.TRADING_TECHNOLOGIES, AccountType.MARGIN)
```

For more information about this model, see the class reference and implementation.

Asset Classes

The `TradingTechnologiesBrokerageModel` supports trading Futures.

Orders

The `TradingTechnologiesBrokerageModel` supports several order types, some `TimeInForce` order properties, and order updates.

Order Types

The following table describes the available order types for each asset class that the `TradingTechnologiesBrokerageModel` supports:

Order Type	Futures
Market	✓
Limit	✓
Stop market	✓
Stop limit	✓

The `TradingTechnologiesBrokerageModel` enforces the following order rules:

- If you are buying (selling) with a `stop_market_order` or a `stop_limit_order`, the stop price of the order must be greater (less) than the current security price.
- If you are buying (selling) with a `stop_limit_order`, the limit price of the order must be greater (less) than the stop price.

Time In Force

The `TradingTechnologiesBrokerageModel` supports the `DAY` and `GOOD_TIL_CANCELED` TimeInForce order properties.

```
def initialize(self) -> None:
    # Set the default order properties
    self.default_order_properties.time_in_force = TimeInForce.GOOD_TIL_CANCELED

def on_data(self, slice: Slice) -> None:
    # Use default order order properties
    self.limit_order(self._symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = OrderProperties()
    order_properties.time_in_force = TimeInForce.DAY
    self.limit_order(self._symbol, quantity, limit_price, order_properties=order_properties)
```

Updates

The `TradingTechnologiesBrokerageModel` supports order updates.

Fills

The `TradingTechnologiesBrokerageModel` uses the FutureFillModel .

Slippage

The `TradingTechnologiesBrokerageModel` uses the NullSlippageModel .

Fees

The `TradingTechnologiesBrokerageModel` uses the ConstantFeeModel with zero fees.

```
security.set_fee_model(ConstantFeeModel(0))
```
PY

Buying Power

The `TradingTechnologiesBrokerageModel` uses the `FutureMarginModel` .

Settlement

The `TradingTechnologiesBrokerageModel` uses the FutureSettlementModel .

Margin Interest Rate

The `TradingTechnologiesBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `TradierBrokerageModel` is `Market.CME` .

Account Currency

The `TradingTechnologiesBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Wolverine

Introduction

This page explains the `WolverineBrokerageModel` , including the asset classes it supports, its default security-level models , and its default markets.

```py
self.set_brokerage_model(BrokerageName.WOLVERINE, AccountType.CASH)
self.set_brokerage_model(BrokerageName.WOLVERINE, AccountType.MARGIN)
```

For more information about this model, see the class reference and implementation .

Asset Classes

The `WolverineBrokerageModel` supports trading US Equities .

Orders

The `WolverineBrokerageModel` supports one order type, but doesn't support order updates or extended market hours trading.

Order Types

The following table describes the available order types for each asset class that the `WolverineBrokerageModel` supports:

Order Type	Equity
Market	✓
Market on Close	✓
Limit	✓
Stop market	✓
Stop limit	✓

Updates

The `WolverineBrokerageModel` doesn't support order updates.

Extended Market Hours

The `WolverineBrokerageModel` doesn't support extended market hours trading. If you place an order outside of regular trading hours, the order is invalid.

Order Properties

The `WolverineBrokerageModel` supports custom order properties. The following table describes the members of the `WolverineOrderProperties` object that you can set to customize order execution:

Property	Description

`time_in_force`	`TimeInForce`
`exchange`	`Exchange`

exchange_post_fix	str
locate_broker	str
position_side	OrderPosition | NoneType

```py
def initialize(self) -> None:
    # Set the default order properties
    self.default_order_properties = WolverineOrderProperties()
    self.default_order_properties.time_in_force = TimeInForce.GOOD_TIL_CANCELED
    self.default_order_properties.exchange = Exchange.SMART
    self.default_order_properties.exchange_post_fix = "-INCA-TX"
    self.default_order_properties.order_position = OrderPosition.BUY_TO_OPEN
    # Optionally, you can specify for equity shorts which broker will provide the stock to short
    # if not specified defaults to broker will provide
    self.default_order_properties.locate_broker = "abn"
```

If the `position_side` is not specified, the engine will determine it from the holdings and the order quantity. For example, if it's a sell short and will send `PositionSide SELL_SHORT` .

Fills

The `WolverineBrokerageModel` uses the EquityFillModel for Equity trades.

Slippage

The `WolverineBrokerageModel` uses the NullSlippageModel .

Fees

The `WolverineBrokerageModel` uses the WolverineFeeModel .

Buying Power

The `WolverineBrokerageModel` uses the `SecurityMarginModel` . If you have a margin account, the `WolverineBrokerageModel` allows up to 2x leverage.

Settlement

The `WolverineBrokerageModel` uses the ImmediateSettlementModel for margin accounts and the DelayedSettlementModel with the default settlement rules for cash accounts.

```py
# For cash accounts:
security.set_settlement_model(DelayedSettlementModel(Equity.DEFAULT_SETTLEMENT_DAYS, Equity.DEFAULT_SETTLEMENT_TIME))

# For margin accounts:
security.set_settlement_model(ImmediateSettlementModel())
```

Margin Interest Rate

The `WolverineBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `WolverineBrokerageModel` is `Market.USA` .

Account Currency

The `WolverineBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Oanda

Introduction

This page explains the `OandaBrokerageModel` , including the asset classes it supports, its default security-level models , and its default markets.

```
self.set_brokerage_model(BrokerageName.OANDA_BROKERAGE, AccountType.MARGIN)
```

PY

For more information about this model, see the class reference and implementation .

Asset Classes

The `OANDABrokerageModel` supports trading Forex and CFDs .

Orders

The `OandaBrokerageModel` supports several order types, the `TimeInForce` order property, and order updates.

Order Types

The following table describes the available order types for each asset class that the `OANDABrokerageModel` supports:

Order Type	Forex	CFD
Market	✓	✓
Limit	✓	✓
Stop market	✓	✓
Stop limit	✓	✓

Time In Force

The `OANDABrokerageModel` the `GOOD_TIL_CANCELED` TimeInForce .

```
self.default_order_properties.time_in_force = TimeInForce.GOOD_TIL_CANCELED
self.limit_order(self._symbol, quantity, limit_price)
```

PY

Updates

The `OANDABrokerageModel` supports order updates .

Fills

The `OandaBrokerageModel` uses the ImmediateFillModel .

Slippage

The `OandaBrokerageModel` uses the NullSlippageModel .

Fees

The `OandaBrokerageModel` uses the ConstantFeeModel with zero fees. OANDA offers "Spread" and "Core + Commission" pricing models. Our data is the spread dataset, so we model the spread pricing. To estimate OANDA Core+Commission data, use a custom fee model and a custom fill model .

```
security.set_fee_model(ConstantFeeModel(0))
```

PY

Buying Power

The `OandaBrokerageModel` uses the `SecurityMarginModel` and allows up to 50x leverage.

Settlement

The `OandaBrokerageModel` uses the ImmediateSettlementModel for Forex trades and the AccountCurrencyImmediateSettlementModel for CFD trades.

Margin Interest Rate

The `OandaBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `OandaBrokerageModel` is `Market.OANDA` .

Account Currency

The `OandaBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Reality Modeling

Brokerage Message Handler

Introduction

When your brokerage sends a message, you receive this information in the algorithm and can take any actions. When you place an order through your brokerage platform instead of placing it through LEAN, you can decide whether the transaction handler should process the order. By default, the transaction handler only process orders that you place through LEAN. Custom brokerage message handlers enable you to instruct the transaction handler to process orders that you create directly through your brokerage's platform.

Set Models

To set a brokerage message handler, in the `initialize` method, call the `set_brokerage_message_handler` method.

```py
def initialize(self) -> None:
    # Set a custom brokerage message handler for the algorithm in Initialize method
    # It handles different type of returned message from the broker, helping you filter or abstract for the ones you care about
    self.set_brokerage_message_handler(MyBrokerageMessageHandler(self))
```

Default Behavior

The default brokerage message handler is the `DefaultBrokerageMessageHandler` . The following table describes how the `DefaultBrokerageMessageHandler` processes brokerage messages:

Brokerage Message Type	Action
`BrokerageMessageType. INFORMATION`	Sends a debug message for the algorithm.
`BrokerageMessageType. WARNING`	Sends an error message for the algorithm.
`BrokerageMessageType. ERROR`	Sets the algorithm runtime error and stops it.
`BrokerageMessageType. DISCONNECT`	Stops the algorithm after 15 minutes if the market is open. Otherwise, it stops five minutes after market open.
`BrokerageMessageType. RECONNECT`	Cancels the disconnection process.

The default brokerage message handler rejects orders you create through the brokerage. An example of this is when you place an order using the brokerage website or a third-party software.

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`algorithm`	`IAlgorithm`	The running algorithm.	
`initial_delay`	`timedelta/NoneType`	The amount of time LEAN will wait after a brokerage disconnection message for a reconnection message. If the reconnection message doesn't arrive before the time limit, LEAN stops running. If you don't provide a value, it uses `timedelta(minutes=15)` .	`None`
`open_threshold`	`timedelta/NoneType`	Defines how long before market open to re-check for brokerage reconnect message. If you don't provide a value, it uses `timedelta(minutes=5)` .	`None`

For more information about this model, see the class reference and implementation .

Model Structure

Brokerage message handlers extend the `DefaultBrokerageMessageHandler` class. Extensions of the `DefaultBrokerageMessageHandler` class should define the `handle_message` and `handle_order` methods.

The `handle_message` method processes the brokerage message event. It triggers any actions in the algorithm or notifications system required.

The `handle_order` method defines whether the transaction handler should process a new order you placed directly through the brokerage's website or third-party software.

```
PY
class CustomBrokerageMessageHandlerExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the brokerage message handler
        self.set_brokerage_message_handler(MyBrokerageMessageHandler(self))

# Define the custom brokerage message handler
class MyBrokerageMessageHandler(DefaultBrokerageMessageHandler):

    def __init__(self, algorithm):
        self._algorithm = algorithm

    def handle_message(self, message: BrokerageMessageEvent) -> None:
        self._algorithm.debug(f"{self._algorithm.time} Event: {message.message}")

    def handle_order(self, event_args: NewBrokerageOrderNotificationEventArgs) -> bool:
        return False
```

The `BrokerageMessageEvent` class has the following properties:

The `NewBrokerageOrderNotificationEventArgs` class has the following properties:

Brokerage Support

Most QuantConnect brokerage integrations don't support brokerage-side orders. If you create an order directly through your brokerage instead of through LEAN, your algorithm won't process the order because the return value of the `handle_order` method is ignored.

Terminal Link is the exception that can support brokerage-side orders. The following algorithm demonstrates how to implement a custom brokerage handler that accepts orders with a target `TerminalLinkOrderProperties.custom_notes_1` value.

```
PY
class CustomBrokerageSideOrderHandlingAlgorithm(QCAlgorithm):
    def initialize(self):
        self.set_start_date(2013, 10, 7)
        self.set_end_date(2013, 10, 11)
        self.set_brokerage_message_handler(CustomBrokerageMessageHandler(self))
        self.brokerage_side_order = None
        self.schedule.on(self.date_rules.every_day(), self.time_rules.every(timedelta(minutes=1)), self.check_brokerage_side_order)

    def check_brokerage_side_order(self):
        if not self.brokerage_side_order:
            return
        open_orders = self.transactions.get_open_orders()
        brokerage_order = next((x for x in open_orders if x.broker_id[0] == self.brokerage_side_order.broker_id[0]), None)
        if not brokerage_order:
            return
        if not self.securities.contains_key(brokerage_order.symbol):
            self.log(f"Security {brokerage_order.symbol} not found in algorithm's securities!")
        self.log(f"{self.time} :: Brokerage-side order found: {brokerage_order}")

class CustomBrokerageMessageHandler(DefaultBrokerageMessageHandler):
    def __init__(self, algorithm):
        super().__init__(algorithm)
        self._algorithm = algorithm

    def handle_order(self, event_args):
        order = event_args.order
        self._algorithm.brokerage_side_order = order

        # Only accept TerminalLink orders with a custom note "AcceptOrder".
        if not isinstance(order.properties, TerminalLinkOrderProperties):
            self._algorithm.log("handle_order(): order properties is not set to expected terminal link type, skipping")
            return False
        custom_notes1 = order.properties.custom_notes1
        result = custom_notes1 and "AcceptOrder" in custom_notes1
        self._algorithm.log(f"handle_order(): returning: {result}")
        return result
```

Examples

The following examples demonstrate common practices for implementing a custom brokerage message handler.

Example 1: Notification

The following algorithm buys and holds SPY. It implemented a custom brokerage message handler to send notifications to users through email and SMS in cases of disconnection, reconnections, and outside trades.

```py
class CustomBrokerageMessageHandlerAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # To simulate the connection to IB brokerage.
        self.set_brokerage_model(BrokerageName.INTERACTIVE_BROKERS_BROKERAGE, AccountType.MARGIN)
        # Set the brokerage message handler to our custom model.
        self.set_brokerage_message_handler(CustomBrokerageMessageHandler(self))

        # Request SPY data for trading.
        self.spy = self.add_equity("SPY").symbol

    def on_data(self, slice: Slice) -> None:
        # Buy and hold SPY as a strategy.
        if not self.portfolio.invested:
            self.set_holdings(self.spy, 1)

class CustomBrokerageMessageHandler(DefaultBrokerageMessageHandler):
    def __init__(self, algorithm: QCAlgorithm) -> None:
        self._algorithm = algorithm

    def handle_message(self, message: BrokerageMessageEvent) -> None:
        # Notify the user by SMS of the disconnection of the algorithm instance from the brokerage.
        if message.type == BrokerageMessageType.DISCONNECT:
            self._algorithm.notify.sms(
                phone_number="<YOUR_PHONE_NUMBER>",
                message="Your QC Algorithm instance 'CustomBrokerageMessageHandlerAlgorithm' was disconnected from the IB brokerage."
            )
        # Notify the user by SMS on reconnection of the algorithm instance to the brokerage after disconnection.
        elif message.type == BrokerageMessageType.RECONNECT:
            self._algorithm.notify.sms(
                phone_number="<YOUR_PHONE_NUMBER>",
                message="Your QC Algorithm instance 'CustomBrokerageMessageHandlerAlgorithm' was reconnected to the IB brokerage."
            )

    def handle_order(self, event_args: NewBrokerageOrderNotificationEventArgs) -> bool:
        # Notify the user by email on receiving an order from outside the algorithm.
        self._algorithm.notify.email(
            address="<YOUR_EMAIL_ADDRESS@example.com>",
            subject="Outside Order",
            message="Your QC Algorithm instance 'CustomBrokerageMessageHandlerAlgorithm' detected an outside order from the IB brokerage;
it has been processed to the algorithm."
        )
        # Process a new order placed through the brokerage's website or third-party software to handle it in the algorithm instance.
        return True
```

Reality Modeling

Buying Power

Introduction

Buying power models (also known as margin models) control how much buying power or leverage your portfolio has to make trades. When you place an order, LEAN uses the buying power model to determine whether the order should be submitted so you avoid placing orders that would be rejected by the brokerage. Buying power calculations can be very complex and depend on many factors, including the brokerage or even the time of day. For example, the `PatternDayTradingMarginModel` lets you have 4x leverage during regular trading hours and 2x leverage during pre-market and post-market trading hours.

What is Buying Power?

Buying power is the total amount of money you can spend in your brokerage account. It depends on the security type and account type. On one hand, Option and Future contracts are leveraged securities with specific buying power rules. On the other hand, the buying power of cash accounts is just the cash in the account while the buying power of margin accounts is leveraged by the brokerage credit.

What is Margin?

Margin is a credit loan from your brokerage you receive after you deposit collateral into your margin account. You need margin to place short-biased trades and you can use margin to increase your buying power, but you incur interest fees. Margin is the dollar value of the loan that the brokerage gives you. A margin requirement of 25% means that to purchase 10,000 worth of securities, you need at least 2,500 worth of collateral in your brokerage account to open the trade and you can borrow the rest on margin. Maintenance margin is the minimum equity (equity = total portfolio value - borrowed funds) you must have in your brokerage account to stay in your positions. If the value of your portfolio falls below the maintenance margin, you receive a margin call . If you receive a margin call, you either need to add more capital to your brokerage account or the brokerage will liquidate some of your holdings to reduce your exposure and their risk.

Some securities have special margin rules. Derivatives are leveraged assets with a floating margin requirement. In particular, long Options have zero maintenance margin requirement and their initial margin requirement is only the premium that you pay upfront.

What is Leverage?

Leverage is using borrowed money to increase your buying power. Leverage has an inverse relationship with your margin requirement and maintenance margin. If you have a margin requirement of 50%, you can use up to 1 / 50% = 2 leverage. Trading with leverage can be risky. It can boost your returns on profitable trades but can make your losing trades more expensive. If you have 10,000 in your brokerage margin account and purchase 20,000 worth of securities, you are trading with 2x leverage. If the value of the securities in your portfolio drops by 50% when you have a 2x leverage position, you lose all of your equity.

What Are Position Groups?

A position group is the combination of holdings. It has lower margin requirement and maintenance margin than the sum of each position of the group. If you have a margin requirement of 29,150 to purchase an in-the-money call Option contract, and a margin requirement of 101,499 to sell an out-of-the money call Option contract, the total margin requirement is $130,649. However, these positions compose a bull call spread with a margin requirement of $0.

Set Models

The brokerage model of your algorithm automatically sets the buying power model for each security, but you can override it. To manually set the buying power model of a security, call the `set_buying_power_model` method on the `Security` object.

```
PY
def initialize(self) -> None:
    security = self.add_equity("SPY")
    # Use 3x leverage on the selected security, which mimic the actual buying power of your broker
    security.set_buying_power_model(BuyingPowerModel(3))
```

You can also set the buying power model in a security initializer . If your algorithm has a universe, use the security initializer technique. In order to

initialize single security subscriptions with the security initializer, call `add_security_initializer` before you create the subscriptions.

```
class AddSecurityInitializerExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the security initializer to set models of assets.
        self.add_security_initializer(self._custom_security_initializer)

    def _custom_security_initializer(self, security: Security) -> None:
        # Overwrite some of the reality models
        security.set_buying_power_model(BuyingPowerModel(3))
```

PY

You cannot change the position group buying power models.

Supported Models

The following buying power models are available:

- BuyingPowerModel
- CashBuyingPowerModel
- ConstantBuyingPowerModel
- CryptoFutureMarginModel
- NullBuyingPowerModel
- FutureMarginModel
- FuturesOptionsMarginModel
- OptionMarginModel
- PatternDayTradingMarginModel

The following position group buying power models are available:

- SecurityPositionGroupBuyingPowerModel
- OptionStrategyPositionGroupBuyingPowerModel

The SecurityMarginModel is an alias to the BuyingPowerModel .

Default Behavior

The brokerage model of your algorithm automatically sets the buying power model of each security. The default brokerage model is the `DefaultBrokerageModel` , which sets the buying power model based on the asset class of the security. The following table shows the default buying power model of each asset class:

Asset Class	Model
Equity Options	`OptionMarginModel`
Futures	`FutureMarginModel`
Future Options	`FuturesOptionsMarginModel`
Index Options	`OptionMarginModel`
Crypto	`CashBuyingPowerModel` for cash accounts or `BuyingPowerModel` for margin accounts
CryptoFuture	`CryptoFutureMarginModel`
Forex	`CashBuyingPowerModel` for cash accounts or `BuyingPowerModel` for margin accounts
Other	`BuyingPowerModel`

Model Structure

Buying power models should extend the `BuyingPowerModel` class. Extensions of the `BuyingPowerModel` class should implement the following methods:

```
class CustomBuyingPowerModelExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        security = self.add_equity("SPY")
        # Set the custom buying power model of the selected security to mimic its actual buying power in your used broker
        security.set_buying_power_model(MyBuyingPowerModel())

# Define the custom buying power model
class MyBuyingPowerModel(BuyingPowerModel):
    def __init__(self,
                 leverage: float = 2,
                 requiredFreeBuyingPowerPercent: float = 0):
        super().__init__(leverage, requiredFreeBuyingPowerPercent)

    def get_leverage(self, security: Security) -> float:
        return super().get_leverage(security)

    def set_leverage(self, security: Security, leverage: float) -> None:
        super().set_leverage(security, leverage)

    def get_initial_margin_required_for_order(self,
                 parameters: InitialMarginRequiredForOrderParameters) -> InitialMargin:
        return super().get_initial_margin_required_for_order(parameters)

    def get_maintenance_margin(self,
                 parameters: MaintenanceMarginParameters) -> MaintenanceMargin:
        return super().get_maintenance_margin(parameters)

    def get_margin_remaining(self,
                 portfolio: SecurityPortfolioManager,
                 security: Security,
                 direction: OrderDirection) -> float:
        return super().get_margin_remaining(portfolio, security, direction)

    def get_initial_margin_requirement(self,
                 parameters: InitialMarginParameters) -> InitialMargin:
        return super().get_initial_margin_requirement(parameters)

    def has_sufficient_buying_power_for_order(self,
                 parameters: HasSufficientBuyingPowerForOrderParameters
                ) -> HasSufficientBuyingPowerForOrderResult:
        return super().has_sufficient_buying_power_for_order(parameters)

    def get_maximum_order_quantity_for_delta_buying_power(self,
                 parameters: GetMaximumOrderQuantityForDeltaBuyingPowerParameters
                ) -> GetMaximumOrderQuantityResult:
        return super().get_maximum_order_quantity_for_delta_buying_power(parameters)

    def get_maximum_order_quantity_for_target_buying_power(self,
                 parameters: GetMaximumOrderQuantityForTargetBuyingPowerParameters
                ) -> GetMaximumOrderQuantityResult:
        return super().get_maximum_order_quantity_for_target_buying_power(parameters)

    def get_reserved_buying_power_for_position(self,
                 parameters: ReservedBuyingPowerForPositionParameters
                ) -> ReservedBuyingPowerForPosition:
        return super().get_reserved_buying_power_for_position(parameters)

    def get_buying_power(self,
                 parameters: BuyingPowerParameters) -> BuyingPower:
        return super().get_buying_power(parameters)
```

Disable Buying Power Models

You can disable order margin checks and opt to let your brokerage decide to accept or reject the trades. This is helpful in live trading if you have a more permissive brokerage margin allowance that what LEAN models. The default position group buying power models are helpful for Option trading strategies. However, it can be counterproductive if it's not a supported Option strategy . To disable the validations of the default position group buying power model, use the `NullSecurityPositionGroupModel` . To set the `NullSecurityPositionGroupModel` for the portfolio, during initialization , call the `set_positions` method with the `SecurityPositionGroupModel. NULL` argument.

```
self.portfolio.set_positions(SecurityPositionGroupModel.NULL)
```

To disable the validations of the default buying power model , use the `NullBuyingPowerModel` . To set the `NullBuyingPowerModel` for a security subscription, call the `set_buying_power_model` method with the `BuyingPowerModel. NULL` argument.

```
def initialize(self) -> None:
    equity = self.add_equity("SPY")
    # To disable any buying power of the selected security
    equity.set_buying_power_model(BuyingPowerModel.NULL)
    # Alias:
    # equity.set_margin_model(SecurityMarginModel.NULL)
```

You can also set the `NullBuyingPowerModel` in a security initializer . If your algorithm has a universe, use the security initializer technique. To set the buying power of securities in the security initializer, set the brokerage model , set the security initializer , and then create security subscriptions.

```
class AddSecurityInitializerExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the security initializer to set models of assets.
        self.add_security_initializer(self._custom_security_initializer)

    def _custom_security_initializer(self, security: Security) -> None:
        # Overwrite the security buying power
        security.set_buying_power_model(BuyingPowerModel.NULL)
```

Set Asset Leverage

The buying power model sets the leverage for each security in your algorithm, but you can override its leverage settings after the buying power model is set.

To set the leverage when you create a security subscription, pass in a `leverage` argument.

```
def initialize(self) -> None:
 # Set the leverage to 3x manually subjected to specific need
 self.add_equity("SPY", leverage=3)
```

You can also set the asset leverage in a security initializer. In order to set the leverage of securities in the security initializer, call `add_security_initializer` before you create security subscriptions and after you call `set_brokerage_model` . If you pass in a `leverage` argument when you create the security subscription, the `leverage` argument takes precedence over the `set_leverage` call in the security initializer.

```
class AddSecurityInitializerExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the security initializer to set models of assets.
        self.add_security_initializer(self._custom_security_initializer)

    def _custom_security_initializer(self, security: Security) -> None:
        # Overwrite the security leverage
        security.set_leverage(3)
```

To set the leverage for all securities in a universe, set the `universe_settings.leverage` property.

```
def initialize(self) ->None:
 # Set the leverage to 3x to all securities, it should only be used for a very narrow spectrum of security universe with the same leverage
 # E.g. US Equities universe composed of only primary stocks in NYSE exchange
 self.universe_settings.leverage = 3
```

In live trading, LEAN doesn't ignore the leverage you set. However, if you set a different leverage from what your brokerage provides, it creates a mismatch between the buying power in your algorithm and the buying power the brokerage gives you. In this case, orders can pass the validations in LEAN but your brokerage may reject them.

PDT Rule

If all of the following statements are true, you are classified as a pattern day trader:

- You reside in the United States.
- You trade in a margin account.
- You execute 4+ intraday US Equity trades within 5 business days.
- Your intraday US Equity trades represent more than 6% of your total trades.

Pattern day traders must maintain a minimum equity of $25,000 in their margin account to continue trading. For more information about pattern day trading, see Am I a Pattern Day Trader? on the FINRA website.

The `PatternDayTradingMarginModel` doesn't enforce minimum equity rules and doesn't limit your trades, but it adjusts your available leverage based on the market state. During regular market hours, you can use up to 4x leverage. During extended market hours, you can use up to 2x leverage. This model is not automatically enforced, see Live Trading Considerations . You must manually set it on your securities.

```
security.margin_model = PatternDayTradingMarginModel()
```

Get Initial Margin Requirements

The following sections explain how to check if you have enough margin remaining to cover the initial margin requirements of various order types.

Check Requirements of Regular Orders

Follow these steps to check if you have enough margin remaining to cover the initial margin requirements of an order:

1. Create an `InitialMarginParameters` object with the security and quantity you want to trade.

   ```
   def on_data(self, slice: Slice) -> None:
       security = self.securities["SPY"]
       quantity = 100
       parameter = InitialMarginParameters(security, quantity)
   ```

2. Call the `get_initial_margin_requirement` method of the security's buying power model with the `InitialMarginParameters` .

   ```
       initial_margin = security.buying_power_model.get_initial_margin_requirement(parameter)
   ```

   The `get_initial_margin_requirement` method returns an `InitialMargin` object, which have the following properties:

3. Compare the margin you have remaining against the initial margin requirement of the order.

   ```
       if self.portfolio.margin_remaining >= initial_margin.value:
           self.market_order(security.symbol, quantity)
       else:
           self.debug("You don't have sufficient margin for this order.")
   ```

Check Requirements of Option Strategy Orders

Follow these steps to check if you have enough margin remaining to cover the initial margin requirements of an Option strategy :

1. Create an `OptionStrategy` object with the strategy you want to trade and its buying power model.

   For example, create a Bull Put Spread strategy.

   ```
   def initialize(self) -> None:
       # Subscribe to option data and cache the canonical symbol to obtain the option data
       self._symbol = self.add_option("SPY").symbol

   def on_data(self, slice: Slice) > None:
       # Trade on updated option chain data
       chain = slice.option_chains.get(self._symbol)
       if not chain:
           return

       itm_strike = max(x.strike for x in chain)
       otm_strike = min(x.strike for x in chain)
       expiry = min(x.expiry for x in chain)

       option_strategy = OptionStrategies.bull_put_spread(self._symbol, itm_strike, otm_strike, expiry)
   ```

2. Create an `OptionStrategyPositionGroupBuyingPowerModel` object of the strategy.

```
buying_power_model = OptionStrategyPositionGroupBuyingPowerModel(option_strategy)
```

3. Create a list of `Position` objects from the strategy legs.

```
def get_symbol(leg):
    return Symbol.CreateOption(
        self._symbol.underlying, self._symbol.id.market, self._symbol.id.option_style,
        leg.right, leg.strike, leg.expiration
    )

positions = [Position(get_symbol(leg), leg.quantity, 1) for leg in option_strategy.option_legs]
```

4. Create a `PositionGroupInitialMarginParameters` objects with the portfolio and the position group.

```
position_group = PositionGroup(buying_power_model, 1, positions)
parameters = PositionGroupInitialMarginParameters(self.portfolio, position_group)
```

5. Call the `get_initial_margin_requirement` method of the strategy's buying power model with the `PositionGroupInitialMarginParameters` .

```
initial_margin = buying_power_model.get_initial_margin_requirement(parameters)
```

   The `get_initial_margin_requirement` method returns an `InitialMargin` object, which have the following properties:

6. Compare the margin you have remaining against the initial margin requirement of the order.

   In this case, the `initial_margin.value` is the initial margin requirement for a trade size of 1. For different trade sizes, multiply the `initial_margin.value` by the quantity.

```
strategy_quantity = 2
if self.portfolio.margin_remaining >= strategy_quantity * initial_margin.value:
    self.buy(option_strategy, strategy_quantity)
else:
    self.debug("You don't have sufficient margin for this order.")
```

Live Trading Considerations

LEAN doesn't infer account type, leverage, margin requirements, or pattern day trading rules from your brokerage account. For example, if you have a cash account, and your algorithm doesn't set `AccountType. CASH` , LEAN will not automatically enforce cash account restrictions such as leverage of 1x or immediate settlement. You must manually configure your algorithm to adhere to these rules. If you set the leverage to 10x and you have a leverage of 2x, LEAN will place orders that can be rejected by your brokerage.

The default leverage of U.S. Equities is 2x. However, your brokerage can reduce the leverage of some securities based on market conditions. For example, leveraged ETFs such as TQQQ might have lower leverage during periods of high volatility. If your algorithm doesn't account for this, LEAN doesn't account for it and your orders can be rejected by your brokerage.

Examples

The following examples demonstrate some common practices for implementing a custom buying power model.

Example 1: Always Sufficient Buying Power

The following algorithm trades protective call strategy. Sometimes, the brokerage's margin requirement differs from the algorithm's default. To avoid errors on order submission at the algorithm level, we can use the `SecurityPositionGroupModel.NULL` and `NullBuyingPowerModel` to disable buying power limitation so the order is sent directly to the broker.

```py
class BuyingPowerModelAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.settings.seed_initial_prices = True
        self.add_security_initializer(self._custom_security_initializer)

        # Disable the validations of the default position group buying power model
        # that evaluates the buying power of multi-leg strategies
        self.portfolio.set_positions(SecurityPositionGroupModel.NULL)

        # Request SPY data for trading. Set the data normalization mode to raw to allow for a fair comparison in strike price.
        self.spy = self.add_equity("SPY", data_normalization_mode=DataNormalizationMode.RAW).symbol

        # Set a scheduled event to rebalance the protective put strategy.
        self.schedule.on(
            self.date_rules.week_start(self.spy),
            self.time_rules.after_market_open(self.spy, 0),
            self.rebalance
        )

    def rebalance(self) -> None:
        # Select the weekend expiring ATM put for the protective put strategy.
        chain = self.option_chain(self.spy)
        filtered = [x for x in chain if x.right == OptionRight.PUT and x.expiry <= self.time + timedelta(6)]
        if not filtered:
            return
        atm_put_contract = sorted(filtered,
            key=lambda x: (-abs(x.strike - x.underlying_last_price), x.expiry),
            reverse=True)[0]
        # Request the ATM put data for trading.
        atm_put = self.add_option_contract(atm_put_contract).symbol

        if self.portfolio[self.spy].invested:
            # If SPY is not assigned, we only need to buy the put.
            self.market_order(atm_put, 1, tag="Protective Put")
        else:
            # Order the protective put strategy by combo order.
            self.combo_market_order([
                    Leg.create(self.spy, 100),
                    Leg.create(atm_put, 1)
                ],
                1,
                tag="Protective Put"
            )

    def _custom_security_initializer(self, security: Security):
        # Do not allow buying power for options; only a hedging strategy with 0 margin is allowed.
        security.SetBuyingPowerModel(NullBuyingPowerModel())
```

Example 2: Default Model Wrapper

The following algorithm defines a subclass of the default `BuyingPowerModel` and overrides its built-in members so you can easily customize the parts you need.

PY

```
class CustomBuyingPowerModelAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        security = self.add_equity('SPY', Resolution.DAILY)
        security.set_buying_power_model(MyBuyingPowerModel())

    def on_data(self, data: Slice) -> None:
        if not self.portfolio.invested:
            self.set_holdings('SPY', 1)

class MyBuyingPowerModel(BuyingPowerModel):

    def __init__(self,
         leverage: float = 2,
         required_free_buying_power_percent: float = 0):
        super().__init__(leverage, required_free_buying_power_percent)

    def get_leverage(self, security: Security) -> float:
        return super().get_leverage(security)

    def set_leverage(self, security: Security, leverage: float) -> None:
        super().set_leverage(security, leverage)

    def get_initial_margin_required_for_order(self,
         parameters: InitialMarginRequiredForOrderParameters) -> InitialMargin:
        return super().get_initial_margin_required_for_order(parameters)

    def get_maintenance_margin(self,
         parameters: MaintenanceMarginParameters) -> MaintenanceMargin:
        return super().get_maintenance_margin(parameters)

    def get_margin_remaining(self,
         portfolio: SecurityPortfolioManager,
         security: Security,
         direction: OrderDirection) -> float:
        return super().get_margin_remaining(portfolio, security, direction)

    def get_initial_margin_requirement(self,
         parameters: InitialMarginParameters) -> InitialMargin:
        return super().get_initial_margin_requirement(parameters)

    def has_sufficient_buying_power_for_order(self,
         parameters: HasSufficientBuyingPowerForOrderParameters
        ) -> HasSufficientBuyingPowerForOrderResult:
        return super().has_sufficient_buying_power_for_order(parameters)

    def get_maximum_order_quantity_for_delta_buying_power(self,
         parameters: GetMaximumOrderQuantityForDeltaBuyingPowerParameters
        ) -> GetMaximumOrderQuantityResult:
        return super().get_maximum_order_quantity_for_delta_buying_power(parameters)

    def get_maximum_order_quantity_for_target_buying_power(self,
         parameters: GetMaximumOrderQuantityForTargetBuyingPowerParameters
        ) -> GetMaximumOrderQuantityResult:
        return super().get_maximum_order_quantity_for_target_buying_power(parameters)

    def get_reserved_buying_power_for_position(self,
         parameters: ReservedBuyingPowerForPositionParameters
        ) -> ReservedBuyingPowerForPosition:
        return super().get_reserved_buying_power_for_position(parameters)

    def get_buying_power(self,
         parameters: BuyingPowerParameters) -> BuyingPower:
        return super().get_buying_power(parameters)
```

Reality Modeling

Settlement

Settlement

Key Concepts

Introduction

After you trade an asset, the brokerage needs to settle the funds in your account. The most common type of settlement is immediate, where the funds are immediately available for trading after the transaction. In some cases, you may have delayed settlement, where you sell an asset and need to wait a few days to spend the cash you receive from the sale. A settlement model simulates these settlement rules.

Set Models

The brokerage model of your algorithm automatically sets the settlement model for each security, but you can override it. To manually set the settlement model of a security, call the `set_settlement_model` method on the `Security` object.

```py
def initialize(self) -> None:
    security = self.add_equity("SPY")
    # Set a delayed settlement model that settles 7 days after the trade at 8 AM
    # This can better mimic actual settlement of some brokerage, providing more realistic fund and margin available
    security.set_settlement_model(DelayedSettlementModel(7, timedelta(hours=8)))
```

You can also set the settlement model in a security initializer . If your algorithm has a universe, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `add_security_initializer` before you create the subscriptions.

```py
class AddSecurityInitializerExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the security initializer to set models of assets.
        self.add_security_initializer(self._custom_security_initializer)

    def _custom_security_initializer(self, security: Security) -> None:
        # Overwrite some of the reality models
        security.set_settlement_model(DelayedSettlementModel(7, timedelta(hours=8)))
```

To view all the pre-built settlement models, see Supported Models .

Default Behavior

The brokerage model of your algorithm automatically sets the settlement model for each security. The default brokerage model is the `DefaultBrokerageModel` , which sets the settlement model based on the security type and your account type. The following table shows how it sets the settlement models:

Security Type	Account Type	Settlement Model
Equity	Cash	DelayedSettlementModel with the default settlement rules
Option	Cash	DelayedSettlementModel with the default settlement rules
Future	Any	FutureSettlementModel

For all other cases, the `DefaultBrokerageModel` uses the ImmediateSettlementModel .

The default delayed settlement rule for US Equity trades is T+2 at 8 AM Eastern Time (ET). For example, if you sell on Monday, the trade settles on Wednesday at 8 AM. The default delayed settlement rule for Future and Option contracts is T+1 at 8 AM.

Model Structure

Settlement models must extend the `ISettlementModel` interface. Extensions of the `ISettlementModel` interface must implement the `scan` and `apply_funds` methods. The `scan` method is automatically called at the top of each hour and it receives a `ScanSettlementModelParameters` object. The `apply_funds` method receives an `ApplyFundsSettlementModelParameters` object and applies the settlement rules. The `apply_funds` method is also automatically called, but its frequency depends on the security type. The `apply_funds` method is automatically called when you fill an order for the following security types:

- Equity
- Equity Options
- Crypto
- Forex
- Future Options
- Index Options

The `apply_funds` method is automatically called when you close a position for the following security types:

- Futures
- Crypto Futures
- CFD

```py
class CustomSettlementModelExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        security = self.add_equity("SPY")
        # Set the custom settlement model of the selected security to reflect actual scenario for more realistic margin available
        security.set_settlement_model(MySettlementModel())

# Define the custom settlement model outside of the algorithm
class MySettlementModel:
    def apply_funds(self, applyFundsParameters: ApplyFundsSettlementModelParameters) -> None:
        currency = applyFundsParameters.cash_amount.currency
        amount = applyFundsParameters.cash_amount.amount
        applyFundsParameters.portfolio.cash_book[currency].add_amount(amount)

    def scan(self, settlementParameters: ScanSettlementModelParameters) -> None:
        pass

    def get_unsettled_cash(self) -> CashAmount:
        return CashAmount(0, 'USD')
```

`ApplyFundsSettlementModelParameters` objects have the following properties:

`ScanSettlementModelParameters` objects have the following properties:

You likely don't need to create a custom settlement model because the supported models already implement immediate and delayed settlement rules.

Examples

The following examples demonstrate some common practices for implementing the settlement model.

Example 1: 2-day Settlement

The following algorithm simulates Interactive Brokers cash account. According to IB's website, cash positions will be settled in 48 hours. Thus, we can implement `DelayedSettlementModel` to mimic that. We hold the intra-day position of SPY to implement the settlement logic.

```py
# region imports
from AlgorithmImports import *
# endregion

class SettlementModelAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Simulate a cash account of IB.
        self.set_brokerage_model(BrokerageName.INTERACTIVE_BROKERS_BROKERAGE, AccountType.CASH)
        # We need to set the settlement model in the security initializer.
        self.set_security_initializer(CustomSecurityInitializer(self.brokerage_model, SecuritySeeder.NULL))

        # Request SPY data for trading.
        self.spy = self.add_equity("SPY").symbol

    def on_data(self, slice: Slice) -> None:
        # Trade based on updated data.
        bar = slice.quote_bars.get(self.spy)
        if bar and not self.portfolio.invested:
            # Order based on the current available cash.
            quantity = (self.portfolio.cash - self.portfolio.unsettled_cash) //  bar.ask.close
            if quantity > 0:
                self.market_order(self.spy, quantity)

        # Exit position before market close; we only hold the intraday position.
        if slice.time.hour == 15 and slice.time.minute == 45:
            self.liquidate()

class CustomSecurityInitializer(BrokerageModelSecurityInitializer):
    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder):
        super().__init__(brokerage_model, security_seeder)
    def initialize(self, security: Security) -> None:
        super().initialize(security)
        # IB settles cash in 48 hours.
        security.set_settlement_model(DelayedSettlementModel(2, timedelta(hours=0)))
```

Example 2: No Unsettled Cash

The following algorithm implements a custom settlement model that states there is always $0 of unsettled cash.

```py

class CustomSettlementModelAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        security = self.add_equity('SPY')
        security.set_settlement_model(MySettlementModel())

        self.schedule.on(
            self.date_rules.every_day('SPY'),
            self.time_rules.every(timedelta(minutes=30)),
            self._plot_cash
        )

        self._traded = False

    def _plot_cash(self):
        self.Plot("Settled Cash", "USD", self.Portfolio.CashBook["USD"].Amount)
        self.Plot("Unsettled Cash", "USD", self.Portfolio.UnsettledCashBook["USD"].Amount)

    def on_data(self, data: Slice) -> None:
        if self._traded:
            return

        self.market_order('SPY', 1)
        self.market_order('SPY', -1)
        self._traded = True

class MySettlementModel:

    def apply_funds(self, apply_funds_parameters: ApplyFundsSettlementModelParameters) -> None:
        currency = apply_funds_parameters.cash_amount.currency
        amount = apply_funds_parameters.cash_amount.amount
        apply_funds_parameters.portfolio.cash_book[currency].add_amount(amount)

    def scan(self, settlement_parameters: ScanSettlementModelParameters) -> None:
        pass

    def get_unsettled_cash(self) -> CashAmount:
        return CashAmount(0, 'USD')
```

Settlement

Supported Models

Introduction

This page describes all of the pre-built settlement models in LEAN. For more brokerage-specific settlement models, see the brokerage model documentation . If none of these models perform exactly how you want, create a custom settlement model .

Immediate Model

The `ImmediateSettlementModel` immediately adds or removes the cash from your portfolio when your transactions fill.

```
security.set_settlement_model(ImmediateSettlementModel())
```

PY

For more information about this model, see the class reference and implementation .

Delayed Model

The `DelayedSettlementModel` immediately removes the cash from your portfolio when your buy orders fill. When your sell orders fill, it adds the cash to your unsettled cash book . When the settlement period ends, the unsettled cash is added to your portfolio.

```
security.set_settlement_model(DelayedSettlementModel(7, timedelta(hours=8)))
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`number_of_days`	`int`	The number of days required for settlement	
`time_of_day`	`timedelta`	The time of day used for settlement	

For more information about this model, see the class reference and implementation .

Account Currency Immediate Model

The `AccountCurrencyImmediateSettlementModel` applies cash settlement immediately and automatically converts the settlement cash into the account currency.

```
security.set_settlement_model(AccountCurrencyImmediateSettlementModel())
```

PY

For more information about this model, see the class reference and implementation .

Future Model

The `FutureSettlementModel` settles the daily profit and loss at the start of each day.

```
security.set_settlement_model(FutureSettlementModel())
```

PY

For more information about this model, see the class reference and implementation .

Reality Modeling

Options Models

Options Models

Pricing

Introduction

Option price models compute the theoretical price of Option contracts, their implied volatility (IV), and their Greek values. Theoretical prices can help you detect undervalued and overvalued contracts, IV can provide you insight into the upcoming volatility of the underlying security, and Greek values can help you hedge your portfolio.

Data Discrepancies

There are several ways for you to get the Greeks and IV values, but you may notice some discrepancies between them.

Greeks in Universe Selection

The Greeks and IV values in the universe filter function are the daily, pre-calculated values based on the end of the previous trading day. You can't customize the Greeks and IV values that the filter function receives.

Greeks in Chain Requests

The Greeks and IV values in the `OptionUniverse` objects that you get from calling the `option_chain` method are the daily, pre-calculated values based on the end of the previous trading day. You can't customize the Greeks and IV values that you get from this method.

Greeks in Data Events

The Greeks and IV values in the Slice that you get in the `on_data` method are the values from the Option price model. To customize the Greeks and IV values in the `Slice` , set a different price model.

Set Models

To set the price model of an Option, set its `price_model` property.

If you have access to the `Option` object when you subscribe to the Option universe or contract, you can set the price model immediately after you create the subscription.

```
PY
def initialize(self):
    self.universe_settings.asynchronous = True
    option = self.add_option("SPY")
    # SPY options are American Options, in which IV and greeks more accurately calculated using Binomial model
    option.price_model = OptionPriceModels.binomial_cox_ross_rubinstein()
```

Otherwise, set the price model in a security initializer .

```
PY
class AddSecurityInitializerExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the security initializer to set models of assets.
        self.add_security_initializer(self._custom_security_initializer)

    def _custom_security_initializer(self, security: Security) -> None:
        # Overwrite the price model
        if security.type == SecurityType.OPTION: # Option type
            security.price_model = OptionPriceModels.binomial_cox_ross_rubinstein()
```

Default Behavior

The default Option price model is the `OptionPriceModels.binomial_cox_ross_rubinstein` model for American Options or `OptionPriceModels.black_scholes` model for European Options.

Model Structure

Option price models should extend the `OptionPriceModel` class. Extensions of the `OptionPriceModel` class must implement the `evaluate` method, which receives `OptionPriceModelParameters` and returns an `OptionPriceModelResult` that contains the theoretical price, the implied volatility, and Greeks.

```
PY
class CustomOptionPriceModelExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the custom price model for an added option chain to use the custom model
        option = self.add_option("SPY")
        option.set_price_model(CustomOptionPriceModel())

# Define the custom price model
class CustomOptionPriceModel(CurrentPriceOptionPriceModel):
    def evaluate(self, parameters: OptionPriceModelParameters) -> OptionPriceModelResult:
        contract = parameters.contract
        underlying = contract.underlying_last_price
        strike = contract.strike
        greeks = Greeks(0.5, 0.2, 0.15, 0.05, 0.1, 2.0)

        if contract.right == OptionRight.CALL:
            intrinsic = max(0, underlying - strike)
        else:
            intrinsic = max(0, strike - underlying)
            # Delta and Rho are negative for a put
            greeks.delta *= -1
            greeks.rho *= -1

        theoretical_price = intrinsic + 1.0
        implied_volatility = 0.2

        return OptionPriceModelResult(theoretical_price, implied_volatility, greeks)
```

The `OptionPriceModelParameters` object has the following members:

Disable Pricing

To turn off the Option price calculations, use the `OptionPriceModels.null` model. This model sets the implied volatility and Greeks to 0, and sets the theoretical price to the current price.

```
PY
option.price_model = OptionPriceModels.null()
```

Legacy Models

On February, 19th, 2026, QuantConnect announced new price models for LEAN under the `OptionPriceModels` namespace. The legacy models are still available under the `OptionPriceModels.QuantLib` namespace. The default legacy Option price model was the `OptionPriceModels.QuantLib.binomial_cox_ross_rubinstein` model for American Options or `OptionPriceModels.QuantLib.black_scholes` model for European Options.

```
PY
# option.price_model = OptionPriceModels.binomial_cox_ross_rubinstein()   # New model
option.price_model = OptionPriceModels.QuantLib.binomial_cox_ross_rubinstein()   # Legacy model
```

Certain legacy models do not have a direct equivalent in the new price models. See Supported Models for available options.

```
PY
option.price_model = OptionPriceModels.QuantLib.crank_nicolson_fd()
```

Supported Models

LEAN supports the following Option price models.

Model `OptionPriceModels`	American Style	European Style
`binomial_cox_ross_rubinstein`	✓	✓
`black_scholes`		✓
`forward_tree`	✓	✓

These models implement the `IndicatorBasedOptionPriceModel` , which uses the implied volatility and Greeks indicators , with different methodologies.

```py
def initialize(self):
    spy_option = self.add_option("SPY")
    spy_option.price_model = OptionPriceModels.binomial_cox_ross_rubinstein()
    spx_option = self.add_index_option("SPX")
    spx_option.price_model = OptionPriceModels.black_scholes()
```

LEAN supports the following legacy Option price models from the QuantLib library.

Model `OptionPriceModels.QuantLib`	American Style	European Style
`additive_equiprobabilities`	✓	✓
`barone_adesi_whaley`	✓	
`binomial_cox_ross_rubinstein`	✓	✓
`binomial_jarrow_rudd`	✓	✓
`binomial_joshi`	✓	✓
`binomial_leisen_reimer`	✓	✓
`binomial_tian`	✓	✓
`binomial_trigeorgis`	✓	✓
`bjerksund_stensland`	✓	
`black_scholes`		✓
`crank_nicolson_fd`	✓	✓
`integral`		✓

```py
def initialize(self):
    aapl_option = self.add_option("AAPL")
    aapl_option.price_model = OptionPriceModels.QuantLib.crank_nicolson_fd()
    spy_option = self.add_option("SPY")
    spy_option.price_model = OptionPriceModels.QuantLib.binomial_cox_ross_rubinstein()
    spx_option = self.add_index_option("SPX")
    spx_option.price_model = OptionPriceModels.QuantLib.black_scholes()
```

If you set the price model of an Option to a model with an incompatible style, LEAN throws an exception.

What are Greeks?

Option Greeks measure the exposure of Option price or Option delta to the movement of different factors such as the underlying price, time, and volatility. The Greeks are a function of implied volatility. For more information about them, see The Greek Letters .

LEAN provides indicator implementations of Option Greeks. It provides higher flexibility on Option price model selection, volatility modeling , and allows IV smoothing through call-put pair. The `IndicatorBasedOptionPriceModel` use these indicators to calculate the Greeks values. For details, see Option Indicators .

What Is Implied Volatility?

Implied volatility is the forecasted future volatility of a security.

LEAN provides an indicator implementation of implied volatility. It provides higher flexibility on Option price model selection, volatility modeling , and allows IV smoothing through call-put pair. The `IndicatorBasedOptionPriceModel` use these indicators to calculate the implied volatility values. For details, see Implied Volatility .

The legacy Option price models use the realized volatility to calculate the implied volatility. By default, they use the formula from Brenner and Subrahmanyam (1988) as the initial guess for implied volatility.

$$\frac{P}{S} \sqrt{\frac{2\pi}{T}}$$

where P is the Option contract price, S is the underlying price, and T is the time until Option expiration. If the volatility model of the underlying security is ready , the price model uses its value as the initial guess for implied volatility and as an input to calculate the theoretical contract prices.

What Is Volatility Smile?

The "volatility smile" is a term used in finance to describe a particular shape that can be observed when plotting IV against strike prices for options that share the same expiration date. Typically, when you plot IVs against strike prices, the curve tends to be concave, resembling a smile. This means that options with strike prices significantly above or below the current market price of the underlying asset tend to have higher IV than options with strike prices closer to the current market price.

Several theories attempt to explain the existence of the volatility smile. One explanation is that it arises from adjustments to the classic Black-Scholes-Merton (BSM) model, which assumes that asset prices follow a log-normal distribution. The volatility smile suggests that the market anticipates a higher probability of extreme price movements (fat tails) than the BSM model predicts. Another explanation is related to market dynamics and the demand for hedging. During periods of heightened market volatility, the volatility smile tends to become steeper, indicating a greater disparity in implied volatilities across different strike prices. This means that options, particularly those with out-of-the-money strike prices, become more expensive as investors seek protection against potential market downturns or increased price fluctuations. As a result, the volatility smile can serve as a valuable tool for investors and traders to assess market sentiment and gauge the level of risk in their portfolios.

According to some volatility models, such as the Heston model, the IV smile/surface should exhibit a smooth pattern. Any deviations from this smoothness, such as non-smooth spikes or irregularities, may signal potential arbitrage opportunities for traders.

Volatility Smirk

However, in some cases, rather than a traditional U-shaped curve, traders may observe what's known as a "smirk." This smirk occurs when the implied volatilities for higher-strike options are lower than those for ATM and lower-strike options. This deviation from the typical volatility smile pattern indicates a market expectation of a significant downward movement in the underlying asset's price. Traders interpret this as a signal that investors are allocating funds towards options with higher probabilities of such downward movements, resulting in increased demand for lower-strike options.

What Is Volatility Smoothing?

Volatility smoothing refers to the creation of a smooth volatility smile/surface. Derivative like options are favorable for maket-making and arbitration trading, due to the existence of fair price modeling. In the contemporary domain of high-frequency trading, the efficiency of calculating IV and Greeks assumes paramount significance. Thus, the quest for swift and refined IV surface computation becomes an inevitable quest for traders. Rather than relying solely on conventional methods involving slow-paced sampling and continuous parameter recalibration, the adoption of approximation techniques and stationary state analyses gains traction, especially in the context of IV estimation.

Accuracy Consideration

The Law of One Price stipulates the existence of a singular fair price for any given underlying asset. Consequently, according to the principles of put-call parity, each strike price for European options at expiration should correspond to a unique IV value. Within the realm of the Black-Scholes-Merton (BSM) framework, for instance, the concept of put-call parity yields insights into the equivalence of IVs for call and put options at identical strike prices and expirations. This equivalence serves as the foundation for formulating objective function: $C(t,K) - P(t,K)=e^{(q-r)t} (S_T - K) \\\Rightarrow e^{(q-r)t} [S_T (\Phi(d_{+}^{call})+\Phi(-d_{+}^{put})) - K (\Phi(d_{-}^{call})+\Phi(-d_{-}^{put}))] = e^{(q-r)t} (S_T - K) \\\Rightarrow \Phi(d_{+}^{call})+\Phi(-d_{+}^{put}) = 1\ \text{and}\ \Phi(d_{-}^{call})+\Phi(-d_{-}^{put}) = 1 \\\Rightarrow d_{\pm}^{call}=d_{\pm}^{put}$ Thus, we can formulate an objective function of $C_{market} + P_{market} = C_{BSM} + P_{BSM}$.

Alternatively, certain schools of thought contend that the bulk of historical volatility information is encapsulated within at-the-money (ATM) options,

with any residual volatility attributable to the extrinsic value of the option. Consequently, a strategy focused on out-of-the-money (OTM) options for IV calculations gains traction.

Speed Consideration

In the realm of high-frequency trading, where split-second decisions are the norm, the traditional process of sampling, evaluating, recalibrating, and deriving implied volatility expectations is simply unfeasible. In response, traders and analysts increasingly turn to polynomial regression techniques as a pragmatic solution for IV modeling.

For example, $IV_t = \beta_0 + \beta_1 M + \beta_2 M^2 + \beta_3 (T-t) + \beta_4 (T-t)^2 + \beta_5 M(T-t) \\\text{where} M = ln(S_t/K)$

Additionally, the utilization of advanced mathematical algorithms, such as the Fast Fourier Transform (FFT), enables the rapid computation of the entire Greek surface, enhancing speed and efficiency. While these approaches may entail minor trade-offs in terms of accuracy, the overarching objective remains the attainment of a seamlessly smooth implied volatility surface that fosters effective arbitrage strategies.

Options Models

Volatility

Volatility

Key Concepts

Introduction

Volatility models measure the historical volatility of an asset. They are mostly used to calculate the volatility of the underlying security of an Option because the implied volatility of an Option contract needs an initial guess. The historical volatility doesn't need to be the standard deviation of the asset prices. The various volatility models in LEAN each have a unique methodology to calculate volatility.

LEAN also provides an indicator implementation of implied volatility. It provides higher flexibility on Option price model selection, volatility modeling , and allows IV smoothing through call-put pair. For details, see Implied Volatility .

Set Models

To set the volatility model of the underlying security of an Option, set the `VolatilityModel` property of the `Security` object. The volatility model can have a different resolution than the underlying asset subscription.

```py
def initialize(self) -> None:
    underlying_security = self.add_equity("SPY")
    # Usually, the historical and implied volatility is calculated using 30-day standard deviation of return
    underlying_security.volatility_model = StandardDeviationOfReturnsVolatilityModel(30)
```

You can also set the volatility model in a security initializer . If your algorithm has a universe of underlying assets, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `add_security_initializer` before you create the subscriptions.

```py
class AddSecurityInitializerExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the security initializer to set models of assets.
        self.add_security_initializer(self._custom_security_initializer)

    def _custom_security_initializer(self, security: Security) -> None:
        # Overwrite the volatility model
        if security.Type == SecurityType.EQUITY:
            security.volatility_model = StandardDeviationOfReturnsVolatilityModel(30)
```

To view all the pre-built volatility models, see Supported Models .

Default Behavior

The default underlying volatility model for Equity Options and Index Options is the StandardDeviationOfReturnsVolatilityModel based on 30 days of daily resolution data. The default underlying volatility model for Future Options is the NullVolatilityModel .

Model Structure

Volatility models should extend the `BaseVolatilityModel` class. Extensions of the `BaseVolatilityModel` class must have `update` and `get_history_requirements` methods and a `volatility` property. The `update` method receives `Security` and `BaseData` objects and then updates the `volatility` . The `get_history_requirements` method receives `Security` and `datetime` objects and then returns a list of `HistoryRequest` objects that represent the history requests to warm up the model. Volatility models receive data at each time step in the algorithm to update their state.

```
class CustomVolatilityModelExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        underlying_security = self.add_index("VIX")
        # Apply custom volatility model for specific underlyings, often they are synthetic products or with different market calendar
        underlying_security.volatility_model = MyVolatilityModel()

# Define the custom volatility model outside of the algorithm
class MyVolatilityModel(BaseVolatilityModel):
    volatility: float = 0

    def set_subscription_data_config_provider(self,
        subscription_data_config_provider: ISubscriptionDataConfigProvider) -> None:
        super().set_subscription_data_config_provider(subscription_data_config_provider)

    def update(self, security: Security, data: BaseData) -> None:
        pass

    def get_history_requirements(
            self,
            security: Security,
            utc_time: datetime | date,
            resolution: Resolution | None = None,
            bar_count: int = 0) -> Iterable[HistoryRequest]:
        return super().get_history_requirements(security, utc_time, resolution, bar_count)
```

Warm Up Models

To use your volatility model as the inital guess for the implied volatility , warm up the volatility model of the underlying security. If you subscribe to all the Options in the `initialize` method, set a warm-up period to warm up their volatility models. The warm-up period should provide the volatility models with enough data to compute their values.

```
def initialize(self) -> None:
    # For default 30-day SD of return as volatility, you need 30+1 trading day to warm up
    self.set_warm_up(30, Resolution.DAILY)

def on_data(self, slice: Slice) -> None:
    # Only take the warmed-up volatility value into account for accuracy issue
    if self.is_warming_up:
        return
```

If you have a dynamic universe of underlying assets and add Option contracts to your algorithm with the `add_option_contract` , `add_index_option_contract` , or `add_future_option_contract` methods, warm up the volatility model when the underlying asset enters your universe. We recommend you do this inside a security initializer .

```
class AddSecurityInitializerExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the security initializer to set models of assets.
        self.add_security_initializer(self._custom_security_initializer)

    def _custom_security_initializer(self, security: Security) -> None:
        # Overwrite and warm up the volatility model
        if security.type == SecurityType.EQUITY:  # Underlying asset type
            security.volatility_model = StandardDeviationOfReturnsVolatilityModel(30)
            trade_bars = self.history[TradeBar](security.symbol, 30, Resolution.DAILY)
            for trade_bar in trade_bars:
                security.volatility_model.update(security, trade_bar)
```

Examples

The following examples demonstrate common practices for implementing a custom volatility model.

Example 1: Default Model Wrapper

The following algorithm defines a subclass of the `BaseVolatilityModel` and overrides its built-in members so you can easily customize the parts you need.

```py
class CustomVolatilityModelAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        security = self.add_equity('SPY', Resolution.DAILY)
        security.volatility_model = MyVolatilityModel()

    def on_data(self, data: Slice) -> None:
        if not self.portfolio.invested:
            self.set_holdings('SPY', 1)

class MyVolatilityModel(BaseVolatilityModel):
    volatility: float = 0

    def set_subscription_data_config_provider(self,
        subscription_data_config_provider: ISubscriptionDataConfigProvider) -> None:
        super().set_subscription_data_config_provider(subscription_data_config_provider)

    def update(self, security: Security, data: BaseData) -> None:
        pass

    def get_history_requirements(
            self,
            security: Security,
            utc_time: datetime | date,
            resolution: Resolution | None = None,
            bar_count: int = 0) -> Iterable[HistoryRequest]:
        return super().get_history_requirements(security, utc_time, resolution, bar_count)
```

Other Examples

Demonstration Algorithms
CustomVolatilityModelAlgorithm.py Python

Volatility

Supported Models

Introduction

This page describes all of the pre-built volatility models in LEAN. If none of these models perform exactly how you want, create a custom volatility model .

Null Model

The `NullVolatilityModel` sets the volatility of the security to zero. It's the default volatility model for the underlying asset of Future Options.

```
underlying_security.volatility_model = VolatilityModel.NULL
```

PY

For more information about this model, see the class reference and implementation .

Standard Deviation of Returns Model

The `StandardDeviationOfReturnsVolatilityModel` sets the volatility of the security to the annualized sample standard deviation of trailing returns. It's the default volatility model for the underlying asset of Equity Options and Index Options.

```
underlying_security.volatility_model = StandardDeviationOfReturnsVolatilityModel(30)
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`periods`	`int`	The max number of samples to use when calculating the standard deviation of returns. This value must be greater than two.	
`resolution`	`Resolution` / `NoneType`	The resolution of the price data used to calculate the standard deviation. This only has a material effect in live mode. For backtesting, this value does not cause any behavioral changes.	`None`
`update_frequency`	`timedelta` / `NoneType`	The frequency at which new values are inserted into the rolling window for the standard deviation calculation. If the value is `None` , it defaults to the `timedelta` representation of `resolution` . If the value and `resolution` are `None` , it defaults to a `timedelta` of one day.	`None`

For more information about this model, see the class reference and implementation .

Relative Standard Deviation Model

The `RelativeStandardDeviationVolatilityModel` sets the volatility of the security to the relative standard deviation of its price. In symbols, the value is

$$\frac{|\mu|}{\sigma}$$

where μ is the average of the samples and σ is the standard deviation of the samples.

```
underlying_security.volatility_model = RelativeStandardDeviationVolatilityModel(timedelta(days=1), 10)
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`period_span`	`timedelta`	The period of time to wait between each sample of the security price	
`periods`	`int`	The number of samples to use to calculate the volatility value	

For more information about this model, see the class reference and implementation .

Options Models

Exercise

Introduction

If you exercise a long Option position or are assigned on your short Option position, LEAN processes an Option exercise order. The Option exercise model converts the Option exercise order into an OrderEvent .

Set Models

To set the exercise model of an Option, call the `set_option_exercise_model` method of the `Option` object inside a security initializer .

```py
class AddSecurityInitializerExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the security initializer to set models of assets.
        self.add_security_initializer(self._custom_security_initializer)

    def _custom_security_initializer(self, security: Security) -> None:
        # Overwrite the Option exercise model
        if security.Type == SecurityType.OPTION: # Option type
            security.set_option_exercise_model(DefaultExerciseModel())
```

Default Behavior

The default Option exercise model is the `DefaultExerciseModel` . The `DefaultExerciseModel` fills exercise orders to the full quantity with zero fees and applies an order tag to represent if the order is an exercise or assignment.

For more information about this model, see the class reference and implementation .

Model Structure

Option exercise models should extend the `DefaultExerciseModel` class. Extensions of the `DefaultExerciseModel` must implement the `option_exercise` method, which receives `Option` and `OptionExerciseOrder` objects and then returns a list of `OrderEvent` objects that contain the order fill information.

```py
class CustomOptionExerciseModelExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        security = self.add_option("SPY")
        # Set custom option exercise model for mimicking specific Brokerage most realistic actions
        security.set_option_exercise_model(MyOptionExerciseModel())

# Define the custom Option exercise model outside of the algorithm
class MyOptionExerciseModel(DefaultExerciseModel):
    def option_exercise(self, option: Option, order: OptionExerciseOrder) -> List[OrderEvent]:
        in_the_money = option.is_auto_exercised(option.underlying.close)
        is_assignment = in_the_money and option.holdings.is_short

        order_event = OrderEvent(
            order.id,
            option.symbol,
            Extensions.convert_to_utc(option.local_time, option.exchange.time_zone),
            OrderStatus.FILLED,
            Extensions.get_order_direction(order.quantity),
            0.0,
            order.quantity,
            OrderFee.ZERO,
            "Tag"
        )
        order_event.is_assignment = is_assignment
        return [ order_event ]
```

`OptionExerciseOrder` objects have the following properties:

The following table describes the arguments of the `OrderEvent` constructor:

Argument Details

Argument: `order_id`

Id of the parent order

Data Type: `int` | Default Value: `-`

Argument: `symbol`

Asset Symbol

Data Type: `Symbol` | Default Value: `-`

Argument: `utc_time`

Date/time of this event

Data Type: `datetime` | Default Value: `-`

Argument: `direction`

The direction of the order. The `OrderDirection` enumeration has the following members:

Data Type: `OrderDirection` | Default Value: `Hold`

Argument: `fill_price`

Fill price information if applicable

Data Type: `float` | Default Value: `0`

Argument: `fill_quantity`

Fill quantity

Data Type: `float` | Default Value: `0`

Argument: `order_fee`

The order fee. You can use `OrderFee.ZERO` or create an `OrderFee` object with a custom fee.

```
OrderFee(CashAmount(0.5, 'USD'))
```

Data Type: `OrderFee` | Default Value: `-`

Argument: `message`

Message from the exchange

Data Type: `str` | Default Value: `""`

`OrderEvent` objects have the following attributes:

Examples

The following examples demonstrate some common practices for implementing a custom Option exercise model.

Example 1: Cash Settlement

The following algorithm trades GOOG 30-day expiring straddle. Yet, instead of settling with the underlying stock, some brokerages will settle with cash for ITM options. To simulate this behavior, we can create a custom option exercise model.

```py
class OptionExerciseModelAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Request GOOG option data for trading.
        security = self.add_option("GOOG")
        self.goog = security.symbol
        # Filter for the 2 ATM contracts expiring in 30 days to form a straddle strategy.
        security.set_filter(lambda universe: universe.straddle(30))
        # Set custom option exercise model for disabling exercise through security initializer.
        self.settings.seed_initial_prices = True

    def on_data(self, slice: Slice) -> None:
        # Open position on updated option chain data.
        chain = slice.option_chains.get(self.goog)
        if chain and not self.portfolio.invested:
            # Only one strike and expiry for the straddle universe.
            strike = min(x.strike for x in chain)
            expiry = min(x.expiry for x in chain)
            # Open the straddle position.
            option_straddle = OptionStrategies.straddle(self.goog, strike, expiry)
            self.buy(option_straddle, 5)

class MySecurityInitializer(BrokerageModelSecurityInitializer):
    def __init__(self, brokerageModel, securitySeeder):
        super().__init__(brokerageModel, securitySeeder)

    def initialize(self, security: Security) -> None:
        super().initialize(security)

        # Set the custom Option exercise model for Option securities
        if security.type == SecurityType.OPTION:
            security.set_option_exercise_model(MyOptionExerciseModel())

# Define the custom Option exercise model outside of the algorithm
class MyOptionExerciseModel(DefaultExerciseModel):
    def option_exercise(self, option: Option, order: OptionExerciseOrder) -> List[OrderEvent]:
        underlying = option.underlying
        utc_time = Extensions.convert_to_utc(option.local_time, option.exchange.time_zone)
        in_the_money = option.is_auto_exercised(underlying.close)
        # Cash settle: using payoff.
        payoff = option.get_intrinsic_value(underlying.close)

        # Only liquidate option positions, but do not add equity positions.
        order_event = OrderEvent(
            order.id,
            option.symbol,
            utc_time,
            OrderStatus.FILLED,
            Extensions.get_order_direction(order.quantity),
            payoff,
            order.quantity,
            OrderFee.ZERO,
            "Option Settlement"
        )
        order_event.is_in_the_money = in_the_money
        return [ order_event ]
```

Example 2: Default Model Implementation

The following algorithm implements the `DefaultExerciseModel` so you can easily customize the parts you need.

PY

```
class CustomExerciseModelAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.settings.seed_initial_prices = True
        self.add_security_initializer(self._custom_security_initializer)
        option = self.add_option("SPY")
        self.option_symbol = option.symbol

    def on_data(self, data: Slice):
        if self.portfolio.invested:
            return
        chain = data.option_chains.get(self.option_symbol)
        if chain:
            contract = sorted([x for x in chain if x.right == OptionRight.CALL],
                key=lambda x: x.strike)[0]
            self.market_order(contract.symbol, 1)
            self.exercise_option(contract.symbol, 1)
            self.quit()

    def _custom_security_initializer(self, security: Security) -> None:
        if security.type == SecurityType.OPTION:
            security.set_option_exercise_model(MyOptionExerciseModel(self))

class MyOptionExerciseModel(DefaultExerciseModel):

    def __init__(self, algorithm):
        self.algorithm = algorithm

    def option_exercise(self, option: Option, order: OptionExerciseOrder) -> List[OrderEvent]:
        order_events = []

        underlying = option.underlying
        utc_time = Extensions.convert_to_utc(option.local_time, option.exchange.time_zone)

        in_the_money = option.is_auto_exercised(underlying.close)
        is_assignment = in_the_money and option.holdings.is_short
        messages = Messages.DefaultExerciseModel

        order_event = OrderEvent(
            order.id,
            option.symbol,
            utc_time,
            OrderStatus.FILLED,
            Extensions.get_order_direction(order.quantity),
            0,
            order.quantity,
            OrderFee.ZERO,
            messages.contract_holdings_adjustment_fill_tag(in_the_money, is_assignment, option)
        )
        order_event.is_assignment = is_assignment
        order_event.is_in_the_money = in_the_money
        order_events.append(order_event)

        if in_the_money and option.exercise_settlement == SettlementType.PHYSICAL_DELIVERY:
            exercise_quantity = option.get_exercise_quantity(order.quantity);
            order_event =  OrderEvent(
                order.id,
                underlying.symbol,
                utc_time,
                OrderStatus.FILLED,
                Extensions.get_order_direction(exercise_quantity),
                option.strike_price,
                exercise_quantity,
                OrderFee.ZERO,
                messages.option_assignment if is_assignment else messages.option_exercise
            )
            order_event.is_in_the_money = True
            order_events.append(order_event)

        return order_events
```

Options Models

Assignment

Introduction

If you sell an Option in a backtest, an assignment model can simulate an Option exercise order on behalf of the buyer and assign you to complete the requirements of the contract.

Set Models

To set the assignment model of an Option, call the `set_option_assignment_model` method of the `Option` object inside a security initializer .

```
PY
class AddSecurityInitializerExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the security initializer to set models of assets.
        self.add_security_initializer(self._custom_security_initializer)

    def _custom_security_initializer(self, security: Security) -> None:
        # Overwrite the assignment model
        if security.Type == SecurityType.OPTION: # Option type
            security.set_option_assignment_model(DefaultOptionAssignmentModel())
```

Default Behavior

The default Option assignment model is the `DefaultOptionAssignmentModel` . The `DefaultOptionAssignmentModel` scans your portfolio every hour. It considers exercising American-style Options if they are within 4 days of their expiration and it considers exercising European-style Options on their day of expiration. If you have sold an Option that's 5% in-the-money and the Option exercise order is profitable after the cost of fees, this model exercises the Option.

For more information about this model, see the class reference and implementation .

Model Structure

Option assignment models should extend the `NullOptionAssignmentModel` class. Extensions of the `NullOptionAssignmentModel` class must implement the `get_assignment` method, which automatically fires at the top of each hour and returns the Option assignments to generate.

```
PY
class CustomOptionAssignmentModelExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        security = self.add_option("SPY")
        # Set custom option assignment model for mimicking specific Brokerage most realistic actions
        security.set_option_assignment_model(MyOptionAssignmentModel())

# Define the custom Option assignment model outside of the algorithm
class MyOptionAssignmentModel(NullOptionAssignmentModel):

    def get_assignment(self, parameters: OptionAssignmentParameters) -> OptionAssignmentResult:
        option = parameters.option
        # Check if the contract is ITM
        if (option.right == OptionRight.CALL and option.underlying.price > option.strike_price or
            option.right == OptionRight.PUT and option.underlying.price < option.strike_price):
            return OptionAssignmentResult(option.holdings.absolute_quantity, "MyTag")
        return OptionAssignmentResult.NULL
```

The `OptionAssignmentParameters` object has the following members:

To exercise the Option, return an `OptionAssignmentResult` with a positive quantity. Otherwise, return `OptionAssignmentResult.Null` . The `OptionAssignmentResult` constructor accepts the following arguments:

Argument	Data Type	Description	Default Value
`quantity`	`float`	The quantity to assign	
`tag`	`str`	The order tag to use	

Disable Assignments

To disable early Option assignments, set the Option assignment model to the `NullOptionAssignmentModel` .

```
security.set_option_assignment_model(NullOptionAssignmentModel())
```

Examples

The following examples demonstrate some common practices for handling Option assignment.

Example 1: Liquidate After Assignment

The following algorithm trades a short straddle strategy on ATM SPY Options that expire within seven days. To capitalize the cash profit, it liquidates the underlying assigned Equity position in the `on_assignment_order_event` method.

```
class OptionAssignmentAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Add SPY Options data for trading.
        self._option = self.add_option("SPY")
        # Filter for the 2 ATM contracts that expire in 7 days to form a straddle.
        self._option.set_filter(lambda universe: universe.straddle(7))

    def on_data(self, slice: Slice) -> None:
        # Get the current Option chain.
        chain = slice.option_chains.get(self._option.symbol)
        # Open a new position if we're not already invested.
        if chain and not self.portfolio.invested:
            # Select the strike and expiry of the contracts.
            strike = list(chain)[0].strike
            expiry = list(chain)[0].expiry
            # Open the straddle position.
            option_strategy = OptionStrategies.short_straddle(self._option.symbol, strike, expiry)
            self.buy(option_strategy, 1)

    def on_assignment_order_event(self, assignment_event: OrderEvent) -> None:
        # Liquidate the assigned SPY position.
        self.market_order(
            assignment_event.symbol.underlying,
            -assignment_event.quantity * self._option.symbol_properties.contract_multiplier
        )
```

Example 2: Wheel Strategy

The following algorithm demonstrates a wheel Option strategy . The strategy is split into separate parts to generate consistent income: selling puts and selling covered call.

PY

```
class WheelStrategyAlgorithm(QCAlgorithm):
    # Define the OTM threshold. A greater value means lower risk of assignment but lower premiums to collect.
    _otm_threshold = 0.05

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000000)

        # Seed the initial price of the each new security so we can add and trade contracts in the same time step.
        self.settings.seed_initial_prices = True
        # Add SPY data for trading. Use raw data normalization mode to enable fair strike price comparison.
        self._equity = self.add_equity("SPY", data_normalization_mode=DataNormalizationMode.RAW)

    def _get_target_contract(self, right: OptionRight, target_price: float) -> Symbol:
        # Get the Option chain.
        chain = self.option_chain(self._equity.symbol, flatten=True).data_frame
        # Select the contracts that are first to expire after 30 days since they have greater premiums and theta
        # to collect.
        expiry_threshold = self.time + timedelta(30)
        expiry = chain[chain.expiry > expiry_threshold].expiry.min()
        # Select the OTM Option contract to start the wheel or covered call.
        symbol = chain[
            (chain.expiry == expiry) &
            (chain.right == right) &
            (chain.strike <= target_price if right == OptionRight.PUT else chain.strike >= target_price)
        ].sort_values('strike', ascending=right == OptionRight.CALL).index[0]
        # Add the Option contract to the algorithm.
        return self.add_option_contract(symbol).symbol

    def on_data(self, slice: Slice) -> None:
        # Start the wheel by selling the OTM put.
        if not self.portfolio.invested and self.is_market_open(self._equity.symbol):
            symbol = self._get_target_contract(OptionRight.PUT, self._equity.price * (1-self._otm_threshold))
            self.set_holdings(symbol, -0.2)

    def on_assignment_order_event(self, assignment_event: OrderEvent) -> None:
        # After the put is assigned, look for an OTM call to form a covered call with the assigned underlying
        # position.
        symbol = self._get_target_contract(OptionRight.CALL, self._equity.price * (1+self._otm_threshold))
        self.market_order(symbol, -self._equity.holdings.quantity / 100)
```

Example 3: Assign ITM Contracts

The following algorithm assigns all in-the-money contracts at the top of each hour.

PY

```
class CustomOptionAssignmentAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        self.add_security_initializer(self._initialize_security)

        option = self.add_option('GOOG')
        option.set_filter(
            lambda option_filter_universe: option_filter_universe.calls_only().strikes(-65, 0).expiration(0, 30)
        )

    def _initialize_security(self, security: Security) -> None:
        # Overwrite the assignment model.
        if security.Type == SecurityType.OPTION: # Option type
            security.set_option_assignment_model(MyOptionAssignmentModel())

    def on_data(self, data) -> None:
        if self.portfolio.invested:
            return

        for canonical_symbol, chain in data.option_chains.items():
            min_expiry = min([contract.expiry for contract in chain])
            contracts = sorted(
                [contract for contract in chain if contract.expiry == min_expiry],
                key=lambda contract: contract.strike
            )
            if contracts:
                self.market_order(contracts[0].symbol, -1)

class MyOptionAssignmentModel(NullOptionAssignmentModel):

    def get_assignment(self, parameters: OptionAssignmentParameters) -> OptionAssignmentResult:
        option = parameters.option
        # Check if the contract is ITM.
        if (option.Right == OptionRight.CALL and option.Underlying.Price > option.StrikePrice or
            option.Right == OptionRight.PUT and option.Underlying.Price < option.StrikePrice):
            return OptionAssignmentResult(option.holdings.absolute_quantity, "MyTag")
        return OptionAssignmentResult.NULL
```

Reality Modeling

Risk Free Interest Rate

Risk Free Interest Rate

Key Concepts

Introduction

The risk free interest rate is the hurdle rate for investments. If investors can get a rate of return with virtually no risk, an investment needs to offer the potential for a greater return to attract capital from rational investors. The risk free interest rate also impacts some performance statistics , like Sharpe and Sortino ratios. Risk free interest rate models provide the interest rate data to your algorithms to enable these calculations.

Set Models

To set the risk free interest rate model, in the Initialize method, call the `set_risk_free_interest_rate_model` method.

```py
def initialize(self) -> None:
    # Set the interest rate model for accurate option IV/greeks and result metrics like Sharpe Ratio
    # You should set it according to the main currency of your trading Securities
    self.set_risk_free_interest_rate_model(ConstantRiskFreeRateInterestRateModel(0.02))
```

To view all the pre-built risk free interest rate models, see Supported Models .

Default Behavior

The default risk free interest rate model is the InterestRateProvider , which provides the primary credit rate from the Federal Open Market Committee (FOMC).

Model Structure

Risk free interest rate models must extend the `IRiskFreeInterestRateModel` interface. Extensions of the `IRiskFreeInterestRateModel` interface must implement a `get_interest_rate` method. The `get_interest_rate` method returns the risk free interest rate for a given date.

```py
class CustomRiskFreeInterestRateModelExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # Set the interest rate model for accurate option IV/greeks and result metrics like Sharpe Ratio
        # You should set it according to the main currency of your trading Securities
        self.set_risk_free_interest_rate_model(MyRiskFreeInterestRateModel())

# Define the custom risk free interest rate model
class MyRiskFreeInterestRateModel(IRiskFreeInterestRateModel):
    def get_interest_rate(self, date: datetime | date) -> float:
        return 0.02
```

Disable Interest Rates

To disable the risk free interest rate, set the model to the `ConstantRiskFreeRateInterestRateModel` and set the risk free rate to zero.

```py
self.set_risk_free_interest_rate_model(ConstantRiskFreeRateInterestRateModel(0))
```

Get Interest Rate

To get the risk free interest rate for a specific time, call the `get_interest_rate` method with the time.

```
def on_data(self, slice: Slice) -> None:
 risk_free_interest_rate = self.risk_free_interest_rate_model.get_interest_rate(slice.time)
```

To get the average risk free interest rate for a window of time, call the `RiskFreeInterestRateModelExtensions.get_risk_free_rate` method with the model, the start date, and end date.

```
def on_data(self, slice: Slice) -> None:
 avg_risk_free_interest_rate = RiskFreeInterestRateModelExtensions.get_risk_free_rate(
  self.risk_free_interest_rate_model,
  self.time-timedelta(7), self.time
 )
```

To get the average risk free interest rate for a set of dates, call the `RiskFreeInterestRateModelExtensions.get_average_risk_free_rate` method with the model and list of dates.

```
def on_data(self, slice: Slice) -> None:
 avg_risk_free_interest_rate = RiskFreeInterestRateModelExtensions.get_average_risk_free_rate(
  self.risk_free_interest_rate_model,
  [self.time, self.time-timedelta(180), self.time-timedelta(365)]
 )
```

Examples

The following examples demonstrate common practices for implementing a custom risk free interest rate model.

Example 1: Fixed Rate

The following algorithm implements a custom risk free interest rate model with a fixed rate of 2%.

```
class CustomFillModelAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.set_risk_free_interest_rate_model(MyRiskFreeInterestRateModel())
        self.add_equity('SPY', Resolution.DAILY)

    def on_data(self, data: Slice) -> None:
        if not self.portfolio.invested:
            self.set_holdings('SPY', 1)

class MyRiskFreeInterestRateModel:

    def get_interest_rate(self, date: datetime | date) -> float:
        return 0.02
```

Risk Free Interest Rate

Supported Models

Introduction

This page describes all of the pre-built risk free interest rate models in LEAN. If none of these models perform exactly how you want, create a custom risk free interest rate model .

Constant Model

The `ConstantRiskFreeRateInterestRateModel` returns a constant rate across time. It's the default risk free interest rate model.

```
self.set_risk_free_interest_rate_model(ConstantRiskFreeRateInterestRateModel(0.02))
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`risk_free_rate`	`float`	The risk free interest rate	

For more information about this model, see the class reference and implementation .

Function Model

The `FuncRiskFreeRateInterestRateModel` calls a function you provide to get the risk free interest rate. The function you pass to the constructor effectively replaces the GetInterestRate method.

```
self.set_risk_free_interest_rate_model(FuncRiskFreeRateInterestRateModel(self.get_interest_rate_func))
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`get_interest_rate_func`	`Callable[[datetime], float]`	A function that returns the risk free interest rate for a given date	

For more information about this model, see the class reference and implementation .

Interest Rate Provider Model

The `InterestRateProvider` returns the primary credit rate from the Federal Open Market Committee (FOMC).

```
self.set_risk_free_interest_rate_model(InterestRateProvider())
```

For more information about this model, see the class reference and implementation .

Reality Modeling

Dividend Yield

Dividend Yield

Key Concepts

Introduction

Dividends are periodic payments a company makes to its shareholders out of its earnings. The dividend yield refers to the rate of return an investor earns in the form of dividends from holding a stock.

In the context of Option pricing models , the dividend yield is a critical factor because it affects the value of the underlying stock. When calculating the theoretical price of an Option using these models, the dividend yield is factored into the equation.

Set Models

To set the dividend yield model for an Option indicator , pass a `DividendYieldProvider` as the `dividend_yield_model` parameter.

```py
def initialize(self) -> None:
    # Before creating the indicator, create the set dividend yield model
    # Using DividendYieldProvider will calculate the continuous dividend yield using all dividend payoffs in 1 year
    dividend_yield_model = DividendYieldProvider(symbol.underlying)
    self.iv = ImpliedVolatility(symbol, self.risk_free_interest_rate_model, dividend_yield_model, OptionPricingModelType.BLACK_SCHOLES)
```

To view all the pre-built dividend yield models, see Supported Models .

Default Behavior

For US Equity Options, the default dividend yield model is the DividendYieldProvider , which provides the continuous yield calculated from all dividend payoffs from the underlying Equity over the previous 350 days.

For other Option types, the default dividend yield model is the `DividendYieldProvider` , but it calculates the yield from the dividends of the SPY ETF.

Model Structure

Dividend yield models must extend the `IDividendYieldModel` interface. Extensions of the `IDividendYieldModel` interface must implement a `get_dividend_yield` method. The `get_dividend_yield` method returns the dividend yield for a given date.

```py
from datetime import date

class CustomDividendYieldModelExampleAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        # Create the dividend yield model.
        dividend_yield_model = MyDividendYieldModel()
        # Add the Option contracts.
        underlying_symbol = self.add_equity('SPY', data_normalization_mode=DataNormalizationMode.RAW).symbol
        strike = 595
        expiry = datetime(2024, 12, 30)
        option = self._add_contract(underlying_symbol, OptionRight.PUT, strike, expiry)
        mirror = self._add_contract(underlying_symbol, OptionRight.CALL, strike, expiry)
        # Add the indicator.
        iv = ImpliedVolatility(option, self.risk_free_interest_rate_model, dividend_yield_model, mirror)

    def _add_contract(self, underlying_symbol, right, strike, expiry) -> Symbol:
        contract_symbol = Symbol.create_option(
            underlying_symbol, Market.USA, OptionStyle.AMERICAN, right, strike, expiry
        )
        self.add_option_contract(contract_symbol)
        return contract_symbol

# Define the custom dividend yield model
class MyDividendYieldModel(DividendYieldProvider):

    def get_dividend_yield(
            self,
            date_or_data: datetime | date | IBaseData,
            security_price: float | None = None) -> float:
        return 0.02
```

Examples

The following examples demonstrate common practices for implementing a custom dividend yield model.

Example 1: Fixed Yield

The following algorithm implements a custom dividend yield model with a fixed yield of 2%.

PY

```
from datetime import date

class CustomDividendYieldModelAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        option = self.add_option('MSFT')
        option.set_filter(0, 1, 0, 31)
        self._symbol = option.symbol
        self._deltas = {}
        self._dividend_yield_model = {self._symbol.underlying : MyDividendYieldModel()}

    def on_data(self, data: Slice) -> None:
        chain = data.option_chains.get(self._symbol)
        if not chain:
            return
        expiry = min([x.expiry for x in chain])
        symbols = [x.symbol for x in chain if x.expiry == expiry and x.right == OptionRight.CALL and x.symbol not in self._deltas]
        for symbol in symbols:
            self._deltas[symbol] = self._deltas.get(symbol, self._create_delta_indicator(symbol))

    def _create_delta_indicator(self, symbol: Symbol) -> Delta:
        dividend_yield_model = self._dividend_yield_model.get(symbol.underlying)
        delta = Delta(symbol.value, symbol, self.risk_free_interest_rate_model, dividend_yield_model)
        self.register_indicator(symbol, delta)
        self.register_indicator(symbol.underlying, delta)
        return delta

    def on_end_of_day(self, symbol) -> None:
        delta = self._deltas.get(symbol)
        if delta:
            self.plot('Delta', symbol.value, delta.current.value)

class MyDividendYieldModel(DividendYieldProvider):

    def get_dividend_yield(
            self,
            date_or_data: datetime | date | IBaseData,
            security_price: float | None = None) -> float:
        return 0.02
```

Dividend Yield

Supported Models

Introduction

This page describes all of the pre-built dividend yield models in LEAN. If none of these models perform exactly how you want, create a custom dividend yield model .

Constant Model

The `ConstantDividendYieldModel` returns a constant yield across time. It's the default dividend yield model for securities that don't pay dividends.

```
self.dividend_yield_model = ConstantDividendYieldModel(0.02)
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`dividend_yield`	`float`	The dividend yield	

For more information about this model, see the class reference and implementation .

Dividend Yield Provider Model

The `DividendYieldProvider` uses historical dividend payments to estimate the annualized continuous dividend yield for a given date.

```
self.dividend_yield_model = DividendYieldProvider()
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`symbol`	`Symbol`	The symbol of a dividend-paying security. If you don't provide a value, it defaults to SPY.	

For more information about this model, see the class reference and implementation .

Reality Modeling

Margin Interest Rate

Margin Interest Rate

Key Concepts

Introduction

Margin interest is a cost associated with trading on margin. Margin interest rate models model margin interest cash flows by directly adding or removing cash from your portfolio.

Set Models

The brokerage model of your algorithm automatically sets the margin interest rate model for each security, but you can override it. To manually set the margin interest rate model of a security, assign a model to the `MarginInterestRateModel` property of the Security object.

```py
def initialize(self) -> None:
    security = self.add_equity("SPY")
    # For US Equity, use the ShortMarginInterestRateModel with IB data
    security.set_shortable_provider(InteractiveBrokersShortableProvider())
    security.margin_interest_rate_model = ShortMarginInterestRateModel()
```

You can also set the margin interest rate model in a security initializer . If your algorithm has a dynamic universe, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `add_security_initializer` before you create the subscriptions.

```py
class AddSecurityInitializerExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the security initializer to set models of assets.
        self.add_security_initializer(self._custom_security_initializer)

    def _custom_security_initializer(self, security: Security) -> None:
        # Overwrite some of the reality models
        security.set_shortable_provider(InteractiveBrokersShortableProvider())
        security.margin_interest_rate_model = ShortMarginInterestRateModel()
```

To view all the pre-built margin interest rate models, see Supported Models .

Default Behavior

The brokerage model of your algorithm automatically sets the margin interest rate model of each security. The default brokerage model is the `DefaultBrokerageModel` , which sets the NullMarginInterestRateModel .

Model Structure

Margin interest rate models should implement the `IMarginInterestRateModel` interface. Extensions of the `IMarginInterestRateModel` interface must implement the `apply_margin_interest_rate` method, which applies margin interest payments to the portfolio.

```
class CustomMarginInterestRateModelExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        security = self.add_equity("SPY")
        # You should set it according to your broker information for the least actual-expected discrepancies
        security.set_margin_interest_rate_model(MyMarginInterestRateModel())

# Define the custom margin interest rate model
class MyMarginInterestRateModel:

    def apply_margin_interest_rate(self, margin_interest_rate_parameters: MarginInterestRateParameters) -> None:
        holdings = margin_interest_rate_parameters.security.holdings
        position_value = holdings.get_quantity_value(holdings.quantity)
        position_value.cash.add_amount(-1)
```

The `apply_margin_interest_rate` method is automatically called at the top of each hour.

Examples

The following examples demonstrate some common practices for implementing a custom margin interest rate model.

Example 1: Based On Interest Rate

The following algorithm buys and holds SPY, with 2x leverage and holds 1.5x of portfolio value. Hence, funds will be borrowed from the broker and are susceptible to margin interest. We implement a custom margin interest rate model to simulate the Interactive Brokers margin interest deduction. While following daily accrual and monthly accounting of the margin interest, we simplify the rate from tiered to fixed at 1% above the current interest rate.

```
class MarginInterestRateModelAlgorithm(QCAlgorithm):

    def initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(1000000)

        # Request SPY data for trading.
        equity = self.add_equity("SPY")
        self.spy = equity.symbol
        # Set a custom margin interest rate model for the SPY security to mimic IB margin interest deduction.
        equity.set_margin_interest_rate_model(MyMarginInterestRateModel(self, self.spy))

    def on_data(self, slice: Slice) -> None:
        if not self.portfolio.invested:
            # Place a position that exceeds available cash to buy with borrowed funds.
            self.set_holdings(self.spy, 1.5)

# Define the custom margin interest rate model
class MyMarginInterestRateModel:
    accrued_margin_interest = {}

    def __init__(self, algorithm: QCAlgorithm, symbol: Symbol) -> None:
        # Save the algorithm instance since we must access the at-the-time interest rate to calculate the margin rate.
        self.algorithm = algorithm
        # IBKR accrues interest daily and posts actual interest monthly on the third business day of the following month.
        algorithm.schedule.on(
            algorithm.date_rules.month_start(symbol, 3),
            algorithm.time_rules.at(0, 0),
            self.margin_deduction
        )

    def margin_deduction(self) -> None:
        for cash, accrued_interest in self.accrued_margin_interest.items():
            # Monthly deduction of cash position with accrued interests.
            cash.add_amount(accrued_interest)
            # Reset the accrued interest accumulator.
            self.accrued_margin_interest[cash] = 0

    def apply_margin_interest_rate(self, margin_interest_rate_parameters: MarginInterestRateParameters) -> None:
        # IBKR accrues interest daily for overnight positions only.
        if self.algorithm.time.hour == 16:
            holdings = margin_interest_rate_parameters.security.holdings
            # Calculate the borrowed capital. The margin interest will only applied to the borrowed capital.
            borrowed_value = holdings.unlevered_absolute_holdings_cost - holdings.absolute_holdings_cost
            # Margin interest rate is 1% above the current risk-free interest rate.
            margin_rate = self.algorithm.risk_free_interest_rate_model.get_interest_rate(self.algorithm.time) + 0.01
            # Deduct the margin interest on the account cash position by the margin rate, multiplying the borrowed sum.
            cash = holdings.get_quantity_value(holdings.quantity).cash
            if cash not in self.accrued_margin_interest:
                self.accrued_margin_interest[cash] = 0
            # Daily rate will be divided by 365.
            self.accrued_margin_interest[cash] += borrowed_value * margin_rate / 365
```

Example 2: Fixed Dollar Rate

The following algorithm defines custom margin interest rate model that reduces your cash by $1 at the top of each hour.

```py
class CustomFillModelAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        security = self.add_equity('SPY', Resolution.DAILY)
        security.set_margin_interest_rate_model(MyMarginInterestRateModel())

    def on_data(self, data: Slice) -> None:
        if not self.portfolio.invested:
            self.set_holdings('SPY', 1)

class MyMarginInterestRateModel:

    def apply_margin_interest_rate(self, margin_interest_rate_parameters: MarginInterestRateParameters) -> None:
        holdings = margin_interest_rate_parameters.security.holdings
        position_value = holdings.get_quantity_value(holdings.quantity)
        position_value.cash.add_amount(-1)
```

Margin Interest Rate

Supported Models

Introduction

This page describes the pre-built margin interest rate models in LEAN. If none of these models perform exactly how you want, create a custom margin interest rate model .

Null Model

The `NullMarginInterestRateModel` doesn't charge any margin interest. It's the default margin interest rate of the DefaultBrokerageModel .

```
PY
security.margin_interest_rate_model = MarginInterestRateModel.NULL
```

For more information about this model, see the class reference and implementation .

Short Equity Model

The `ShortMarginInterestRateModel` simulates the margin cost and payments of your Equity holdings. This model use the fee rate to compute the amount due to borrowing the asset to short, and the rebate rate to compute the amount due to lending the asset for shorting. For more information about these rates providers, see Short Availability .

```
PY
security.set_shortable_provider(InteractiveBrokersShortableProvider())
security.margin_interest_rate_model = ShortMarginInterestRateModel()
```

For more information about this model, see the class reference and implementation .

Binance Futures Model

The `BinanceFutureMarginInterestRateModel` simulates the margin cost and payments of your Crypto Future holdings. When the funding rate is positive, the price of the perpetual contract is higher than the mark price, so traders who are long pay for short positions. Conversely, a negative funding rate indicates that perpetual prices are below the mark price, so traders who are short pay for long positions. The interest amount is

Nominal \ Value \ of \ Positions * Funding \ Rate

The interest amount is periodically credited or debited from your currency holdings while you hold open positions. The interest amount is charged at 12 AM, 8 AM, 4 PM in your algorithm time zone .

```
PY
security.margin_interest_rate_model = BinanceFutureMarginInterestRateModel()
```

For more information about this model, see the class reference and implementation .

Bybit Futures Model

The `BybitFutureMarginInterestRateModel` has the same behavior as the BinanceFutureMarginInterestRateModel .

```
PY
security.margin_interest_rate_model = BybitFutureMarginInterestRateModel()
```

For more information about this model, see the class reference and implementation .

dYdX Futures Model

The `dYdXFutureMarginInterestRateModel` simulates the margin cost and payments of your Crypto Future holdings. When the funding rate is positive, the price of the perpetual contract is higher than the mark price, so traders who are long pay for short positions. Conversely, a negative funding rate indicates that perpetual prices are below the mark price, so traders who are short pay for long positions. The interest amount is

Nominal \ Value \ of \ Positions * Funding \ Rate

The interest amount is periodically credited or debited from your currency holdings while you hold open positions. The interest amount is charged at 12 AM, 8 AM, and 4 PM in your algorithm time zone .

```
security.margin_interest_rate_model = dYdXFutureMarginInterestRateModel()
```

PY

For more information about this model, see the class reference and implementation .

Reality Modeling

Margin Calls

Introduction

If the value of your portfolio falls below the maintenance margin, you receive a margin call. If you receive a margin call, you either need to add more capital to your brokerage account or the brokerage will liquidate some of your holdings to reduce your exposure and their risk. A margin call model monitors the margin levels of your portfolio, issues margin call warnings, and submits orders when margin calls occur.

Set Models

To set the margin call model, call the `set_margin_call_model` method of the `portfolio` object.

```py
def initialize(self) -> None:
 # Set margin call model for the whole portfolio, better with reference to your broker information
 self.portfolio.set_margin_call_model(DefaultMarginCallModel(self.portfolio, self.default_order_properties))
```

Default Behavior

The brokerage model of your algorithm automatically sets the margin call model for the portfolio. The default brokerage model is the `DefaultBrokerageModel` , which sets the `DefaultMarginCallModel` . The `DefaultMarginCallModel` issues margin call warnings when the margin remaining in your portfolio is less than or equal to 5% of the total portfolio value. When your total margin used exceeds 10% of the total portfolio value, this model creates margin call orders. It sorts the generated margin call orders in ascending order by their unrealized profit and then synchronously executes each order until your portfolio is within the margin requirements.

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`portfolio`	`SecurityPortfolioManager`	The portfolio object to receive margin calls.	
`default_order_properties`	`IOrderProperties`	The default order properties to be use in margin call orders.	
`margin_buffer`	`float`	The percent margin buffer to use when checking whether the total margin used is above the total portfolio value to generate margin call orders.	`0.10` (10%)

For more information about this model, see the class reference and implementation .

Model Structure

Margin call models must extend the `DefaultMarginCallModel` class. Extensions of the `DefaultMarginCallModel` class can override the `get_margin_call_orders` and `execute_margin_call` methods.

The `get_margin_call_orders` method scans the portfolio and the updated data for a potential margin call situation that may get the equity below zero. The method must return a tuple where the first element is a list of `SubmitOrderRequest` objects that represent the margin call orders and the second element is a boolean that represents whether or not to issue a margin call warning.

The `execute_margin_call` method receives the list of `SubmitOrderRequest` objects from the `get_margin_call_orders` method, executes some of them, and returns a list of `OrderTicket` objects.

```
class CustomMarginCallModelExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # Set margin call model for the whole portfolio, better with reference to your broker information
        self.portfolio.set_margin_call_model(MyMarginCallModel(self.portfolio, self.default_order_properties))

# Define the custom margin call model
class MyMarginCallModel(DefaultMarginCallModel):
    def __init__(self,
                 portfolio: SecurityPortfolioManager,
                 default_order_properties: IOrderProperties):
        super().__init__(portfolio, default_order_properties)

    def execute_margin_call(self,
                 generatedMarginCallOrders: List[SubmitOrderRequest]) -> List[OrderTicket]:
        return super().execute_margin_call(generatedMarginCallOrders)

    def get_margin_call_orders(self,
                 issue_margin_call_warning: bool | None) -> tuple[List[SubmitOrderRequest], bool]:
        (margin_call_orders, issue_margin_call_warning) = super().get_margin_call_orders(issue_margin_call_warning)
        return (margin_call_orders, issue_margin_call_warning)
```

Disable Margin Calls

To disable margin calls, set the margin call model to the `NullMarginCallModel` .

```
def initialize(self) -> None:
 self.portfolio.margin_call_model = MarginCallModel.NULL
```

Monitor Margin Call Events

When the margin call model of your portfolio issues a margin call warning, we notify your algorithm through the `on_margin_call_warning` event handler.

```
def on_margin_call_warning(self) -> None:
    self.debug(f"Warning: Close to margin call")
```

Before we send the orders that the margin call model produces, we notify your algorithm through the `on_margin_call` event handler. This notification gives your algorithm a chance to liquidate some positions or modify the margin call orders. To modify the orders, adjust the list of `SubmitOrderRequest` objects the event handler receives.

```
def on_margin_call(self, requests: List[SubmitOrderRequest]) -> List[SubmitOrderRequest]:
    for i, order in enumerate(requests):
        # liquidate an extra 10% each time you get a margin call to give yourself more padding
        new_quantity = int(order.quantity * 1.1)
        requests[i] = SubmitOrderRequest(order.order_type, order.security_type,
                                         order.symbol, new_quantity, order.stop_price,
                                         order.limit_price, 0, self.time, "OnMarginCall")
    return requests
```

Submit Order Request

If you receive a margin call or create a margin call model, you'll need to work with `SubmitOrderRequest` objects. These objects have the following properties:

The following table describes the arguments of the `SubmitOrderRequest` constructor:

Argument	Data Type	Description	Default Value
order_type	OrderType	The order type to be submitted	
security_type	SecurityType	The security type of the asset	
symbol	Symbol	The symbol to be traded	
quantity	float	The number of units to order	
stop_price	float	The stop price for stop orders	
limit_price	float	The limit price for limit orders	
trigger_price	float	The trigger price for limit if touched orders	
time	datetime	The time this request was created	
tag	str	A custom tag for this request	
properties	IOrderProperties	The order properties for this request	None

Examples

The following examples demonstrate common practices for implementing a custom margin call model.

Example 1: Default Model Wrapper

The following algorithm defines a subclass of the DefaultMarginCallModel and overrides its built-in members so you can easily customize the parts you need.

```py
class CustomFillModelAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)
        self.portfolio.set_margin_call_model(MyMarginCallModel(self.portfolio, self.default_order_properties))
        self.add_equity('SPY', Resolution.DAILY)

    def on_data(self, data: Slice) -> None:
        if not self.portfolio.invested:
            self.set_holdings('SPY', -2)

class MyMarginCallModel(DefaultMarginCallModel):
    def __init__(self,
         portfolio: SecurityPortfolioManager,
         default_order_properties: IOrderProperties):
        super().__init__(portfolio, default_order_properties)

    def execute_margin_call(self,
         generatedMarginCallOrders: List[SubmitOrderRequest]) -> List[OrderTicket]:
        return super().execute_margin_call(generatedMarginCallOrders)

    def get_margin_call_orders(self,
         issue_margin_call_warning: bool | None) -> tuple[List[SubmitOrderRequest], bool]:
        (margin_call_orders, issue_margin_call_warning) = super().get_margin_call_orders(issue_margin_call_warning)
        return (margin_call_orders, issue_margin_call_warning)
```

Other Examples

Reality Modeling

Short Availability

Short Availability

Key Concepts

Introduction

To short a security, you need to borrow shares from another investor or organization that owns the shares. A shortable provider is a model that tracks the number of shares that are available for you to borrow. A shortable provider can make your backtest results more realistic because it doesn't let you place a short trade if there are no shares available for you to borrow.

Set Providers

The brokerage model of your algorithm automatically sets the settlement model for each security, but you can override it. To manually set the shortable provider of a security, call the `set_shortable_provider` method on the `Security` object.

PY

```
def initialize(self) -> None:
    security = self.add_equity("SPY")
    # Get shortable stocks and quantity from local disk
    security.set_shortable_provider(LocalDiskShortableProvider("axos"))
```

You can also set the shortable provider in a security initializer. If your algorithm has a universe, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `add_security_initializer` before you create the subscriptions.

PY

```
def initialize(self) -> None:
    # Set the security initializer before requesting data to apply to all requested securities afterwards
    self.set_security_initializer(self.custom_security_initializer)
    self.add_equity("SPY")

def custom_security_initializer(self, security: Security) -> None:
    security.set_shortable_provider(LocalDiskShortableProvider("axos"))
```

If you call the `set_security_initializer` method, it overwrites the default security initializer. The default security initializer uses the security-level reality models of the brokerage model to set the following reality models of each security:

- Fill
- Slippage
- Fee
- Buying Power
- Settlement
- Short availability
- Margin Interest Rate

To extend upon the default security initializer instead of overwriting it, call `add_security_initializer` before you create the subscriptions before you create the subscriptions.

```
class AddSecurityInitializerExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        # In the Initialize method, set the security initializer to set models of assets.
        self.add_security_initializer(self._custom_security_initializer)

    def _custom_security_initializer(self, security: Security) -> None:
        # Overwrite some of the reality models
        security.set_shortable_provider(LocalDiskShortableProvider("axos"))
```

To view all the pre-built shortable providers, see Supported Providers .

Default Behavior

The brokerage model of your algorithm automatically sets the shortable provider for each security. The default brokerage model is the `DefaultBrokerageModel` , which uses the NullShortableProvider .

Provider Structure

Shortable providers must implement the `IShortableProvider` interface. Shortable providers that implement the `IShortableProvider` interface must implement the `fee_rate` , `rebate_rate` , and `shortable_quantity` methods. These methods receives a Symbol and the local time of the algorithm. The `fee_rate` method returns the borrow fee rate. The `rebate_rate` method returns the borrow rebate rate. The `shortable_quantity` returns the shortable quantity.

```
class CustomShortableProviderExampleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        security = self.add_equity("SPY")
        # Provide the selected security with your broker's shortable information
        security.set_shortable_provider(MyShortableProvider())

# Define the custom shortable provider
class MyShortableProvider(NullShortableProvider):

    def fee_rate(self, symbol: Symbol, local_time: datetime) -> float:
        return 0.0025

    def rebate_rate(self, symbol: Symbol, local_time: datetime) -> float:
        return 0.0507

    def shortable_quantity(self, symbol: Symbol, local_time: datetime) -> int:
        return 10000
```

Order Failures

If you place an order to short more shares than are available to borrow, LEAN rejects the order and applies the following tag: "Order exceeds maximum shortable quantity for Symbol ticker (requested short: quantity)".

Borrowing Costs

In live trading, your brokerage charges an interest fee when you borrow shares to short a security. In backtesting, use the ShortMarginInterestRateModel .

To get valid borrowing rates, use the InteractiveBrokersShortableProvider .

```
def initialize(self) -> None:
    security = self.add_equity("SPY")
    # For US Equity, use the ShortMarginInterestRateModel with IB data
    security.set_shortable_provider(InteractiveBrokersShortableProvider())
    security.margin_interest_rate_model = ShortMarginInterestRateModel()
```

Examples

The following examples demonstrate common practices for using a shortable provider.

Example 1: Fixed Rates

The following algorithm defines a custom short availability model with fixed values for the fee rate, rebate rate, and shortable quantity.

PY

```
class CustomShortableProviderAlgorithm(QCAlgorithm):

    def Initialize(self):
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        self._security = self.add_equity("QQQ", Resolution.DAILY)
        self._security.set_shortable_provider(MyShortableProvider())

    def on_data(self, data: Slice) -> None:
        if self.portfolio.invested:
            return
        shortable_quantity = self._security.shortable_provider.shortable_quantity(self._security.symbol, self.Time)
        if not shortable_quantity:
            return
        fee_rate = self._security.shortable_provider.fee_rate(self._security.symbol, self.time)
        rebate_rate = self._security.shortable_provider.rebate_rate(self._security.symbol, self.time)
        self.set_holdings(self._security.symbol, -0.05, tag=f'Borrow fee rate {fee_rate}. Borrow rebate rate {rebate_rate}')

class MyShortableProvider(NullShortableProvider):

    def fee_rate(self, symbol: Symbol, local_time: datetime) -> float:
        return 0.0025

    def rebate_rate(self, symbol: Symbol, local_time: datetime) -> float:
        return 0.0507

    def shortable_quantity(self, symbol: Symbol, local_time: datetime) -> int:
        return 10000
```

Example 2: Sizing By Shortable Quantity

The following algorithm trades arbitrage of class A and class C price divergence of Google stocks using cointegration analysis. However, the position sizing may be limited by the available quantity to be shorted by the brokerage, breaking the paired trade. Thus, we need to make use of the `shortable_quantity` method of the shortable provider to calculate the quantity.

PY

```
from sklearn.linear_model import LinearRegression
from statsmodels.tsa.stattools import adfuller

class ShortableProviderAlgorithm(QCAlgorithm):
    # The threshold that the spread/residual of the cointegrated series triggers a trade.
    threshold = 0
    # Store the coefficient and intercept of the cointegrated series for calculating the spread of a new data point.
    coefficients = [0, 0]

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)

        # Subscribe to 2 classes of Google stocks to trade their price divergence.
        goog1 = self.add_equity("GOOGL", Resolution.DAILY)        # Class A
        goog2 = self.add_equity("GOOG", Resolution.DAILY)         # Class C
        self.goog1 = goog1.symbol
        self.goog2 = goog2.symbol
        # Set the shortable providers to simulate the available shares to trade realistically.
        goog1.set_shortable_provider(InteractiveBrokersShortableProvider())
        goog2.set_shortable_provider(InteractiveBrokersShortableProvider())

        # Use rolling windows to save the price data for cointegration analysis.
        goog1.window = RollingWindow(252)
        goog2.window = RollingWindow(252)
        # Warm up the rolling windows.
        history = self.history[TradeBar]([self.goog1, self.goog2], 252, Resolution.DAILY)
        for bar in history:
            goog1.window.add(bar[self.goog1].close)
            goog2.window.add(bar[self.goog2].close)

        # Adjust the cointegration factor between the 2 classes' monthly price series.
        self.schedule.on(
            self.date_rules.month_start(),
            self.time_rules.at(0, 1),
            self.calculate_cointegration
        )
        self.calculate_cointegration()

    def on_data(self, slice: Slice) -> None:
        bar1 = slice.bars.get(self.goog1)
        bar2 = slice.bars.get(self.goog2)
        if bar1 and bar2:
            # Update the rolling windows for cointegration analysis.
            self.securities[self.goog1].window.add(bar1.close)
            self.securities[self.goog2].window.add(bar2.close)

            # Calculate the current cointegrated series spread
```

```
            # Calculate the current cointegrated series spread.
            residual = self.coefficients[0] * bar2.close + self.coefficients[1] - bar1.close

            quantity = self.calculate_order_quantity(self.goog1, 0.2)
            # If the residual is lower than the negative threshold, it means class A's price is much higher than it should be compared to
class C.
            # We sell class A and buy class C to bet on their price convergence.
            if residual < -self.threshold and not self.portfolio[self.goog1].is_short:
                # Since it will be limited by shortable quantity, we max{shortable, 20% of portfolio value}.
                shortable_quantity = self.securities[self.goog1].shortable_provider.shortable_quantity(self.goog1, bar1.end_time)
                quantity = min(quantity, shortable_quantity)
                self.market_order(self.goog1, -quantity)
                self.market_order(self.goog2, quantity * self.coefficients[0])
            # If the residual is higher than the threshold, it means class A price is much lower than what it should be compared to class
C.
            # We buy class A and sell class C to bet on their price convergence.
            elif residual > self.threshold and not self.portfolio[self.goog1].is_long:
                # Since it will be limited by shortable quantity, we max{shortable, 20% of portfolio value}.
                shortable_quantity = self.securities[self.goog2].shortable_provider.shortable_quantity(self.goog2, bar2.end_time)
                quantity = min(quantity, shortable_quantity)
                self.market_order(self.goog1, quantity)
                self.market_order(self.goog2, -quantity * self.coefficients[0])
            # Close positions of the price are converged.
            elif (self.portfolio[self.goog1].is_short and residual > 0) or (self.portfolio[self.goog1].is_long and residual < 0):
                self.liquidate()

    def calculate_cointegration(self) -> None:
        # Lag direction is unimportant; it is just a sign flip in the linear regression, so we don't need to flip the window order.
        y = np.array(list(self.securities[self.goog1].window)).reshape(-1, 1)
        x = np.array(list(self.securities[self.goog2].window)).reshape(-1, 1)

        # Perform Linear Regression on both price series to investigate their relationship.
        lr = LinearRegression().fit(x, y)
        slope = lr.coef_[0]
        intercept = lr.intercept_

        # Calculate the residuals series to check if it is stationary, meaning if the 2 price series move together.
        residuals = y - (intercept + slope * x)

        # Check if the residuals are stationary using the augmented Dickey-Fuller test.
        # Reject the null hypothesis of a unit root is present if test statistic <= -3.45 (approximate α=0.05 for n=250)
        # This means no unit root exists for the difference series, and the residuals are stationary.
        adf_reject = adfuller(residuals)[0] <= -3.45
        if adf_reject:
            # If cointegrated, update the positional sizing ratio and the spread threshold of the trade trigger.
            self.coefficients = [slope, intercept]
            self.threshold = 2 * np.std(residuals)
        else:
            # If not cointegrated, liquidate and set the size to zeros for no positions.
            self.liquidate()
            self.coefficients = [0, 0]
            self.threshold = 100000000          # An arbitrarily large number that the class A price will never reach.
```

Other Examples

Example 3: Interactive Brokers Shortable Provider

The following algorithm uses the `InteractiveBrokersShortableProvider` to check the shortable quantity and borrowing costs of GME before placing a short order.

```
class InteractiveBrokersShortableProviderAlgorithm(QCAlgorithm):

    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 12, 31)
        self.set_cash(100000)

        self._security = self.add_equity("GME", Resolution.DAILY)
        self._security.set_shortable_provider(InteractiveBrokersShortableProvider())

    def on_data(self, data: Slice) -> None:
        if self.portfolio.invested:
            return
        shortable_quantity = self._security.shortable_provider.shortable_quantity(self._security.symbol, self.time)
        if not shortable_quantity:
            return
        fee_rate = self._security.shortable_provider.fee_rate(self._security.symbol, self.time)
        rebate_rate = self._security.shortable_provider.rebate_rate(self._security.symbol, self.time)
        # Only short if the borrow fee is reasonable.
        if fee_rate < 0.05:
            quantity = int(min(self.calculate_order_quantity(self._security.symbol, -0.5), shortable_quantity))
            if quantity != 0:
                self.market_order(self._security.symbol, quantity, tag=f'Fee rate: {fee_rate}, Rebate rate: {rebate_rate}, Shortable:
{shortable_quantity}')
```

Short Availability

Supported Providers

Introduction

This page describes all of the pre-built shortable providers in LEAN. .

Null Provider

The `NullShortableProvider` doesn't provide shortable data, so it allows you to infinitely short assets. It's the shortable provider of the `DefaultBrokerageModel` .

```
security.set_shortable_provider(NullShortableProvider())
```

For more information about this model, see the class reference and implementation .

Local Disk Provider

The `LocalDiskShortableProvider` sources short availability data from the local disk of a specific brokerage.

```
security.set_shortable_provider(LocalDiskShortableProvider("axos"))
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`brokerage`	`str`	Brokerage to read data	

For more information about this model, see the class reference and implementation .

Interactive Brokers Provider

The `InteractiveBrokersShortableProvider` sources short availability data from Interactive Brokers.

```
security.set_shortable_provider(InteractiveBrokersShortableProvider())
```

For more information about this model, see the class reference and implementation .

Scheduled Events

Introduction

Scheduled Events let you trigger code to run at specific times of day, regardless of your algorithm's data subscriptions. It's easier and more reliable to execute time-based events with Scheduled Events than checking the current algorithm time in the `on_data` event handler.

Create Scheduled Events

To create a Scheduled Event, call the `schedule.on` method. The method expects a `DateRules` object, a `TimeRules` object, and a function to execute. The following examples demonstrate some common Scheduled Events.

Schedule Events Before Market Open

You may want to train a model or fetch historical data before the market opens. The following example demonstrates how to set a Scheduled Event for 10 minutes before the market opens.

```py
def initialize(self):
    # Call the _before_market_open method 10 minutes before open every day SPY is trading.
    self.schedule.on(
        self.date_rules.every_day('SPY'),
        self.time_rules.before_market_open('SPY', 10),
        self._before_market_open
    )
```

Schedule Events on the Last Trading Day of the Week

You may want to rebalance your portfolio on the last trading day of each week and factor in market holidays. The following example demonstrates how to set a Scheduled Event for the last trading day of each week 30 minutes before the market closes.

```py
def initialize(self):
# Call the _rebalance method 30 minutes before the end of the SPY trading week.
    self.schedule.on(
        self.date_rules.week_end('SPY'),
        self.time_rules.before_market_close('SPY', 30),
        self._rebalance
    )
```

Schedule Events on Regular Intervals Throughout the Trading Day

You may want to perform some action on a regular interval through each trading day. The following example demonstrates how to set a Scheduled Event for every 30 minutes through the trading day for SPY.

```py
def initialize(self):
    # Every day SPY is trading, call the '_some_action' method every 30 minutes.
    self.schedule.on(
        self.date_rules.every_day('SPY'),
        self.time_rules.every(timedelta(minutes=30)),
        self._some_action
    )
```

Date Rules

The following table describes the supported `DateRules` :

Member	Description
`self.date_rules.set_default_time_zone(time_zone: DateTimeZone)`	Sets the time zone for the `DateRules` object used in all methods in this table. The default time zone is the algorithm time zone .
`self.date_rules.on(year: int, month: int, day: int)`	Trigger an event on a specific date.
`self.date_rules.on(dates: list[datetime])`	Trigger an event on specific dates.
`self.date_rules.every_day()`	Trigger an event all seven days of the week.
`self.date_rules.every_day(symbol: Symbol, extended_market_hours: bool = False)`	Trigger an event every day a specific symbol is trading.
`self.date_rules.every(days: list[DayOfWeek])`	Trigger an event on specific days throughout the week. To view the `DayOfWeek` enum members, see DayOfWeek Enum in the .NET documentation.
`self.date_rules.month_start(days_offset: int = 0)`	Trigger an event on the first day of each month plus an offset.
`self.date_rules.month_start(symbol: Symbol, daysOffset: int = 0)`	Trigger an event on the first tradable date of each month for a specific symbol plus an offset.
`self.date_rules.month_end(days_offset: int = 0)`	Trigger an event on the last day of each month minus an offset.
`self.date_rules.month_end(symbol: Symbol, daysOffset: int = 0)`	Trigger an event on the last tradable date of each month for a specific symbol minus an offset.
`self.date_rules.week_start(days_offset: int = 0)`	Trigger an event on the first day of each week plus an offset.
`self.date_rules.week_start(symbol: Symbol, days_offset: int = 0)`	Trigger an event on the first tradable date of each week for a specific symbol plus an offset.
`self.date_rules.week_end(days_offset: int = 0)`	Trigger an event on the last day of each week minus an offset.
`self.date_rules.week_end(symbol: Symbol, days_offset: int = 0)`	Trigger an event on the last tradable date of each week for a specific symbol minus an offset.
`self.date_rules.year_start(days_offset: int = 0)`	Trigger an event on the first day of each year plus an offset.
`self.date_rules.year_start(symbol: Symbol, days_offset: int = 0)`	Trigger an event on the first tradable date of each year for a specific symbol plus an offset.
`self.date_rules.year_end(days_offset: int = 0)`	Trigger an event on the last day of each year minus an offset.
`self.date_rules.year_end(symbol: Symbol, days_offset: int = 0)`	Trigger an event on the last tradable date of each year for a specific symbol minus an offset.
`self.date_rules.today`	Trigger an event once today.
`self.date_rules.tomorrow`	Trigger an event once tomorrow.

To define custom date rules, create a `FuncDateRule` object. The `FuncDateRule` constructor expects a `name` argument of type `str` and a `get_dates_function` argument of type `Callable[[datetime, datetime], list[datetime]]` . The `get_dates_function` function receives the start and end dates of the algorithm and returns a list of dates for the date rule. In live trading, the end date is 12/31/2025. The following example demonstrates how to define a date rule that represents the 10th day of each month:

```py
# Create a date rule that specifies the 10th day of each month.
date_rule = FuncDateRule(
    name="10th_day_of_the_month",
    get_dates_function=lambda start, end: [
        datetime(year, month, 10)
        for year in range(start.year, end.year) for month in range(1,12)
    ]
)
```

Some date rules require a Symbol. However, they accept a string representation of the Symbol as well. If your algorithm doesn't add the security , it assumes the string refers to a US Equity Symbol. For example, if you use the `self.date_rules.every_day('ES')` method, it assumes that 'ES' refers to a US Equity. To create a Symbol without adding a security to your algorithm, call the `Symbol.create` method.

```
symbol = Symbol.create('ES', SecurityType.FUTURE, Market.CME)
```

Time Rules

The following table describes the supported `TimeRules` :

Member	Description
`self.time_rules.set_default_time_zone(time_zone: DateTimeZone)`	Sets the time zone for the `TimeRules` object used in all methods in this table, except when a different time zone is given. The default time zone is the algorithm time zone .
`self.time_rules.before_market_open(symbol: Symbol, minutes_before_open: float = 0, extended_market_open: bool = False)`	Trigger an event a few minutes before market open for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`self.time_rules.after_market_open(symbol: Symbol, minutes_after_open: float = 0, extended_market_open: bool = False)`	Trigger an event a few minutes after market open for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`self.time_rules.before_market_close(symbol: Symbol, minutes_before_close: float = 0, extended_market_open: bool = False)`	Trigger an event a few minutes before market close for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`self.time_rules.after_market_close(symbol: Symbol, minutes_after_close: float = 0, extended_market_open: bool = False)`	Trigger an event a few minutes after market close for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`self.time_rules.every(interval: timedelta)`	Trigger an event every period interval starting at midnight. This time rule triggers every period, regardless of whether or not the market is open.
`self.time_rules.now`	Trigger an event at the current time of day.
`self.time_rules.midnight`	Trigger an event at midnight.
`self.time_rules.noon`	Trigger an event at noon.
`self.time_rules.at(hour: int, minute: int, second: int = 0)`	Trigger an event at a specific time of day (e.g. 13:10).
`self.time_rules.at(hour: int, minute: int, second: int, time_zone: DateTimeZone)`	Trigger an event at a specific time of day in the given time zone (e.g. 13:10 UTC).

To define custom time rules, create a `FuncTimeRule` object. The `FuncTimeRule` constructor expects a `name` argument of type `str` and a `create_utc_event_times_function` argument of type `Callable[[list[datetime]], list[datetime]]` . The function receives the list of dates from the date rule and then returns a list of `datetime` that define the time rule.

```
time_rule = FuncTimeRule(
    name="CustomTimeRule",
    create_utc_event_times_function=lambda dates: [d + timedelta(hours=10) for d in dates]
)
```

Some time rules require a Symbol. However, they accept a string representation of the Symbol as well. If your algorithm doesn't add the security , it assumes the string refers to a US Equity Symbol. For example, if you use the `self.time_rules.before_market_open('ES', 15)` method, it assumes that 'ES' refers to a US Equity. To create a Symbol without adding a security to your algorithm, call the `Symbol.create` method.

```
symbol = Symbol.create('ES', SecurityType.FUTURE, Market.CME)
```

Remove Scheduled Events

If you no longer need a Scheduled Event in your algorithm, remove it so your algorithm doesn't execute unnecessary functions. To remove a Scheduled Event, save a reference to the Scheduled Event when you create it and then call the `remove` method to remove it.

```
PY
def initialize(self):
    # Remove a scheduled event by keeping a copy of the object on creation.
    self.scheduled_event = self.schedule.on(
        self.date_rules.every_day('SPY'),
        self.time_rules.after_market_open('SPY', 10),
        self._ten_minutes_after_open)

# Remove the scheduled event using the object reference in any method
self.schedule.remove(self.scheduled_event)
```

Common Errors

Common errors with Scheduled Events include stale fills and execution timeouts.

Stale Fills

A common error is to subscribe to daily resolution data and set a Scheduled Event intraday to place trades. If you trade intraday with daily data, you get stale fills.

Another common error is to set a Scheduled Event to trade immediately after the market open on illiquid securities. Illiquid securities can have no trades for the first few minutes after the market open. If you trade during this time, you get stale fills.

Execution Timeouts

If your Scheduled Event takes longer than 10 minutes to execute, your algorithm will timeout. To increase the amount of time that your Scheduled Event can run, replace your Scheduled Event with a training session .

Invoking the Callback Method

Make sure to not accidentally invote the event handler method by adding trailing braces `()` . Use `self._event_handler_func` , not `self._event_handler_func()` .

Execution Sequence

The algorithm manager calls events in the following order:

1. Scheduled Events
2. Consolidation event handlers
3. `on_data` event handler

This event flow is important to note. For instance, if your consolidation handlers or `on_data` event handler appends data to a `RollingWindow` and you use that `RollingWindow` in your Scheduled Event, when the Scheduled Event executes, the `RollingWindow` won't contain the most recent data.

Live Trading Considerations

In live trading, Scheduled Events execute in a parallel thread based on a real-time clock. If you set a Scheduled Event to fire at 10:00 AM, it executes at exactly 10:00 AM. In backtesting, Scheduled Events are part of the main algorithm manager loop, so they may not execute exactly when you set them. For example, if your algorithm subscribes to minute resolution US Equity data with regular trading hours and you set a Scheduled Event to occur at 2:00 AM, your Scheduled Event will execute at 9:31 AM when the next bar is fed into your algorithm.

The difference between live trading and backtesting is important to note because it can affect your algorithm's behavior. There are two common scenarios to consider.

Execution Timing and Backtest Timeouts

Take the following scenario:

- You set Scheduled Events for 2:00 AM, 3:00 AM, and 4:00 AM each day.
- Each Scheduled Event takes eight minutes to execute.
- Your algorithm only subscribes to US Equity securities without extended market hours (9:30 AM - 4:00 PM).

In this scenario, the Scheduled Events each fire at the correct time and execute without error in live trading. In backtesting, all of the Scheduled Events execute at 9:31 AM when your algorithm receives the first bar of the trading day. Since all the Scheduled Events take eight minutes to execute, the algorithm tries to execute all the Scheduled Events but reaches the 10-minute timeout and the backtest stops execution.

Live Data Delays

In backtests, your algorithm receives data at perfect timing. If you request minute resolution data, your algorithm receives the bars at the top of each minute. In live trading, bars have a slight delay, so you may receive them milliseconds after the top of each minute. Take the following scenario:

- You subscribe to minute resolution data
- You set a Scheduled Event for 10:00 AM
- The Scheduled Event checks the current asset price

In live trading, the Scheduled Event executes at exactly 10:00 AM but your algorithm may receive the 9:59-10:00 AM bar at 10:00:00.01 AM. Therefore, when you check the price in the Scheduled Event, the price from the 9:58-9:59 AM bar is the latest price. In backtesting, the Scheduled Event gets the price from the 9:59-10:00 AM bar since your algorithm receives the bar at perfect timing.

Examples

PY

```
def initialize(self):
    # Schedule an event to fire at a specific date/time using inline callback function.
    self.schedule.on(self.date_rules.on(2013, 10, 7),

Abandoned Baby

Introduction

Create a new Abandoned Baby candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using AbandonedBaby Indicator

To create an automatic indicator for `AbandonedBaby` , call the `abandoned_baby` helper method from the `QCAlgorithm` class. The `abandoned_baby` method creates a `AbandonedBaby` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class AbandonedBabyAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._abandoned_baby = self.candlestick_patterns.abandoned_baby(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._abandoned_baby.is_ready:
            # The current value of self._abandoned_baby is represented by self._abandoned_baby.current.value
            self.plot("AbandonedBaby", "abandoned_baby", self._abandoned_baby.current.value)
```

PY

For more information about this method, see the CandlestickPatterns class .

You can manually create a `AbandonedBaby` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class AbandonedBabyAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._abandoned_baby = AbandonedBaby()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._abandoned_baby.update(bar)

        if self._abandoned_baby.is_ready:
            # The current value of self._abandoned_baby is represented by self._abandoned_baby.current.value
            self.plot("AbandonedBaby", "abandoned_baby", self._abandoned_baby.current.value)
```

PY

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `AbandonedBaby` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class AbandonedBabyAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._abandoned_baby = self.candlestick_patterns.abandoned_baby(self._symbol)

        indicator_history = self.indicator_history(self._abandoned_baby, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._abandoned_baby, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._abandoned_baby, self._symbol, datetime(2024, 7, 1), datetime(2024,
7, 5), Resolution.MINUTE)
```

Supported Indicators

Advance Block

Introduction

Create a new Advance Block candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using AdvanceBlock Indicator

To create an automatic indicator for `AdvanceBlock` , call the `advance_block` helper method from the `QCAlgorithm` class. The `advance_block` method creates a `AdvanceBlock` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class AdvanceBlockAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._advance_block = self.candlestick_patterns.advance_block(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._advance_block.is_ready:
            # The current value of self._advance_block is represented by self._advance_block.current.value
            self.plot("AdvanceBlock", "advance_block", self._advance_block.current.value)
```

PY

For more information about this method, see the CandlestickPatterns class .

You can manually create a `AdvanceBlock` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class AdvanceBlockAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._advance_block = AdvanceBlock()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._advance_block.update(bar)

        if self._advance_block.is_ready:
            # The current value of self._advance_block is represented by self._advance_block.current.value
            self.plot("AdvanceBlock", "advance_block", self._advance_block.current.value)
```

PY

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `AdvanceBlock` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class AdvanceBlockAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._advance_block = self.candlestick_patterns.advance_block(self._symbol)

        indicator_history = self.indicator_history(self._advance_block, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._advance_block, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._advance_block, self._symbol, datetime(2024, 7, 1), datetime(2024, 7,
5), Resolution.MINUTE)
```

Supported Indicators

Belt Hold

Introduction

Create a new Belt Hold candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using BeltHold Indicator

To create an automatic indicator for `BeltHold` , call the `belt_hold` helper method from the `QCAlgorithm` class. The `belt_hold` method creates a `BeltHold` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class BeltHoldAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._belt_hold = self.candlestick_patterns.belt_hold(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._belt_hold.is_ready:
            # The current value of self._belt_hold is represented by self._belt_hold.current.value
            self.plot("BeltHold", "belt_hold", self._belt_hold.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `BeltHold` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class BeltHoldAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._belt_hold = BeltHold()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._belt_hold.update(bar)

        if self._belt_hold.is_ready:
            # The current value of self._belt_hold is represented by self._belt_hold.current.value
            self.plot("BeltHold", "belt_hold", self._belt_hold.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `BeltHold` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class BeltHoldAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._belt_hold = self.candlestick_patterns.belt_hold(self._symbol)

        indicator_history = self.indicator_history(self._belt_hold, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._belt_hold, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._belt_hold, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Supported Indicators

Breakaway

Introduction

Create a new Breakaway candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Breakaway Indicator

To create an automatic indicator for `Breakaway` , call the `breakaway` helper method from the `QCAlgorithm` class. The `breakaway` method creates a `Breakaway` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class BreakawayAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._breakaway = self.candlestick_patterns.breakaway(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._breakaway.is_ready:
            # The current value of self._breakaway is represented by self._breakaway.current.value
            self.plot("Breakaway", "breakaway", self._breakaway.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Breakaway` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class BreakawayAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._breakaway = Breakaway()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._breakaway.update(bar)

        if self._breakaway.is_ready:
            # The current value of self._breakaway is represented by self._breakaway.current.value
            self.plot("Breakaway", "breakaway", self._breakaway.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Breakaway` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class BreakawayAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._breakaway = self.candlestick_patterns.breakaway(self._symbol)

        indicator_history = self.indicator_history(self._breakaway, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._breakaway, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._breakaway, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Supported Indicators

Closing Marubozu

Introduction

Create a new Closing Marubozu candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ClosingMarubozu Indicator

To create an automatic indicator for `ClosingMarubozu` , call the `closing_marubozu` helper method from the `QCAlgorithm` class. The `closing_marubozu` method creates a `ClosingMarubozu` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class ClosingMarubozuAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._closing_marubozu = self.candlestick_patterns.closing_marubozu(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._closing_marubozu.is_ready:
            # The current value of self._closing_marubozu is represented by self._closing_marubozu.current.value
            self.plot("ClosingMarubozu", "closing_marubozu", self._closing_marubozu.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `ClosingMarubozu` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class ClosingMarubozuAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._closing_marubozu = ClosingMarubozu()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._closing_marubozu.update(bar)

        if self._closing_marubozu.is_ready:
            # The current value of self._closing_marubozu is represented by self._closing_marubozu.current.value
            self.plot("ClosingMarubozu", "closing_marubozu", self._closing_marubozu.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `ClosingMarubozu` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class ClosingMarubozuAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._closing_marubozu = self.candlestick_patterns.closing_marubozu(self._symbol)

        indicator_history = self.indicator_history(self._closing_marubozu, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._closing_marubozu, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._closing_marubozu, self._symbol, datetime(2024, 7, 1), datetime(2024,
7, 5), Resolution.MINUTE)
```

Supported Indicators

Concealed Baby Swallow

Introduction

Create a new Concealed Baby Swallow candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ConcealedBabySwallow Indicator

To create an automatic indicator for `ConcealedBabySwallow` , call the `concealed_baby_swallow` helper method from the `QCAlgorithm` class. The `concealed_baby_swallow` method creates a `ConcealedBabySwallow` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class ConcealedBabySwallowAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._concealed_baby_swallow = self.candlestick_patterns.concealed_baby_swallow(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._concealed_baby_swallow.is_ready:
            # The current value of self._concealed_baby_swallow is represented by self._concealed_baby_swallow.current.value
            self.plot("ConcealedBabySwallow", "concealed_baby_swallow", self._concealed_baby_swallow.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `ConcealedBabySwallow` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class ConcealedBabySwallowAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._concealed_baby_swallow = ConcealedBabySwallow()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._concealed_baby_swallow.update(bar)

        if self._concealed_baby_swallow.is_ready:
            # The current value of self._concealed_baby_swallow is represented by self._concealed_baby_swallow.current.value
            self.plot("ConcealedBabySwallow", "concealed_baby_swallow", self._concealed_baby_swallow.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `ConcealedBabySwallow` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class ConcealedBabySwallowAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._concealed_baby_swallow = self.candlestick_patterns.concealed_baby_swallow(self._symbol)

        indicator_history = self.indicator_history(self._concealed_baby_swallow, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._concealed_baby_swallow, self._symbol, timedelta(days=10),
Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._concealed_baby_swallow, self._symbol, datetime(2024, 7, 1),
datetime(2024, 7, 5), Resolution.MINUTE)
```

Counterattack

Introduction

Create a new Counterattack candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Counterattack Indicator

To create an automatic indicator for `Counterattack` , call the `counterattack` helper method from the `QCAlgorithm` class. The `counterattack` method creates a `Counterattack` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class CounterattackAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._counterattack = self.candlestick_patterns.counterattack(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._counterattack.is_ready:
            # The current value of self._counterattack is represented by self._counterattack.current.value
            self.plot("Counterattack", "counterattack", self._counterattack.current.value)
```

PY

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Counterattack` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class CounterattackAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._counterattack = Counterattack()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._counterattack.update(bar)

        if self._counterattack.is_ready:
            # The current value of self._counterattack is represented by self._counterattack.current.value
            self.plot("Counterattack", "counterattack", self._counterattack.current.value)
```

PY

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Counterattack` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class CounterattackAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._counterattack = self.candlestick_patterns.counterattack(self._symbol)

        indicator_history = self.indicator_history(self._counterattack, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._counterattack, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._counterattack, self._symbol, datetime(2024, 7, 1), datetime(2024, 7,
5), Resolution.MINUTE)
```

Dark Cloud Cover

Introduction

Create a new Dark Cloud Cover candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using DarkCloudCover Indicator

To create an automatic indicator for `DarkCloudCover` , call the `dark_cloud_cover` helper method from the `QCAlgorithm` class. The `dark_cloud_cover` method creates a `DarkCloudCover` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class DarkCloudCoverAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._dark_cloud_cover = self.candlestick_patterns.dark_cloud_cover(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._dark_cloud_cover.is_ready:
            # The current value of self._dark_cloud_cover is represented by self._dark_cloud_cover.current.value
            self.plot("DarkCloudCover", "dark_cloud_cover", self._dark_cloud_cover.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `DarkCloudCover` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class DarkCloudCoverAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._dark_cloud_cover = DarkCloudCover()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._dark_cloud_cover.update(bar)

        if self._dark_cloud_cover.is_ready:
            # The current value of self._dark_cloud_cover is represented by self._dark_cloud_cover.current.value
            self.plot("DarkCloudCover", "dark_cloud_cover", self._dark_cloud_cover.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `DarkCloudCover` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class DarkCloudCoverAlgorithm(QCAlgorithm):
    def initialize(self) -> None:

Engulfing

Introduction

Create a new Engulfing candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Engulfing Indicator

To create an automatic indicator for `Engulfing` , call the `engulfing` helper method from the `QCAlgorithm` class. The `engulfing` method creates a `Engulfing` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class EngulfingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._engulfing = self.candlestick_patterns.engulfing(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._engulfing.is_ready:
            # The current value of self._engulfing is represented by self._engulfing.current.value
            self.plot("Engulfing", "engulfing", self._engulfing.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Engulfing` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class EngulfingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._engulfing = Engulfing()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._engulfing.update(bar)

        if self._engulfing.is_ready:
            # The current value of self._engulfing is represented by self._engulfing.current.value
            self.plot("Engulfing", "engulfing", self._engulfing.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Engulfing` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class EngulfingAlgorithm(QCAlgorithm):

Evening Doji Star

Introduction

Create a new Evening Doji Star candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using EveningDojiStar Indicator

To create an automatic indicator for `EveningDojiStar` , call the `evening_doji_star` helper method from the `QCAlgorithm` class. The `evening_doji_star` method creates a `EveningDojiStar` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class EveningDojiStarAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._evening_doji_star = self.candlestick_patterns.evening_doji_star(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._evening_doji_star.is_ready:
            # The current value of self._evening_doji_star is represented by self._evening_doji_star.current.value
            self.plot("EveningDojiStar", "evening_doji_star", self._evening_doji_star.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `EveningDojiStar` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class EveningDojiStarAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._evening_doji_star = EveningDojiStar()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._evening_doji_star.update(bar)

        if self._evening_doji_star.is_ready:
            # The current value of self._evening_doji_star is represented by self._evening_doji_star.current.value
            self.plot("EveningDojiStar", "evening_doji_star", self._evening_doji_star.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `EveningDojiStar` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class EveningDojiStarAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._evening_doji_star = self.candlestick_patterns.evening_doji_star(self._symbol)

        indicator_history = self.indicator_history(self._evening_doji_star, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._evening_doji_star, self._symbol, timedelta(days=10),
Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._evening_doji_star, self._symbol, datetime(2024, 7, 1),
datetime(2024, 7, 5), Resolution.MINUTE)
```

Evening Star

Introduction

Create a new Evening Star candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using EveningStar Indicator

To create an automatic indicator for `EveningStar` , call the `evening_star` helper method from the `QCAlgorithm` class. The `evening_star` method creates a `EveningStar` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class EveningStarAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._evening_star = self.candlestick_patterns.evening_star(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._evening_star.is_ready:
            # The current value of self._evening_star is represented by self._evening_star.current.value
            self.plot("EveningStar", "evening_star", self._evening_star.current.value)
```

PY

For more information about this method, see the CandlestickPatterns class .

You can manually create a `EveningStar` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class EveningStarAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._evening_star = EveningStar()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._evening_star.update(bar)

        if self._evening_star.is_ready:
            # The current value of self._evening_star is represented by self._evening_star.current.value
            self.plot("EveningStar", "evening_star", self._evening_star.current.value)
```

PY

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `EveningStar` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class EveningStarAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._evening_star = self.candlestick_patterns.evening_star(self._symbol)

        indicator_history = self.indicator_history(self._evening_star, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._evening_star, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._evening_star, self._symbol, datetime(2024, 7, 1), datetime(2024, 7,
5), Resolution.MINUTE)
```

Gap Side By Side White

Introduction

Create a new Gap Side By Side White candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using GapSideBySideWhite Indicator

To create an automatic indicator for `GapSideBySideWhite` , call the `gap_side_by_side_white` helper method from the `QCAlgorithm` class. The `gap_side_by_side_white` method creates a `GapSideBySideWhite` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class GapSideBySideWhiteAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._gap_side_by_side_white = self.candlestick_patterns.gap_side_by_side_white(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._gap_side_by_side_white.is_ready:
            # The current value of self._gap_side_by_side_white is represented by self._gap_side_by_side_white.current.value
            self.plot("GapSideBySideWhite", "gap_side_by_side_white", self._gap_side_by_side_white.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `GapSideBySideWhite` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class GapSideBySideWhiteAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._gap_side_by_side_white = GapSideBySideWhite()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._gap_side_by_side_white.update(bar)

        if self._gap_side_by_side_white.is_ready:
            # The current value of self._gap_side_by_side_white is represented by self._gap_side_by_side_white.current.value
            self.plot("GapSideBySideWhite", "gap_side_by_side_white", self._gap_side_by_side_white.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `GapSideBySideWhite` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class GapSideBySideWhiteAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._gap_side_by_side_white = self.candlestick_patterns.gap_side_by_side_white(self._symbol)

        indicator_history = self.indicator_history(self._gap_side_by_side_white, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._gap_side_by_side_white, self._symbol, timedelta(days=10),
Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._gap_side_by_side_white, self._symbol, datetime(2024, 7, 1),
datetime(2024, 7, 5), Resolution.MINUTE)
```

Gravestone Doji

Introduction

Create a new Gravestone Doji candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using GravestoneDoji Indicator

To create an automatic indicator for `GravestoneDoji` , call the `gravestone_doji` helper method from the `QCAlgorithm` class. The `gravestone_doji` method creates a `GravestoneDoji` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class GravestoneDojiAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._gravestone_doji = self.candlestick_patterns.gravestone_doji(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._gravestone_doji.is_ready:
            # The current value of self._gravestone_doji is represented by self._gravestone_doji.current.value
            self.plot("GravestoneDoji", "gravestone_doji", self._gravestone_doji.current.value)
```

PY

For more information about this method, see the CandlestickPatterns class .

You can manually create a `GravestoneDoji` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class GravestoneDojiAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._gravestone_doji = GravestoneDoji()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._gravestone_doji.update(bar)

        if self._gravestone_doji.is_ready:
            # The current value of self._gravestone_doji is represented by self._gravestone_doji.current.value
            self.plot("GravestoneDoji", "gravestone_doji", self._gravestone_doji.current.value)
```

PY

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `GravestoneDoji` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class GravestoneDojiAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._gravestone_doji = self.candlestick_patterns.gravestone_doji(self._symbol)

        indicator_history = self.indicator_history(self._gravestone_doji, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._gravestone_doji, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._gravestone_doji, self._symbol, datetime(2024, 7, 1), datetime(2024,
7, 5), Resolution.MINUTE)

Hammer

Introduction

Create a new Hammer candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Hammer Indicator

To create an automatic indicator for `Hammer` , call the `hammer` helper method from the `QCAlgorithm` class. The `hammer` method creates a `Hammer` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class HammerAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._hammer = self.candlestick_patterns.hammer(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._hammer.is_ready:
            # The current value of self._hammer is represented by self._hammer.current.value
            self.plot("Hammer", "hammer", self._hammer.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Hammer` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class HammerAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._hammer = Hammer()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._hammer.update(bar)

        if self._hammer.is_ready:
            # The current value of self._hammer is represented by self._hammer.current.value
            self.plot("Hammer", "hammer", self._hammer.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Hammer` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class HammerAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._hammer = self.candlestick_patterns.hammer(self._symbol)

        indicator_history = self.indicator_history(self._hammer, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._hammer, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._hammer, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Harami Cross

Introduction

Create a new Harami Cross candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using HaramiCross Indicator

To create an automatic indicator for `HaramiCross` , call the `harami_cross` helper method from the `QCAlgorithm` class. The `harami_cross` method creates a `HaramiCross` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class HaramiCrossAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._harami_cross = self.candlestick_patterns.harami_cross(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._harami_cross.is_ready:
            # The current value of self._harami_cross is represented by self._harami_cross.current.value
            self.plot("HaramiCross", "harami_cross", self._harami_cross.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `HaramiCross` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class HaramiCrossAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._harami_cross = HaramiCross()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._harami_cross.update(bar)

        if self._harami_cross.is_ready:
            # The current value of self._harami_cross is represented by self._harami_cross.current.value
            self.plot("HaramiCross", "harami_cross", self._harami_cross.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `HaramiCross` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class HaramiCrossAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._harami_cross = self.candlestick_patterns.harami_cross(self._symbol)

        indicator_history = self.indicator_history(self._harami_cross, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._harami_cross, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._harami_cross, self._symbol, datetime(2024, 7, 1), datetime(2024, 7,
5), Resolution.MINUTE)
```

Supported Indicators

High Wave Candle

Introduction

Create a new High Wave Candle candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using HighWaveCandle Indicator

To create an automatic indicator for `HighWaveCandle` , call the `high_wave_candle` helper method from the `QCAlgorithm` class. The `high_wave_candle` method creates a `HighWaveCandle` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class HighWaveCandleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._high_wave_candle = self.candlestick_patterns.high_wave_candle(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._high_wave_candle.is_ready:
            # The current value of self._high_wave_candle is represented by self._high_wave_candle.current.value
            self.plot("HighWaveCandle", "high_wave_candle", self._high_wave_candle.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `HighWaveCandle` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class HighWaveCandleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._high_wave_candle = HighWaveCandle()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._high_wave_candle.update(bar)

        if self._high_wave_candle.is_ready:
            # The current value of self._high_wave_candle is represented by self._high_wave_candle.current.value
            self.plot("HighWaveCandle", "high_wave_candle", self._high_wave_candle.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `HighWaveCandle` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class HighWaveCandleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._high_wave_candle = self.candlestick_patterns.high_wave_candle(self._symbol)

        indicator_history = self.indicator_history(self._high_wave_candle, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._high_wave_candle, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._high_wave_candle, self._symbol, datetime(2024, 7, 1), datetime(2024,
7, 5), Resolution.MINUTE)
```

Hikkake

Introduction

Create a new Hikkake candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Hikkake Indicator

To create an automatic indicator for `Hikkake` , call the `hikkake` helper method from the `QCAlgorithm` class. The `hikkake` method creates a `Hikkake` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class HikkakeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._hikkake = self.candlestick_patterns.hikkake(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._hikkake.is_ready:
            # The current value of self._hikkake is represented by self._hikkake.current.value
            self.plot("Hikkake", "hikkake", self._hikkake.current.value)
```

PY

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Hikkake` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class HikkakeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._hikkake = Hikkake()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._hikkake.update(bar)

        if self._hikkake.is_ready:
            # The current value of self._hikkake is represented by self._hikkake.current.value
            self.plot("Hikkake", "hikkake", self._hikkake.current.value)
```

PY

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Hikkake` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class HikkakeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._hikkake = self.candlestick_patterns.hikkake(self._symbol)

        indicator_history = self.indicator_history(self._hikkake, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._hikkake, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._hikkake, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Hikkake Modified

Introduction

Create a new Hikkake Modified candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using HikkakeModified Indicator

To create an automatic indicator for `HikkakeModified` , call the `hikkake_modified` helper method from the `QCAlgorithm` class. The `hikkake_modified` method creates a `HikkakeModified` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class HikkakeModifiedAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._hikkake_modified = self.candlestick_patterns.hikkake_modified(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._hikkake_modified.is_ready:
            # The current value of self._hikkake_modified is represented by self._hikkake_modified.current.value
            self.plot("HikkakeModified", "hikkake_modified", self._hikkake_modified.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `HikkakeModified` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class HikkakeModifiedAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._hikkake_modified = HikkakeModified()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._hikkake_modified.update(bar)

        if self._hikkake_modified.is_ready:
            # The current value of self._hikkake_modified is represented by self._hikkake_modified.current.value
            self.plot("HikkakeModified", "hikkake_modified", self._hikkake_modified.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `HikkakeModified` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class HikkakeModifiedAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._hikkake_modified = self.candlestick_patterns.hikkake_modified(self._symbol)

        indicator_history = self.indicator_history(self._hikkake_modified, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._hikkake_modified, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._hikkake_modified, self._symbol, datetime(2024, 7, 1), datetime(2024,
7, 5), Resolution.MINUTE)
```

Homing Pigeon

Introduction

Create a new Homing Pigeon candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using HomingPigeon Indicator

To create an automatic indicator for `HomingPigeon` , call the `homing_pigeon` helper method from the `QCAlgorithm` class. The `homing_pigeon` method creates a `HomingPigeon` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class HomingPigeonAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._homing_pigeon = self.candlestick_patterns.homing_pigeon(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._homing_pigeon.is_ready:
            # The current value of self._homing_pigeon is represented by self._homing_pigeon.current.value
            self.plot("HomingPigeon", "homing_pigeon", self._homing_pigeon.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `HomingPigeon` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class HomingPigeonAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._homing_pigeon = HomingPigeon()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._homing_pigeon.update(bar)

        if self._homing_pigeon.is_ready:
            # The current value of self._homing_pigeon is represented by self._homing_pigeon.current.value
            self.plot("HomingPigeon", "homing_pigeon", self._homing_pigeon.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `HomingPigeon` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class HomingPigeonAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._homing_pigeon = self.candlestick_patterns.homing_pigeon(self._symbol)

        indicator_history = self.indicator_history(self._homing_pigeon, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._homing_pigeon, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._homing_pigeon, self._symbol, datetime(2024, 7, 1), datetime(2024, 7,
5), Resolution.MINUTE)
```

Identical Three Crows

Introduction

Create a new Identical Three Crows candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using IdenticalThreeCrows Indicator

To create an automatic indicator for `IdenticalThreeCrows` , call the `identical_three_crows` helper method from the `QCAlgorithm` class. The `identical_three_crows` method creates a `IdenticalThreeCrows` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class IdenticalThreeCrowsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._identical_three_crows = self.candlestick_patterns.identical_three_crows(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._identical_three_crows.is_ready:
            # The current value of self._identical_three_crows is represented by self._identical_three_crows.current.value
            self.plot("IdenticalThreeCrows", "identical_three_crows", self._identical_three_crows.current.value)
```

PY

For more information about this method, see the CandlestickPatterns class .

You can manually create a `IdenticalThreeCrows` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class IdenticalThreeCrowsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._identical_three_crows = IdenticalThreeCrows()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._identical_three_crows.update(bar)

        if self._identical_three_crows.is_ready:
            # The current value of self._identical_three_crows is represented by self._identical_three_crows.current.value
            self.plot("IdenticalThreeCrows", "identical_three_crows", self._identical_three_crows.current.value)
```

PY

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `IdenticalThreeCrows` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class IdenticalThreeCrowsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._identical_three_crows = self.candlestick_patterns.identical_three_crows(self._symbol)

        indicator_history = self.indicator_history(self._identical_three_crows, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._identical_three_crows, self._symbol, timedelta(days=10),
Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._identical_three_crows, self._symbol, datetime(2024, 7, 1),
datetime(2024, 7, 5), Resolution.MINUTE)

In Neck

Introduction

Create a new In Neck candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using InNeck Indicator

To create an automatic indicator for `InNeck` , call the `in_neck` helper method from the `QCAlgorithm` class. The `in_neck` method creates a `InNeck` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class InNeckAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._in_neck = self.candlestick_patterns.in_neck(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._in_neck.is_ready:
            # The current value of self._in_neck is represented by self._in_neck.current.value
            self.plot("InNeck", "in_neck", self._in_neck.current.value)
```

PY

For more information about this method, see the CandlestickPatterns class .

You can manually create a `InNeck` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class InNeckAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._in_neck = InNeck()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._in_neck.update(bar)

        if self._in_neck.is_ready:
            # The current value of self._in_neck is represented by self._in_neck.current.value
            self.plot("InNeck", "in_neck", self._in_neck.current.value)
```

PY

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `InNeck` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class InNeckAlgorithm(QCAlgorithm):

Inverted Hammer

Introduction

Create a new Inverted Hammer candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using InvertedHammer Indicator

To create an automatic indicator for `InvertedHammer` , call the `inverted_hammer` helper method from the `QCAlgorithm` class. The `inverted_hammer` method creates a `InvertedHammer` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class InvertedHammerAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._inverted_hammer = self.candlestick_patterns.inverted_hammer(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._inverted_hammer.is_ready:
            # The current value of self._inverted_hammer is represented by self._inverted_hammer.current.value
            self.plot("InvertedHammer", "inverted_hammer", self._inverted_hammer.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `InvertedHammer` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class InvertedHammerAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._inverted_hammer = InvertedHammer()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._inverted_hammer.update(bar)

        if self._inverted_hammer.is_ready:
            # The current value of self._inverted_hammer is represented by self._inverted_hammer.current.value
            self.plot("InvertedHammer", "inverted_hammer", self._inverted_hammer.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `InvertedHammer` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class InvertedHammerAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._inverted_hammer = self.candlestick_patterns.inverted_hammer(self._symbol)

        indicator_history = self.indicator_history(self._inverted_hammer, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._inverted_hammer, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._inverted_hammer, self._symbol, datetime(2024, 7, 1), datetime(2024,
7, 5), Resolution.MINUTE)
```

Kicking

Introduction

Create a new Kicking candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Kicking Indicator

To create an automatic indicator for `Kicking` , call the `kicking` helper method from the `QCAlgorithm` class. The `kicking` method creates a `Kicking` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class KickingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._kicking = self.candlestick_patterns.kicking(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._kicking.is_ready:
            # The current value of self._kicking is represented by self._kicking.current.value
            self.plot("Kicking", "kicking", self._kicking.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Kicking` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class KickingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._kicking = Kicking()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._kicking.update(bar)

        if self._kicking.is_ready:
            # The current value of self._kicking is represented by self._kicking.current.value
            self.plot("Kicking", "kicking", self._kicking.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Kicking` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class KickingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._kicking = self.candlestick_patterns.kicking(self._symbol)

        indicator_history = self.indicator_history(self._kicking, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._kicking, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._kicking, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Kicking By Length

Introduction

Create a new Kicking By Length candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using KickingByLength Indicator

To create an automatic indicator for `KickingByLength` , call the `kicking_by_length` helper method from the `QCAlgorithm` class. The `kicking_by_length` method creates a `KickingByLength` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class KickingByLengthAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._kicking_by_length = self.candlestick_patterns.kicking_by_length(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._kicking_by_length.is_ready:
            # The current value of self._kicking_by_length is represented by self._kicking_by_length.current.value
            self.plot("KickingByLength", "kicking_by_length", self._kicking_by_length.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `KickingByLength` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class KickingByLengthAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._kicking_by_length = KickingByLength()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._kicking_by_length.update(bar)

        if self._kicking_by_length.is_ready:
            # The current value of self._kicking_by_length is represented by self._kicking_by_length.current.value
            self.plot("KickingByLength", "kicking_by_length", self._kicking_by_length.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `KickingByLength` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class KickingByLengthAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._kicking_by_length = self.candlestick_patterns.kicking_by_length(self._symbol)

        indicator_history = self.indicator_history(self._kicking_by_length, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._kicking_by_length, self._symbol, timedelta(days=10),
Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._kicking_by_length, self._symbol, datetime(2024, 7, 1),
datetime(2024, 7, 5), Resolution.MINUTE)
```

Ladder Bottom

Introduction

Create a new Ladder Bottom candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using LadderBottom Indicator

To create an automatic indicator for `LadderBottom` , call the `ladder_bottom` helper method from the `QCAlgorithm` class. The `ladder_bottom` method creates a `LadderBottom` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class LadderBottomAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._ladder_bottom = self.candlestick_patterns.ladder_bottom(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._ladder_bottom.is_ready:
            # The current value of self._ladder_bottom is represented by self._ladder_bottom.current.value
            self.plot("LadderBottom", "ladder_bottom", self._ladder_bottom.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `LadderBottom` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class LadderBottomAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._ladder_bottom = LadderBottom()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._ladder_bottom.update(bar)

        if self._ladder_bottom.is_ready:
            # The current value of self._ladder_bottom is represented by self._ladder_bottom.current.value
            self.plot("LadderBottom", "ladder_bottom", self._ladder_bottom.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `LadderBottom` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class LadderBottomAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._ladder_bottom = self.candlestick_patterns.ladder_bottom(self._symbol)

        indicator_history = self.indicator_history(self._ladder_bottom, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._ladder_bottom, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._ladder_bottom, self._symbol, datetime(2024, 7, 1), datetime(2024, 7,
5), Resolution.MINUTE)
```

Long Legged Doji

Introduction

Create a new Long Legged Doji candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using LongLeggedDoji Indicator

To create an automatic indicator for `LongLeggedDoji` , call the `long_legged_doji` helper method from the `QCAlgorithm` class. The `long_legged_doji` method creates a `LongLeggedDoji` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class LongLeggedDojiAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._long_legged_doji = self.candlestick_patterns.long_legged_doji(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._long_legged_doji.is_ready:
            # The current value of self._long_legged_doji is represented by self._long_legged_doji.current.value
            self.plot("LongLeggedDoji", "long_legged_doji", self._long_legged_doji.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `LongLeggedDoji` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class LongLeggedDojiAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._long_legged_doji = LongLeggedDoji()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._long_legged_doji.update(bar)

        if self._long_legged_doji.is_ready:
            # The current value of self._long_legged_doji is represented by self._long_legged_doji.current.value
            self.plot("LongLeggedDoji", "long_legged_doji", self._long_legged_doji.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `LongLeggedDoji` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class LongLeggedDojiAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._long_legged_doji = self.candlestick_patterns.long_legged_doji(self._symbol)

        indicator_history = self.indicator_history(self._long_legged_doji, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._long_legged_doji, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._long_legged_doji, self._symbol, datetime(2024, 7, 1), datetime(2024,
7, 5), Resolution.MINUTE)
```

Long Line Candle

Introduction

Create a new Long Line Candle candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using LongLineCandle Indicator

To create an automatic indicator for `LongLineCandle` , call the `long_line_candle` helper method from the `QCAlgorithm` class. The `long_line_candle` method creates a `LongLineCandle` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class LongLineCandleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._long_line_candle = self.candlestick_patterns.long_line_candle(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._long_line_candle.is_ready:
            # The current value of self._long_line_candle is represented by self._long_line_candle.current.value
            self.plot("LongLineCandle", "long_line_candle", self._long_line_candle.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `LongLineCandle` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class LongLineCandleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._long_line_candle = LongLineCandle()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._long_line_candle.update(bar)

        if self._long_line_candle.is_ready:
            # The current value of self._long_line_candle is represented by self._long_line_candle.current.value
            self.plot("LongLineCandle", "long_line_candle", self._long_line_candle.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `LongLineCandle` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class LongLineCandleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._long_line_candle = self.candlestick_patterns.long_line_candle(self._symbol)

        indicator_history = self.indicator_history(self._long_line_candle, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._long_line_candle, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._long_line_candle, self._symbol, datetime(2024, 7, 1), datetime(2024,
7, 5), Resolution.MINUTE)
```

Marubozu

Introduction

Create a new Marubozu candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Marubozu Indicator

To create an automatic indicator for `Marubozu` , call the `marubozu` helper method from the `QCAlgorithm` class. The `marubozu` method creates a `Marubozu` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class MarubozuAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._marubozu = self.candlestick_patterns.marubozu(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._marubozu.is_ready:
            # The current value of self._marubozu is represented by self._marubozu.current.value
            self.plot("Marubozu", "marubozu", self._marubozu.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Marubozu` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class MarubozuAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._marubozu = Marubozu()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._marubozu.update(bar)

        if self._marubozu.is_ready:
            # The current value of self._marubozu is represented by self._marubozu.current.value
            self.plot("Marubozu", "marubozu", self._marubozu.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Marubozu` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class MarubozuAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._marubozu = self.candlestick_patterns.marubozu(self._symbol)

        indicator_history = self.indicator_history(self._marubozu, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._marubozu, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._marubozu, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Mat Hold

Introduction

Create a new Mat Hold candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using MatHold Indicator

To create an automatic indicator for `MatHold` , call the `mat_hold` helper method from the `QCAlgorithm` class. The `mat_hold` method creates a `MatHold` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class MatHoldAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._mat_hold = self.candlestick_patterns.mat_hold(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._mat_hold.is_ready:
            # The current value of self._mat_hold is represented by self._mat_hold.current.value
            self.plot("MatHold", "mat_hold", self._mat_hold.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `MatHold` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class MatHoldAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._mat_hold = MatHold()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._mat_hold.update(bar)

        if self._mat_hold.is_ready:
            # The current value of self._mat_hold is represented by self._mat_hold.current.value
            self.plot("MatHold", "mat_hold", self._mat_hold.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `MatHold` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class MatHoldAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._mat_hold = self.candlestick_patterns.mat_hold(self._symbol)

        indicator_history = self.indicator_history(self._mat_hold, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._mat_hold, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._mat_hold, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Matching Low

Introduction

Create a new Matching Low candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using MatchingLow Indicator

To create an automatic indicator for `MatchingLow` , call the `matching_low` helper method from the `QCAlgorithm` class. The `matching_low` method creates a `MatchingLow` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class MatchingLowAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._matching_low = self.candlestick_patterns.matching_low(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._matching_low.is_ready:
            # The current value of self._matching_low is represented by self._matching_low.current.value
            self.plot("MatchingLow", "matching_low", self._matching_low.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `MatchingLow` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class MatchingLowAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._matching_low = MatchingLow()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._matching_low.update(bar)

        if self._matching_low.is_ready:
            # The current value of self._matching_low is represented by self._matching_low.current.value
            self.plot("MatchingLow", "matching_low", self._matching_low.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `MatchingLow` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class MatchingLowAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._matching_low = self.candlestick_patterns.matching_low(self._symbol)

        indicator_history = self.indicator_history(self._matching_low, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._matching_low, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._matching_low, self._symbol, datetime(2024, 7, 1), datetime(2024, 7,
5), Resolution.MINUTE)
```

Supported Indicators

Morning Doji Star

Introduction

Create a new Morning Doji Star candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using MorningDojiStar Indicator

To create an automatic indicator for `MorningDojiStar` , call the `morning_doji_star` helper method from the `QCAlgorithm` class. The `morning_doji_star` method creates a `MorningDojiStar` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class MorningDojiStarAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._morning_doji_star = self.candlestick_patterns.morning_doji_star(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._morning_doji_star.is_ready:
            # The current value of self._morning_doji_star is represented by self._morning_doji_star.current.value
            self.plot("MorningDojiStar", "morning_doji_star", self._morning_doji_star.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `MorningDojiStar` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class MorningDojiStarAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._morning_doji_star = MorningDojiStar()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._morning_doji_star.update(bar)

        if self._morning_doji_star.is_ready:
            # The current value of self._morning_doji_star is represented by self._morning_doji_star.current.value
            self.plot("MorningDojiStar", "morning_doji_star", self._morning_doji_star.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `MorningDojiStar` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class MorningDojiStarAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._morning_doji_star = self.candlestick_patterns.morning_doji_star(self._symbol)

        indicator_history = self.indicator_history(self._morning_doji_star, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._morning_doji_star, self._symbol, timedelta(days=10),
Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._morning_doji_star, self._symbol, datetime(2024, 7, 1),
datetime(2024, 7, 5), Resolution.MINUTE)
```

Morning Star

Introduction

Create a new Morning Star candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using MorningStar Indicator

To create an automatic indicator for `MorningStar` , call the `morning_star` helper method from the `QCAlgorithm` class. The `morning_star` method creates a `MorningStar` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class MorningStarAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._morning_star = self.candlestick_patterns.morning_star(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._morning_star.is_ready:
            # The current value of self._morning_star is represented by self._morning_star.current.value
            self.plot("MorningStar", "morning_star", self._morning_star.current.value)
```

PY

For more information about this method, see the CandlestickPatterns class .

You can manually create a `MorningStar` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class MorningStarAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._morning_star = MorningStar()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._morning_star.update(bar)

        if self._morning_star.is_ready:
            # The current value of self._morning_star is represented by self._morning_star.current.value
            self.plot("MorningStar", "morning_star", self._morning_star.current.value)
```

PY

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `MorningStar` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class MorningStarAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._morning_star = self.candlestick_patterns.morning_star(self._symbol)

        indicator_history = self.indicator_history(self._morning_star, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._morning_star, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._morning_star, self._symbol, datetime(2024, 7, 1), datetime(2024, 7,
5), Resolution.MINUTE)
```

On Neck

Introduction

Create a new On Neck candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using OnNeck Indicator

To create an automatic indicator for `OnNeck` , call the `on_neck` helper method from the `QCAlgorithm` class. The `on_neck` method creates a `OnNeck` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class OnNeckAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._on_neck = self.candlestick_patterns.on_neck(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._on_neck.is_ready:
            # The current value of self._on_neck is represented by self._on_neck.current.value
            self.plot("OnNeck", "on_neck", self._on_neck.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `OnNeck` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class OnNeckAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._on_neck = OnNeck()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._on_neck.update(bar)

        if self._on_neck.is_ready:
            # The current value of self._on_neck is represented by self._on_neck.current.value
            self.plot("OnNeck", "on_neck", self._on_neck.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `OnNeck` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class OnNeckAlgorithm(QCAlgorithm):

Separating Lines

Introduction

Create a new Separating Lines candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using SeparatingLines Indicator

To create an automatic indicator for `SeparatingLines` , call the `separating_lines` helper method from the `QCAlgorithm` class. The `separating_lines` method creates a `SeparatingLines` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class SeparatingLinesAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._separating_lines = self.candlestick_patterns.separating_lines(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._separating_lines.is_ready:
            # The current value of self._separating_lines is represented by self._separating_lines.current.value
            self.plot("SeparatingLines", "separating_lines", self._separating_lines.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `SeparatingLines` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class SeparatingLinesAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._separating_lines = SeparatingLines()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._separating_lines.update(bar)

        if self._separating_lines.is_ready:
            # The current value of self._separating_lines is represented by self._separating_lines.current.value
            self.plot("SeparatingLines", "separating_lines", self._separating_lines.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `SeparatingLines` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class SeparatingLinesAlgorithm(QCAlgorithm):
    def initialize(self) -> None:

Shooting Star

Introduction

Create a new Shooting Star candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ShootingStar Indicator

To create an automatic indicator for `ShootingStar` , call the `shooting_star` helper method from the `QCAlgorithm` class. The `shooting_star` method creates a `ShootingStar` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class ShootingStarAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._shooting_star = self.candlestick_patterns.shooting_star(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._shooting_star.is_ready:
            # The current value of self._shooting_star is represented by self._shooting_star.current.value
            self.plot("ShootingStar", "shooting_star", self._shooting_star.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `ShootingStar` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class ShootingStarAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._shooting_star = ShootingStar()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._shooting_star.update(bar)

        if self._shooting_star.is_ready:
            # The current value of self._shooting_star is represented by self._shooting_star.current.value
            self.plot("ShootingStar", "shooting_star", self._shooting_star.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `ShootingStar` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class ShootingStarAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._shooting_star = self.candlestick_patterns.shooting_star(self._symbol)

        indicator_history = self.indicator_history(self._shooting_star, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._shooting_star, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._shooting_star, self._symbol, datetime(2024, 7, 1), datetime(2024, 7,
5), Resolution.MINUTE)
```

Short Line Candle

Introduction

Create a new Short Line Candle candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ShortLineCandle Indicator

To create an automatic indicator for `ShortLineCandle` , call the `short_line_candle` helper method from the `QCAlgorithm` class. The `short_line_candle` method creates a `ShortLineCandle` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class ShortLineCandleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._short_line_candle = self.candlestick_patterns.short_line_candle(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._short_line_candle.is_ready:
            # The current value of self._short_line_candle is represented by self._short_line_candle.current.value
            self.plot("ShortLineCandle", "short_line_candle", self._short_line_candle.current.value)
```

PY

For more information about this method, see the CandlestickPatterns class .

You can manually create a `ShortLineCandle` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class ShortLineCandleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._short_line_candle = ShortLineCandle()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._short_line_candle.update(bar)

        if self._short_line_candle.is_ready:
            # The current value of self._short_line_candle is represented by self._short_line_candle.current.value
            self.plot("ShortLineCandle", "short_line_candle", self._short_line_candle.current.value)
```

PY

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `ShortLineCandle` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class ShortLineCandleAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._short_line_candle = self.candlestick_patterns.short_line_candle(self._symbol)

        indicator_history = self.indicator_history(self._short_line_candle, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._short_line_candle, self._symbol, timedelta(days=10),
Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._short_line_candle, self._symbol, datetime(2024, 7, 1),
datetime(2024, 7, 5), Resolution.MINUTE)
```

Spinning Top

Introduction

Create a new Spinning Top candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using SpinningTop Indicator

To create an automatic indicator for `SpinningTop` , call the `spinning_top` helper method from the `QCAlgorithm` class. The `spinning_top` method creates a `SpinningTop` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```py
class SpinningTopAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._spinning_top = self.candlestick_patterns.spinning_top(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._spinning_top.is_ready:
            # The current value of self._spinning_top is represented by self._spinning_top.current.value
            self.plot("SpinningTop", "spinning_top", self._spinning_top.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `SpinningTop` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```py
class SpinningTopAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._spinning_top = SpinningTop()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._spinning_top.update(bar)

        if self._spinning_top.is_ready:
            # The current value of self._spinning_top is represented by self._spinning_top.current.value
            self.plot("SpinningTop", "spinning_top", self._spinning_top.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `SpinningTop` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class SpinningTopAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._spinning_top = self.candlestick_patterns.spinning_top(self._symbol)

        indicator_history = self.indicator_history(self._spinning_top, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._spinning_top, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._spinning_top, self._symbol, datetime(2024, 7, 1), datetime(2024, 7,
5), Resolution.MINUTE)
```

Stalled Pattern

Introduction

Create a new Stalled Pattern candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using StalledPattern Indicator

To create an automatic indicator for `StalledPattern` , call the `stalled_pattern` helper method from the `QCAlgorithm` class. The `stalled_pattern` method creates a `StalledPattern` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class StalledPatternAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._stalled_pattern = self.candlestick_patterns.stalled_pattern(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._stalled_pattern.is_ready:
            # The current value of self._stalled_pattern is represented by self._stalled_pattern.current.value
            self.plot("StalledPattern", "stalled_pattern", self._stalled_pattern.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `StalledPattern` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class StalledPatternAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._stalled_pattern = StalledPattern()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._stalled_pattern.update(bar)

        if self._stalled_pattern.is_ready:
            # The current value of self._stalled_pattern is represented by self._stalled_pattern.current.value
            self.plot("StalledPattern", "stalled_pattern", self._stalled_pattern.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `StalledPattern` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class StalledPatternAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._stalled_pattern = self.candlestick_patterns.stalled_pattern(self._symbol)

        indicator_history = self.indicator_history(self._stalled_pattern, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._stalled_pattern, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._stalled_pattern, self._symbol, datetime(2024, 7, 1), datetime(2024,
7, 5), Resolution.MINUTE)
```

Stick Sandwich

Introduction

Create a new Stick Sandwich candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using StickSandwich Indicator

To create an automatic indicator for `StickSandwich` , call the `stick_sandwich` helper method from the `QCAlgorithm` class. The `stick_sandwich` method creates a `StickSandwich` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class StickSandwichAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._stick_sandwich = self.candlestick_patterns.stick_sandwich(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._stick_sandwich.is_ready:
            # The current value of self._stick_sandwich is represented by self._stick_sandwich.current.value
            self.plot("StickSandwich", "stick_sandwich", self._stick_sandwich.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `StickSandwich` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class StickSandwichAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._stick_sandwich = StickSandwich()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._stick_sandwich.update(bar)

        if self._stick_sandwich.is_ready:
            # The current value of self._stick_sandwich is represented by self._stick_sandwich.current.value
            self.plot("StickSandwich", "stick_sandwich", self._stick_sandwich.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `StickSandwich` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class StickSandwichAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._stick_sandwich = self.candlestick_patterns.stick_sandwich(self._symbol)

Three Black Crows

Introduction

Create a new Three Black Crows candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ThreeBlackCrows Indicator

To create an automatic indicator for `ThreeBlackCrows` , call the `three_black_crows` helper method from the `QCAlgorithm` class. The `three_black_crows` method creates a `ThreeBlackCrows` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class ThreeBlackCrowsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._three_black_crows = self.candlestick_patterns.three_black_crows(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._three_black_crows.is_ready:
            # The current value of self._three_black_crows is represented by self._three_black_crows.current.value
            self.plot("ThreeBlackCrows", "three_black_crows", self._three_black_crows.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `ThreeBlackCrows` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class ThreeBlackCrowsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._three_black_crows = ThreeBlackCrows()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._three_black_crows.update(bar)

        if self._three_black_crows.is_ready:
            # The current value of self._three_black_crows is represented by self._three_black_crows.current.value
            self.plot("ThreeBlackCrows", "three_black_crows", self._three_black_crows.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `ThreeBlackCrows` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class ThreeBlackCrowsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol

Three Inside

Introduction

Create a new Three Inside candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ThreeInside Indicator

To create an automatic indicator for `ThreeInside` , call the `three_inside` helper method from the `QCAlgorithm` class. The `three_inside` method creates a `ThreeInside` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class ThreeInsideAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._three_inside = self.candlestick_patterns.three_inside(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._three_inside.is_ready:
            # The current value of self._three_inside is represented by self._three_inside.current.value
            self.plot("ThreeInside", "three_inside", self._three_inside.current.value)
```

PY

For more information about this method, see the CandlestickPatterns class .

You can manually create a `ThreeInside` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class ThreeInsideAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._three_inside = ThreeInside()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._three_inside.update(bar)

        if self._three_inside.is_ready:
            # The current value of self._three_inside is represented by self._three_inside.current.value
            self.plot("ThreeInside", "three_inside", self._three_inside.current.value)
```

PY

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `ThreeInside` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class ThreeInsideAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._three_inside = self.candlestick_patterns.three_inside(self._symbol)

        indicator_history = self.indicator_history(self._three_inside, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._three_inside, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._three_inside, self._symbol, datetime(2024, 7, 1), datetime(2024, 7,
5), Resolution.MINUTE)
```

Three Line Strike

Introduction

Create a new Three Line Strike candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ThreeLineStrike Indicator

To create an automatic indicator for `ThreeLineStrike` , call the `three_line_strike` helper method from the `QCAlgorithm` class. The `three_line_strike` method creates a `ThreeLineStrike` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class ThreeLineStrikeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._three_line_strike = self.candlestick_patterns.three_line_strike(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._three_line_strike.is_ready:
            # The current value of self._three_line_strike is represented by self._three_line_strike.current.value
            self.plot("ThreeLineStrike", "three_line_strike", self._three_line_strike.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `ThreeLineStrike` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class ThreeLineStrikeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._three_line_strike = ThreeLineStrike()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._three_line_strike.update(bar)

        if self._three_line_strike.is_ready:
            # The current value of self._three_line_strike is represented by self._three_line_strike.current.value
            self.plot("ThreeLineStrike", "three_line_strike", self._three_line_strike.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `ThreeLineStrike` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class ThreeLineStrikeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._three_line_strike = self.candlestick_patterns.three_line_strike(self._symbol)

        indicator_history = self.indicator_history(self._three_line_strike, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._three_line_strike, self._symbol, timedelta(days=10),
Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._three_line_strike, self._symbol, datetime(2024, 7, 1),
datetime(2024, 7, 5), Resolution.MINUTE)
```

Supported Indicators

Three Outside

Introduction

Create a new Three Outside candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ThreeOutside Indicator

To create an automatic indicator for `ThreeOutside` , call the `three_outside` helper method from the `QCAlgorithm` class. The `three_outside` method creates a `ThreeOutside` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class ThreeOutsideAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._three_outside = self.candlestick_patterns.three_outside(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._three_outside.is_ready:
            # The current value of self._three_outside is represented by self._three_outside.current.value
            self.plot("ThreeOutside", "three_outside", self._three_outside.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `ThreeOutside` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class ThreeOutsideAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._three_outside = ThreeOutside()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._three_outside.update(bar)

        if self._three_outside.is_ready:
            # The current value of self._three_outside is represented by self._three_outside.current.value
            self.plot("ThreeOutside", "three_outside", self._three_outside.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `ThreeOutside` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class ThreeOutsideAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._three_outside = self.candlestick_patterns.three_outside(self._symbol)

        indicator_history = self.indicator_history(self._three_outside, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._three_outside, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._three_outside, self._symbol, datetime(2024, 7, 1), datetime(2024, 7,
5), Resolution.MINUTE)
```

Three Stars In South

Introduction

Create a new Three Stars In South candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ThreeStarsInSouth Indicator

To create an automatic indicator for `ThreeStarsInSouth` , call the `three_stars_in_south` helper method from the `QCAlgorithm` class. The `three_stars_in_south` method creates a `ThreeStarsInSouth` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class ThreeStarsInSouthAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._three_stars_in_south = self.candlestick_patterns.three_stars_in_south(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._three_stars_in_south.is_ready:
            # The current value of self._three_stars_in_south is represented by self._three_stars_in_south.current.value
            self.plot("ThreeStarsInSouth", "three_stars_in_south", self._three_stars_in_south.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `ThreeStarsInSouth` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class ThreeStarsInSouthAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._three_stars_in_south = ThreeStarsInSouth()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._three_stars_in_south.update(bar)

        if self._three_stars_in_south.is_ready:
            # The current value of self._three_stars_in_south is represented by self._three_stars_in_south.current.value
            self.plot("ThreeStarsInSouth", "three_stars_in_south", self._three_stars_in_south.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `ThreeStarsInSouth` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class ThreeStarsInSouthAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._three_stars_in_south = self.candlestick_patterns.three_stars_in_south(self._symbol)

        indicator_history = self.indicator_history(self._three_stars_in_south, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._three_stars_in_south, self._symbol, timedelta(days=10),
Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._three_stars_in_south, self._symbol, datetime(2024, 7, 1),
datetime(2024, 7, 5), Resolution.MINUTE)
```

Three White Soldiers

Introduction

Create a new Three White Soldiers candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ThreeWhiteSoldiers Indicator

To create an automatic indicator for `ThreeWhiteSoldiers` , call the `three_white_soldiers` helper method from the `QCAlgorithm` class. The `three_white_soldiers` method creates a `ThreeWhiteSoldiers` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class ThreeWhiteSoldiersAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._three_white_soldiers = self.candlestick_patterns.three_white_soldiers(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._three_white_soldiers.is_ready:
            # The current value of self._three_white_soldiers is represented by self._three_white_soldiers.current.value
            self.plot("ThreeWhiteSoldiers", "three_white_soldiers", self._three_white_soldiers.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `ThreeWhiteSoldiers` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class ThreeWhiteSoldiersAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._three_white_soldiers = ThreeWhiteSoldiers()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._three_white_soldiers.update(bar)

        if self._three_white_soldiers.is_ready:
            # The current value of self._three_white_soldiers is represented by self._three_white_soldiers.current.value
            self.plot("ThreeWhiteSoldiers", "three_white_soldiers", self._three_white_soldiers.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `ThreeWhiteSoldiers` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class ThreeWhiteSoldiersAlgorithm(QCAlgorithm):
    def initialize(self) -> None:

Thrusting

Introduction

Create a new Thrusting candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Thrusting Indicator

To create an automatic indicator for `Thrusting` , call the `thrusting` helper method from the `QCAlgorithm` class. The `thrusting` method creates a `Thrusting` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class ThrustingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._thrusting = self.candlestick_patterns.thrusting(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._thrusting.is_ready:
            # The current value of self._thrusting is represented by self._thrusting.current.value
            self.plot("Thrusting", "thrusting", self._thrusting.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Thrusting` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class ThrustingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._thrusting = Thrusting()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._thrusting.update(bar)

        if self._thrusting.is_ready:
            # The current value of self._thrusting is represented by self._thrusting.current.value
            self.plot("Thrusting", "thrusting", self._thrusting.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Thrusting` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```

Tristar

Introduction

Create a new Tristar candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Tristar Indicator

To create an automatic indicator for `Tristar` , call the `tristar` helper method from the `QCAlgorithm` class. The `tristar` method creates a `Tristar` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class TristarAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._tristar = self.candlestick_patterns.tristar(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._tristar.is_ready:
            # The current value of self._tristar is represented by self._tristar.current.value
            self.plot("Tristar", "tristar", self._tristar.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Tristar` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class TristarAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._tristar = Tristar()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._tristar.update(bar)

        if self._tristar.is_ready:
            # The current value of self._tristar is represented by self._tristar.current.value
            self.plot("Tristar", "tristar", self._tristar.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Tristar` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class TristarAlgorithm(QCAlgorithm):

Two Crows

Introduction

Create a new Two Crows candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using TwoCrows Indicator

To create an automatic indicator for `TwoCrows` , call the `two_crows` helper method from the `QCAlgorithm` class. The `two_crows` method creates a `TwoCrows` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class TwoCrowsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._two_crows = self.candlestick_patterns.two_crows(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._two_crows.is_ready:
            # The current value of self._two_crows is represented by self._two_crows.current.value
            self.plot("TwoCrows", "two_crows", self._two_crows.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `TwoCrows` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class TwoCrowsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._two_crows = TwoCrows()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._two_crows.update(bar)

        if self._two_crows.is_ready:
            # The current value of self._two_crows is represented by self._two_crows.current.value
            self.plot("TwoCrows", "two_crows", self._two_crows.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `TwoCrows` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class TwoCrowsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._two_crows = self.candlestick_patterns.two_crows(self._symbol)

        indicator_history = self.indicator_history(self._two_crows, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._two_crows, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._two_crows, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),

Unique Three River

Introduction

Create a new Unique Three River candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using UniqueThreeRiver Indicator

To create an automatic indicator for `UniqueThreeRiver` , call the `unique_three_river` helper method from the `QCAlgorithm` class. The `unique_three_river` method creates a `UniqueThreeRiver` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class UniqueThreeRiverAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._unique_three_river = self.candlestick_patterns.unique_three_river(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._unique_three_river.is_ready:
            # The current value of self._unique_three_river is represented by self._unique_three_river.current.value
            self.plot("UniqueThreeRiver", "unique_three_river", self._unique_three_river.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `UniqueThreeRiver` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class UniqueThreeRiverAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._unique_three_river = UniqueThreeRiver()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._unique_three_river.update(bar)

        if self._unique_three_river.is_ready:
            # The current value of self._unique_three_river is represented by self._unique_three_river.current.value
            self.plot("UniqueThreeRiver", "unique_three_river", self._unique_three_river.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `UniqueThreeRiver` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class UniqueThreeRiverAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._unique_three_river = self.candlestick_patterns.unique_three_river(self._symbol)

        indicator_history = self.indicator_history(self._unique_three_river, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._unique_three_river, self._symbol, timedelta(days=10),
Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._unique_three_river, self._symbol, datetime(2024, 7, 1),
datetime(2024, 7, 5), Resolution.MINUTE)
```

Up Down Gap Three Methods

Introduction

Create a new Up Down Gap Three Methods candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using UpDownGapThreeMethods Indicator

To create an automatic indicator for `UpDownGapThreeMethods` , call the `up_down_gap_three_methods` helper method from the `QCAlgorithm` class. The `up_down_gap_three_methods` method creates a `UpDownGapThreeMethods` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class UpDownGapThreeMethodsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._up_down_gap_three_methods = self.candlestick_patterns.up_down_gap_three_methods(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._up_down_gap_three_methods.is_ready:
            # The current value of self._up_down_gap_three_methods is represented by self._up_down_gap_three_methods.current.value
            self.plot("UpDownGapThreeMethods", "up_down_gap_three_methods", self._up_down_gap_three_methods.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `UpDownGapThreeMethods` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class UpDownGapThreeMethodsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._up_down_gap_three_methods = UpDownGapThreeMethods()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._up_down_gap_three_methods.update(bar)

        if self._up_down_gap_three_methods.is_ready:
            # The current value of self._up_down_gap_three_methods is represented by self._up_down_gap_three_methods.current.value
            self.plot("UpDownGapThreeMethods", "up_down_gap_three_methods", self._up_down_gap_three_methods.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `UpDownGapThreeMethods` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class UpDownGapThreeMethodsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._up_down_gap_three_methods = self.candlestick_patterns.up_down_gap_three_methods(self._symbol)

        indicator_history = self.indicator_history(self._up_down_gap_three_methods, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._up_down_gap_three_methods, self._symbol, timedelta(days=10),
Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._up_down_gap_three_methods, self._symbol, datetime(2024, 7, 1),
datetime(2024, 7, 5), Resolution.MINUTE)
```

Upside Gap Two Crows

Introduction

Create a new Upside Gap Two Crows candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using UpsideGapTwoCrows Indicator

To create an automatic indicator for `UpsideGapTwoCrows` , call the `upside_gap_two_crows` helper method from the `QCAlgorithm` class. The `upside_gap_two_crows` method creates a `UpsideGapTwoCrows` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class UpsideGapTwoCrowsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._upside_gap_two_crows = self.candlestick_patterns.upside_gap_two_crows(self._symbol)

    def on_data(self, slice: Slice) -> None:
        if self._upside_gap_two_crows.is_ready:
            # The current value of self._upside_gap_two_crows is represented by self._upside_gap_two_crows.current.value
            self.plot("UpsideGapTwoCrows", "upside_gap_two_crows", self._upside_gap_two_crows.current.value)
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `UpsideGapTwoCrows` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class UpsideGapTwoCrowsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._upside_gap_two_crows = UpsideGapTwoCrows()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._upside_gap_two_crows.update(bar)

        if self._upside_gap_two_crows.is_ready:
            # The current value of self._upside_gap_two_crows is represented by self._upside_gap_two_crows.current.value
            self.plot("UpsideGapTwoCrows", "upside_gap_two_crows", self._upside_gap_two_crows.current.value)
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `UpsideGapTwoCrows` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class UpsideGapTwoCrowsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._upside_gap_two_crows = self.candlestick_patterns.upside_gap_two_crows(self._symbol)

        indicator_history = self.indicator_history(self._upside_gap_two_crows, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._upside_gap_two_crows, self._symbol, timedelta(days=10),
Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._upside_gap_two_crows, self._symbol, datetime(2024, 7, 1),
datetime(2024, 7, 5), Resolution.MINUTE)
```

Absolute Price Oscillator

Introduction

This indicator computes the Absolute Price Oscillator (APO) The Absolute Price Oscillator is calculated using the following formula: APO[i] = FastMA[i] - SlowMA[i]

To view the implementation of this indicator, see the LEAN GitHub repository .

Using APO Indicator

To create an automatic indicator for `AbsolutePriceOscillator` , call the `apo` helper method from the `QCAlgorithm` class. The `apo` method creates a `AbsolutePriceOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class AbsolutePriceOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._apo = self.apo(self._symbol, 10, 20, MovingAverageType.SIMPLE)

    def on_data(self, slice: Slice) -> None:

        if self._apo.is_ready:
            # The current value of self._apo is represented by self._apo.current.value
            self.plot("AbsolutePriceOscillator", "apo", self._apo.current.value)
            # Plot all attributes of self._apo
            self.plot("AbsolutePriceOscillator", "fast", self._apo.fast.current.value)
            self.plot("AbsolutePriceOscillator", "slow", self._apo.slow.current.value)
            self.plot("AbsolutePriceOscillator", "signal", self._apo.signal.current.value)
            self.plot("AbsolutePriceOscillator", "histogram", self._apo.histogram.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AbsolutePriceOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class AbsolutePriceOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._absolutepriceoscillator = AbsolutePriceOscillator(10, 20, MovingAverageType.SIMPLE)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._absolutepriceoscillator.update(bar.end_time, bar.close)

        if self._absolutepriceoscillator.is_ready:
            # The current value of self._absolutepriceoscillator is represented by self._absolutepriceoscillator.current.value
            self.plot("AbsolutePriceOscillator", "absolutepriceoscillator", self._absolutepriceoscillator.current.value)
            # Plot all attributes of self._absolutepriceoscillator
            self.plot("AbsolutePriceOscillator", "fast", self._absolutepriceoscillator.fast.current.value)
            self.plot("AbsolutePriceOscillator", "slow", self._absolutepriceoscillator.slow.current.value)
            self.plot("AbsolutePriceOscillator", "signal", self._absolutepriceoscillator.signal.current.value)
            self.plot("AbsolutePriceOscillator", "histogram", self._absolutepriceoscillator.histogram.current.value)
```

For more information about this indicator, see its reference .

Accumulation Distribution Oscillator

Introduction

This indicator computes the Accumulation/Distribution Oscillator (ADOSC) The Accumulation/Distribution Oscillator is calculated using the following formula: ADOSC = EMA(fast,AD) - EMA(slow,AD)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ADOSC Indicator

To create an automatic indicator for `AccumulationDistributionOscillator` , call the `adosc` helper method from the `QCAlgorithm` class. The `adosc` method creates a `AccumulationDistributionOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class AccumulationDistributionOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._adosc = self.adosc(self._symbol, 10, 20)

    def on_data(self, slice: Slice) -> None:

        if self._adosc.is_ready:
            # The current value of self._adosc is represented by self._adosc.current.value
            self.plot("AccumulationDistributionOscillator", "adosc", self._adosc.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AccumulationDistributionOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class AccumulationDistributionOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._accumulationdistributionoscillator = AccumulationDistributionOscillator(10, 20)

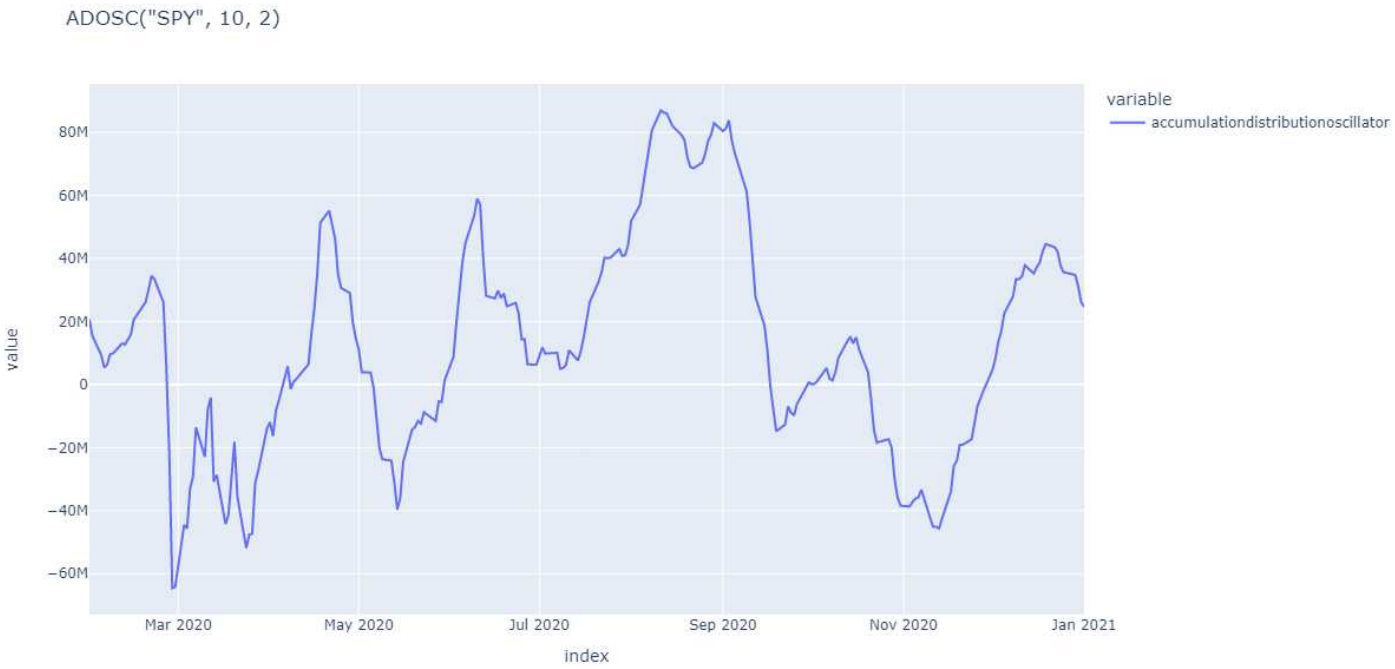
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._accumulationdistributionoscillator.update(bar)

        if self._accumulationdistributionoscillator.is_ready:
            # The current value of self._accumulationdistributionoscillator is represented by
self._accumulationdistributionoscillator.current.value
            self.plot("AccumulationDistributionOscillator", "accumulationdistributionoscillator",
self._accumulationdistributionoscillator.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `AccumulationDistributionOscillator` indicator properties:



Indicator History

To get the historical data of the `AccumulationDistributionOscillator` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class AccumulationDistributionOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._adosc = self.adosc(self._symbol, 10, 20)

        indicator_history = self.indicator_history(self._adosc, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._adosc, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._adosc, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Supported Indicators

Advance Decline Difference

Introduction

The Advance Decline Difference compute the difference between the number of stocks that closed higher and the number of stocks that closed lower than their previous day's closing prices.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ADDIFF Indicator

To create an automatic indicator for `AdvanceDeclineDifference` , call the `addiff` helper method from the `QCAlgorithm` class. The `addiff` method creates a `AdvanceDeclineDifference` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class AdvanceDeclineDifferenceAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._addiff = self.addiff([self._symbol, self._reference])

    def on_data(self, slice: Slice) -> None:

        if self._addiff.is_ready:
            # The current value of self._addiff is represented by self._addiff.current.value
            self.plot("AdvanceDeclineDifference", "addiff", self._addiff.current.value)
```

To create an automatic indicator for `AdvanceDeclineDifference` using universe constituents, call the `addiff` helper method from the `QCAlgorithm` class. The `addiff` method creates a `AdvanceDeclineDifference` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In this case, you should call the helper method in the `on_securities_changed` method.

```
PY
class AdvanceDeclineDifferenceAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024,1,1)
        self.set_end_date(2024,12,31)
        self.universe_settings.resolution = Resolution.DAILY
        self.universe_settings.schedule.on(self.date_rules.month_start())
        self._universe = self.add_universe(self.universe.etf('SPY'))

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        self._addiff = self.addiff(list(self._universe.selected))

    def on_data(self, slice: Slice) -> None:

        if self._addiff.is_ready:
            # The current value of self._addiff is represented by self._addiff.current.value
            self.plot("AdvanceDeclineDifference", "addiff", self._addiff.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AdvanceDeclineDifference` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class AdvanceDeclineDifferenceAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._advancedeclinedifference = AdvanceDeclineDifference()
        self._advancedeclinedifference.add(self._symbol);
        self._advancedeclinedifference.add(self._reference);

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._advancedeclinedifference.update(bar)
        bar = slice.bars.get(self._reference)
        if bar:
            self._advancedeclinedifference.update(bar)

        if self._advancedeclinedifference.is_ready:
            # The current value of self._advancedeclinedifference is represented by self._advancedeclinedifference.current.value
            self.plot("AdvanceDeclineDifference", "advancedeclinedifference", self._advancedeclinedifference.current.value)
```

For more information about this indicator, see its reference .

Supported Indicators

Advance Decline Ratio

Introduction

The advance-decline ratio (ADR) compares the number of stocks that closed higher against the number of stocks that closed lower than their previous day's closing prices.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ADR Indicator

To create an automatic indicator for `AdvanceDeclineRatio` , call the `adr` helper method from the `QCAlgorithm` class. The `adr` method creates a `AdvanceDeclineRatio` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class AdvanceDeclineRatioAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._adr = self.adr([self._symbol, self._reference])

    def on_data(self, slice: Slice) -> None:

        if self._adr.is_ready:
            # The current value of self._adr is represented by self._adr.current.value
            self.plot("AdvanceDeclineRatio", "adr", self._adr.current.value)
```

To create an automatic indicator for `AdvanceDeclineRatio` using universe constituents, call the `adr` helper method from the `QCAlgorithm` class. The `adr` method creates a `AdvanceDeclineRatio` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In this case, you should call the helper method in the `on_securities_changed` method.

```
PY
class AdvanceDeclineRatioAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024,1,1)
        self.set_end_date(2024,12,31)
        self.universe_settings.resolution = Resolution.DAILY
        self.universe_settings.schedule.on(self.date_rules.month_start())
        self._universe = self.add_universe(self.universe.etf('SPY'))

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        self._adr = self.adr(list(self._universe.selected))

    def on_data(self, slice: Slice) -> None:

        if self._adr.is_ready:
            # The current value of self._adr is represented by self._adr.current.value
            self.plot("AdvanceDeclineRatio", "adr", self._adr.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AdvanceDeclineRatio` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class AdvanceDeclineRatioAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._advancedeclineratio = AdvanceDeclineRatio()
        self._advancedeclineratio.add(self._symbol);
        self._advancedeclineratio.add(self._reference);

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._advancedeclineratio.update(bar)
        bar = slice.bars.get(self._reference)
        if bar:
            self._advancedeclineratio.update(bar)

        if self._advancedeclineratio.is_ready:
            # The current value of self._advancedeclineratio is represented by self._advancedeclineratio.current.value
            self.plot("AdvanceDeclineRatio", "advancedeclineratio", self._advancedeclineratio.current.value)
```

For more information about this indicator, see its reference .

Supported Indicators

Advance Decline Volume Ratio

Introduction

The Advance Decline Volume Ratio is a Breadth indicator calculated as ratio of summary volume of advancing stocks to summary volume of declining stocks. AD Volume Ratio is used in technical analysis to see where the main trading activity is focused.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ADVR Indicator

To create an automatic indicator for `AdvanceDeclineVolumeRatio` , call the `advr` helper method from the `QCAlgorithm` class. The `advr` method creates a `AdvanceDeclineVolumeRatio` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class AdvanceDeclineVolumeRatioAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._advr = self.advr([self._symbol, self._reference])

    def on_data(self, slice: Slice) -> None:

        if self._advr.is_ready:
            # The current value of self._advr is represented by self._advr.current.value
            self.plot("AdvanceDeclineVolumeRatio", "advr", self._advr.current.value)
```

To create an automatic indicator for `AdvanceDeclineVolumeRatio` using universe constituents, call the `advr` helper method from the `QCAlgorithm` class. The `advr` method creates a `AdvanceDeclineVolumeRatio` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In this case, you should call the helper method in the `on_securities_changed` method.

```
PY
class AdvanceDeclineVolumeRatioAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024,1,1)
        self.set_end_date(2024,12,31)
        self.universe_settings.resolution = Resolution.DAILY
        self.universe_settings.schedule.on(self.date_rules.month_start())
        self._universe = self.add_universe(self.universe.etf('SPY'))

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        self._advr = self.advr(list(self._universe.selected))

    def on_data(self, slice: Slice) -> None:

        if self._advr.is_ready:
            # The current value of self._advr is represented by self._advr.current.value
            self.plot("AdvanceDeclineVolumeRatio", "advr", self._advr.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AdvanceDeclineVolumeRatio` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class AdvanceDeclineVolumeRatioAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._advancedeclinevolumeratio = AdvanceDeclineVolumeRatio()
        self._advancedeclinevolumeratio.add(self._symbol);
        self._advancedeclinevolumeratio.add(self._reference);

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._advancedeclinevolumeratio.update(bar)
        bar = slice.bars.get(self._reference)
        if bar:
            self._advancedeclinevolumeratio.update(bar)

        if self._advancedeclinevolumeratio.is_ready:
            # The current value of self._advancedeclinevolumeratio is represented by self._advancedeclinevolumeratio.current.value
            self.plot("AdvanceDeclineVolumeRatio", "advancedeclinevolumeratio", self._advancedeclinevolumeratio.current.value)
```

Alpha

Introduction

In financial analysis, the Alpha indicator is used to measure the performance of an investment (such as a stock or ETF) relative to a benchmark index, often representing the broader market. Alpha indicates the excess return of the investment compared to the return of the benchmark index. The S P 500 index is frequently used as a benchmark in Alpha calculations to represent the overall market performance. Alpha is an essential tool for investors to understand the idiosyncratic returns of their investment that aren't caused by movement in the underlying benchmark.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using A Indicator

To create an automatic indicator for `Alpha` , call the `a` helper method from the `QCAlgorithm` class. The `a` method creates a `Alpha` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class AlphaAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._a = self.a(self._symbol, self._reference, 20)

    def on_data(self, slice: Slice) -> None:

        if self._a.is_ready:
            # The current value of self._a is represented by self._a.current.value
            self.plot("Alpha", "a", self._a.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Alpha` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class AlphaAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._alpha = Alpha(self._symbol, self._reference, 20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._alpha.update(bar)
        bar = slice.bars.get(self._reference)
        if bar:
            self._alpha.update(bar)

        if self._alpha.is_ready:
            # The current value of self._alpha is represented by self._alpha.current.value
            self.plot("Alpha", "alpha", self._alpha.current.value)
```

For more information about this indicator, see its reference .

Supported Indicators

Arms Index

Introduction

The Arms Index, also called the Short-Term Trading Index (TRIN) is a technical analysis indicator that compares the number of advancing and declining stocks (AD Ratio) to advancing and declining volume (AD volume).

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TRIN Indicator

To create an automatic indicator for `ArmsIndex` , call the `trin` helper method from the `QCAlgorithm` class. The `trin` method creates a `ArmsIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class ArmsIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._trin = self.trin([self._symbol, self._reference])

    def on_data(self, slice: Slice) -> None:

        if self._trin.is_ready:
            # The current value of self._trin is represented by self._trin.current.value
            self.plot("ArmsIndex", "trin", self._trin.current.value)
            # Plot all attributes of self._trin
            self.plot("ArmsIndex", "ad_ratio", self._trin.ad_ratio.current.value)
            self.plot("ArmsIndex", "adv_ratio", self._trin.adv_ratio.current.value)
```

To create an automatic indicator for `ArmsIndex` using universe constituents, call the `trin` helper method from the `QCAlgorithm` class. The `trin` method creates a `ArmsIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In this case, you should call the helper method in the `on_securities_changed` method.

```
PY
class ArmsIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024,1,1)
        self.set_end_date(2024,12,31)
        self.universe_settings.resolution = Resolution.DAILY
        self.universe_settings.schedule.on(self.date_rules.month_start())
        self._universe = self.add_universe(self.universe.etf('SPY'))

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        self._trin = self.trin(list(self._universe.selected))

    def on_data(self, slice: Slice) -> None:

        if self._trin.is_ready:
            # The current value of self._trin is represented by self._trin.current.value
            self.plot("ArmsIndex", "trin", self._trin.current.value)
            # Plot all attributes of self._trin
            self.plot("ArmsIndex", "ad_ratio", self._trin.ad_ratio.current.value)
            self.plot("ArmsIndex", "adv_ratio", self._trin.adv_ratio.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ArmsIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class ArmsIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._armsindex = ArmsIndex()
        self._armsindex.add(self._symbol);
        self._armsindex.add(self._reference);

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._armsindex.update(bar)
        bar = slice.bars.get(self._reference)
        if bar:
            self._armsindex.update(bar)

        if self._armsindex.is_ready:
            # The current value of self._armsindex is represented by self._armsindex.current.value
            self.plot("ArmsIndex", "armsindex", self._armsindex.current.value)
            # Plot all attributes of self._armsindex
            self.plot("ArmsIndex", "ad_ratio", self._armsindex.ad_ratio.current.value)
            self.plot("ArmsIndex", "adv_ratio", self._armsindex.adv_ratio.current.value)
```

For more information about this indicator, see its reference .

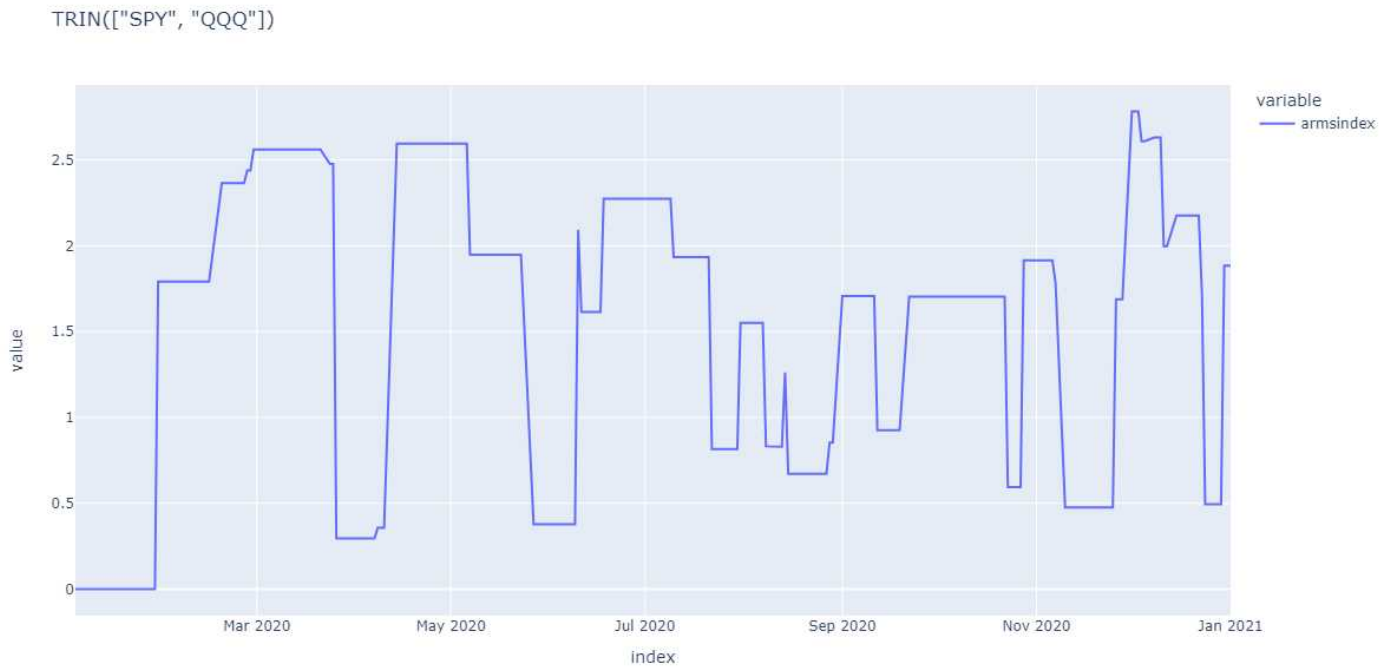
The following plot shows values for some of the `ArmsIndex` indicator properties:



Indicator History

To get the historical data of the `ArmsIndex` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class ArmsIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._trin = self.trin([self._symbol, self._reference])

        indicator_history = self.indicator_history(self._trin, [ self._symbol, self._reference ], 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._trin, [ self._symbol, self._reference ], timedelta(days=10),
Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._trin, [ self._symbol, self._reference ], datetime(2024, 7, 1),
datetime(2024, 7, 5), Resolution.MINUTE)

        # Access all attributes of indicator_history
        indicator_history_df = indicator_history.data_frame
        ad_ratio = indicator_history_df["adratio"]
        adv_ratio = indicator_history_df["advratio"]

Arnaud Legoux Moving Average

Introduction

Smooth and high sensitive moving Average. This moving average reduce lag of the information but still being smooth to reduce noises. Is a weighted moving average, which weights have a Normal shape; the parameters Sigma and Offset affect the kurtosis and skewness of the weights respectively. source

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ALMA Indicator

To create an automatic indicator for `ArnaudLegouxMovingAverage` , call the `alma` helper method from the `QCAlgorithm` class. The `alma` method creates a `ArnaudLegouxMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class ArnaudLegouxMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._alma = self.alma(self._symbol, 10, 6, 0.85)

    def on_data(self, slice: Slice) -> None:

        if self._alma.is_ready:
            # The current value of self._alma is represented by self._alma.current.value
            self.plot("ArnaudLegouxMovingAverage", "alma", self._alma.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ArnaudLegouxMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

Aroon Oscillator

Introduction

The Aroon Oscillator is the difference between AroonUp and AroonDown. The value of this indicator fluctuates between -100 and +100. An upward trend bias is present when the oscillator is positive, and a negative trend bias is present when the oscillator is negative. AroonUp/Down values over 75 identify strong trends in their respective direction.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using AROON Indicator

To create an automatic indicator for `AroonOscillator` , call the `aroon` helper method from the `QCAlgorithm` class. The `aroon` method creates a `AroonOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class AroonOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._aroon = self.aroon(self._symbol, 10, 20)

    def on_data(self, slice: Slice) -> None:

        if self._aroon.is_ready:
            # The current value of self._aroon is represented by self._aroon.current.value
            self.plot("AroonOscillator", "aroon", self._aroon.current.value)
            # Plot all attributes of self._aroon
            self.plot("AroonOscillator", "aroon_up", self._aroon.aroon_up.current.value)
            self.plot("AroonOscillator", "aroon_down", self._aroon.aroon_down.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AroonOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class AroonOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._aroonoscillator = AroonOscillator(10, 20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._aroonoscillator.update(bar)

        if self._aroonoscillator.is_ready:
            # The current value of self._aroonoscillator is represented by self._aroonoscillator.current.value
            self.plot("AroonOscillator", "aroonoscillator", self._aroonoscillator.current.value)
            # Plot all attributes of self._aroonoscillator
            self.plot("AroonOscillator", "aroon_up", self._aroonoscillator.aroon_up.current.value)
            self.plot("AroonOscillator", "aroon_down", self._aroonoscillator.aroon_down.current.value)
```

For more information about this indicator, see its reference .

Auto Regressive Integrated Moving Average

Introduction

An Autoregressive Intergrated Moving Average (ARIMA) is a time series model which can be used to describe a set of data. In particular,with X_t representing the series, the model assumes the data are of form (after differencing times): $X_t = c + \varepsilon_t + \Sigma_i \varphi_i X_{t-i} + \Sigma_i \theta_i \varepsilon_{t-i}$ where the first sum has an upper limit of and the second .

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ARIMA Indicator

To create an automatic indicator for `AutoRegressiveIntegratedMovingAverage` , call the `arima` helper method from the `QCAlgorithm` class. The `arima` method creates a `AutoRegressiveIntegratedMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class AutoRegressiveIntegratedMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._arima = self.arima(self._symbol, 1, 1, 1, 20)

    def on_data(self, slice: Slice) -> None:

        if self._arima.is_ready:
            # The current value of self._arima is represented by self._arima.current.value
            self.plot("AutoRegressiveIntegratedMovingAverage", "arima", self._arima.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AutoRegressiveIntegratedMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class AutoRegressiveIntegratedMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._autoregressiveintegratedmovingaverage = AutoRegressiveIntegratedMovingAverage(1, 1, 1, 20, True)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._autoregressiveintegratedmovingaverage.update(bar.end_time, bar.close)

        if self._autoregressiveintegratedmovingaverage.is_ready:
            # The current value of self._autoregressiveintegratedmovingaverage is represented by
self._autoregressiveintegratedmovingaverage.current.value
            self.plot("AutoRegressiveIntegratedMovingAverage", "autoregressiveintegratedmovingaverage",
self._autoregressiveintegratedmovingaverage.current.value)
```

Supported Indicators

Average Directional Index

Introduction

This indicator computes Average Directional Index which measures trend strength without regard to trend direction. Firstly, it calculates the Directional Movement and the True Range value, and then the values are accumulated and smoothed using a custom smoothing method proposed by Wilder. For an n period smoothing, 1/n of each period's value is added to the total period. From these accumulated values we are therefore able to derived the 'Positive Directional Index' (+DI) and 'Negative Directional Index' (-DI) which is used to calculate the Average Directional Index. Computation source: https://stockcharts.com/school/doku.php?id=chart_school:technical_indicators:average_directional_index_adx

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ADX Indicator

To create an automatic indicator for `AverageDirectionalIndex` , call the `adx` helper method from the `QCAlgorithm` class. The `adx` method creates a `AverageDirectionalIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class AverageDirectionalIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._adx = self.adx(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._adx.is_ready:
            # The current value of self._adx is represented by self._adx.current.value
            self.plot("AverageDirectionalIndex", "adx", self._adx.current.value)
            # Plot all attributes of self._adx
            self.plot("AverageDirectionalIndex", "positive_directional_index", self._adx.positive_directional_index.current.value)
            self.plot("AverageDirectionalIndex", "negative_directional_index", self._adx.negative_directional_index.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AverageDirectionalIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class AverageDirectionalIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._averagedirectionalindex = AverageDirectionalIndex(20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._averagedirectionalindex.update(bar)

        if self._averagedirectionalindex.is_ready:
            # The current value of self._averagedirectionalindex is represented by self._averagedirectionalindex.current.value
            self.plot("AverageDirectionalIndex", "averagedirectionalindex", self._averagedirectionalindex.current.value)
            # Plot all attributes of self._averagedirectionalindex
            self.plot("AverageDirectionalIndex", "positive_directional_index",
self._averagedirectionalindex.positive_directional_index.current.value)
            self.plot("AverageDirectionalIndex", "negative_directional_index",
self._averagedirectionalindex.negative_directional_index.current.value)
```

For more information about this indicator, see its reference .

The following plot shows values for some of the `AverageDirectionalIndex` indicator properties:

Indicator History

To get the historical data of the `AverageDirectionalIndex` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class AverageDirectionalIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._adx = self.adx(self._symbol, 20)

        indicator_history = self.indicator_history(self._adx, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._adx, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._adx, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)

        # Access all attributes of indicator_history
        indicator_history_df = indicator_history.data_frame
        positive_directional_index = indicator_history_df["positivedirectionalindex"]
        negative_directional_index = indicator_history_df["negativedirectionalindex"]
```

Supported Indicators

Average Directional Movement Index Rating

Introduction

This indicator computes the Average Directional Movement Index Rating (ADXR). The Average Directional Movement Index Rating is calculated with the following formula: ADXR[i] = (ADX[i] + ADX[i - period + 1]) / 2

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ADXR Indicator

To create an automatic indicator for `AverageDirectionalMovementIndexRating` , call the `adxr` helper method from the `QCAlgorithm` class. The `adxr` method creates a `AverageDirectionalMovementIndexRating` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class AverageDirectionalMovementIndexRatingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._adxr = self.adxr(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._adxr.is_ready:
            # The current value of self._adxr is represented by self._adxr.current.value
            self.plot("AverageDirectionalMovementIndexRating", "adxr", self._adxr.current.value)
            # Plot all attributes of self._adxr
            self.plot("AverageDirectionalMovementIndexRating", "adx", self._adxr.adx.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AverageDirectionalMovementIndexRating` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class AverageDirectionalMovementIndexRatingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._averagedirectionalmovementindexrating = AverageDirectionalMovementIndexRating(20)

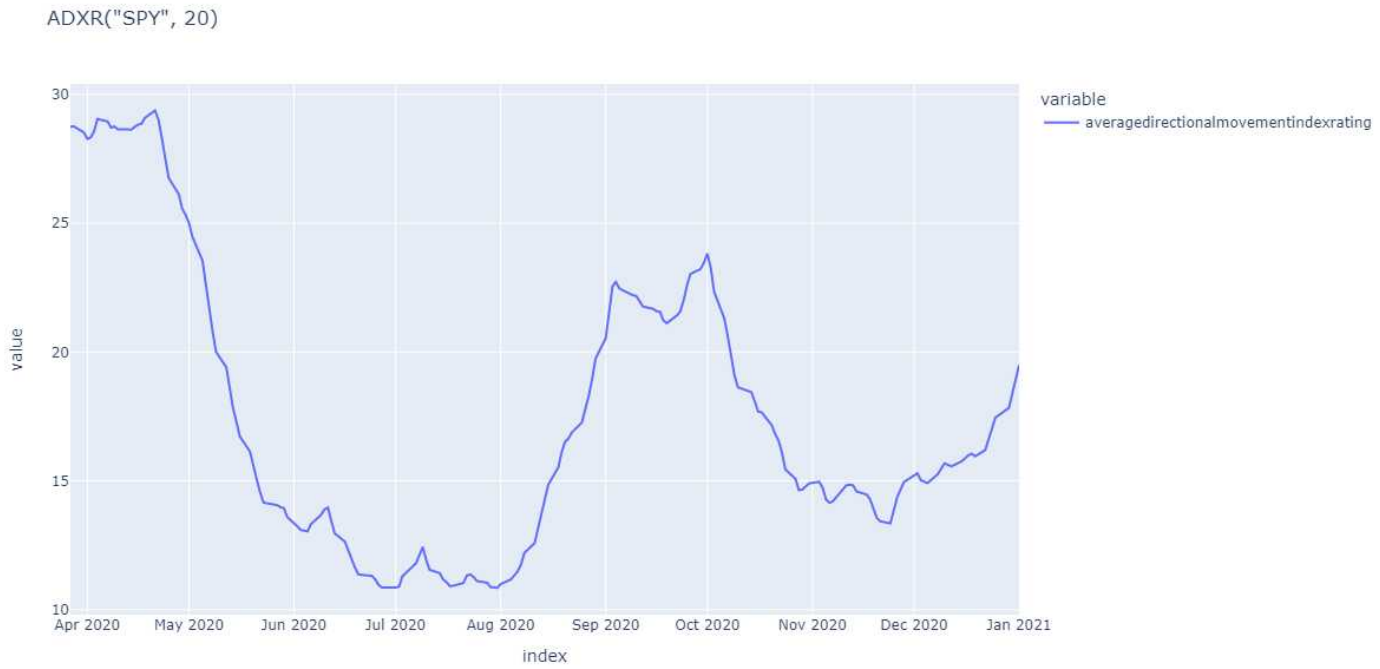
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._averagedirectionalmovementindexrating.update(bar)

        if self._averagedirectionalmovementindexrating.is_ready:
            # The current value of self._averagedirectionalmovementindexrating is represented by
self._averagedirectionalmovementindexrating.current.value
            self.plot("AverageDirectionalMovementIndexRating", "averagedirectionalmovementindexrating",
self._averagedirectionalmovementindexrating.current.value)
            # Plot all attributes of self._averagedirectionalmovementindexrating
            self.plot("AverageDirectionalMovementIndexRating", "adx", self._averagedirectionalmovementindexrating.adx.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `AverageDirectionalMovementIndexRating` indicator properties:



Indicator History

To get the historical data of the `AverageDirectionalMovementIndexRating` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
class AverageDirectionalMovementIndexRatingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._adxr = self.adxr(self._symbol, 20)

        indicator_history = self.indicator_history(self._adxr, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._adxr, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._adxr, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)

        # Access all attributes of indicator_history
        indicator_history_df = indicator_history.data_frame
        adx = indicator_history_df["adx"]
```

Supported Indicators

Average Range

Introduction

This indicator represents the Average Range (AR) indicator, which calculates the average price range

To view the implementation of this indicator, see the LEAN GitHub repository .

Using AR Indicator

To create an automatic indicator for `AverageRange` , call the `ar` helper method from the `QCAlgorithm` class. The `ar` method creates a `AverageRange` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class AverageRangeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._ar = self.ar(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._ar.is_ready:
            # The current value of self._ar is represented by self._ar.current.value
            self.plot("AverageRange", "ar", self._ar.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AverageRange` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class AverageRangeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._averagerange = AverageRange(20)

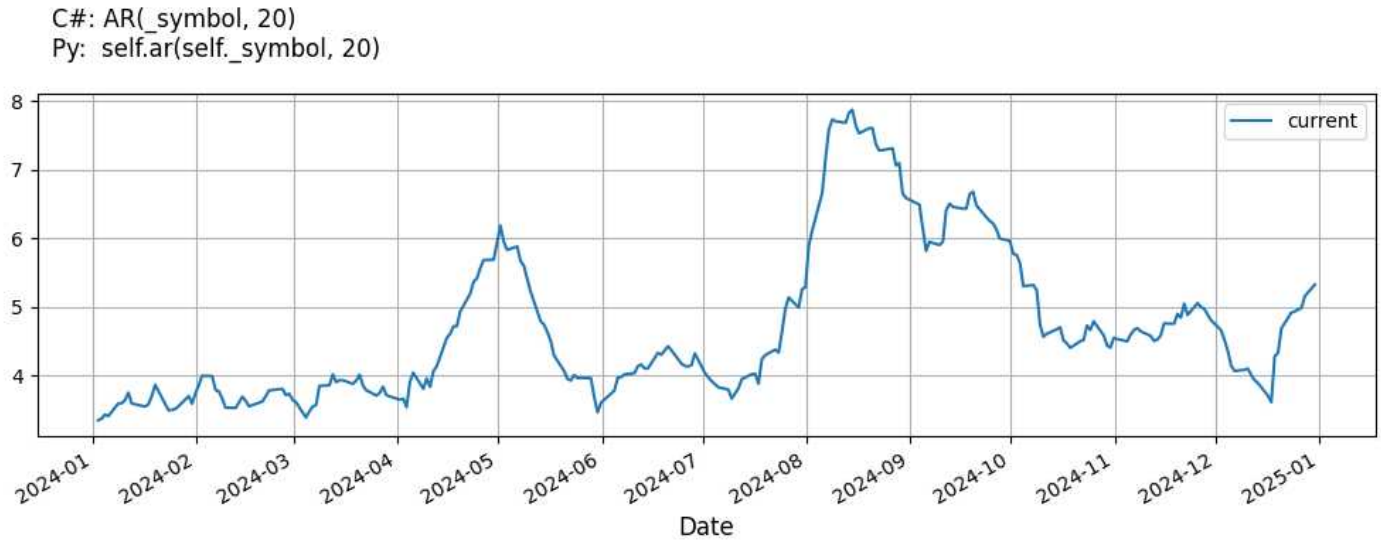
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._averagerange.update(bar)

        if self._averagerange.is_ready:
            # The current value of self._averagerange is represented by self._averagerange.current.value
            self.plot("AverageRange", "averagerange", self._averagerange.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `AverageRange` indicator properties:



Indicator History

To get the historical data of the `AverageRange` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
PY
class AverageRangeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._ar = self.ar(self._symbol, 20)

        indicator_history = self.indicator_history(self._ar, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._ar, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._ar, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Supported Indicators

Average True Range

Introduction

The AverageTrueRange indicator is a measure of volatility introduced by Welles Wilder in his book: New Concepts in Technical Trading Systems. This indicator computes the TrueRange and then smoothes the TrueRange over a given period. TrueRange is defined as the maximum of the following: High - Low ABS(High - PreviousClose) ABS(Low - PreviousClose)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ATR Indicator

To create an automatic indicator for `AverageTrueRange` , call the `atr` helper method from the `QCAlgorithm` class. The `atr` method creates a `AverageTrueRange` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class AverageTrueRangeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._atr = self.atr(self._symbol, 20, MovingAverageType.SIMPLE)

    def on_data(self, slice: Slice) -> None:

        if self._atr.is_ready:
            # The current value of self._atr is represented by self._atr.current.value
            self.plot("AverageTrueRange", "atr", self._atr.current.value)
            # Plot all attributes of self._atr
            self.plot("AverageTrueRange", "true_range", self._atr.true_range.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AverageTrueRange` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class AverageTrueRangeAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._averagetruerange = AverageTrueRange(20, MovingAverageType.SIMPLE)

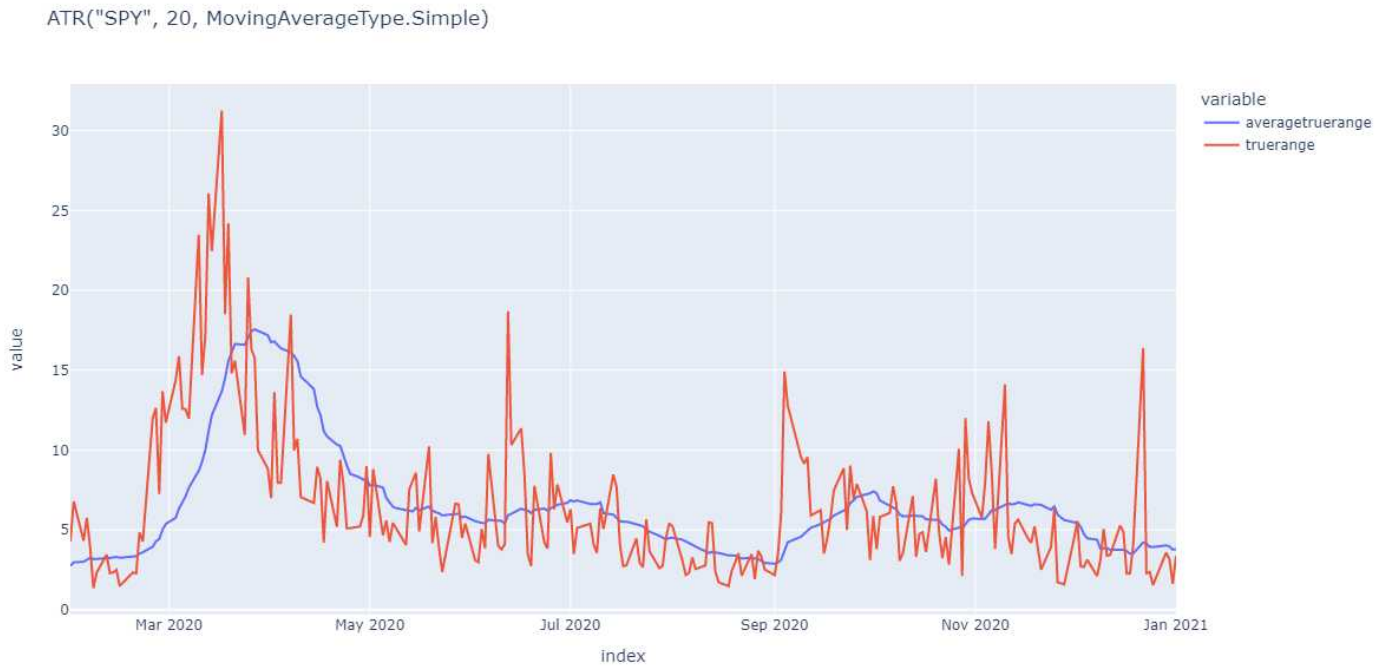
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._averagetruerange.update(bar)

        if self._averagetruerange.is_ready:
            # The current value of self._averagetruerange is represented by self._averagetruerange.current.value
            self.plot("AverageTrueRange", "averagetruerange", self._averagetruerange.current.value)
            # Plot all attributes of self._averagetruerange
            self.plot("AverageTrueRange", "true_range", self._averagetruerange.true_range.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `AverageTrueRange` indicator properties:



Indicator History

To get the historical data of the `AverageTrueRange` indicator, call the `self.indicator_history` method. Supported Indicators

Awesome Oscillator

Introduction

The Awesome Oscillator Indicator tracks the price midpoint-movement of a security. Specifically, AO = MAfast[(H+L)/2] - MAslow[(H+L)/2] where MAfast and MAslow denote simple moving averages wherein fast has a shorter period. https://www.barchart.com/education/technical-indicators/awesome_oscillator

To view the implementation of this indicator, see the LEAN GitHub repository .

Using AO Indicator

To create an automatic indicator for `AwesomeOscillator` , call the `ao` helper method from the `QCAlgorithm` class. The `ao` method creates a `AwesomeOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class AwesomeOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._ao = self.ao(self._symbol, 10, 20, MovingAverageType.SIMPLE)

    def on_data(self, slice: Slice) -> None:

        if self._ao.is_ready:
            # The current value of self._ao is represented by self._ao.current.value
            self.plot("AwesomeOscillator", "ao", self._ao.current.value)
            # Plot all attributes of self._ao
            self.plot("AwesomeOscillator", "slow_ao", self._ao.slow_ao.current.value)
            self.plot("AwesomeOscillator", "fast_ao", self._ao.fast_ao.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AwesomeOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

Supported Indicators

Balance Of Power

Introduction

This indicator computes the Balance Of Power (BOP). The Balance Of Power is calculated with the following formula: BOP = (Close - Open) / (High - Low)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using BOP Indicator

To create an automatic indicator for `BalanceOfPower` , call the `bop` helper method from the `QCAlgorithm` class. The `bop` method creates a `BalanceOfPower` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class BalanceOfPowerAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._bop = self.bop(self._symbol)

    def on_data(self, slice: Slice) -> None:

        if self._bop.is_ready:
            # The current value of self._bop is represented by self._bop.current.value
            self.plot("BalanceOfPower", "bop", self._bop.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `BalanceOfPower` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class BalanceOfPowerAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._balanceofpower = BalanceOfPower()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._balanceofpower.update(bar)

        if self._balanceofpower.is_ready:
            # The current value of self._balanceofpower is represented by self._balanceofpower.current.value
            self.plot("BalanceOfPower", "balanceofpower", self._balanceofpower.current.value)
```

For more information about this indicator, see its reference .

Supported Indicators

Beta

Introduction

In technical analysis Beta indicator is used to measure volatility or risk of a target (ETF) relative to the overall risk (volatility) of the reference (market indexes). The Beta indicators compares target's price movement to the movements of the indexes over the same period of time. It is common practice to use the SPX index as a benchmark of the overall reference market when it comes to Beta calculations. The indicator only updates when both assets have a price for a time step. When a bar is missing for one of the assets, the indicator value fills forward to improve the accuracy of the indicator.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using B Indicator

To create an automatic indicator for `Beta` , call the `b` helper method from the `QCAlgorithm` class. The `b` method creates a `Beta` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class BetaAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._b = self.b(self._symbol, self._reference, 20)

    def on_data(self, slice: Slice) -> None:

        if self._b.is_ready:
            # The current value of self._b is represented by self._b.current.value
            self.plot("Beta", "b", self._b.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Beta` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class BetaAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._beta = Beta(self._symbol, self._reference, 20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._beta.update(bar)
        bar = slice.bars.get(self._reference)
        if bar:
            self._beta.update(bar)

        if self._beta.is_ready:
            # The current value of self._beta is represented by self._beta.current.value
            self.plot("Beta", "beta", self._beta.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `Beta` indicator properties:

Indicator History

To get the historical data of the `Beta` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```

Supported Indicators

Bollinger Bands

Introduction

This indicator creates a moving average (middle band) with an upper band and lower band fixed at k standard deviations above and below the moving average.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using BB Indicator

To create an automatic indicator for `BollingerBands` , call the `bb` helper method from the `QCAlgorithm` class. The `bb` method creates a `BollingerBands` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class BollingerBandsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._bb = self.bb(self._symbol, 30, 2)

    def on_data(self, slice: Slice) -> None:

        if self._bb.is_ready:
            # The current value of self._bb is represented by self._bb.current.value
            self.plot("BollingerBands", "bb", self._bb.current.value)
            # Plot all attributes of self._bb
            self.plot("BollingerBands", "standard_deviation", self._bb.standard_deviation.current.value)
            self.plot("BollingerBands", "middle_band", self._bb.middle_band.current.value)
            self.plot("BollingerBands", "upper_band", self._bb.upper_band.current.value)
            self.plot("BollingerBands", "lower_band", self._bb.lower_band.current.value)
            self.plot("BollingerBands", "band_width", self._bb.band_width.current.value)
            self.plot("BollingerBands", "percent_b", self._bb.percent_b.current.value)
            self.plot("BollingerBands", "price", self._bb.price.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `BollingerBands` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class BollingerBandsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._bollingerbands = BollingerBands(30, 2)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._bollingerbands.update(bar.end_time, bar.close)

        if self._bollingerbands.is_ready:
            # The current value of self._bollingerbands is represented by self._bollingerbands.current.value
            self.plot("BollingerBands", "bollingerbands", self._bollingerbands.current.value)
            # Plot all attributes of self._bollingerbands
            self.plot("BollingerBands", "standard_deviation", self._bollingerbands.standard_deviation.current.value)
            self.plot("BollingerBands", "middle_band", self._bollingerbands.middle_band.current.value)
            self.plot("BollingerBands", "upper_band", self._bollingerbands.upper_band.current.value)
            self.plot("BollingerBands", "lower_band", self._bollingerbands.lower_band.current.value)
            self.plot("BollingerBands", "band_width", self._bollingerbands.band_width.current.value)
            self.plot("BollingerBands", "percent_b", self._bollingerbands.percent_b.current.value)
            self.plot("BollingerBands", "price", self._bollingerbands.price.current.value)
```

The following plot shows values for some of the `BollingerBands` indicator properties:

Indicator History

To get the historical data of the `BollingerBands` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
PY
class BollingerBandsAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._bb = self.bb(self._symbol, 30, 2)

        indicator_history = self.indicator_history(self._bb, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._bb, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._bb, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)

        # Access all attributes of indicator_history
        indicator_history_df = indicator_history.data_frame
        standard_deviation = indicator_history_df["standarddeviation"]

Supported Indicators

Chaikin Money Flow

Introduction

The Chaikin Money Flow Index (CMF) is a volume-weighted average of accumulation and distribution over a specified period. CMF = n-day Sum of [((C - L) - (H - C)) / (H - L)) x Vol] / n-day Sum of Vol Where: n = number of periods, typically 21 H = high L = low C = close Vol = volume https://www.fidelity.com/learning-center/trading-investing/technical-analysis/technical-indicator-guide/cmf

To view the implementation of this indicator, see the LEAN GitHub repository .

Using CMF Indicator

To create an automatic indicator for `ChaikinMoneyFlow` , call the `cmf` helper method from the `QCAlgorithm` class. The `cmf` method creates a `ChaikinMoneyFlow` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class ChaikinMoneyFlowAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._cmf = self.cmf(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._cmf.is_ready:
            # The current value of self._cmf is represented by self._cmf.current.value
            self.plot("ChaikinMoneyFlow", "cmf", self._cmf.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ChaikinMoneyFlow` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class ChaikinMoneyFlowAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._chaikinmoneyflow = ChaikinMoneyFlow(20)

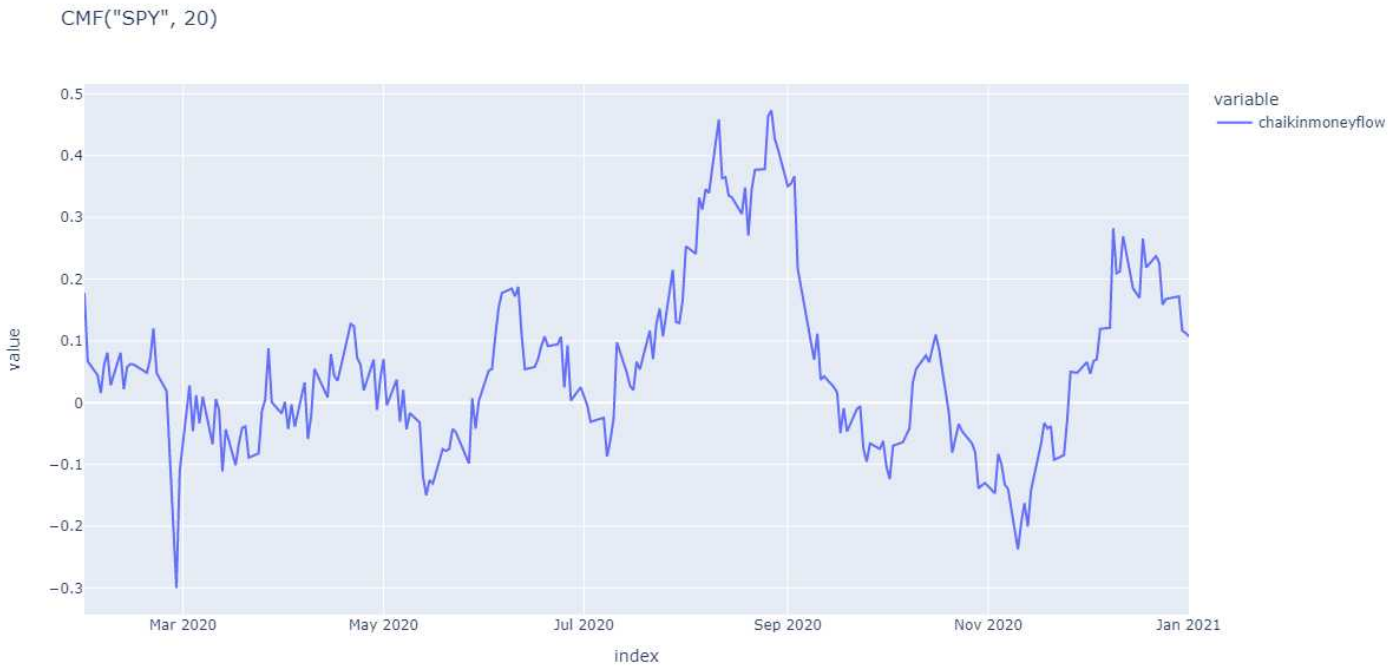
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._chaikinmoneyflow.update(bar)

        if self._chaikinmoneyflow.is_ready:
            # The current value of self._chaikinmoneyflow is represented by self._chaikinmoneyflow.current.value
            self.plot("ChaikinMoneyFlow", "chaikinmoneyflow", self._chaikinmoneyflow.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `ChaikinMoneyFlow` indicator properties:



Indicator History

To get the historical data of the `ChaikinMoneyFlow` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. Chaikin Oscillator

Introduction

This class is an alias for AccumulationDistributionOscillator (also known as Chaikin Oscillator).

To view the implementation of this indicator, see the LEAN GitHub repository .

Using CO Indicator

To create an automatic indicator for `ChaikinOscillator` , call the `co` helper method from the `QCAlgorithm` class. The `co` method creates a `ChaikinOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class ChaikinOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._co = self.co(self._symbol, 3, 10)

    def on_data(self, slice: Slice) -> None:

        if self._co.is_ready:
            # The current value of self._co is represented by self._co.current.value
            self.plot("ChaikinOscillator", "co", self._co.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ChaikinOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class ChaikinOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._chaikinoscillator = ChaikinOscillator(3,10)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._chaikinoscillator.update(bar)

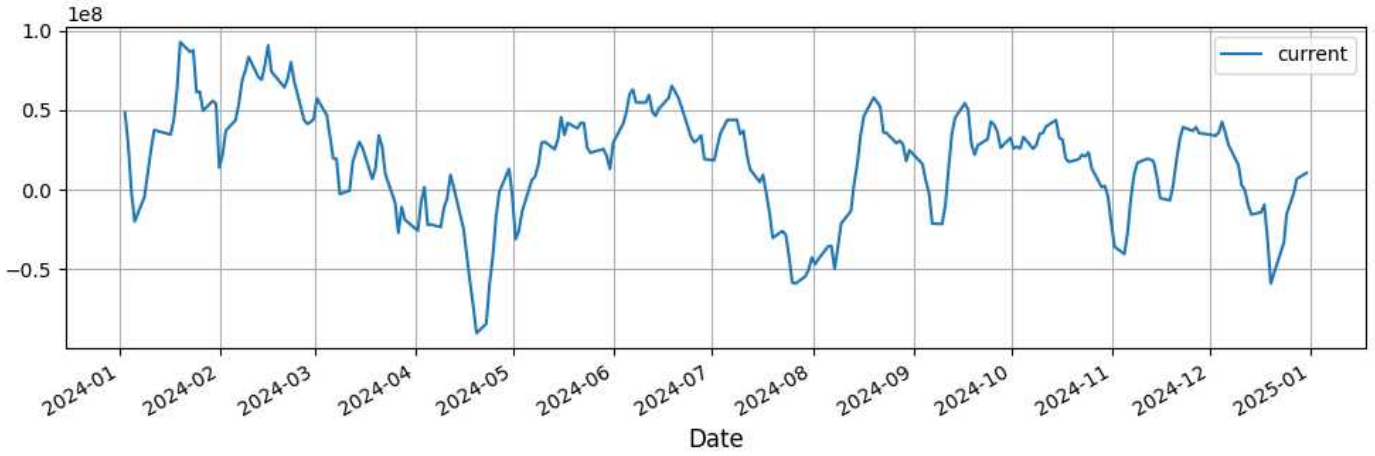
        if self._chaikinoscillator.is_ready:
            # The current value of self._chaikinoscillator is represented by self._chaikinoscillator.current.value
            self.plot("ChaikinOscillator", "chaikinoscillator", self._chaikinoscillator.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `ChaikinOscillator` indicator properties:

C#: CO(_symbol, 3, 10)
Py: self.co(self._symbol, 3, 10)



Indicator History

To get the historical data of the `ChaikinOscillator` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class ChaikinOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:

Chande Kroll Stop

Introduction

This indicator computes the short stop and lower stop values of the Chande Kroll Stop Indicator. It is used to determine the optimal placement of a stop-loss order.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using CKS Indicator

To create an automatic indicator for `ChandeKrollStop` , call the `cks` helper method from the `QCAlgorithm` class. The `cks` method creates a `ChandeKrollStop` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class ChandeKrollStopAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._cks = self.cks(self._symbol, 10, 1, 9)

    def on_data(self, slice: Slice) -> None:

        if self._cks.is_ready:
            # The current value of self._cks is represented by self._cks.current.value
            self.plot("ChandeKrollStop", "cks", self._cks.current.value)
            # Plot all attributes of self._cks
            self.plot("ChandeKrollStop", "short_stop", self._cks.short_stop.current.value)
            self.plot("ChandeKrollStop", "long_stop", self._cks.long_stop.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ChandeKrollStop` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class ChandeKrollStopAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._chandekrollstop = ChandeKrollStop(10, 1, 9)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._chandekrollstop.update(bar)

        if self._chandekrollstop.is_ready:
            # The current value of self._chandekrollstop is represented by self._chandekrollstop.current.value
            self.plot("ChandeKrollStop", "chandekrollstop", self._chandekrollstop.current.value)
            # Plot all attributes of self._chandekrollstop
            self.plot("ChandeKrollStop", "short_stop", self._chandekrollstop.short_stop.current.value)
            self.plot("ChandeKrollStop", "long_stop", self._chandekrollstop.long_stop.current.value)
```

For more information about this indicator, see its reference .

Visualization

Resolution.MINUTE)

        # Access all attributes of indicator_history
        indicator_history_df = indicator_history.data_frame
        short_stop = indicator_history_df["shortstop"]
        long_stop = indicator_history_df["longstop"]
```

Supported Indicators

Chande Momentum Oscillator

Introduction

This indicator computes the Chande Momentum Oscillator (CMO). CMO calculation is mostly identical to RSI. The only difference is in the last step of calculation: RSI = gain / (gain+loss) CMO = (gain-loss) / (gain+loss)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using CMO Indicator

To create an automatic indicator for `ChandeMomentumOscillator` , call the `cmo` helper method from the `QCAlgorithm` class. The `cmo` method creates a `ChandeMomentumOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class ChandeMomentumOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._cmo = self.cmo(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._cmo.is_ready:
            # The current value of self._cmo is represented by self._cmo.current.value
            self.plot("ChandeMomentumOscillator", "cmo", self._cmo.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ChandeMomentumOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class ChandeMomentumOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._chandemomentumoscillator = ChandeMomentumOscillator(20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._chandemomentumoscillator.update(bar.end_time, bar.close)

        if self._chandemomentumoscillator.is_ready:
            # The current value of self._chandemomentumoscillator is represented by self._chandemomentumoscillator.current.value
            self.plot("ChandeMomentumOscillator", "chandemomentumoscillator", self._chandemomentumoscillator.current.value)
```

For more information about this indicator, see its reference .

Choppiness Index

Introduction

The ChoppinessIndex indicator is an indicator designed to determine if the market is choppy (trading sideways) or not choppy (trading within a trend in either direction)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using CHOP Indicator

To create an automatic indicator for `ChoppinessIndex` , call the `chop` helper method from the `QCAlgorithm` class. The `chop` method creates a `ChoppinessIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class ChoppinessIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._chop = self.chop(self._symbol, 14)

    def on_data(self, slice: Slice) -> None:

        if self._chop.is_ready:
            # The current value of self._chop is represented by self._chop.current.value
            self.plot("ChoppinessIndex", "chop", self._chop.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ChoppinessIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class ChoppinessIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._choppinessindex = ChoppinessIndex(14)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._choppinessindex.update(bar)

        if self._choppinessindex.is_ready:
            # The current value of self._choppinessindex is represented by self._choppinessindex.current.value
            self.plot("ChoppinessIndex", "choppinessindex", self._choppinessindex.current.value)
```

For more information about this indicator, see its reference .

Commodity Channel Index

Introduction

This indicator represents the traditional commodity channel index (CCI) CCI = (Typical Price - 20-period SMA of TP) / (.015 * Mean Deviation) Typical Price (TP) = (High + Low + Close)/3 Constant = 0.015 There are four steps to calculating the Mean Deviation, first, subtract the most recent 20-period average of the typical price from each period's typical price. Second, take the absolute values of these numbers. Third, sum the absolute values. Fourth, divide by the total number of periods (20).

To view the implementation of this indicator, see the LEAN GitHub repository .

Using CCI Indicator

To create an automatic indicator for `CommodityChannelIndex` , call the `cci` helper method from the `QCAlgorithm` class. The `cci` method creates a `CommodityChannelIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class CommodityChannelIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._cci = self.cci(self._symbol, 20, MovingAverageType.SIMPLE)

    def on_data(self, slice: Slice) -> None:

        if self._cci.is_ready:
            # The current value of self._cci is represented by self._cci.current.value
            self.plot("CommodityChannelIndex", "cci", self._cci.current.value)
            # Plot all attributes of self._cci
            self.plot("CommodityChannelIndex", "typical_price_average", self._cci.typical_price_average.current.value)
            self.plot("CommodityChannelIndex", "typical_price_mean_deviation", self._cci.typical_price_mean_deviation.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `CommodityChannelIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class CommodityChannelIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._commoditychannelindex = CommodityChannelIndex(20, MovingAverageType.SIMPLE)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._commoditychannelindex.update(bar)

        if self._commoditychannelindex.is_ready:
            # The current value of self._commoditychannelindex is represented by self._commoditychannelindex.current.value
            self.plot("CommodityChannelIndex", "commoditychannelindex", self._commoditychannelindex.current.value)
            # Plot all attributes of self._commoditychannelindex
            self.plot("CommodityChannelIndex", "typical_price_average", self._commoditychannelindex.typical_price_average.current.value)
            self.plot("CommodityChannelIndex", "typical_price_mean_deviation",
self._commoditychannelindex.typical_price_mean_deviation.current.value)
```

For more information about this indicator, see its reference .

Supported Indicators

Connors Relative Strength Index

Introduction

This indicator represents the Connors Relative Strength Index (CRSI), a combination of the traditional Relative Strength Index (RSI), a Streak RSI (SRSI), and Percent Rank. This index is designed to provide a more robust measure of market strength by combining momentum, streak behavior, and price change.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using CRSI Indicator

To create an automatic indicator for `ConnorsRelativeStrengthIndex` , call the `crsi` helper method from the `QCAlgorithm` class. The `crsi` method creates a `ConnorsRelativeStrengthIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class ConnorsRelativeStrengthIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._crsi = self.crsi(self._symbol, 3, 2, 100)

    def on_data(self, slice: Slice) -> None:

        if self._crsi.is_ready:
            # The current value of self._crsi is represented by self._crsi.current.value
            self.plot("ConnorsRelativeStrengthIndex", "crsi", self._crsi.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ConnorsRelativeStrengthIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class ConnorsRelativeStrengthIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._connorsrelativestrengthindex = ConnorsRelativeStrengthIndex(3, 2, 100)

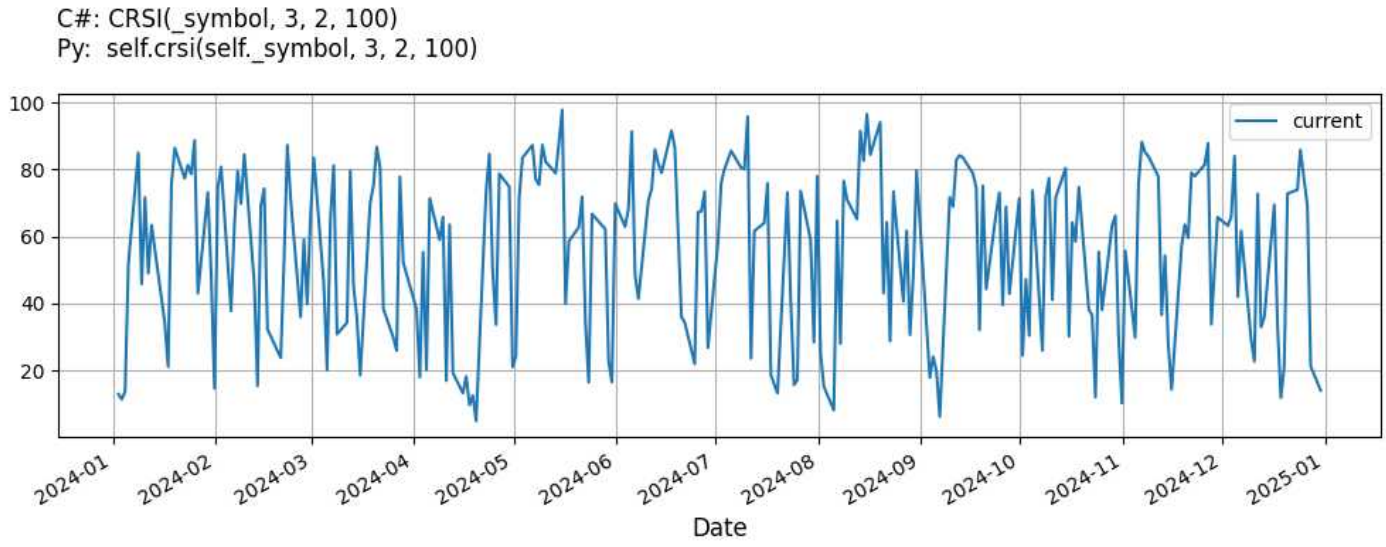
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._connorsrelativestrengthindex.update(bar.end_time, bar.close)

        if self._connorsrelativestrengthindex.is_ready:
            # The current value of self._connorsrelativestrengthindex is represented by self._connorsrelativestrengthindex.current.value
            self.plot("ConnorsRelativeStrengthIndex", "connorsrelativestrengthindex", self._connorsrelativestrengthindex.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `ConnorsRelativeStrengthIndex` indicator properties:



Indicator History

To get the historical data of the `ConnorsRelativeStrengthIndex` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
class ConnorsRelativeStrengthIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._crsi = self.crsi(self._symbol, 3, 2, 100)

        indicator_history = self.indicator_history(self._crsi, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._crsi, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._crsi, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Supported Indicators

Coppock Curve

Introduction

A momentum indicator developed by Edwin “Sedge” Coppock in October 1965. The goal of this indicator is to identify long-term buying opportunities in the S&P500 and Dow Industrials. source

To view the implementation of this indicator, see the LEAN GitHub repository .

Using CC Indicator

To create an automatic indicator for `CoppockCurve` , call the `cc` helper method from the `QCAlgorithm` class. The `cc` method creates a `CoppockCurve` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class CoppockCurveAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._cc = self.cc(self._symbol, 11, 14, 10)

    def on_data(self, slice: Slice) -> None:

        if self._cc.is_ready:
            # The current value of self._cc is represented by self._cc.current.value
            self.plot("CoppockCurve", "cc", self._cc.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `CoppockCurve` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class CoppockCurveAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._coppockcurve = CoppockCurve(11, 14, 10)

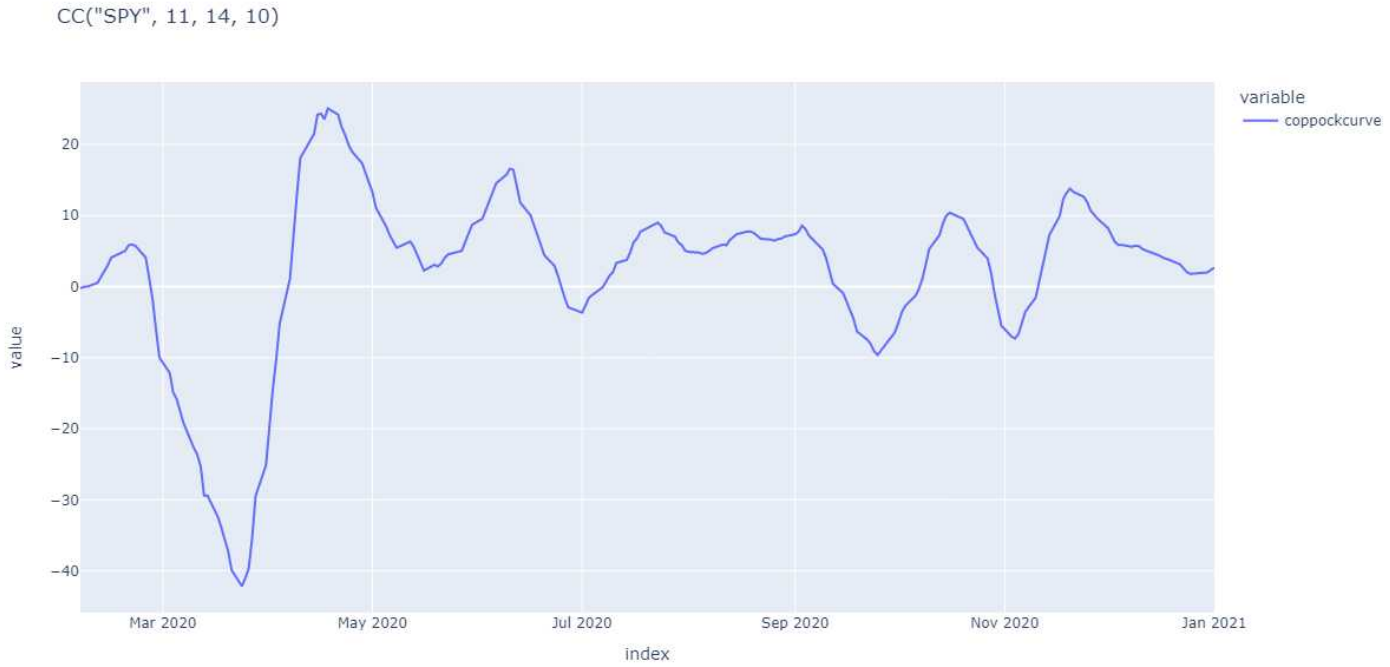
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._coppockcurve.update(bar.end_time, bar.close)

        if self._coppockcurve.is_ready:
            # The current value of self._coppockcurve is represented by self._coppockcurve.current.value
            self.plot("CoppockCurve", "coppockcurve", self._coppockcurve.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `CoppockCurve` indicator properties:



Indicator History

To get the historical data of the `CoppockCurve` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
class CoppockCurveAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._cc = self.cc(self._symbol, 11, 14, 10)

        indicator_history = self.indicator_history(self._cc, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._cc, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._cc, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Supported Indicators

Correlation

Introduction

The Correlation Indicator is a valuable tool in technical analysis, designed to quantify the degree of relationship between the price movements of a target security (e.g., a stock or ETF) and a reference market index. It measures how closely the target's price changes are aligned with the fluctuations of the index over a specific period of time, providing insights into the target's susceptibility to market movements. A positive correlation indicates that the target tends to move in the same direction as the market index, while a negative correlation suggests an inverse relationship. A correlation close to 0 implies a weak or no linear relationship. Commonly, the SPX index is employed as the benchmark for the overall market when calculating correlation, ensuring a consistent and reliable reference point. This helps traders and investors make informed decisions regarding the risk and behavior of the target security in relation to market trends. The indicator only updates when both assets have a price for a time step. When a bar is missing for one of the assets, the indicator value fills forward to improve the accuracy of the indicator.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using C Indicator

To create an automatic indicator for `Correlation` , call the `c` helper method from the `QCAlgorithm` class. The `c` method creates a `Correlation` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class CorrelationAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._c = self.c(self._symbol, self._reference, 20, CorrelationType.PEARSON)

    def on_data(self, slice: Slice) -> None:

        if self._c.is_ready:
            # The current value of self._c is represented by self._c.current.value
            self.plot("Correlation", "c", self._c.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Correlation` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class CorrelationAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._correlation = Correlation(self._symbol, self._reference, 20, CorrelationType.PEARSON)

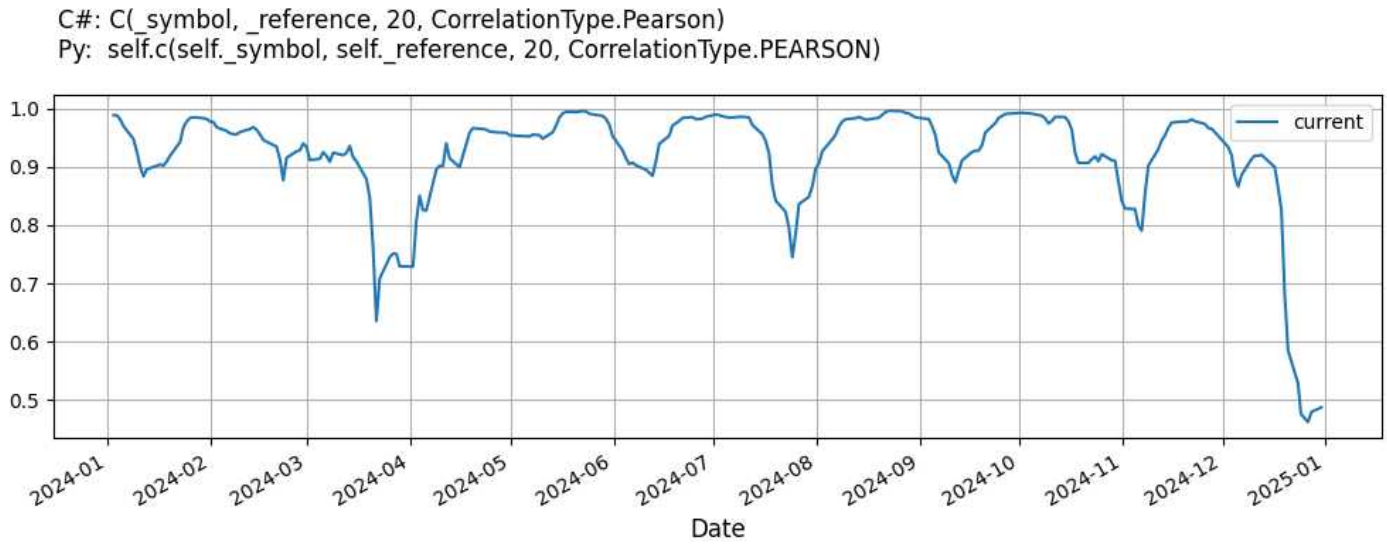
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._correlation.update(bar)
        bar = slice.bars.get(self._reference)
        if bar:
            self._correlation.update(bar)

        if self._correlation.is_ready:
            # The current value of self._correlation is represented by self._correlation.current.value
            self.plot("Correlation", "correlation", self._correlation.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `Correlation` indicator properties:



Indicator History

To get the historical data of the `Correlation` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
PY

Supported Indicators

Covariance

Introduction

This indicator computes the Covariance of two assets using the given Look-Back period. The Covariance of two assets is a measure of their co-movement.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using COV Indicator

To create an automatic indicator for `Covariance` , call the `cov` helper method from the `QCAlgorithm` class. The `cov` method creates a `Covariance` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class CovarianceAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._cov = self.cov([self._symbol, self._reference])

    def on_data(self, slice: Slice) -> None:

        if self._cov.is_ready:
            # The current value of self._cov is represented by self._cov.current.value
            self.plot("Covariance", "cov", self._cov.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Covariance` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class CovarianceAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._covariance = Covariance(self._symbol, self._reference, 5)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._covariance.update(bar)
        bar = slice.bars.get(self._reference)
        if bar:
            self._covariance.update(bar)

        if self._covariance.is_ready:
            # The current value of self._covariance is represented by self._covariance.current.value
            self.plot("Covariance", "covariance", self._covariance.current.value)
```

For more information about this indicator, see its reference .

Supported Indicators

DeMarker Indicator

Introduction

In the DeMarker strategy, for some period of size N, set: DeMax = High - Previous High, and DeMin = Previous Low - Low where, in the prior, if either term is less than zero (DeMax or DeMin), set it to zero. We can now define the indicator itself, DEM, as: DEM = MA(DeMax)/(MA(DeMax)+MA(DeMin)) where MA denotes a Moving Average of period N.
https://www.investopedia.com/terms/d/demarkerindicator.asp

To view the implementation of this indicator, see the LEAN GitHub repository .

Using DEM Indicator

To create an automatic indicator for `DeMarkerIndicator` , call the `dem` helper method from the `QCAlgorithm` class. The `dem` method creates a `DeMarkerIndicator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class DeMarkerIndicatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._dem = self.dem(self._symbol, 20, MovingAverageType.SIMPLE)

    def on_data(self, slice: Slice) -> None:

        if self._dem.is_ready:
            # The current value of self._dem is represented by self._dem.current.value
            self.plot("DeMarkerIndicator", "dem", self._dem.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `DeMarkerIndicator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class DeMarkerIndicatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._demarkerindicator = DeMarkerIndicator(20, MovingAverageType.SIMPLE)

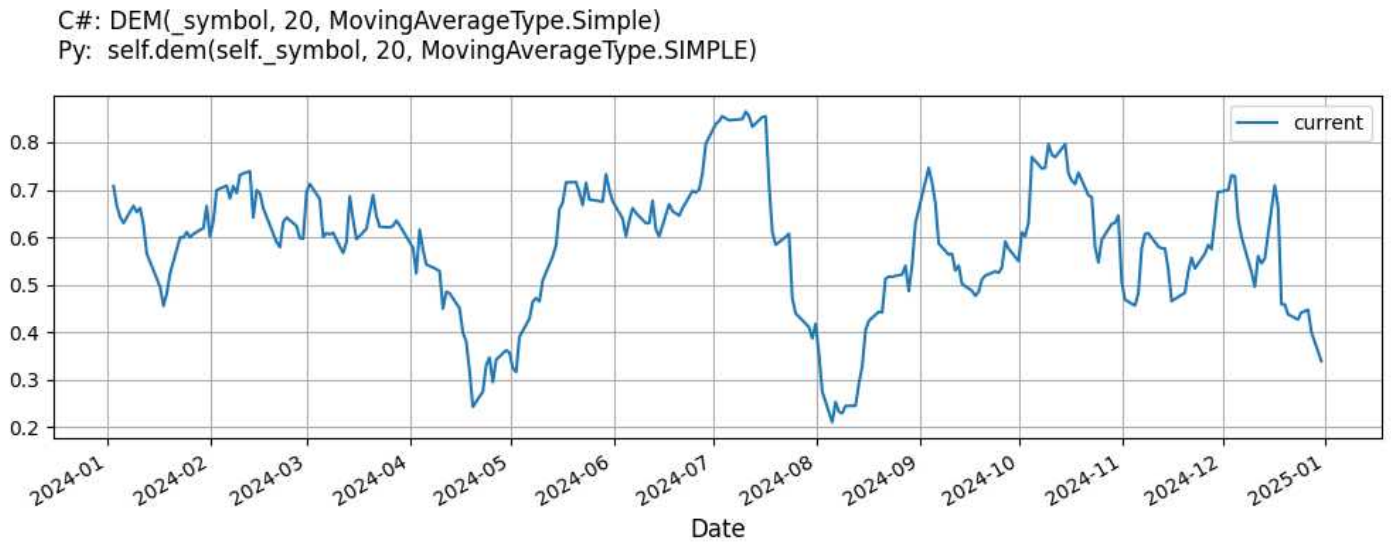
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._demarkerindicator.update(bar)

        if self._demarkerindicator.is_ready:
            # The current value of self._demarkerindicator is represented by self._demarkerindicator.current.value
            self.plot("DeMarkerIndicator", "demarkerindicator", self._demarkerindicator.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `DeMarkerIndicator` indicator properties:



Indicator History

To get the historical data of the `DeMarkerIndicator` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

Delta

Introduction

Option Delta indicator that calculate the delta of an option

To view the implementation of this indicator, see the LEAN GitHub repository .

Using D Indicator

To create an automatic indicator for `Delta` , call the `d` helper method from the `QCAlgorithm` class. The `d` method creates a `Delta` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```py
class DeltaAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 20)

        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._option = SymbolRepresentation.parse_option_ticker_osi("SPY 240920C00564000");
        self._mirror_option = SymbolRepresentation.parse_option_ticker_osi("SPY 240920P00564000");
        self.add_option_contract(self._option, Resolution.DAILY);
        self.add_option_contract(self._mirror_option, Resolution.DAILY);

        self._d = self.d(self._option, self._mirror_option)

    def on_data(self, slice: Slice) -> None:
        if self._d.is_ready:
            # The current value of self._d is represented by self._d.current.value
            self.plot("Delta", "d", self._d.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Delta` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```py

Derivative Oscillator

Introduction

This indicator represents the Derivative Oscillator Indicator, utilizing a moving average convergence-divergence (MACD) histogram to a double-smoothed relative strength index (RSI).

To view the implementation of this indicator, see the LEAN GitHub repository .

Using DO Indicator

To create an automatic indicator for `DerivativeOscillator` , call the `do` helper method from the `QCAlgorithm` class. The `do` method creates a `DerivativeOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class DerivativeOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._do = self.do(self._symbol, 14, 5, 3, 9)

    def on_data(self, slice: Slice) -> None:

        if self._do.is_ready:
            # The current value of self._do is represented by self._do.current.value
            self.plot("DerivativeOscillator", "do", self._do.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `DerivativeOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class DerivativeOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._derivativeoscillator = DerivativeOscillator(14, 5, 3, 9)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._derivativeoscillator.update(bar.end_time, bar.close)

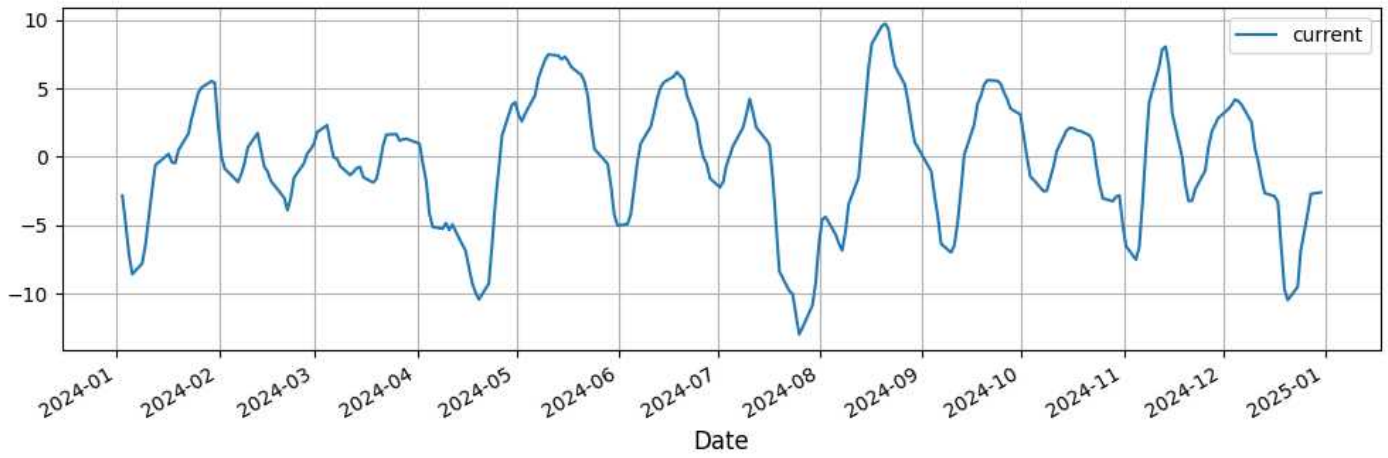
        if self._derivativeoscillator.is_ready:
            # The current value of self._derivativeoscillator is represented by self._derivativeoscillator.current.value
            self.plot("DerivativeOscillator", "derivativeoscillator", self._derivativeoscillator.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `DerivativeOscillator` indicator properties:

C#: DO(_symbol, 14, 5, 3, 9)
Py: self.do(self._symbol, 14, 5, 3, 9)



Indicator History

To get the historical data of the `DerivativeOscillator` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class DerivativeOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._do = self.do(self._symbol, 14, 5, 3, 9)

        indicator_history = self.indicator_history(self._do, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._do, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._do, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Detrended Price Oscillator

Introduction

The Detrended Price Oscillator is an indicator designed to remove trend from price and make it easier to identify cycles. DPO does not extend to the last date because it is based on a displaced moving average. Is estimated as Price {X/2 + 1} periods ago less the X-period simple moving average. E.g.DPO(20) equals price 11 days ago less the 20-day SMA.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using DPO Indicator

To create an automatic indicator for `DetrendedPriceOscillator` , call the `dpo` helper method from the `QCAlgorithm` class. The `dpo` method creates a `DetrendedPriceOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class DetrendedPriceOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._dpo = self.dpo(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._dpo.is_ready:
            # The current value of self._dpo is represented by self._dpo.current.value
            self.plot("DetrendedPriceOscillator", "dpo", self._dpo.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `DetrendedPriceOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class DetrendedPriceOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._detrendedpriceoscillator = DetrendedPriceOscillator(20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._detrendedpriceoscillator.update(bar.end_time, bar.close)

        if self._detrendedpriceoscillator.is_ready:
            # The current value of self._detrendedpriceoscillator is represented by self._detrendedpriceoscillator.current.value
            self.plot("DetrendedPriceOscillator", "detrendedpriceoscillator", self._detrendedpriceoscillator.current.value)
```

For more information about this indicator, see its reference .

Supported Indicators

Donchian Channel

Introduction

This indicator computes the upper and lower band of the Donchian Channel. The upper band is computed by finding the highest high over the given period. The lower band is computed by finding the lowest low over the given period. The primary output value of the indicator is the mean of the upper and lower band for the given timeframe.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using DCH Indicator

To create an automatic indicator for `DonchianChannel` , call the `dch` helper method from the `QCAlgorithm` class. The `dch` method creates a `DonchianChannel` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class DonchianChannelAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._dch = self.dch(self._symbol, 20, 20)

    def on_data(self, slice: Slice) -> None:

        if self._dch.is_ready:
            # The current value of self._dch is represented by self._dch.current.value
            self.plot("DonchianChannel", "dch", self._dch.current.value)
            # Plot all attributes of self._dch
            self.plot("DonchianChannel", "upper_band", self._dch.upper_band.current.value)
            self.plot("DonchianChannel", "lower_band", self._dch.lower_band.current.value)
```

PY

For more information about this method, see the QCAlgorithm class .

You can manually create a `DonchianChannel` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class DonchianChannelAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._donchianchannel = DonchianChannel(20, 20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._donchianchannel.update(bar)

        if self._donchianchannel.is_ready:
            # The current value of self._donchianchannel is represented by self._donchianchannel.current.value
            self.plot("DonchianChannel", "donchianchannel", self._donchianchannel.current.value)
            # Plot all attributes of self._donchianchannel
            self.plot("DonchianChannel", "upper_band", self._donchianchannel.upper_band.current.value)
            self.plot("DonchianChannel", "lower_band", self._donchianchannel.lower_band.current.value)
```

PY

For more information about this indicator, see its reference .

Supported Indicators

Double Exponential Moving Average

Introduction

This indicator computes the Double Exponential Moving Average (DEMA). The Double Exponential Moving Average is calculated with the following formula: EMA2 = EMA(EMA(t,period),period) DEMA = 2 * EMA(t,period) - EMA2 The Generalized DEMA (GD) is calculated with the following formula: GD = (volumeFactor+1) * EMA(t,period) - volumeFactor * EMA2

To view the implementation of this indicator, see the LEAN GitHub repository .

Using DEMA Indicator

To create an automatic indicator for `DoubleExponentialMovingAverage` , call the `dema` helper method from the `QCAlgorithm` class. The `dema` method creates a `DoubleExponentialMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class DoubleExponentialMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._dema = self.dema(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._dema.is_ready:
            # The current value of self._dema is represented by self._dema.current.value
            self.plot("DoubleExponentialMovingAverage", "dema", self._dema.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `DoubleExponentialMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class DoubleExponentialMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._doubleexponentialmovingaverage = DoubleExponentialMovingAverage(20)

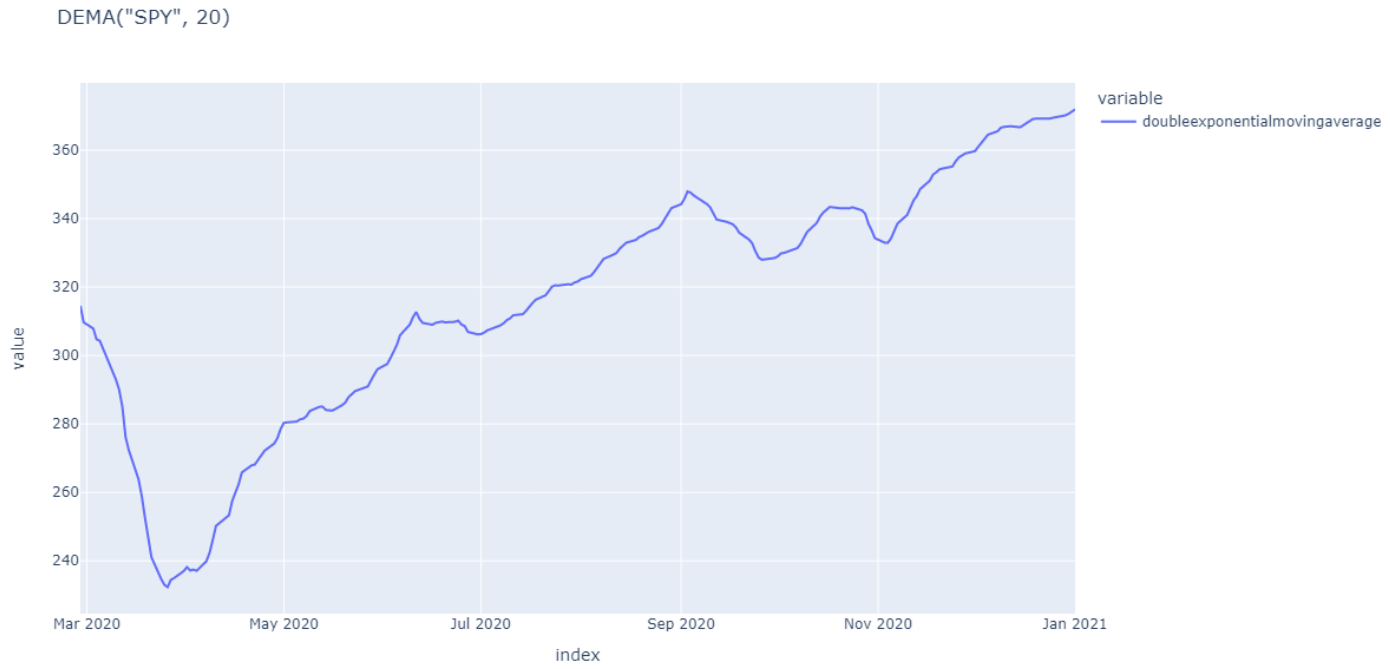
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._doubleexponentialmovingaverage.update(bar.end_time, bar.close)

        if self._doubleexponentialmovingaverage.is_ready:
            # The current value of self._doubleexponentialmovingaverage is represented by
self._doubleexponentialmovingaverage.current.value
            self.plot("DoubleExponentialMovingAverage", "doubleexponentialmovingaverage",
self._doubleexponentialmovingaverage.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `DoubleExponentialMovingAverage` indicator properties:



Indicator History

To get the historical data of the `DoubleExponentialMovingAverage` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```

```

Supported Indicators

Ease Of Movement Value

Introduction

This indicator computes the n-period Ease of Movement Value using the following: MID = (high_1 + low_1)/2 - (high_0 + low_0)/2 RATIO = (currentVolume/10000) / (high_1 - low_1) EMV = MID/RATIO _SMA = n-period of EMV Returns _SMA source

To view the implementation of this indicator, see the LEAN GitHub repository .

Using EMV Indicator

To create an automatic indicator for `EaseOfMovementValue` , call the `emv` helper method from the `QCAlgorithm` class. The `emv` method creates a `EaseOfMovementValue` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class EaseOfMovementValueAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._emv = self.emv(self._symbol, 1, 10000)

    def on_data(self, slice: Slice) -> None:

        if self._emv.is_ready:
            # The current value of self._emv is represented by self._emv.current.value
            self.plot("EaseOfMovementValue", "emv", self._emv.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `EaseOfMovementValue` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

Supported Indicators

Exponential Moving Average

Introduction

This indicator represents the traditional exponential moving average indicator (EMA). When the indicator is ready, the first value of the EMA is equivalent to the simple moving average. After the first EMA value, the EMA value is a function of the previous EMA value. Therefore, depending on the number of samples you feed into the indicator, it can provide different EMA values for a single security and lookback period. To make the indicator values consistent across time, warm up the indicator with all the trailing security price history.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using EMA Indicator

To create an automatic indicator for `ExponentialMovingAverage` , call the `ema` helper method from the `QCAlgorithm` class. The `ema` method creates a `ExponentialMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

PY

```
class ExponentialMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._ema = self.ema(self._symbol, 20, 0.5)

    def on_data(self, slice: Slice) -> None:

        if self._ema.is_ready:
            # The current value of self._ema is represented by self._ema.current.value
            self.plot("ExponentialMovingAverage", "ema", self._ema.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ExponentialMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

PY

```
class ExponentialMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._exponentialmovingaverage = ExponentialMovingAverage(20, 0.5)

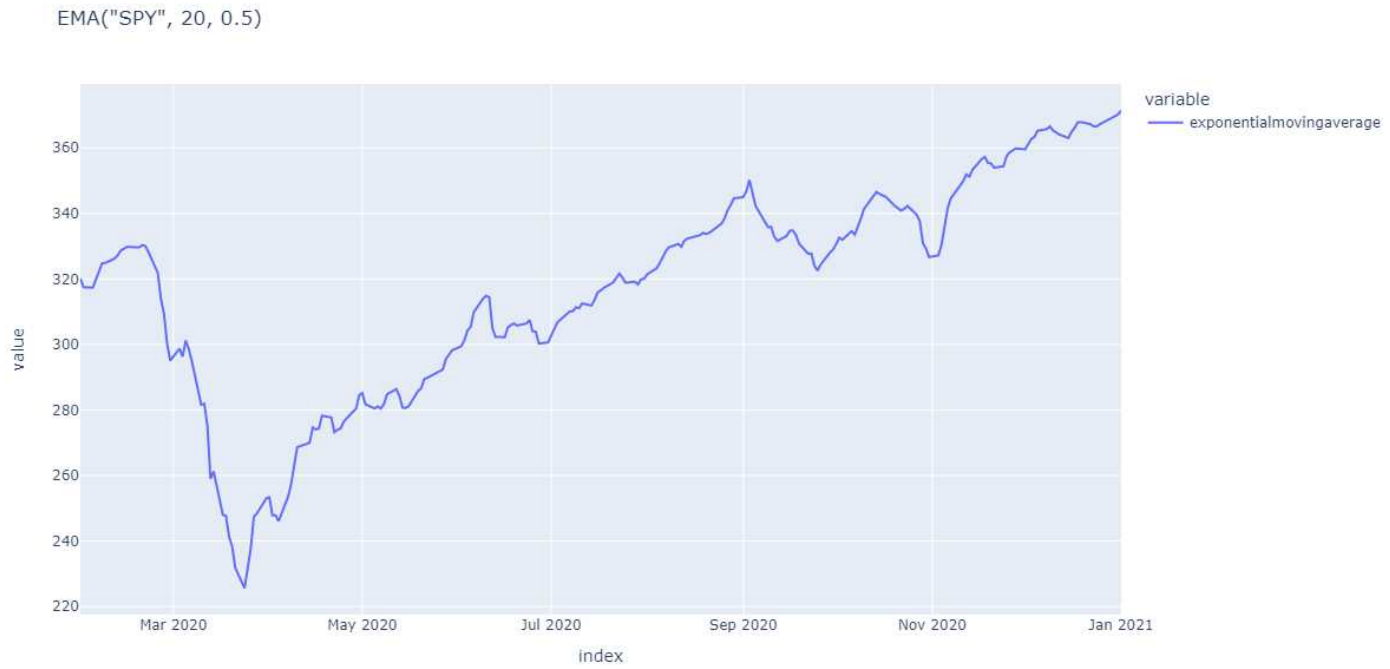
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._exponentialmovingaverage.update(bar.end_time, bar.close)

        if self._exponentialmovingaverage.is_ready:
            # The current value of self._exponentialmovingaverage is represented by self._exponentialmovingaverage.current.value
            self.plot("ExponentialMovingAverage", "exponentialmovingaverage", self._exponentialmovingaverage.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `ExponentialMovingAverage` indicator properties:



Indicator History

To get the historical data of the `ExponentialMovingAverage` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
class ExponentialMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._ema = self.ema(self._symbol, 20, 0.5)

        indicator_history = self.indicator_history(self._ema, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._ema, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._ema, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),

Filtered Identity

Introduction

This indicator represents an indicator that is a ready after ingesting a single sample and always returns the same value as it is given if it passes a filter condition

To view the implementation of this indicator, see the LEAN GitHub repository .

Using FilteredIdentity Indicator

To create an automatic indicator for `FilteredIdentity` , call the `filtered_identity` helper method from the `QCAlgorithm` class. The `filtered_identity` method creates a `FilteredIdentity` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class FilteredIdentityAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._filtered_identity = self.filtered_identity(self._symbol, filter=lambda x: x.close > x.open)

    def on_data(self, slice: Slice) -> None:

        if self._filtered_identity.is_ready:
            # The current value of self._filtered_identity is represented by self._filtered_identity.current.value
            self.plot("FilteredIdentity", "filtered_identity", self._filtered_identity.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `FilteredIdentity` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class FilteredIdentityAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._filteredidentity = FilteredIdentity(filter=lambda x: x.close > x.open)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._filteredidentity.update(bar)

        if self._filteredidentity.is_ready:
            # The current value of self._filteredidentity is represented by self._filteredidentity.current.value
            self.plot("FilteredIdentity", "filteredidentity", self._filteredidentity.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `FilteredIdentity` indicator properties:

Indicator History

To get the historical data of the `FilteredIdentity` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
class FilteredIdentityAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._filtered_identity = self.filtered_identity(self._symbol, filter=lambda x: x.close > x.open)

        indicator_history = self.indicator_history(self._filtered_identity, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._filtered_identity, self._symbol, timedelta(days=10),
Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._filtered_identity, self._symbol, datetime(2024, 7, 1),
datetime(2024, 7, 5), Resolution.MINUTE)

Fisher Transform

Introduction

The Fisher transform is a mathematical process which is used to convert any data set to a modified data set whose Probability Distribution Function is approximately Gaussian. Once the Fisher transform is computed, the transformed data can then be analyzed in terms of it's deviation from the mean. The equation is y = .5 * ln [1 + x / 1 - x] where x is the input y is the output ln is the natural logarithm The Fisher transform has much sharper turning points than other indicators such as MACD For more info, read chapter 1 of Cybernetic Analysis for Stocks and Futures by John F. Ehlers We are implementing the latest version of this indicator found at Fig. 4 of http://www.mesasoftware.com/papers/UsingTheFisherTransform.pdf

To view the implementation of this indicator, see the LEAN GitHub repository .

Using FISH Indicator

To create an automatic indicator for `FisherTransform` , call the `fish` helper method from the `QCAlgorithm` class. The `fish` method creates a `FisherTransform` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

PY

```
class FisherTransformAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._fish = self.fish(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._fish.is_ready:
            # The current value of self._fish is represented by self._fish.current.value
            self.plot("FisherTransform", "fish", self._fish.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `FisherTransform` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

PY

```
class FisherTransformAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._fishertransform = FisherTransform(20)

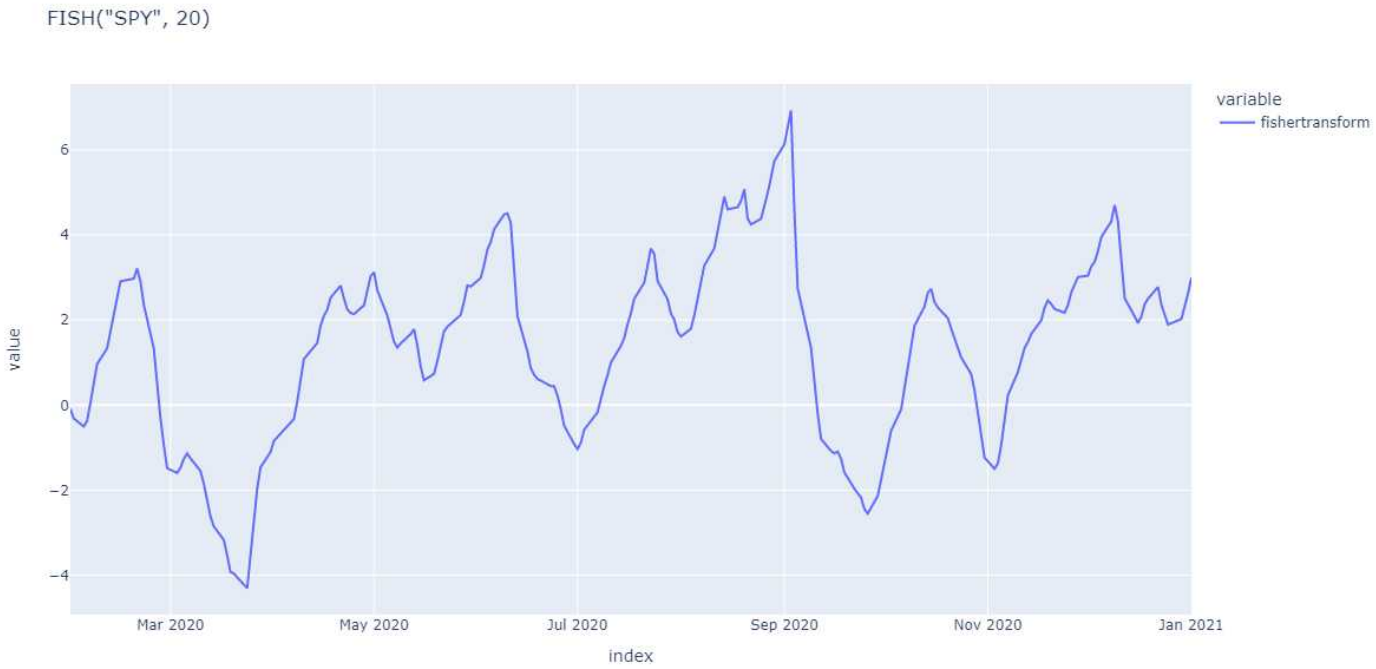
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._fishertransform.update(bar)

        if self._fishertransform.is_ready:
            # The current value of self._fishertransform is represented by self._fishertransform.current.value
            self.plot("FisherTransform", "fishertransform", self._fishertransform.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `FisherTransform` indicator properties:



Indicator History

To get the historical data of the `FisherTransform` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
class FisherTransformAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._fish = self.fish(self._symbol, 20)

        indicator_history = self.indicator_history(self._fish, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._fish, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._fish, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Supported Indicators

Force Index

Introduction

The Force Index is calculated by comparing the current market price with the previous market price and multiplying its difference with the traded volume during a specific time period.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using FI Indicator

To create an automatic indicator for `ForceIndex` , call the `fi` helper method from the `QCAlgorithm` class. The `fi` method creates a `ForceIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class ForceIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._fi = self.fi(self._symbol, 13)

    def on_data(self, slice: Slice) -> None:

        if self._fi.is_ready:
            # The current value of self._fi is represented by self._fi.current.value
            self.plot("ForceIndex", "fi", self._fi.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ForceIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class ForceIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._forceindex = ForceIndex(13)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._forceindex.update(bar)

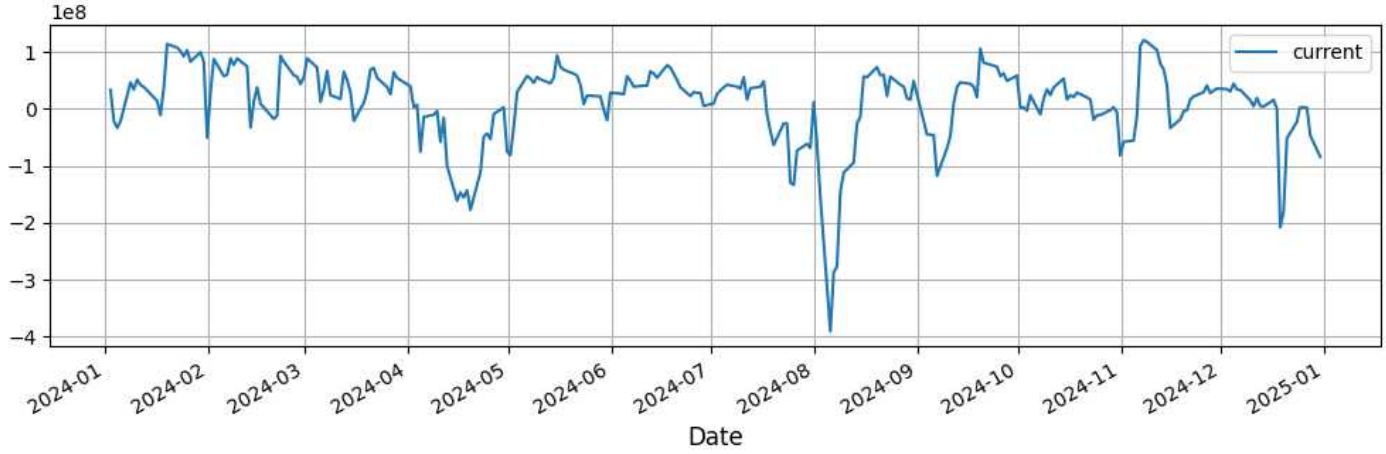
        if self._forceindex.is_ready:
            # The current value of self._forceindex is represented by self._forceindex.current.value
            self.plot("ForceIndex", "forceindex", self._forceindex.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `ForceIndex` indicator properties:

C#: FI(_symbol, 13)
Py: self.fi(self._symbol, 13)



Indicator History

To get the historical data of the `ForceIndex` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
class ForceIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._fi = self.fi(self._symbol, 13)

        indicator_history = self.indicator_history(self._fi, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._fi, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._fi, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Fractal Adaptive Moving Average

Introduction

The Fractal Adaptive Moving Average (FRAMA) by John Ehlers

To view the implementation of this indicator, see the LEAN GitHub repository .

Using FRAMA Indicator

To create an automatic indicator for `FractalAdaptiveMovingAverage` , call the `frama` helper method from the `QCAlgorithm` class. The `frama` method creates a `FractalAdaptiveMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class FractalAdaptiveMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._frama = self.frama(self._symbol, 20, 198)

    def on_data(self, slice: Slice) -> None:

        if self._frama.is_ready:
            # The current value of self._frama is represented by self._frama.current.value
            self.plot("FractalAdaptiveMovingAverage", "frama", self._frama.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `FractalAdaptiveMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class FractalAdaptiveMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._fractaladaptivemovingaverage = FractalAdaptiveMovingAverage(20, 198)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._fractaladaptivemovingaverage.update(bar)

        if self._fractaladaptivemovingaverage.is_ready:
            # The current value of self._fractaladaptivemovingaverage is represented by self._fractaladaptivemovingaverage.current.value
            self.plot("FractalAdaptiveMovingAverage", "fractaladaptivemovingaverage", self._fractaladaptivemovingaverage.current.value)
```

For more information about this indicator, see its reference .

Gamma

Introduction

Option Gamma indicator that calculate the gamma of an option

To view the implementation of this indicator, see the LEAN GitHub repository .

Using G Indicator

To create an automatic indicator for `Gamma` , call the `g` helper method from the `QCAlgorithm` class. The `g` method creates a `Gamma` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```py
class GammaAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024, 9, 1)
        self.set_end_date(2024, 9, 20)

        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._option = SymbolRepresentation.parse_option_ticker_osi("SPY 240920C00564000");
        self._mirror_option = SymbolRepresentation.parse_option_ticker_osi("SPY 240920P00564000");
        self.add_option_contract(self._option, Resolution.DAILY);
        self.add_option_contract(self._mirror_option, Resolution.DAILY);

        self._g = self.g(self._option, self._mirror_option)

    def on_data(self, slice: Slice) -> None:
        if self._g.is_ready:
            # The current value of self._g is represented by self._g.current.value
            self.plot("Gamma", "g", self._g.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Gamma` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

Heikin Ashi

Introduction

This indicator computes the Heikin-Ashi bar (HA) The Heikin-Ashi bar is calculated using the following formulas: HA_Close[0] = (Open[0] + High[0] + Low[0] + Close[0]) / 4 HA_Open[0] = (HA_Open[1] + HA_Close[1]) / 2 HA_High[0] = MAX(High[0], HA_Open[0], HA_Close[0]) HA_Low[0] = MIN(Low[0], HA_Open[0], HA_Close[0])

To view the implementation of this indicator, see the LEAN GitHub repository .

Using HeikinAshi Indicator

To create an automatic indicator for `HeikinAshi` , call the `heikin_ashi` helper method from the `QCAlgorithm` class. The `heikin_ashi` method creates a `HeikinAshi` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class HeikinAshiAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._heikin_ashi = self.heikin_ashi(self._symbol)

    def on_data(self, slice: Slice) -> None:

        if self._heikin_ashi.is_ready:
            # The current value of self._heikin_ashi is represented by self._heikin_ashi.current.value
            self.plot("HeikinAshi", "heikin_ashi", self._heikin_ashi.current.value)
            # Plot all attributes of self._heikin_ashi
            self.plot("HeikinAshi", "open", self._heikin_ashi.open.current.value)
            self.plot("HeikinAshi", "high", self._heikin_ashi.high.current.value)
            self.plot("HeikinAshi", "low", self._heikin_ashi.low.current.value)
            self.plot("HeikinAshi", "close", self._heikin_ashi.close.current.value)
            self.plot("HeikinAshi", "volume", self._heikin_ashi.volume.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `HeikinAshi` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class HeikinAshiAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._heikinashi = HeikinAshi()

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._heikinashi.update(bar)

        if self._heikinashi.is_ready:
            # The current value of self._heikinashi is represented by self._heikinashi.current.value
            self.plot("HeikinAshi", "heikinashi", self._heikinashi.current.value)
            # Plot all attributes of self._heikinashi
            self.plot("HeikinAshi", "open", self._heikinashi.open.current.value)
            self.plot("HeikinAshi", "high", self._heikinashi.high.current.value)
            self.plot("HeikinAshi", "low", self._heikinashi.low.current.value)
            self.plot("HeikinAshi", "close", self._heikinashi.close.current.value)
            self.plot("HeikinAshi", "volume", self._heikinashi.volume.current.value)
```

For more information about this indicator, see its reference .

Hilbert Transform

Introduction

This indicator computes the Hilbert Transform Indicator by John Ehlers. By using present and prior price differences, and some feedback, price values are split into their complex number components of real (inPhase) and imaginary (quadrature) parts. source

To view the implementation of this indicator, see the LEAN GitHub repository .

Using HT Indicator

To create an automatic indicator for `HilbertTransform` , call the `ht` helper method from the `QCAlgorithm` class. The `ht` method creates a `HilbertTransform` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class HilbertTransformAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._ht = self.ht(self._symbol, 7, 0.635, 0.338)

    def on_data(self, slice: Slice) -> None:

        if self._ht.is_ready:
            # The current value of self._ht is represented by self._ht.current.value
            self.plot("HilbertTransform", "ht", self._ht.current.value)
            # Plot all attributes of self._ht
            self.plot("HilbertTransform", "in_phase", self._ht.in_phase.current.value)
            self.plot("HilbertTransform", "quadrature", self._ht.quadrature.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `HilbertTransform` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class HilbertTransformAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._hilberttransform = HilbertTransform(7, 0.635, 0.338)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._hilberttransform.update(bar.end_time, bar.close)

        if self._hilberttransform.is_ready:
            # The current value of self._hilberttransform is represented by self._hilberttransform.current.value
            self.plot("HilbertTransform", "hilberttransform", self._hilberttransform.current.value)
            # Plot all attributes of self._hilberttransform
            self.plot("HilbertTransform", "in_phase", self._hilberttransform.in_phase.current.value)
            self.plot("HilbertTransform", "quadrature", self._hilberttransform.quadrature.current.value)
```

For more information about this indicator, see its reference .

Hull Moving Average

Introduction

Produces a Hull Moving Average as explained at http://www.alanhull.com/hull-moving-average/ and derived from the instructions for the Excel VBA code at http://finance4traders.blogspot.com/2009/06/how-to-calculate-hull-moving-average.html

To view the implementation of this indicator, see the LEAN GitHub repository .

Using HMA Indicator

To create an automatic indicator for `HullMovingAverage` , call the `hma` helper method from the `QCAlgorithm` class. The `hma` method creates a `HullMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class HullMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._hma = self.hma(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._hma.is_ready:
            # The current value of self._hma is represented by self._hma.current.value
            self.plot("HullMovingAverage", "hma", self._hma.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `HullMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class HullMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._hullmovingaverage = HullMovingAverage(20)

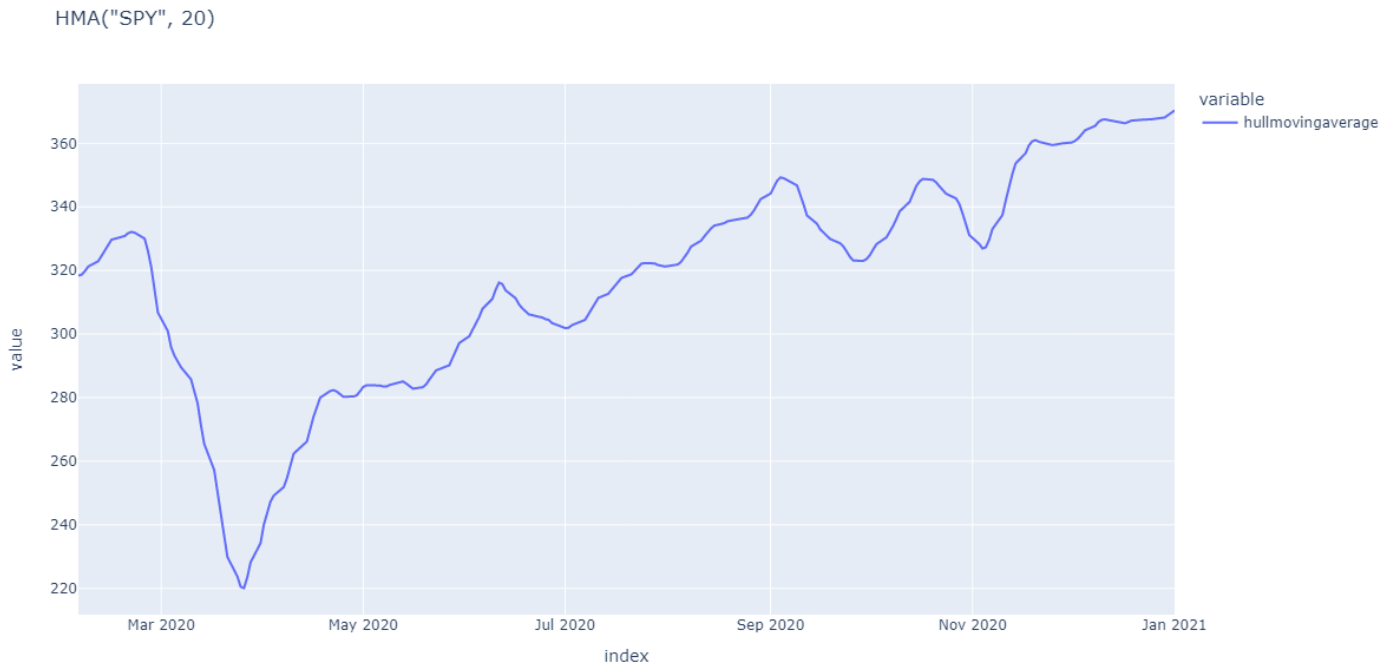
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._hullmovingaverage.update(bar.end_time, bar.close)

        if self._hullmovingaverage.is_ready:
            # The current value of self._hullmovingaverage is represented by self._hullmovingaverage.current.value
            self.plot("HullMovingAverage", "hullmovingaverage", self._hullmovingaverage.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `HullMovingAverage` indicator properties:



Indicator History

To get the historical data of the `HullMovingAverage` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class HullMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._hma = self.hma(self._symbol, 20)

        indicator_history = self.indicator_history(self._hma, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._hma, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._hma, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Supported Indicators

Hurst Exponent

Introduction

This indicator represents the Hurst Exponent indicator, which is used to measure the long-term memory of a time series. - H less than 0.5: Mean-reverting; high values followed by low ones, stronger as H approaches 0. - H equal to 0.5: Random walk (geometric). - H greater than 0.5: Trending; high values followed by higher ones, stronger as H approaches 1.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using HE Indicator

To create an automatic indicator for `HurstExponent` , call the `he` helper method from the `QCAlgorithm` class. The `he` method creates a `HurstExponent` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class HurstExponentAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._he = self.he(self._symbol, 32)

    def on_data(self, slice: Slice) -> None:

        if self._he.is_ready:
            # The current value of self._he is represented by self._he.current.value
            self.plot("HurstExponent", "he", self._he.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `HurstExponent` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class HurstExponentAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._hurstexponent = HurstExponent(32)

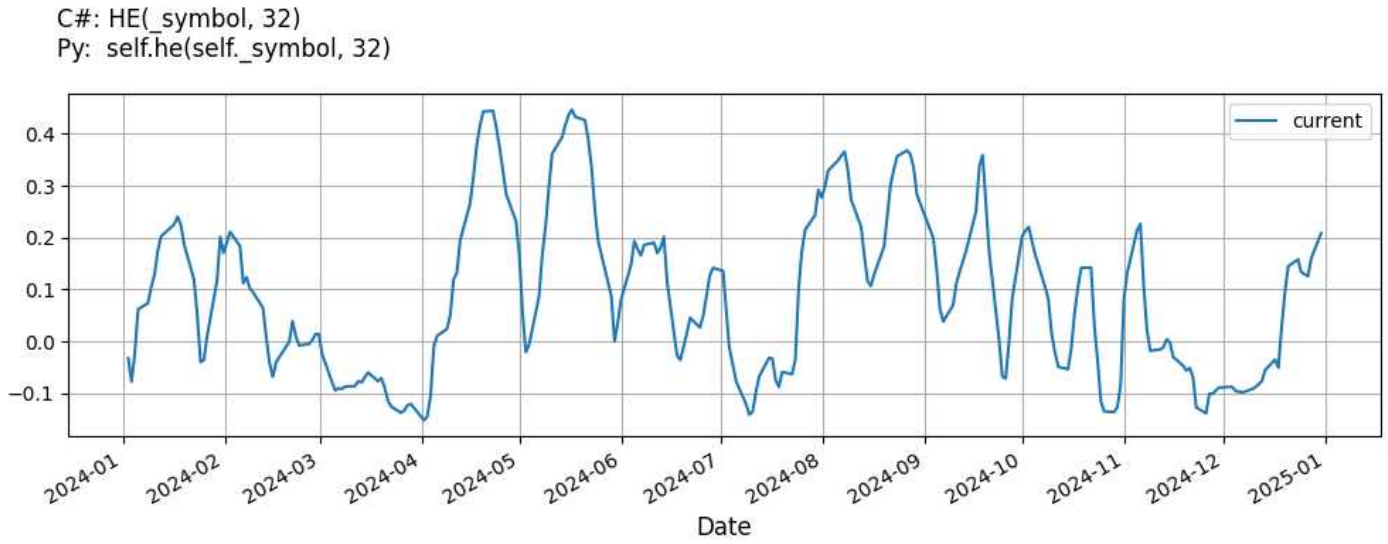
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._hurstexponent.update(bar.end_time, bar.close)

        if self._hurstexponent.is_ready:
            # The current value of self._hurstexponent is represented by self._hurstexponent.current.value
            self.plot("HurstExponent", "hurstexponent", self._hurstexponent.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `HurstExponent` indicator properties:



Indicator History

To get the historical data of the `HurstExponent` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class HurstExponentAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._he = self.he(self._symbol, 32)

        indicator_history = self.indicator_history(self._he, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._he, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._he, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Supported Indicators

Ichimoku Kinko Hyo

Introduction

This indicator computes the Ichimoku Kinko Hyo indicator. It consists of the following main indicators: Tenkan-sen: (Highest High + Lowest Low) / 2 for the specific period (normally 9) Kijun-sen: (Highest High + Lowest Low) / 2 for the specific period (normally 26) Senkou A Span: (Tenkan-sen + Kijun-sen)/ 2 from a specific number of periods ago (normally 26) Senkou B Span: (Highest High + Lowest Low) / 2 for the specific period (normally 52), from a specific number of periods ago (normally 26)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ICHIMOKU Indicator

To create an automatic indicator for `IchimokuKinkoHyo` , call the `ichimoku` helper method from the `QCAlgorithm` class. The `ichimoku` method creates a `IchimokuKinkoHyo` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class IchimokuKinkoHyoAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._ichimoku = self.ichimoku(self._symbol, 9, 26, 17, 52, 26, 26)

    def on_data(self, slice: Slice) -> None:

        if self._ichimoku.is_ready:
            # The current value of self._ichimoku is represented by self._ichimoku.current.value
            self.plot("IchimokuKinkoHyo", "ichimoku", self._ichimoku.current.value)
            # Plot all attributes of self._ichimoku
            self.plot("IchimokuKinkoHyo", "tenkan", self._ichimoku.tenkan.current.value)
            self.plot("IchimokuKinkoHyo", "kijun", self._ichimoku.kijun.current.value)
            self.plot("IchimokuKinkoHyo", "senkou_a", self._ichimoku.senkou_a.current.value)
            self.plot("IchimokuKinkoHyo", "senkou_b", self._ichimoku.senkou_b.current.value)
            self.plot("IchimokuKinkoHyo", "chikou", self._ichimoku.chikou.current.value)
            self.plot("IchimokuKinkoHyo", "tenkan_maximum", self._ichimoku.tenkan_maximum.current.value)
            self.plot("IchimokuKinkoHyo", "tenkan_minimum", self._ichimoku.tenkan_minimum.current.value)
            self.plot("IchimokuKinkoHyo", "kijun_maximum", self._ichimoku.kijun_maximum.current.value)
            self.plot("IchimokuKinkoHyo", "kijun_minimum", self._ichimoku.kijun_minimum.current.value)
            self.plot("IchimokuKinkoHyo", "senkou_b_maximum", self._ichimoku.senkou_b_maximum.current.value)
            self.plot("IchimokuKinkoHyo", "senkou_b_minimum", self._ichimoku.senkou_b_minimum.current.value)
            self.plot("IchimokuKinkoHyo", "delayed_tenkan_senkou_a", self._ichimoku.delayed_tenkan_senkou_a.current.value)
            self.plot("IchimokuKinkoHyo", "delayed_kijun_senkou_a", self._ichimoku.delayed_kijun_senkou_a.current.value)
            self.plot("IchimokuKinkoHyo", "delayed_maximum_senkou_b", self._ichimoku.delayed_maximum_senkou_b.current.value)
            self.plot("IchimokuKinkoHyo", "delayed_minimum_senkou_b", self._ichimoku.delayed_minimum_senkou_b.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `IchimokuKinkoHyo` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class IchimokuKinkoHyoAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._ichimokukinkohyo = IchimokuKinkoHyo(9, 26, 17, 52, 26, 26)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._ichimokukinkohyo.update(bar)

        if self._ichimokukinkohyo.is_ready:
            # The current value of self._ichimokukinkohyo is represented by self._ichimokukinkohyo.current.value
            self.plot("IchimokuKinkoHyo", "ichimokukinkohyo", self._ichimokukinkohyo.current.value)
            # Plot all attributes of self._ichimokukinkohyo
            self.plot("IchimokuKinkoHyo", "tenkan", self._ichimokukinkohyo.tenkan.current.value)
            self.plot("IchimokuKinkoHyo", "kijun", self._ichimokukinkohyo.kijun.current.value)
            self.plot("IchimokuKinkoHyo", "senkou_a", self._ichimokukinkohyo.senkou_a.current.value)
            self.plot("IchimokuKinkoHyo", "senkou_b", self._ichimokukinkohyo.senkou_b.current.value)
            self.plot("IchimokuKinkoHyo", "chikou", self._ichimokukinkohyo.chikou.current.value)
            self.plot("IchimokuKinkoHyo", "tenkan_maximum", self._ichimokukinkohyo.tenkan_maximum.current.value)
            self.plot("IchimokuKinkoHyo", "tenkan_minimum", self._ichimokukinkohyo.tenkan_minimum.current.value)
            self.plot("IchimokuKinkoHyo", "kijun_maximum", self._ichimokukinkohyo.kijun_maximum.current.value)
            self.plot("IchimokuKinkoHyo", "kijun_minimum", self._ichimokukinkohyo.kijun_minimum.current.value)
            self.plot("IchimokuKinkoHyo", "senkou_b_maximum", self._ichimokukinkohyo.senkou_b_maximum.current.value)
            self.plot("IchimokuKinkoHyo", "senkou_b_minimum", self._ichimokukinkohyo.senkou_b_minimum.current.value)
            self.plot("IchimokuKinkoHyo", "delayed_tenkan_senkou_a", self._ichimokukinkohyo.delayed_tenkan_senkou_a.current.value)
            self.plot("IchimokuKinkoHyo", "delayed_kijun_senkou_a", self._ichimokukinkohyo.delayed_kijun_senkou_a.current.value)
            self.plot("IchimokuKinkoHyo", "delayed_maximum_senkou_b", self._ichimokukinkohyo.delayed_maximum_senkou_b.current.value)
            self.plot("IchimokuKinkoHyo", "delayed_minimum_senkou_b", self._ichimokukinkohyo.delayed_minimum_senkou_b.current.value)

Supported Indicators

Identity

Introduction

This indicator represents an indicator that is a ready after ingesting a single sample and always returns the same value as it is given.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using Identity Indicator

To create an automatic indicator for `Identity` , call the `identity` helper method from the `QCAlgorithm` class. The `identity` method creates a `Identity` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class IdentityAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._identity = self.identity(self._symbol)

    def on_data(self, slice: Slice) -> None:

        if self._identity.is_ready:
            # The current value of self._identity is represented by self._identity.current.value
            self.plot("Identity", "identity", self._identity.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Identity` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class IdentityAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._identity = Identity()

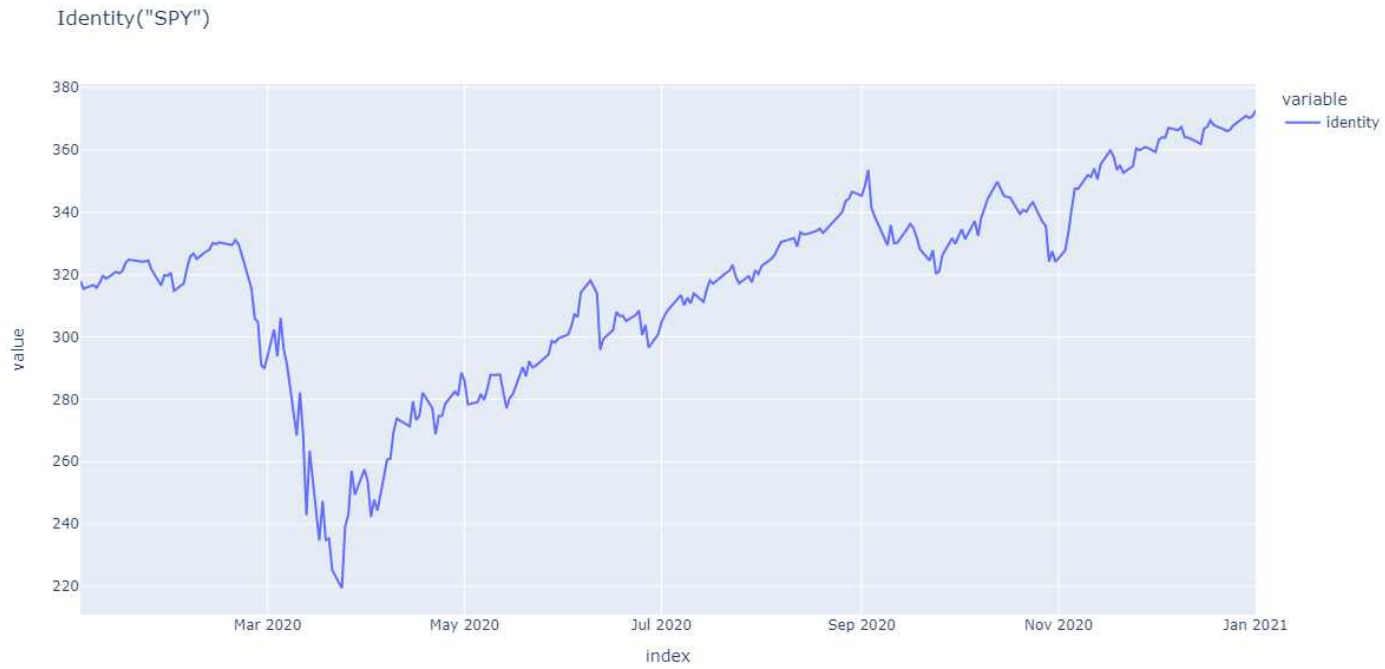
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._identity.update(bar.end_time, bar.close)

        if self._identity.is_ready:
            # The current value of self._identity is represented by self._identity.current.value
            self.plot("Identity", "identity", self._identity.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `Identity` indicator properties:



Indicator History

To get the historical data of the `Identity` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class IdentityAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._identity = self.identity(self._symbol)

        indicator_history = self.indicator_history(self._identity, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._identity, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._identity, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Supported Indicators

Internal Bar Strength

Introduction

The InternalBarStrenght indicator is a measure of the relative position of a period's closing price to the same period's high and low. The IBS can be interpreted to predict a bullish signal when displaying a low value and a bearish signal when presenting a high value.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using IBS Indicator

To create an automatic indicator for `InternalBarStrength` , call the `ibs` helper method from the `QCAlgorithm` class. The `ibs` method creates a `InternalBarStrength` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class InternalBarStrengthAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._ibs = self.ibs(self._symbol)

    def on_data(self, slice: Slice) -> None:

        if self._ibs.is_ready:
            # The current value of self._ibs is represented by self._ibs.current.value
            self.plot("InternalBarStrength", "ibs", self._ibs.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `InternalBarStrength` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class InternalBarStrengthAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._internalbarstrength = InternalBarStrength()

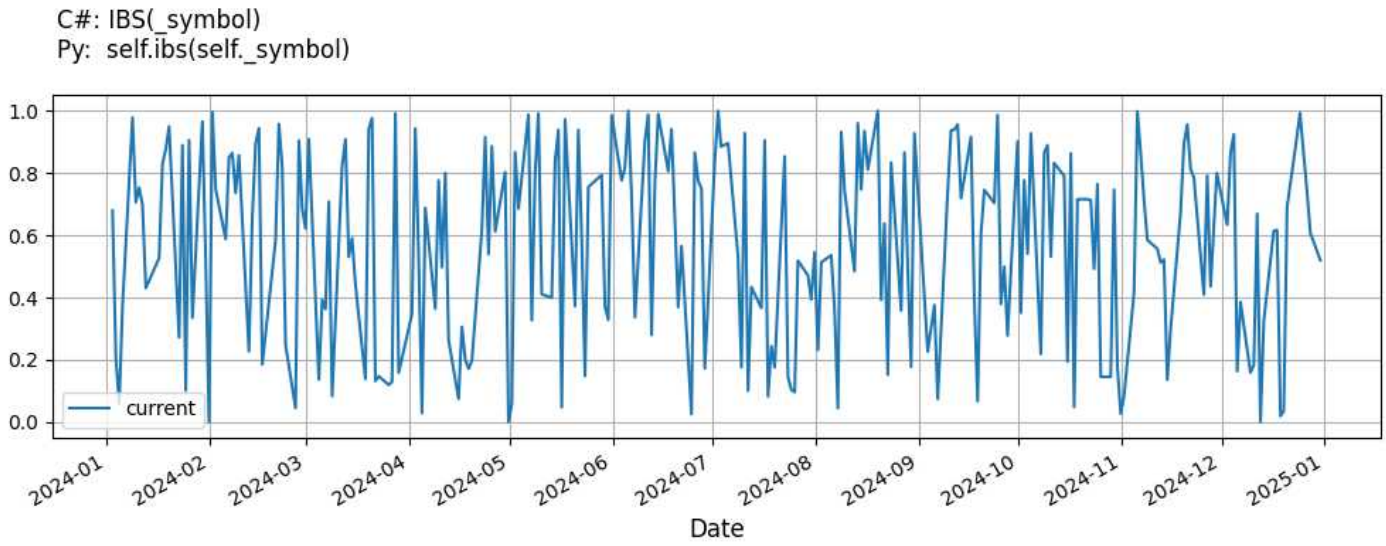
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._internalbarstrength.update(bar)

        if self._internalbarstrength.is_ready:
            # The current value of self._internalbarstrength is represented by self._internalbarstrength.current.value
            self.plot("InternalBarStrength", "internalbarstrength", self._internalbarstrength.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `InternalBarStrength` indicator properties:



Indicator History

To get the historical data of the `InternalBarStrength` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```py
class InternalBarStrengthAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._ibs = self.ibs(self._symbol)

        indicator_history = self.indicator_history(self._ibs, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._ibs, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._ibs, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Intraday Vwap

Introduction

Defines the canonical intraday VWAP indicator

To view the implementation of this indicator, see the LEAN GitHub repository .

Using VWAP Indicator

To create an automatic indicator for `IntradayVwap` , call the `vwap` helper method from the `QCAlgorithm` class. The `vwap` method creates a `IntradayVwap` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class IntradayVwapAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.MINUTE).symbol
        self._vwap = self.vwap(self._symbol)

    def on_data(self, slice: Slice) -> None:

        if self._vwap.is_ready:
            # The current value of self._vwap is represented by self._vwap.current.value
            self.plot("IntradayVwap", "vwap", self._vwap.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `IntradayVwap` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class IntradayVwapAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.MINUTE).symbol
        self._intradayvwap = IntradayVwap()

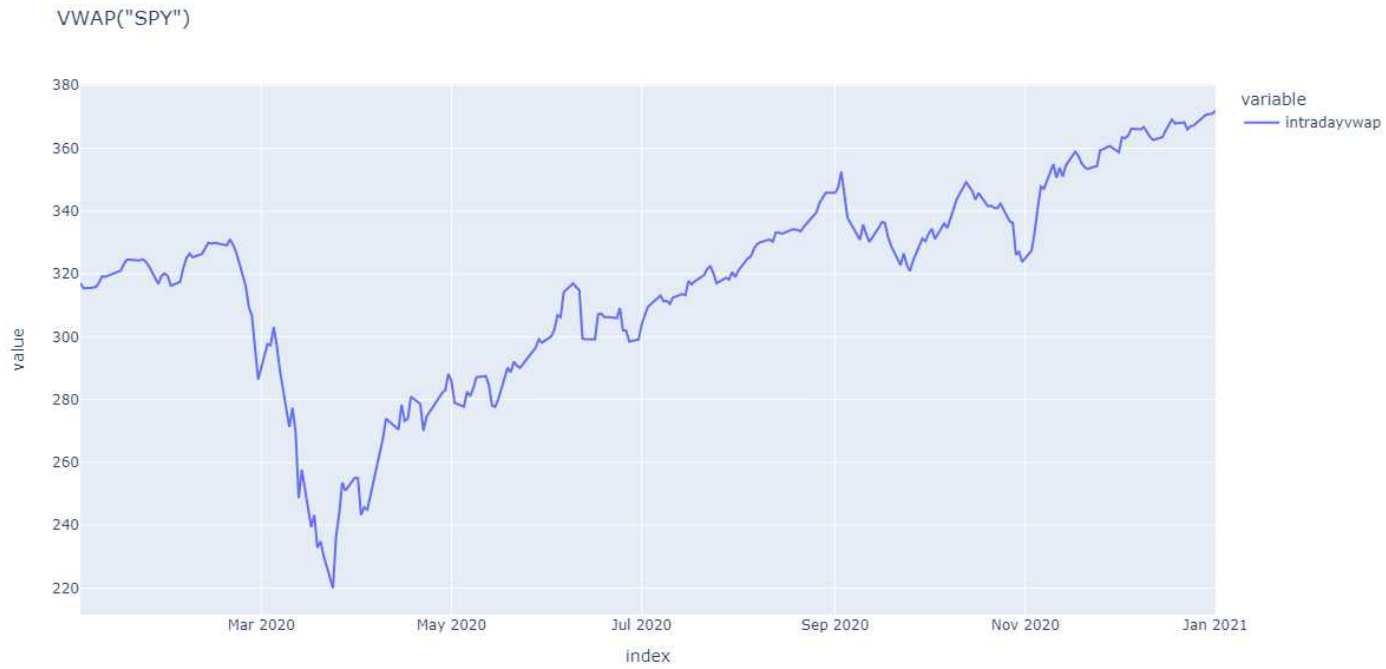
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._intradayvwap.update(bar)

        if self._intradayvwap.is_ready:
            # The current value of self._intradayvwap is represented by self._intradayvwap.current.value
            self.plot("IntradayVwap", "intradayvwap", self._intradayvwap.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `IntradayVwap` indicator properties:



Indicator History

To get the historical data of the `IntradayVwap` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```
class IntradayVwapAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.MINUTE).symbol
        self._vwap = self.vwap(self._symbol)

        indicator_history = self.indicator_history(self._vwap, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._vwap, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._vwap, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)

Kaufman Adaptive Moving Average

Introduction

This indicator computes the Kaufman Adaptive Moving Average (KAMA). The Kaufman Adaptive Moving Average is calculated as explained here: http://stockcharts.com/school/doku.php?id=chart_school:technical_indicators:kaufman_s_adaptive_moving_average

To view the implementation of this indicator, see the LEAN GitHub repository .

Using KAMA Indicator

To create an automatic indicator for `KaufmanAdaptiveMovingAverage` , call the `kama` helper method from the `QCAlgorithm` class. The `kama` method creates a `KaufmanAdaptiveMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class KaufmanAdaptiveMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._kama = self.kama(self._symbol, 20, 10, 20)

    def on_data(self, slice: Slice) -> None:

        if self._kama.is_ready:
            # The current value of self._kama is represented by self._kama.current.value
            self.plot("KaufmanAdaptiveMovingAverage", "kama", self._kama.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `KaufmanAdaptiveMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class KaufmanAdaptiveMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._kaufmanadaptivemovingaverage = KaufmanAdaptiveMovingAverage(20, 10, 20)

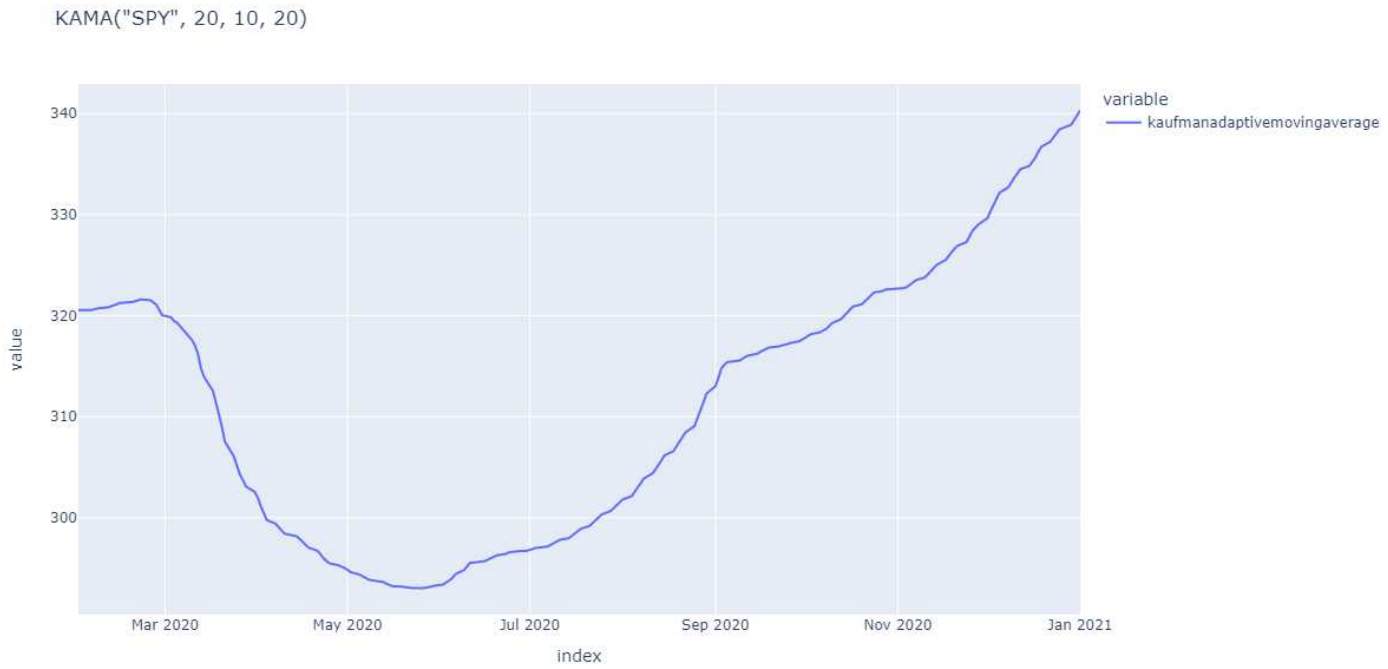
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._kaufmanadaptivemovingaverage.update(bar.end_time, bar.close)

        if self._kaufmanadaptivemovingaverage.is_ready:
            # The current value of self._kaufmanadaptivemovingaverage is represented by self._kaufmanadaptivemovingaverage.current.value
            self.plot("KaufmanAdaptiveMovingAverage", "kaufmanadaptivemovingaverage", self._kaufmanadaptivemovingaverage.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `KaufmanAdaptiveMovingAverage` indicator properties:



Indicator History

To get the historical data of the `KaufmanAdaptiveMovingAverage` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

Kaufman Efficiency Ratio

Introduction

This indicator computes the Kaufman Efficiency Ratio (KER). The Kaufman Efficiency Ratio is calculated as explained here: https://www.marketvolume.com/technicalanalysis/efficiencyratio.asp

To view the implementation of this indicator, see the LEAN GitHub repository .

Using KER Indicator

To create an automatic indicator for `KaufmanEfficiencyRatio` , call the `ker` helper method from the `QCAlgorithm` class. The `ker` method creates a `KaufmanEfficiencyRatio` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class KaufmanEfficiencyRatioAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._ker = self.ker(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._ker.is_ready:
            # The current value of self._ker is represented by self._ker.current.value
            self.plot("KaufmanEfficiencyRatio", "ker", self._ker.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `KaufmanEfficiencyRatio` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class KaufmanEfficiencyRatioAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._kaufmanefficiencyratio = KaufmanEfficiencyRatio(20)

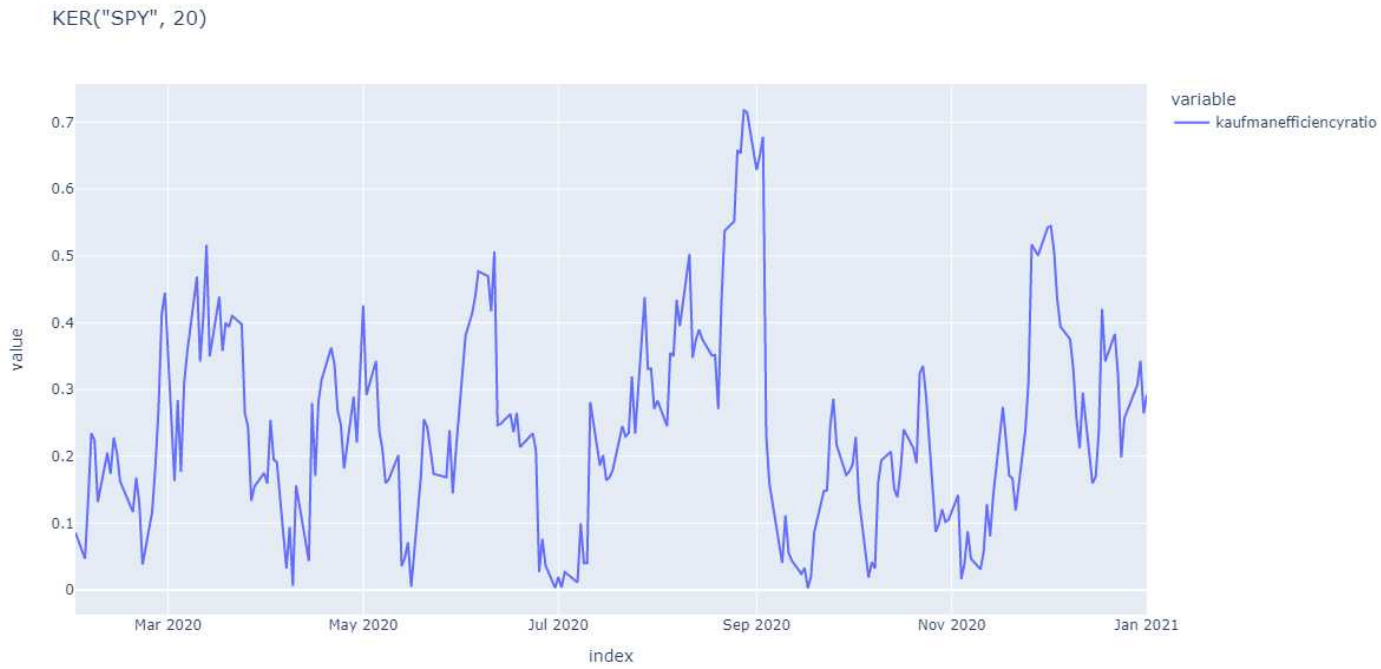
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._kaufmanefficiencyratio.update(bar.end_time, bar.close)

        if self._kaufmanefficiencyratio.is_ready:
            # The current value of self._kaufmanefficiencyratio is represented by self._kaufmanefficiencyratio.current.value
            self.plot("KaufmanEfficiencyRatio", "kaufmanefficiencyratio", self._kaufmanefficiencyratio.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `KaufmanEfficiencyRatio` indicator properties:



Indicator History

To get the historical data of the `KaufmanEfficiencyRatio` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

```

Klinger Volume Oscillator

Introduction

The Klinger Volume Oscillator (KVO) is a technical indicator that analyzes the relationship between price movement and trading volume to assess the strength of market trends and identify potential trend reversals. As a volume-based oscillator, it measures the force behind price movements by incorporating volume data adjusted for price trends and specific conditions. Traders use the KVO to analyze its behavior relative to price action, looking for patterns such as divergences or crossovers that can provide insights into market trends and potential turning points.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using KVO Indicator

To create an automatic indicator for `KlingerVolumeOscillator` , call the `kvo` helper method from the `QCAlgorithm` class. The `kvo` method creates a `KlingerVolumeOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class KlingerVolumeOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._kvo = self.kvo(self._symbol, 5, 10, 13)

    def on_data(self, slice: Slice) -> None:

        if self._kvo.is_ready:
            # The current value of self._kvo is represented by self._kvo.current.value
            self.plot("KlingerVolumeOscillator", "kvo", self._kvo.current.value)
            # Plot all attributes of self._kvo
            self.plot("KlingerVolumeOscillator", "signal", self._kvo.signal.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `KlingerVolumeOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class KlingerVolumeOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._klingervolumeoscillator = KlingerVolumeOscillator(5, 10, 13)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._klingervolumeoscillator.update(bar)

        if self._klingervolumeoscillator.is_ready:
            # The current value of self._klingervolumeoscillator is represented by self._klingervolumeoscillator.current.value
            self.plot("KlingerVolumeOscillator", "klingervolumeoscillator", self._klingervolumeoscillator.current.value)
            # Plot all attributes of self._klingervolumeoscillator
            self.plot("KlingerVolumeOscillator", "signal", self._klingervolumeoscillator.signal.current.value)
```

For more information about this indicator, see its reference .

Visualization

Know Sure Thing

Introduction

This indicator creates a moving average (middle band) with an upper band and lower band fixed at k standard deviations above and below the moving average.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using KST Indicator

To create an automatic indicator for `KnowSureThing` , call the `kst` helper method from the `QCAlgorithm` class. The `kst` method creates a `KnowSureThing` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class KnowSureThingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._kst = self.kst(self._symbol, 5, 5, 10, 5, 15, 5, 25, 10, 9, MovingAverageType.SIMPLE)

    def on_data(self, slice: Slice) -> None:

        if self._kst.is_ready:
            # The current value of self._kst is represented by self._kst.current.value
            self.plot("KnowSureThing", "kst", self._kst.current.value)
            # Plot all attributes of self._kst
            self.plot("KnowSureThing", "roc_1", self._kst.roc_1.current.value)
            self.plot("KnowSureThing", "roc_2", self._kst.roc_2.current.value)
            self.plot("KnowSureThing", "roc_3", self._kst.roc_3.current.value)
            self.plot("KnowSureThing", "roc_4", self._kst.roc_4.current.value)
            self.plot("KnowSureThing", "roc_1_ma", self._kst.roc_1_ma.current.value)
            self.plot("KnowSureThing", "roc_2_ma", self._kst.roc_2_ma.current.value)
            self.plot("KnowSureThing", "roc_3_ma", self._kst.roc_3_ma.current.value)
            self.plot("KnowSureThing", "roc_4_ma", self._kst.roc_4_ma.current.value)
            self.plot("KnowSureThing", "signal_line", self._kst.signal_line.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `KnowSureThing` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class KnowSureThingAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._knowsurething = KnowSureThing(5, 5, 10, 5, 15, 5, 25, 10, 9, MovingAverageType.SIMPLE)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._knowsurething.update(bar.end_time, bar.close)

        if self._knowsurething.is_ready:
            # The current value of self._knowsurething is represented by self._knowsurething.current.value
            self.plot("KnowSureThing", "knowsurething", self._knowsurething.current.value)
            # Plot all attributes of self._knowsurething
            self.plot("KnowSureThing", "roc_1", self._knowsurething.roc_1.current.value)
            self.plot("KnowSureThing", "roc_2", self._knowsurething.roc_2.current.value)
            self.plot("KnowSureThing", "roc_3", self._knowsurething.roc_3.current.value)
            self.plot("KnowSureThing", "roc_4", self._knowsurething.roc_4.current.value)
            self.plot("KnowSureThing", "roc_1_ma", self._knowsurething.roc_1_ma.current.value)
            self.plot("KnowSureThing", "roc_2_ma", self._knowsurething.roc_2_ma.current.value)
            self.plot("KnowSureThing", "roc_3_ma", self._knowsurething.roc_3_ma.current.value)
            self.plot("KnowSureThing", "roc_4_ma", self._knowsurething.roc_4_ma.current.value)
            self.plot("KnowSureThing", "signal_line", self._knowsurething.signal_line.current.value)
```

For more information about this indicator, see its reference .

Supported Indicators

Least Squares Moving Average

Introduction

The Least Squares Moving Average (LSMA) first calculates a least squares regression line over the preceding time periods, and then projects it forward to the current period. In essence, it calculates what the value would be if the regression line continued. source

To view the implementation of this indicator, see the LEAN GitHub repository .

Using LSMA Indicator

To create an automatic indicator for `LeastSquaresMovingAverage` , call the `lsma` helper method from the `QCAlgorithm` class. The `lsma` method creates a `LeastSquaresMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

PY

```
class LeastSquaresMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._lsma = self.lsma(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._lsma.is_ready:
            # The current value of self._lsma is represented by self._lsma.current.value
            self.plot("LeastSquaresMovingAverage", "lsma", self._lsma.current.value)
            # Plot all attributes of self._lsma
            self.plot("LeastSquaresMovingAverage", "intercept", self._lsma.intercept.current.value)
            self.plot("LeastSquaresMovingAverage", "slope", self._lsma.slope.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `LeastSquaresMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

PY

```
class LeastSquaresMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._leastsquaresmovingaverage = LeastSquaresMovingAverage(20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._leastsquaresmovingaverage.update(bar.end_time, bar.close)

        if self._leastsquaresmovingaverage.is_ready:
            # The current value of self._leastsquaresmovingaverage is represented by self._leastsquaresmovingaverage.current.value
            self.plot("LeastSquaresMovingAverage", "leastsquaresmovingaverage", self._leastsquaresmovingaverage.current.value)
            # Plot all attributes of self._leastsquaresmovingaverage
            self.plot("LeastSquaresMovingAverage", "intercept", self._leastsquaresmovingaverage.intercept.current.value)
            self.plot("LeastSquaresMovingAverage", "slope", self._leastsquaresmovingaverage.slope.current.value)
```

For more information about this indicator, see its reference .

        time_period_indicator_history = self.indicator_history(self._lsma, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)

        # Access all attributes of indicator_history
        indicator_history_df = indicator_history.data_frame
        intercept = indicator_history_df["intercept"]
        slope = indicator_history_df["slope"]
```

Supported Indicators

Linear Weighted Moving Average

Introduction

This indicator represents the traditional Weighted Moving Average indicator. The weight are linearly distributed according to the number of periods in the indicator. For example, a 4 period indicator will have a numerator of (4 * window[0]) + (3 * window[1]) + (2 * window[2]) + window[3] and a denominator of 4 + 3 + 2 + 1 = 10 During the warm up period, IsReady will return False, but the LWMA will still be computed correctly because the denominator will be the minimum of Samples factorial or Size factorial and the computation iterates over that minimum value. The RollingWindow of inputs is created when the indicator is created. A RollingWindow of LWMAs is not saved. That is up to the caller.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using LWMA Indicator

To create an automatic indicator for `LinearWeightedMovingAverage` , call the `lwma` helper method from the `QCAlgorithm` class. The `lwma` method creates a `LinearWeightedMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class LinearWeightedMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._lwma = self.lwma(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._lwma.is_ready:
            # The current value of self._lwma is represented by self._lwma.current.value
            self.plot("LinearWeightedMovingAverage", "lwma", self._lwma.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `LinearWeightedMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class LinearWeightedMovingAverageAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._linearweightedmovingaverage = LinearWeightedMovingAverage(20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._linearweightedmovingaverage.update(bar.end_time, bar.close)

        if self._linearweightedmovingaverage.is_ready:
            # The current value of self._linearweightedmovingaverage is represented by self._linearweightedmovingaverage.current.value
            self.plot("LinearWeightedMovingAverage", "linearweightedmovingaverage", self._linearweightedmovingaverage.current.value)
```

For more information about this indicator, see its reference .

Supported Indicators

Log Return

Introduction

This indicator represents the LogReturn indicator (LOGR) - log returns are useful for identifying price convergence/divergence in a given period - logr = log (current price / last price in period)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using LOGR Indicator

To create an automatic indicator for `LogReturn` , call the `logr` helper method from the `QCAlgorithm` class. The `logr` method creates a `LogReturn` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class LogReturnAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._logr = self.logr(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._logr.is_ready:
            # The current value of self._logr is represented by self._logr.current.value
            self.plot("LogReturn", "logr", self._logr.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `LogReturn` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
PY
class LogReturnAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._logreturn = LogReturn(20)

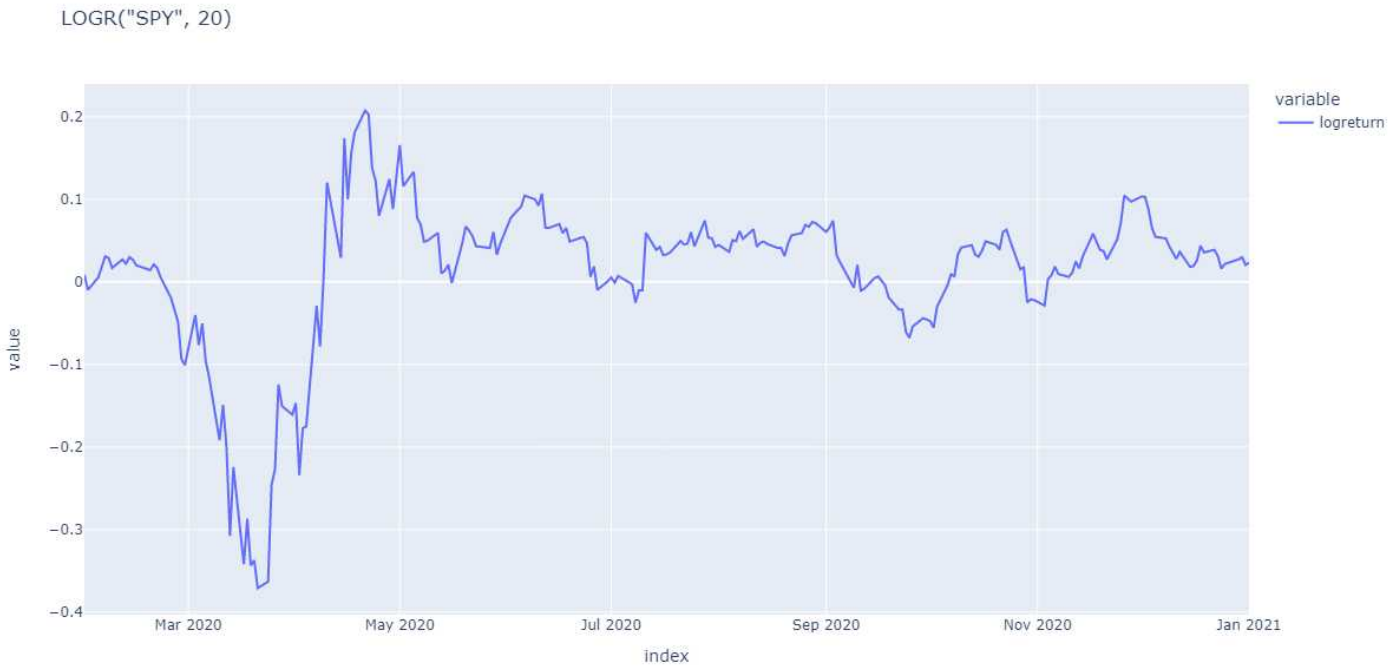
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._logreturn.update(bar.end_time, bar.close)

        if self._logreturn.is_ready:
            # The current value of self._logreturn is represented by self._logreturn.current.value
            self.plot("LogReturn", "logreturn", self._logreturn.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `LogReturn` indicator properties:



Indicator History

To get the historical data of the `LogReturn` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

PY

        indicator_history = self.indicator_history(self._logr, self._symbol, 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._logr, self._symbol, timedelta(days=10), Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._logr, self._symbol, datetime(2024, 7, 1), datetime(2024, 7, 5),
Resolution.MINUTE)
```

Supported Indicators

Mass Index

Introduction

The Mass Index uses the high-low range to identify trend reversals based on range expansions. In this sense, the Mass Index is a volatility indicator that does not have a directional bias. Instead, the Mass Index identifies range bulges that can foreshadow a reversal of the current trend. Developed by Donald Dorsey.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MASS Indicator

To create an automatic indicator for `MassIndex` , call the `mass` helper method from the `QCAlgorithm` class. The `mass` method creates a `MassIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class MassIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._mass = self.mass(self._symbol, 9, 25)

    def on_data(self, slice: Slice) -> None:

        if self._mass.is_ready:
            # The current value of self._mass is represented by self._mass.current.value
            self.plot("MassIndex", "mass", self._mass.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `MassIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class MassIndexAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._massindex = MassIndex(9, 25)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._massindex.update(bar)

        if self._massindex.is_ready:
            # The current value of self._massindex is represented by self._massindex.current.value
            self.plot("MassIndex", "massindex", self._massindex.current.value)
```

For more information about this indicator, see its reference .

Maximum

Introduction

This indicator represents an indicator capable of tracking the maximum value and how many periods ago it occurred

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MAX Indicator

To create an automatic indicator for `Maximum` , call the `max` helper method from the `QCAlgorithm` class. The `max` method creates a `Maximum` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class MaximumAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._max = self.max(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._max.is_ready:
            # The current value of self._max is represented by self._max.current.value
            self.plot("Maximum", "max", self._max.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Maximum` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class MaximumAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._maximum = Maximum(20)

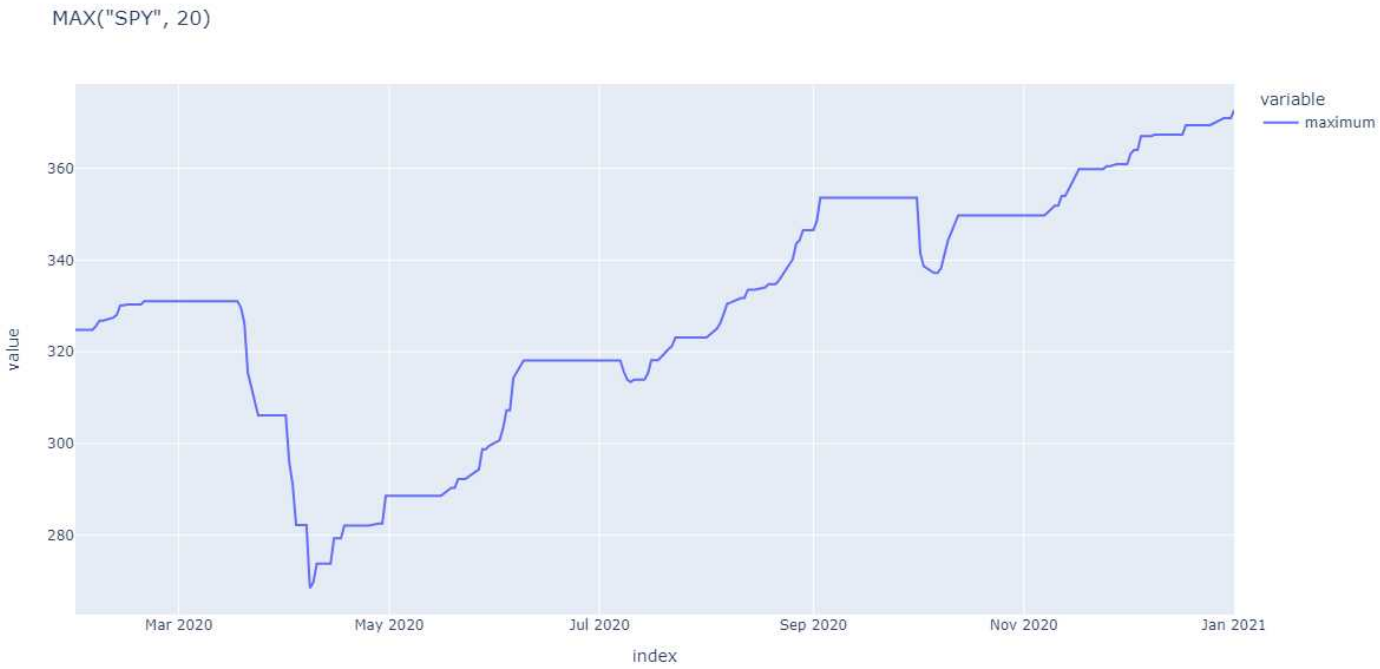
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._maximum.update(bar.end_time, bar.close)

        if self._maximum.is_ready:
            # The current value of self._maximum is represented by self._maximum.current.value
            self.plot("Maximum", "maximum", self._maximum.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `Maximum` indicator properties:



Indicator History

To get the historical data of the `Maximum` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

McClellan Oscillator

Introduction

The McClellan Oscillator is a market breadth indicator which was developed by Sherman and Marian McClellan. It is based on the difference between the number of advancing and declining periods.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MOSC Indicator

To create an automatic indicator for `McClellanOscillator` , call the `mosc` helper method from the `QCAlgorithm` class. The `mosc` method creates a `McClellanOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class McClellanOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._mosc = self.mosc([self._symbol, self._reference])

    def on_data(self, slice: Slice) -> None:

        if self._mosc.is_ready:
            # The current value of self._mosc is represented by self._mosc.current.value
            self.plot("McClellanOscillator", "mosc", self._mosc.current.value)
            # Plot all attributes of self._mosc
            self.plot("McClellanOscillator", "ema_fast", self._mosc.ema_fast.current.value)
            self.plot("McClellanOscillator", "ema_slow", self._mosc.ema_slow.current.value)
            self.plot("McClellanOscillator", "ad_difference", self._mosc.ad_difference.current.value)
```

To create an automatic indicator for `McClellanOscillator` using universe constituents, call the `mosc` helper method from the `QCAlgorithm` class. The `mosc` method creates a `McClellanOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In this case, you should call the helper method in the `on_securities_changed` method.

```
class McClellanOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self.set_start_date(2024,1,1)
        self.set_end_date(2024,12,31)
        self.universe_settings.resolution = Resolution.DAILY
        self.universe_settings.schedule.on(self.date_rules.month_start())
        self._universe = self.add_universe(self.universe.etf('SPY'))

    def on_securities_changed(self, changes: SecurityChanges) -> None:
        self._mosc = self.mosc(list(self._universe.selected))

    def on_data(self, slice: Slice) -> None:

        if self._mosc.is_ready:
            # The current value of self._mosc is represented by self._mosc.current.value
            self.plot("McClellanOscillator", "mosc", self._mosc.current.value)
            # Plot all attributes of self._mosc
            self.plot("McClellanOscillator", "ema_fast", self._mosc.ema_fast.current.value)
            self.plot("McClellanOscillator", "ema_slow", self._mosc.ema_slow.current.value)
            self.plot("McClellanOscillator", "ad_difference", self._mosc.ad_difference.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `McClellanOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class McClellanOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._mcclellanoscillator = McClellanOscillator(19, 39)
        self._mcclellanoscillator.add(self._symbol);
        self._mcclellanoscillator.add(self._reference);

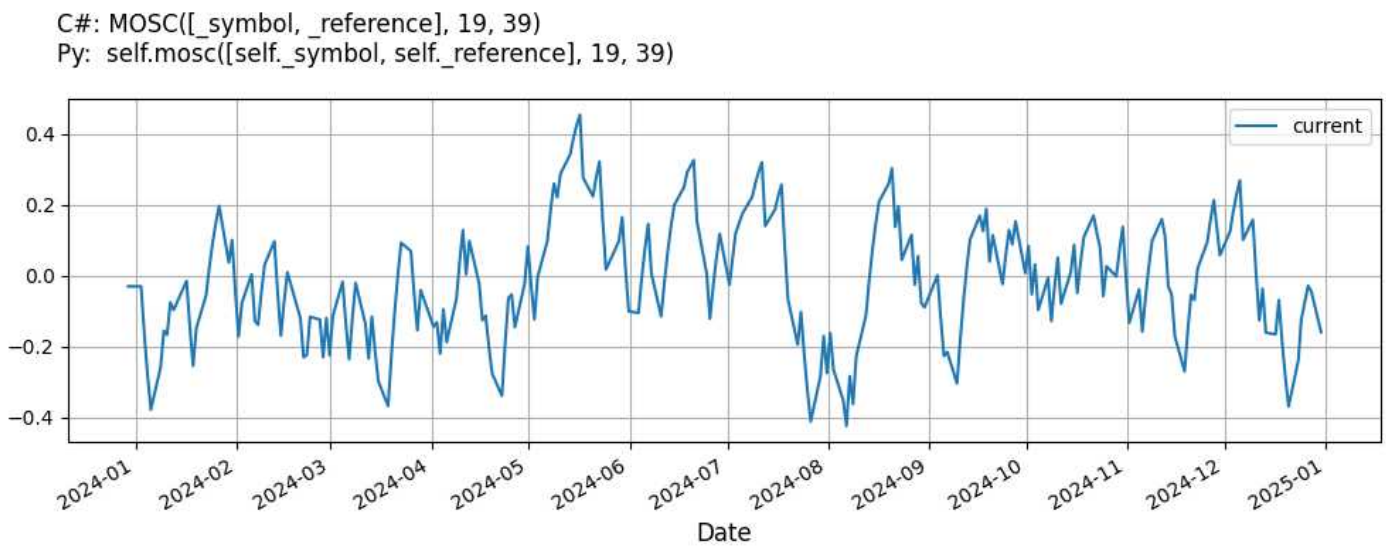
    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._mcclellanoscillator.update(bar)
        bar = slice.bars.get(self._reference)
        if bar:
            self._mcclellanoscillator.update(bar)

        if self._mcclellanoscillator.is_ready:
            # The current value of self._mcclellanoscillator is represented by self._mcclellanoscillator.current.value
            self.plot("McClellanOscillator", "mcclellanoscillator", self._mcclellanoscillator.current.value)
            # Plot all attributes of self._mcclellanoscillator
            self.plot("McClellanOscillator", "ema_fast", self._mcclellanoscillator.ema_fast.current.value)
            self.plot("McClellanOscillator", "ema_slow", self._mcclellanoscillator.ema_slow.current.value)
            self.plot("McClellanOscillator", "ad_difference", self._mcclellanoscillator.ad_difference.current.value)
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `McClellanOscillator` indicator properties:



Indicator History

To get the historical data of the `McClellanOscillator` indicator, call the `self.indicator_history` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `indicator_history` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
class McClellanOscillatorAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("QQQ", Resolution.DAILY).symbol
        self._reference = self.add_equity("SPY", Resolution.DAILY).symbol
        self._mosc = self.mosc([self._symbol, self._reference])

        indicator_history = self.indicator_history(self._mosc, [ self._symbol, self._reference ], 100, Resolution.MINUTE)
        timedelta_indicator_history = self.indicator_history(self._mosc, [ self._symbol, self._reference ], timedelta(days=10),
Resolution.MINUTE)
        time_period_indicator_history = self.indicator_history(self._mosc, [ self._symbol, self._reference ], datetime(2024, 7, 1),
datetime(2024, 7, 5), Resolution.MINUTE)

        # Access all attributes of indicator_history
        indicator_history_df = indicator_history.data_frame
        ema_fast = indicator_history_df["emafast"]
        ema_slow = indicator_history_df["emaslow"]
        ad_difference = indicator_history_df["addifference"]

McGinley Dynamic

Introduction

This indicator represents the McGinley Dynamic (MGD) It is a type of moving average that was designed to track the market better than existing moving average indicators. It is a technical indicator that improves upon moving average lines by adjusting for shifts in market speed.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MGD Indicator

To create an automatic indicator for `McGinleyDynamic` , call the `mgd` helper method from the `QCAlgorithm` class. The `mgd` method creates a `McGinleyDynamic` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
PY
class McGinleyDynamicAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._mgd = self.mgd(self._symbol, 10)

    def on_data(self, slice: Slice) -> None:

        if self._mgd.is_ready:
            # The current value of self._mgd is represented by self._mgd.current.value
            self.plot("McGinleyDynamic", "mgd", self._mgd.current.value)
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `McGinleyDynamic` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

Mean Absolute Deviation

Introduction

This indicator computes the n-period mean absolute deviation.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MAD Indicator

To create an automatic indicator for `MeanAbsoluteDeviation` , call the `mad` helper method from the `QCAlgorithm` class. The `mad` method creates a `MeanAbsoluteDeviation` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `initialize` method.

```
class MeanAbsoluteDeviationAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._mad = self.mad(self._symbol, 20)

    def on_data(self, slice: Slice) -> None:

        if self._mad.is_ready:
            # The current value of self._mad is represented by self._mad.current.value
            self.plot("MeanAbsoluteDeviation", "mad", self._mad.current.value)
            # Plot all attributes of self._mad
            self.plot("MeanAbsoluteDeviation", "mean", self._mad.mean.current.value)
```

PY

For more information about this method, see the QCAlgorithm class .

You can manually create a `MeanAbsoluteDeviation` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `update` method. The indicator will only be ready after you prime it with enough data.

```
class MeanAbsoluteDeviationAlgorithm(QCAlgorithm):
    def initialize(self) -> None:
        self._symbol = self.add_equity("SPY", Resolution.DAILY).symbol
        self._meanabsolutedeviation = MeanAbsoluteDeviation(20)

    def on_data(self, slice: Slice) -> None:
        bar = slice.bars.get(self._symbol)
        if bar:
            self._meanabsolutedeviation.update(bar.end_time, bar.close)

        if self._meanabsolutedeviation.is_ready:
            # The current value of self._meanabsolutedeviation is represented by self._meanabsolutedeviation.current.value
            self.plot("MeanAbsoluteDeviation", "meanabsolutedeviation", self._meanabsolutedeviation.current.value)
            # Plot all attributes of self._meanabsolutedeviation
            self.plot("MeanAbsoluteDeviation", "mean", self._meanabsolutedeviation.mean.current.value)
```
